In this study, *D. magna* were exposed for 21 days to up to 600 $\mu g.L^{-1}$ to a mixture of Gadolinium (Gd), Neodymium (Nd) and Ytterbium (Yb). At the end of the exposure period, juveniles from the fifth brood were kept and exposed for 48h to up to 600 $\mu g.L^{-1}$ to REE mixture (Gd + Nd + Yb). Effects of REE on the expression of a set of stress-related genes have been evaluated using RT-qPCR. Genes involved in apoptosis, osmoregulation, energy metabolism, antioxidant defense, metallic stress, digestion… etc. have been assessed
A concentration-dependent effect was observed on *D. magna* gene expression. The higher concentrations of the REE mixture led to an up-regulation of genes involved in general stress responses (e.g. HSP70, Glutathione-S-Transferase), apoptosis (P53, Caspase 8), energy metabolism (Fructose-bisphosphate aldolase, phosphofructokinase, and GAPDH), and osmoregulation (Na^+K^+-ATPase). Our results on the gene expression of *D. magna* suggest that REE do not impair a specific pathway but seems to have generalized impacts. The large number of candidates genes and proteins identified by the omic approaches applied for this study provides a solid starting point for further findings to identify REE mechanism of action towards aquatic organisms.

4.03.P-Tu344 Protective Role of Colloids against Cr and Ni Ecotoxicity in a Small Ultramafic Catchment
Elsa Salles[1], *Pavel Kram*[2], *Thi Tuyen Nguyen*[3], *Yulia V Erban Kochergina*[2], *Yann Sivry*[3], *Alexis Groleau*[3], *Maximilien Beuret*[4], *Carole Cossu-Leguille*[4], *Vincent Normant*[4] *and Davide A.L. Vignati*[4], *(1)University of Lorraine (LIEC), CNRS, France, (2)Czech Geological Survey, Czech Republic, (3)IPGP (CNRS UMR7154, Université de Paris), France, (4)University of Lorraine, France*
In ultramafic environments, nickel (Ni) and chromium (Cr) often exceed the corresponding environmental quality standards (4 µg/L as bioavailable Ni) or guideline values (*e.g.*, 10 µg/L for Cr(III) and 4 µg/L Cr(VI) according to WHO). Water samples were collected in a small ultramafic creek (Pluhuv Bor, Czech Republic) located far from anthropogenic sources of trace elements other than atmospheric deposition. Sample collection was carried out in December 2021 during the rising limb of a small flood with water discharge increasing from about 0.2 L/s (baseflow) to 2.6 L/s. Filtered waters (0.22 µm) were analyzed for Ni and Cr content and tested for ecotoxicity with the freshwater alga *Raphidocelis subcapitata*. Filtered waters had concentrations of Ni (80-

190 μg/L) and Cr (10-23 μg/L) above the corresponding ecotoxicological threshold values, but did not adversely affect the growth of *R. subcapitata*. Analysis of ultrafiltered water aliqouts (3 kDa) showed that 60 to 95% of the filterable Ni and Cr were associated with the operationally defined colloidal fraction (3 kDa–0.22 μm), suggesting a possible protective effect of colloids against Ni and Cr ecotoxicity. Both total filterable concentrations and the colloidal Ni and Cr pools increased with flow, while concentrations < 3 kDa remained constant at around 25-30 μg/L for Ni and 1.3-1.6 μg/L for Cr. In situ measurements of Ni and Cr levels by DGTs (Diffusive Gradients in Thin Films) were in excellent agreement with ultrafilterable concentrations. In the case of Cr, DGT-labile concentrations mainly occurred as Cr(VI), while ionic Cr(III) levels were close to analytical detection limits. Measurements by ion-chromatography high-resolution ICP-MS gave ionic Cr(VI) and Cr(III) concentrations equivalent to those determined by DGTs, but also highlighted the presence of an unknown Cr species. Ecotoxicity tests with addition of Cr(III) and Cr(VI) to filtered waters showed no toxicity to *R. subcapitata* for concentrations up to 0.9 mg/L of Cr(III), while the EC_{50} of Cr(VI) increased 4-fold compared with results obtained in standard ISO medium for freshwater algae. Overall, the presence of colloidal carrier phases (likely Fe oxides and natural organic matter) seems to play an important role in limiting Ni and Cr bioavailability and ecotoxicity to algae in freshwater ultramafic environments. The possible contribution of colloidal Ni and Cr to elemental bioavailability for e.g., filter feeders deserves further investigation.

4.03.P-Tu345 Microcosms as a Tool to Study REE Toxicity in a Simulated Aquatic Food Web
***Chantal K.E. van Drimmelen**[1], Andrew Hursthouse[2] and Susanne Heise[3], (1)Ecotoxicology, University of Applied Science Hamburg, Germany, (2)University of the West of Scotland, United Kingdom, (3)Hamburg University of Applied Sciences (HAW), Germany*
Rare Earth Elements (REE) show high adsorption affinity for sediment particles and fine organic matter, making it likely that benthic organisms are the species most exposed to REE in the environment. Resuspension of sediment or exchange of porewater may mobilize REE and re-introduce it to the water phase. This bentho-pelagic coupling might also lead to affects on pelagic as well as benthic species. Indoor microcosms are artificial and simplified ecosystems that under controlled conditions aid in the research of the effects of contaminants and stressors in the natural systems. This makes microcosms highly suitable for our objective to investigate the impact of sediment resuspension on the transfer of lanthanum (La) and gadolinium (Gd) from benthic layer to the pelagic layer at the first consumer level. The objective for this study is to combine the information gathered from previous studies and add a deeper insight in the role of sediment re-suspension on the aquatic food web. The 2 L salinized glass microcosms used in this study will contain five aquatic grown laboratory species; daphnia (*Daphnia magna*), microalgae (*Raphidocelis subcapitata*), nematodes (*Caenorhabditis elegans*), bacteria (*Escherichia coli*), and ostracods (*Heterocypris incongruens*). The microcosm will be set-up in four gradual steps, in order for the ecosystem to stabilize with each addition: 1) bacteria and algae are added to a layer of uncontaminated sediment and media, 2) nematodes and daphnia are added to the established bacteria and microalgae populations, 3) introduction of the ostracod population, and 4) resuspension of sediment. We will look at parameters such as death rate (EC_{50}), reproduction rate (RC_{50}), population count, according to the guidelines of the bioassays related to the species. The microcosms will be spiked with (nominal) environmentally relevant (1 and 10 μg L^{-1}) and anthropogenic concentrations (100 and 1000 μg L^{-1}) of La and Gd. Our hypothesis is that benthic organisms higher will be more impacted by a REE-supply to the "environment" than pelagic species or primary consumers. From previous studies it is also most likely that Gd is more toxic than La. We will further elaborate on this study and present preliminary results in the poster.

4.03.P-Tu346 Leaching of Elements from Smartphones and their Toxicity to Marine Organisms
***Julia Farkas**[1], Tomasz Ciesielski[2], Dag Altin[3], Stefania Piarulli[1], Bjørn Henrik Hansen[1] and Trond Nordtug[1], (1)SINTEF, Norway, (2)Department of Biology, Norwegian University of Science & Technology (NTNU), Norway, (3)Research Infrastructure SeaLab, Norwegian University of Science & Technology (NTNU), Norway*
Rapid development, increasing demands and short lifespans of electronic equipment causes high generation of electronic waste (e-waste). In 2019 alone, approximately 1.5 billion smartphones were sold world-wide, with around 1.7 million smartphones sold in Norway. Mobile phones, especially smartphones are composed of different materials, including toxic metals such as nickel, copper, zinc, silver, cadmium and lead, several of the rare earth elements (praseodymium, gadolinium, terbium, dysprosium) and organic chemicals, e.g., flame retardants and perfluorinated chemicals. E-waste can thus pose an environmental threat, when not properly handled. In this study we conducted a first investigation on the leaching of elements, including heavy metals and rare earth elements from smartphones into seawater. We further studied effects of leachates on marine species from three trophic levels. Four mobile phones of the same brand and similar type were shattered and incubated in natural, seawater under gentle agitation (20 °C, darkness). Water samples are taken after 1 week, 1 month and 2 month and were analysed for elemental concentrations with ICP-MS. Incubation in seawater resulted in a rapid release/formation of large amounts of fine particles. Results show that after two month, the mobile phones leached significant amounts of the major elements like Na, Mg, Si, K, and Ca, but also significant amounts of Al, Fe, Ni, Zn, Ge, Sr, Mo, Sn. Further, we detected La, Nd and Pr from the group of REYs. Results further showed that both the dissolved (particles removed with centrifugation) and total (particulate and dissolved) fraction of the 1-week leachate inhibited the growth of the marine algae *Skeletonema pseudocostatum*, with the total fraction causing more pronounced effects. Further, the total fraction increased mortality in the marine copepod *Acartia tonsa*. While we did not see effects of most leachates, the leachate of one of the mobile phones caused a 70 % mortality in exposed cod embryos. Further studies are needed to identify which elements or potentially other contaminants are responsible for the observed toxic effects.

4.03.P-Tu347 Rare Earth Element Pollution Recording in the Saltwater Mussel Mytilus Spp. in Norwegian Coastal Waters

*Lyen Castro[1], Tomasz Ciesielski[2], Stefania Piarulli[3], Bjørn Munro Jenssen[2] and **Julia Farkas**[3], (1)University of the Basque Country (UPV/EHU), Spain, (2)Department of Biology, Norwegian University of Science & Technology (NTNU), Norway, (3)SINTEF, Norway*
Growing extraction and usage of rare earth elements and yttrium (REY) in different industrial sectors has culminated in their increased discharge into the marine environment. In particular, globally observed anthropogenic enrichment of gadolinium (Gd) in aquatic systems near populated areas is due to its use as a magnetic resonance imaging (MRI) contrast agent. This study aimed to analyze the accumulation, spatial distribution, and shale-normalized patterns of REYs in *Mytilus spp*. soft tissue at a potential release hot-spot in southern Norway. Mussel specimens (n=49) were collected at three sites around a spillwater pipe of an industry producing Gd-based MRI contrast agents (GBCAs) and compared to a reference site. Results show that mussels at an enclosed bay in the vicinity of discharge point accumulated significant, over fourfold higher total mean REY (4.88 µg g^{-1} d.w.) in its soft tissue in comparison to other locations and the reference site (0.95 – 1.08 µg g^{-1} d.w.). Normalization with European shale highlighted positive Gd anomalies in all sites, including the reference. However, a notable fourfold Gd anomaly (Gd/Gd* = 4.4) was observed in the mussels downstream of the GBCA industry outfall, indicating a clear excess uptake of anthropogenic Gd by mussels in this area. The mussels at the enclosed bay, despite carrying the highest total REY concentrations, retained a similar Gd anomaly with the reference site. Moreover, our results show that mussel soft tissue in southern Norway is generally characterized by an enrichment of LREYs over HREYs, with LREYs contributing to 82 ± 4% of total REY burden. The three metals representing the majority of REY concentration were Ce (33 ± 3%), La (26 ± 4%), and Nd (16 ± 2%). Among the heavy REYs, Y contributed the most (10 ± 1%) to the total REY burden in mussels. This study constitutes the first record of Gd excess and REY accumulation in marine bivalves in Norway, and will be useful for future biomonitoring studies on REY contamination.

4.03.P-Tu348 Tissue-Specific Bioaccumulation of Rare Earth Elements in Brown Crab (*Cancer Pagurus*) at an Industrially-Affected Fjord in Porsgrunn, Norway

*Lyen Castro[1], **Julia Farkas**[2], Stefania Piarulli[2], Bjørn Munro Jenssen[3] and Tomasz Ciesielski[3], (1)University of the Basque Country (UPV/EHU), Spain, (2)SINTEF, Norway, (3)Department of Biology, Norwegian University of Science & Technology (NTNU), Norway*
The critical use of rare earth elements and yttrium (REY) in a wide range of emerging applications has led to their release in aquatic systems through urban and industrial wastewater runoff and rivers. Benthic organisms near industrial zones can be increasingly exposed via contaminated substrate or diet, yet information is still limited regarding REY bioaccumulation and organotropism in marine biota. In this study, we investigated the tissue-specific accumulation and profile of REYs in a commercially important marine species, the edible brown crab *Cancer pagurus*. Mature female crabs (n=18) were taken from three sites around Frier fjord in Grenland district, a heavily industrialized region in southern Norway. From each crab, the hepatopancreas (brown meat), claw muscle (white meat), and gills were dissected, and REY concentrations were determined using ICP-MS. The results show that *C. pagurus* accumulated majority of REYs burden in gills (17 - 69 µg total REY g^{-1} d.w), and much less in hepatopancreas (0.69 - 1.2 µg g^{-1} d.w) and muscle (0.23 - 0.58 µg g^{-1} d.w). Using the results from the gills, we assessed the spatial distribution of REY concentrations in Frier fjord. Crabs in the sites closer to the Knardalstrand wastewater treatment plant discharge point and the Skien river outlet had three to four times higher total REY concentrations than those in the reference site 8 km away. European-shale normalized REY patterns showed that all tissues exhibited an enrichment of light REYs over heavy REYs, and small positive Gd anomalies (Gd/Gd* = 1.07 - 1.26). La, Ce, Nd, and Y were the most abundant REYs across all three tissues. The percentage of La in claw muscle was significantly higher than in the gills and hepatopancreas, while for Ce the hepatopancreas had significantly lower percentage than the in gills and claw muscle. This study provides the first report of REY accumulation and organotropism in brown crabs, and demonstrates the use of crab gills as a sensitive organ for future biomonitoring of REY contamination.

4.03.P-Tu349 Are Technologically Critical Metals (Rare Earth Elements, REE) Accumulating in Harbour Porpoise (P*hocoena phocoena*) from Norwegian Coastal Waters?

*Tomasz Ciesielski[1], Ulf Lindstrøm[2], **Julia Farkas**[3] and Bjørn Munro Jenssen[1], (1)Department of Biology, Norwegian University of Science & Technology (NTNU), Norway, (2)Institute of Marine Research, Norway, (3)SINTEF, Norway*
Harbour porpoises (*Phocoena phocoena*) are the most abundant cetacean in Norwegian waters. Rare earth elements (REE) are essential components in a wide range of products and applications, including innovative and green technologies. This causes a rapidly rising production and use of REEs, leading to their release into the environment - with so far unknown consequences. Being a part of the Fennoscandian shield, Norway has high potential for REE exploration and production. The potential toxicity of REEs and their accumulation in marine mammals is not well documented. The aim of this study was to determine REEs concentrations in liver and muscles of harbour porpoise and examine their spatial distribution in relation to potential sources. In addition, the influence of age and sex on the accumulation of REE in porpoises was examined. In 2016 and 2017, 134 specimens were collected along Norwegian coast. REEs (Ce, Dy, Er, Eu, Gd, Ho, La, Lu, Nd, Pr, Pm, Sm, Tb, Tm, Yb), Sc, Y, U and Th were quantified in the muscles and livers by HR-ICP-MS. Animals were divided into different locations, corresponding to fishing areas. Highest hepatic concentrations for Ce, La, Nd, Pr and Y were found in individuals from Grøtsundet and Varangerfjorden, northern Norway. This may be attributed either to increased mining of minerals that contain various complexes of REEs or to natural geological differences in bedrock composition. Hepatic Ce, La, Nd, Pr and Sm concentrations were positively correlated with body size, indicating accumulation of these metals with age. No sex differences in accumulation of REE were found, suggesting lack of reproduction elimination mechanism for these metals in harbour porpoise. This study provides important background data for REE in top predators in marine environment for future studies on anthropogenic pollution which is expected due to high demand for REEs in modern technological applications.

4.03.P-Tu350 Rare Earths and Other Elements in Transplanted Blue Mussels (*Mytilus edulis*) and Seaweeds (*Saccharina latissima*) Near Salmon Farms: First Results from a Site in Trøndelag, Norway

Juliane Annemieke Riedel[1], *Stefania Piarulli*[2], *Tomasz Maciej Ciesielski*[3], *Ailin Østerås*[3], *Pal A Olsvik*[1], *Torstein Kristensen*[1], *Bjørn Henrik Hansen*[2] *and Julia Farkas*[2], *(1)Nord University, Norway, (2)SINTEF, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway*

Intensive sea-based Atlantic salmon (*Salmo salar*) farming is a source for multiple stressors to the marine ecosystem, such as parasites and diseases, contaminants including (heavy) metals, microplastics, pesticides and other organic pollutants, and excess nutrients. Many of these pollutants are directly associated with salmon feed, which is released and spread via the open net-pens either as uneaten pellets or faeces. Recent analyses have revealed that the technology-critical rare earth elements and yttrium (REY), which were lately classified as contaminants of emerging concern in aquatic systems, can be found in salmon feeds at levels exceeding background seawater concentrations by about 4 orders of magnitude. REY tend to bioaccumulate especially in lower trophic level organisms such as invertebrates and algae, with toxic effects at surplus levels. The magnitude of potential REY emissions from salmon farms and their relevance as contaminants in adjacent ecosystems have not been considered before, yet, this knowledge is crucial for identifying the risks of REY to marine wildlife.
Here, we will present the first findings from a four-month screening of REY at a salmon farm in Trøndelag, Norway. We transplanted both blue mussels (*Mytilus edulis*) and sugar kelp (*Saccharina latissima*) seeded twines from February to June 2022 near the salmon cages (S1: at the cages, S2: around 50 m downstream in the main current direction) using three replicates per station. As controls we used mussels sampled at time zero and seaweeds that were farmed since January in the same area, but > 1 km away from all fish farming activity. After retrieval, biometric measures were taken and the mussel soft tissues as well as total sugar kelp fronds were deep-frozen, freeze-dried, homogenised, digested and are currently analysed for REY and other relevant elements using ICP-MS. The results will provide novel insights into the potential spread of REY with salmon aquaculture wastes to the marine ecosystem and species-specific bioaccumulation patterns of REY and other elements.

4.03.P-Tu351 Toxicity of Three Rare Earth Elements on the Deep-sea Scavenging Amphipod *Tmetonyx cicada* (Lysianassidae): Linking Molecular and Behavioural Responses

Juliane Annemieke Riedel[1], *Linn Hjelmeland Svendheim*[1], *Coline Donat*[1], *Julia Farkas*[2], *Bjørn Henrik Hansen*[2] *and Pal A Olsvik*[1], *(1)Nord University, Norway, (2)SINTEF, Norway*

In response to a sharp rise in demand for the technology-critical rare earth elements (lanthanides) and yttrium (together: REY), Norway has recently announced plans for deep-sea mining of these metals. In other parts of the world, REY mining has led to emissions of environmental concern. Recent research points out their persistence and enrichment in aquatic sediments, potential for bioaccumulation and toxicity to wildlife. Existing studies indicate coherent toxicity and modes of action across the group of REY, likewise, REY toxicity has been shown to vary across study organisms and with dependence on atomic weight. By interference with key physiological pathways such as cellular Ca^{2+} signalling, REY have the potential to cause a broad range of toxicological effects, from neurotoxicity, over developmental and cardiovascular effects, geno- and proteotoxicity to lethality at high levels. Yet, the underlying effect mechanisms are insufficiently understood. Moreover, most existing studies were performed on model species, many of which showed low sensitivity to REY. Environmental relevant ecotoxicological data, especially for the marine ecosystem, are scarce but urgently needed to assess the risks of REY.
In this work we studied the effects of three REY on the health of the lysianassid amphipod *Tmetonyx cicada* (Fabricius, 1780), a locally abundant scavenger that inhabits the deep seafloor from the North Atlantic up to the Arctic. *T. cicada* were collected in spring 2022 from Saltfjorden (Bodø, Norway) at 180 m depth using herring-baited traps. Not fully matured specimens of 1-2 mm size were exposed for 10 d to a light, medium and heavy REY (Nd (144.24 g/mol), Gd (157.25 g/mol) and Yb (173.04 g/mol)), at concentrations of 0, 3, 30, 300 and 3000 µg L^{-1} in a dark climate cabinet at 8 °C. We observed mortality for all three REY at 3000 µg L^{-1} and increased swimming speed under a white-light stimulus at sublethal concentrations. Transcriptomic analyses will further provide insight to underlying molecular modes of action. Our results so far indicate that REY mining in Norway may adversely affect the marine ecosystem, as aquatic REY loads downstream of existing mining sites have been shown to reach several mg/L up to g/L. This emphasises the need for a risk assessment of REY and establishment of a regulatory framework to prevent toxic REY releases from existing sources and future mining sites.

4.03.P-Tu352 Effects of Cu Exposure on Atlantic Cod (*Gadus Morhua*) Embryos and Larvae

Linn Hjelmeland Svendheim[1], *Julia Farkas*[2], *Tomasz Maciej Ciesielski*[3], *Bjørn Henrik Hansen*[2], *Torstein Kristensen*[1], *Bjarne Kvæstad*[2] *and Pal A Olsvik*[1], *(1)Nord University, Norway, (2)SINTEF, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway*

While copper (Cu) is a natural constituent of the environment it is also a toxicant for aquatic species. Due to increased demand for Cu (up to 50% over the next 20 years), its levels in areas with high anthropogenic activities are of concern, especially in mining and deposition areas. Deposition of tailings on the seafloor, as practiced in several sites along the Norwegian coast, releases particles to the marine environment that may contain both process chemicals and heavy metals.
Atlantic cod is a commercially important fish species that spawns in coastal areas. The pelagic larvae can be retained in fjord systems for long periods of time, making them a potential target for marine tailing exposure.
In this study we exposed Atlantic cod embryos (6 replicates) from 3 days post fertilization (dpf) to 4 days post hatch (dph) to three different Cu concentrations: 5, 15 and 30 µg/L Cu, and a control. Biometric images were taken, and respiration was measured daily. Samples were also collected for differential gene expression and metabolomic analysis at two time points, one for embryos (96 h) and one for larvae (2 dph).

Embryos in the high treatment group hatched earlier and total mortality was significantly higher compared to all other groups. While no significant difference was found in respiration, larvae in the high treatment group were smaller and had higher deformation rates. Transcriptomic profiling and metabolomics analysis revealed a higher expression of stress related genes and a significant increase in oxidized glutathione (GSSG) in embryos and larvae from the high treatment group which is indicative of oxidative stress. Also, changes in metabolites related to energy metabolism and upregulation of genes related to haemoglobin transport and metabolic rate suggests an active detoxification process in larvae from the high treatment group which could help explain the slower growth of larvae.
Our result show that early life stages of Atlantic cod is sensitive to environmentally relevant levels Cu around marine tailing deposition sites.

4.03.P-Tu353 Effects of Short-Term Mine Tailing Exposure on Stage CV *Calanus Finmarchicus*
Linn Hjelmeland Svendheim[1]*, Julia Farkas*[2]*, Tomasz Maciej Ciesielski*[3]*, Bjørn Henrik Hansen*[2]*, Torstein Kristensen*[1]*, Dag Altin*[4] *and Pal A Olsvik*[1]*, (1)Nord University, Norway, (2)SINTEF, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway, (4)Research Infrastructure SeaLab, Norwegian University of Science & Technology (NTNU), Norway*
Mineral demand for new technologies and industries drives an increase in mining activities worldwide. As tailing deposition on land takes up large areas and give rise to numerous environmental challenges, marine tailing disposal has been proposed as an alternative in some areas.
The marine filter feeding copepod *Calanus finmarchicus* is an important food source for commercially important fish species and other marine animals due to its high lipid content. The release of particles and chemicals associated with marine tailing deposition may pose a potential threat to fat-rich zooplankton, as previous study revealed a delay in development and lower lipid accumulation in developing *C. finmarchicus* exposed to mine tailings.
To investigate the potential short-term effect of mine tailing exposure on later life stages, *C. finmarchicus* stage CV was exposed to pure calcium carbonate particles and Cu in high and low concentrations, as well as calcium carbonate and copper tailings in low, medium, and high concentrations, with five replicates per group, for 96 hours (10 °C). In addition, five replicates of control (clean sea water with food) and starved control (clean sea water with no food added) were included. At termination, respiration measurements and biometry images were taken, and samples for metabolomic analysis were collected.
The results showed that the lipid reserve was lower in all treatment groups compared to the control, and significantly lower for the high calcium carbonate particles and tailing treatments and the starved control. Respiration rates in animals from low tailing and high and low Cu exposures were higher than respiration rates in the control group, while medium and high tailing exposures generally caused lower respiration rates. The lowest respiration rates were observed in animals from the starved control group. The global metabolic profiling results revealed changes across a broad range of pathways, including mechanisms linked to energy metabolism and growth. One of the most striking changes occurred in the glutathione pathway, which is highly consistent with previous work demonstrating the role of reactive oxygen species (ROS) and redox imbalance in starved animals.
Our result suggests that ingestion of tailing particles most likely impair metabolism and induce a response resembling starvation in copepods exposed to mine tailings.

4.04 Bioremediation and Phytoremediation of Aquatic and Terrestrial Contaminated Ecosystems

4.04.T-01 Increasing the Removal of Micropollutants in Municipal Wastewater by Natural Adsorbents Addition in Constructed Wetlands: Road to Circular Economy
Nuria López Vinent[1]*, Nicola Montemurro*[1]*, Alberto Cruz-Alcalde*[2]*, Albert Sales Alba*[1]*, Ana Piera Santacruz*[1]*, Jordi Llado*[1]*, Xavier Borrell-Diaz*[3] *and Sandra Pérez*[1]*, (1)Department of Environmental Chemistry, IDAEA-CSIC, Spain, (2)Department of Chemical Engineering and Analytical Chemistry, University of Barcelona, Spain, (3)IDAEA-CSIC, Spain*
The occurrence of micropollutants (MPs) in aquatic ecosystems are mainly attributed to the discharge of wastewater from conventional wastewater treatment plants (WWTPs), which are not specifically designed to eliminate them. Even at low concentrations, many of these compounds can cause hazardous effects on human health and ecosystems. Thus, additional treatments are required at WWTPs to eliminate these MPs. Although some processes have been tested, research on Nature-based Solutions (NbS) is limited investigated.
Among NbS, constructed wetland (CW) is one of the technology recognized for their ecofriendliness, low costs of operation and maintenance and simplicity. However, the requirement of large time of operation, since are natural treatments, could limit the implementation of CW on a full scale. In this sense, this work aimed to investigate the performance of addition of various natural support matrices (two of them wastes of food industry) since they present high adsorption properties, in CW for their capacity to remove 27 selected MPs at 1 µg/L in secondary wastewater effluent. With this purpose, it was intended to reduce the time of operation in CW by the addition of potential adsorbents and framing the project in circular economy.
In this study, four vertical flow CW (VFCW) planted with Sparganium erectum were assembled at semi-pilot scale (15 L water capacity) with recirculation. Each one was filled with a layer of cobbles, volcanic rocks, fine gravel and sand. In three of them, an additional material mixed with sand was added (burnt cork, almond shell and chestnut shell). The last one, without any aditional material was used as control.
The results at 6 days of retention time revealed good performances of VFCW filled with almond and chestnut shell reporting a MP elimination in water higher than 90% for overall compounds (25 of 27). VFCW containing burnt cork and control showed the lowest removals (only 15 and 13 of 27 MPs, respectively, achieved eliminations higher than 90%). The total average abatements were: 88, 87, 77 and 68% for chestnut, almond, burnt cork and control, respectively. Comparing 3 and 6 days of RT the results were very close in systems containing chestnut and almond shell. For instance, in VFCW with chestnut shell the average removal

was only increased 7% from 1 to 6 days. However, in control CW the differences increased by 18%. This data revealed the possible reduction in operation time when additional material was added to CW.

4.04.T-02 Towards the Transformation of a Contaminated Industrial Wasteland into a Living-lab Based on a Phytomanagement Approach

Michel Chalot[1]*, Jordan Collot*[2]*, Lisa Ciadamidaro*[2]*, Philippe Binet*[2]*, Benjamin Pauget*[3]*, Coralie Bertheau-Rossel*[2] *and Annette de Vaufleury*[2]*, (1)UMR 6249 Laboratoire Chrono-environnement, University of Bourgogne Franche-Comté, France, (2)University of Bourgogne Franche-Comté, France, (3)TESORA*

The main goal of the ECOPOLIS project is the restauration by phytomanagement of the industrial wasteland of Vieux-Charmont (Doubs, France), located in an urban area and contaminated by metallic trace elements (TE) and hydrocarbons. With the collaboration of different public and private partners, a living-lab will be implemented on the area for research activities and communication with the public. This implementation is based on three specific objectives, (1) to characterized spatially and quantitively the contamination, mobility, health and environmental impacts due to contaminants on the site. This will be done by monitoring biodiversity on the site and measuring contaminants transfers into ground and surface water, vegetation and animals, (2) To test different management scenarios for the contaminants based on phytoremediation methods in accordance with the principles of the National Methodology for the Management of Polluted Sites and Soils and its associated standard (NF X31-620) and (3) To assess the potential reproducibility of the methods on similar industrial wasteland though the territory. In this presentation, we will address objective 1 mostly. The presentation will focus of the data sets obtained within the period 2020-2022. The first set of data showed that 3 TE are dominant on the site, Zn, Pb and Cd, that have been shown to have potential toxic effect on human health, based on the exposure scenarios and bioaccessibility tests. A botanical survey led to the identification of some native plants that can accumulate Zn (> 2000 mg/kg DW) and Cd (> 15 mg/kg DW) in aerial parts. Some of these plants are further being studied for their phytoextraction potential, with the final aim to develop tools to reduce the available contents of these elements in the soil and their toxicity.

4.04.T-03 Effects of the Addition of Organic Amendments on the Adsorption of Atenolol, Ibuprofen and Tetracycline in Two Agricultural Soils

Marco A. A. Jiménez-González[1]*, Carlos García-Delgado*[1]*, Ana Isabel Ruiz*[1]*, Enrique Eymar*[2]*, Laura Delgado-Moreno*[2] *and Teresa Fresno*[2]*, (1)Geology and Geochemistry, University of Madrid (UAM), Spain, (2)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain*

The presence of pharmaceuticals in wastewater is an issue of major concern, especially due to its use in agricultural systems, which might lead to an increase of these persistent compounds in the soil-plant system and groundwater. Sustainable practices in agriculture, such as the addition of organic amendments, can benefit not only from the improvement of soil physicochemical and biological properties, but also from the capacity of several organic materials, such as composts or biochars, to adsorb organic contaminants. The aim of this work was to evaluate the potential of four organic amendments to increase the capacity of two agricultural soils to adsorb pharmaceuticals. The two agricultural soils selected for this work, S and B, have similar texture (sandy loam) but different pH (S: 7.44; B: 8.39), OM contents (S: 1.39%; B: 0.77%). Four organic amendments were added to the soils in a 5% ratio (w:w): a hydrochar (HC) and a biochar (BC) from pruning waste, a green waste compost (GWC) and spent mushroom substrate (SMS). The analysis of the chemical composition of the organic materials revealed a high content of aromatic groups in BC, while HC, GWC and SMS showed a more heterogeneous composition and the presence of other functional groups. The three pharmaceuticals studied, Atenolol (AT), Ibuprofen (IB) and Tetracycline (TC), are frequently found in wastewater and the environment and show very different chemical structures and acid dissociation constants (AT: pK_a 9.6; IB: pK_a 5.2; TC: pK_{a1} 3.3, pK_{a2} 7.7 and pK_{a3} 9.7), which greatly affects their mobility in soils. Batch adsorption isotherms were performed with incresing concentrations of ibuprofen (1-20 mg/L), tetracycline and atenolol (50-800 mg/L) for the soils and the soil-amendment mixtures. After 24 h of interaction, pH values were measured in the supernatans and the concentration of the pharmaceuticals was analysed by HPLC-PDA. The data were fitted to the Freundlich adsorption model ($Q_e = K_f C_e^n$). The soil S, with lower pH and higher OM content, showed a higher soprtion capacity for AT, IB and TC than soil B. The addition of all the amendments had in general a positive effect on the sorption capacity of both soils for the three compounds, which was more significant for AT. BC and GWC were the amendments that showed a higher potential to improve sorption of pharmaceuticals in agricultural soils in case of multi-contamination events.

4.04.T-04 Harnessing Waterfleas for Water Reclamation

Muhammad Abdullahi[1]*, Iesty Stead*[2]*, Mohamed Abou-Elwafa Abdallah*[3]*, Karl DD Dearn*[2]*, Robert Gregory Lee*[4]*, Sara Jabbari*[5]*, Alexandra Tzella*[3] *and* ***Luisa Orsini***[3]*, (1)Biosciences, University of Birmingham, United Kingdom, (2)Mechanical Engineering, University of Birmingham, United Kingdom, (3)University of Birmingham, United Kingdom, (4)Law School, University of Birmingham, United Kingdom, (5)Mathematics, University of Birmingham, United Kingdom*

Access to clean water is a human right. Yet, more than two billion people worldwide have no access to clean water. Urbanisation, population growth, unsustainable food production and climate change have put unprecedented pressure on water resources systems, leading to global water scarcity. Sustainable use of water resources and water reclamation are urgently needed for people's societal, economic and environmental future. However, water reuse is not safe unless chemical pollutants are removed. Typically, wastewater treatment consists of two main stages that remove pathogens and solids but not persistent pollutants, such as pesticides, pharmaceuticals, and industrial chemicals. Introducing a third stage for the reduction of chemical pollutants typically involves high operational and energy costs, large infrastructure, and can generate toxic by-products (e.g. bromate from

ozonation). Nature-based tertiary treatments are being developed, yet their efficiency is too low for industrial-scale applications and they often demand significant space, infrastructure, and investment, undercutting sustainability objectives.
We have developed a scalable, low-cost, low-carbon, and retrofittable bio-based water bioremediation technology for industrial applications. It uses the waterflea *Daphnia*, a tiny crustacean the size of a grain of rice, as a microscopic vacuum cleaner to non-selectively uptake and retain persistent chemical pollutants and organics from wastewater, enabling water reuse. In a proof of concept study, we benchmarked Daphnia's removal of pharmaceuticals from wastewater against other biological agents, and demonstrated strain-specific removal of chemicals in laboratory settings. Here, we demonstrate the technology at prototype scale (single household) for applications in municipal wastewater treatment. The technology has the potential to maximise the shift to clean growth, enabling water reuse, reducing resource depletion and environmental pollution, and sustaining vital ecosystem services.

4.04.T-05 Bioremediation of Alkaline Spoil Material Using Organic Amendments in the Circular Economy Context
*Ludovica Rolando[1], **Anna Barra Caracciolo**[2], Gian Luigi Garbini[1], Andrea Visca[1], Livia Mariani[3], Antonio Finizio[4], Valentina Mazzurco Miritana[5], Maria Isabel Nogues Gonzalez[6] and Paola Grenni[1], (1)CNR-IRSA Rome, Italy, (2)Water Research Institute - Italian National Research Council IRSA-CNR, Italy, (3)Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (4)University Milano - Bicocca, Italy, (5)Italian National Research Council, Italy, (6)Research Institute on Terrestrial Ecosystems (IRET), National Research Council (CNR)*
Several tunnelling projects have been implementing in Europe and worldwide for easily connecting people in areas with geographical constrains, such as the presence of mountains. For this purpose, tunnel industry produces huge amounts of excavated soil (spoil material) which can be re-used for different purposes, in line with circular economy. The addition of lime can be a practical procedure at a construction site for the chemical stabilization of excavated material making it possible a better managing in the final destination site.
This work reports a nature-based solution, applying different organic amendments (compost, pomace or digestate), for decreasing the highly basic pH (12.5) of the spoil material after adding lime. Microcosm experiments were set-up with spoil material amended with different organic fertilizers and with *Medicago sativa*.
The changes in pH and in the structure and functioning of the microbial community were evaluated in the amended spoil material at 4 months from the start of the experiment. Aerial and root biomass and concentrations of leaf chlorophyll and phenolic compounds were also measured. The microbial community structure was analysed by metagenomic analysis based on the gene for 16S rRNA (NGS); moreover a predictive functional analysis was also performed by data processing with PICRUSt2. Adding the amendments significantly decreased pH values (8.41) and increased microbial abundance and activity. The pomace addition promoted the highest microbial abundance and metabolic activity values and the lowest decrease in pH. However, pomace did not favour plant biomass growth. Compost and digestate showed to be the best solutions for pH decreasing and favouring plant growth. The plant did not have any direct effect on pH lowering, demonstrating in this study the key role of microbial populations in responding efficiently to this environmental stress, mitigating it. In accordance with how mentioned, several genes decoding for membrane proteins (*nuo, mrp*) and for indole acetic acid metabolism (*ami, nthA, ipdC*) involved in pH regulation were found in the amended microbial communities.

4.04.P Bioremediation and Phytoremediation of Aquatic and Terrestrial Contaminated Ecosystems

4.04.P-Th243 Assisted Phytoremediation: Use of TiO_2 Nanoparticles to Enhance Sunflower Capabilities in Recovering Soil Contaminated by PCBs and HMs
***Valeria Ancona**[1], Giorgia Aimola[2], Lucia Maria Curri[3], Angela Gatto[2], Paola Grenni[4], Roberto Comparelli[5], Gian Luigi Garbini[4] and Anna Barra Caracciolo[6], (1)CNR-IRSA Bari, Italy, (2)Italian National Research Council, Italy, (3)Dept. of Chemistry, University of Bari, Italy, (4)CNR-IRSA Rome, Italy, (5)Italian National Research Council, Institute of Chemical and Physical Processes, Italy, (6)Water Research Institute - Italian National Research Council IRSA-CNR, Italy*
Soil pollution is one of the global problems that affected humanity. Recently, Nature-Based Solutions (NBSs) are widely recognized as promising, profitable and sustainable bioremediation strategies to degrade or stabilize organic and inorganic contaminants from the environment. Among these strategies, Plant Assisted BioRemediation (PABR), based on the synergistic action established between root system and soil rhizosphere microorganisms, has been proved to be efficient in restoring historically multi-contaminated soils. In recent years, the use of nanomaterials (particles of 1-100 nm size) in assisting phytoremediation has been studied for recovery soils from pollution. Among these, titanium dioxide (TiO_2) nanoparticles have been investigated on laboratory-scale to assist phytoremediation of soil contaminated by heavy metals (HMs). The use of TiO_2 nanoparticles for enhancing sunflower capabilities for recovering a soil multi-contaminated from polychlorinated biphenyls (PCBs) and HMs, was assessed in greenhouse microcosms. Sunflower (Argentario var) seeds were employed as plant species to favor soil restoration. To set up microcosms, soil was collected from a multi-contaminated area of Southern Italy, located close to Taranto city). Then, it was spiked with TiO_2 nanoparticles, synthetized by IPCF-CNR (Bari). A series of soil microcosms (no planted/ no planted + TiO_2) were also set up as Control samples. Soil chemical-physical parameters (pH, EC, Available P, Organic C), contaminant analytical determinations and microbiological analyses (microbial abundance and dehydrogenase activity) were carried out at different sampling times (0, 45, 90 days). Moreover, the structure of the main microbiological groups was evaluated by qPCR assays. Pollutants analyses were also carried out on biomass (roots, leaves and stems) samples. The main results obtained in sunflower planted microcosms evidenced that soil PCB concentration reduced at end of the experiment (90 days), showing a re-arrangement of the main congener groups (dioxin-like DXL, marker MRK, non-dioxin-like NO-DXL). HM concentrations in soils didn’t vary significantly. HM determinations performed on plant tissues evidenced high accumulation of

Zn and Pb, in leaves and in roots, respectively. The highest values of microbial abundance have been observed in sunflower microcosms spiked with TiO_2.

4.04.P-Th245 Application of Digestate as a Nature Based Solution for Stemming Antibiotic Resistance Spread in Agroecosystems

Andrea Visca[1], Jasmin Rauseo[2], Francesca Spataro[3], Gian Luigi Garbini[1], Ludovica Rolando[1], Paola Grenni[4], Valentina Mazzurco Miritana[5], Giulia Massini[5], Luisa Patrolecco[2] and ***Anna Barra Caracciolo****[6], (1)CNR-IRSA Rome, Italy, (2)National Research Council- Institute of Polar Science (ISP-CNR), Italy, (3)National Reasearch Council Institute of Polar Sciences, Italy, (4)Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (5)ENEA-Italian Agency for New Technologies, Italy, (6)Water Research Institute - Italian National Research Council IRSA-CNR, Italy*

Cattle manure digestate is a valuable and common resource for obtaining energy (e.g., biomethane), recycling organic waste, reducing odors associated with manure storage and decomposition, and removing harmful pathogens and chemicals. Digestate from the production of biogas is an excellent fertilizer and a good substitute for manure. The use of organic fertilizers, including digestate, has been encouraged at the European level by the introduction of the Fertilizing Product Regulation (EU, 2019/1009). However, in recent years, a great concern arises from antibiotics (ABs) regularly detected in agroecosystems from organic fertilizers. Animal husbandry is one of the most common sources of AB contamination in soils (through direct discharge of urine and feces by medicated animals and application of contaminated manure); the predicted increase in global livestock worldwide in the near future could exacerbate this phenomenon. Recent works have demonstrated how the anaerobic digestion process decreases both the AB (biodegradation) and antibiotic genes (ARGs) concentration of cattle manure used as bioreactor feed. Consequently, the use of digestate as an organic fertilizer can potentially reduce the risk of ABs and ARGs spread in agroecosystems. Results regarding AB biodegradation under anaerobic digestion, in soil amended with digestate and the fate of ABs and ARGs from soil it to edible plants (such as lettuce) will be displayed. A significant decrease in AB and ARG transfer from soil to plants in soil amended with digestate, comparing to the same soil amended with manure will be shown. Overall predictive and real functional analyses of ARGs in manure and digestate will support how digestate can be considered a Nature-Based Solution for mitigating the spread of ARGs in agroecosystems.

4.04.P-Th246 Cyanotoxin Degradation in Constructed Wetlands: The Forgotten Degraders

Ángela González*, University of Copenhagen, Denmark*

Events of harmful cyanobacterial blooms and the subsequent release of cyanotoxins have increased globally in the recent years. This trend is expected to continue as the effects of climate change develop, posing a serious threat to the quality of water resources. Conventional water treatment relies on expensive and energy demanding methods that require specialized infrastructure, restricting their use in isolated and rural areas. As an alternative, constructed wetlands (CWs) have been proposed as a nature-based low-cost solution that can purify water by assimilating nutrients and degrading other contaminants, including cyanotoxins. In fact, CW mesocosms have already been shown to efficiently biodegrade Microcystin-LR (MC-LR). However, the majority of the research in this area only focuses on bacterial degradation, neglecting other microorganisms that may also transform these toxins. Therefore, the aim of this study was to fulfill some of the knowledge gaps on cyanotoxin biodegradation in CWs by uncovering the role of their fungal communities on the removal of MC-LR and cylindrospermopsin (CYN). To do so, different plate culture techniques were used to isolate potential fungal degrader strains from CW mesocosms. The isolates were later identified by Sanger sequencing and finally tested in *in vitro* biodegradation experiments. Moreover, the fungal communities of 28 mesocosms were analyzed by amplicon sequencing. The main results showed that the presence of cyanotoxins explained 23 % of the variation observed in the community composition between the treatments. Even though no biodegradation was observed by the selected fungi, some of the isolated strains belonged to genera harboring MC-LR degrading fungi. Thus, the results from this study, which is one of the few focusing on fungal communities in CWs, should be used as a starting point towards understanding the contribution of fungi to cyanotoxin removal, and their importance in CWs.

4.04.P-Th247 Flumequine Accumulation in *Potamogeton pusillus* Under Hydroponic Conditions

Maria Eugenia Valdes*[1], Facundo Cortés[2], Daniel Alberto Wunderlin[1] and Magdalena Monferran[2], (1)Instituto de Ciencia y Tecnología de Alimentos Córdoba (ICYTAC), CONICET and Department of Organic Chemistry, Argentina, (2)Centro de Inmunología y Bioquímica Clínica, CONICET-Universidad Nacional de Córdoba, Argentina*

Water pollution by veterinary antibiotics (VA) is an increasing worldwide problem, due to intensive animal production practices. Phytoremediation is a low-cost and eco-friendly technology to remove emerging pollutants by the use of plants and associated microorganisms. Nevertheless, operational conditions need to be optimized to achieve efficient removals. *Potamogeton pusillus* is a submerged rooted macrophyte that has proven to be a good accumulator of metals. In this study, we proposed to evaluate the removal of flumequine (VA) by *P. pusillus* and its accumulation in the macrophyte organs. To achieve this goal, we exposed the macrophyte (8 g w.w./L) in hydroponic conditions: Hoagland nutrient solution with or without flumequine at 50 and 500 µg/L, during 14 days. Static experiments were performed in a greenhouse room without temperature/light control (n = 4). Hoagland nutrient solution was renewed every 7 days. Water samples were taken at 0, 2, 5, 7 and 14 days for flumequine analysis by UPLC-MS/MS. At the end of the experiments, macrophytes were carefully washed with distilled water; roots, stem and leaves separated, freezed using liquid nitrogen and homogenized to perform extractions. Flumequine was analysed in each organ by an adapted QuEChERs extraction method, followed by UPLC-MS/MS quantification. Leaves were extracted with ethanol 96% V/V to perform pigments analysis by spectrophotometry. After 14 days, flumequine removal from water was greater at 50 /L (62±15 %) compared to the exposure at 500 µg/L (38±12 %). Flumequine accumulation by *P. Pusillus* was dose-dependent, with roots showing the hi er concentration (7±2 µg/g w.w. and 40±7 µg/g w.w. upon exposure to 50 and 500 µg/L, respectively), followed by leaves (2,3±0,3 μg/g w.w.; 13±2 μg/g w.w.) and stems (0,9±0,4 μg/g w.w.; 5±1 μg/g w.w.). Pigments content (chlorophyll-a, chlorophyll-b, pheophytins and carotenoids) decreased after 14 days but ratios of damage (chl-b/chl-a; pheo-a/chl-a) were ≤ 1, indicating no significant damage. Taking into account removal percentages and accumulation of flumequine by *P. pusillus*, this macrophyte could be considered a good candidate for phytoextraction, although further studies under more complex and real conditions are necessary to fully assess this point.

4.04.P-Th248 Adsorption, Leaching and Degradation of Sulfamethoxazole in Amended Soil

Carlos García-Delgado[1], *Enrique Eymar*[2], *Laura Delgado-Moreno*[2], *Marcos Puñal*[1], *Marta Toro*[1], *María Martín-Trueba*[1], *Marco A. A. Jiménez-González*[1], *Teresa Fresno*[2] *and Ana Isabel Ruiz*[1], *(1)Geology and Geochemistry, University of Madrid (UAM), Spain, (2)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain*

Sulfamethoxazole (SMX) is a wide antibiotic used for human and veterinary medicine. Antibiotics reach agricultural soils via wastewater, sewage sludge, and manure. Their environmental fate is controlled by several phenomena such as soil sorption-desorption and degradation. This work aimed to assess the effects of two organic amendments, biochar (B) and green compost (GC), on the adsorption, leaching, and degradation of SMX in basic agricultural soil. The soil was sampled from a vineyard located in Burgos province (Spain). General soil characteristics: sandy loamy texture, basic pH, low organic matter, and presence of $CaCO_3$. The soil was amended with B or GC at 5%. Adsorption properties of organic amendments and soils were evaluated by adsorption isotherms of SMX. The data were fitted to the Freundlich adsorption model ($Q_e = K_f C_e^n$). The leaching of SMX from soil and B- and GC-amended soils were determined by leaching columns. Finally, the 500g of unamended and B- and GC-amended soils were spiked with SMX and incubated for 42 days. SMX degradation and microbial activity were periodically monitored. Adsorption isotherms reveal the low adsorption capacity of SMX in unamended soil. B and CG showed good adsorption capacity of SMX and the resulting amended soil increased the SMX adsorption capacity of soil. The low SMX adsorption in unamended soil produced quick and intense SMX leaching. B-amended soil reduced SMX leaching. In contrast, GC-amended soil promoted the leaching of SMX. The pH of adsorption isotherms and leachates indicate that the anion of SMX was the major specie in unamended and amended soils. CG amendment enhanced the microbial activity of soil and promoted the degradability of SMX in soil. In contrast, the high adsorption and low biostimulation effect of B in soil reduced the degradation of SMX. The half-life of SMX was 2.6, 6.9 and 11.9 days for GC-amended soil, unamended soil, and B-amended soil, respectively. This work shows the benefits and risks of two organic amendments, B and GC, for the environmental fate of SMX. The different nature of the organic carbon of B and GC was responsible for the different effects on soil. The results highlight the variability of results with respect to the different parameters determined and the need to carefully assess the fate of SMX in amended soils to avoid the accumulation of SMX in soil or copious leaching.

4.04.P-Th249 Cefuroxime Adsorption by Soils Amended with Three Low-cost Bioadsorbents

Raquel Cela Cela-Dablanca[1], *Ana Barreiro*[1], *Manuel Arias-Estevez*[2], *Avelino Núñez-Delgado*[1], *Esperanza Alvarez-Rodriguez*[1] *and María J. Fernández-Sanjurjo*[1], *(1)Soil Science and Agricultural Chemistry, University of Santiago de Compostela, Spain, (2)Soil Science and Agricultural Chemistry, University of Vigo, Spain*

The presence of antibiotics in soils is both an environmental and a public health issue, since it favors the proliferation of resistant bacteria, and entails the risk of being introduced in the food chain, which is an important health risk. Cefuroxime is an antibiotic belonging to the β-lactams group that is widely used in the treatment of different diseases, such as bacterial sinusitis, otitis, or tonsillitis. Several studies have found its presence in irrigation waters, rivers and even in food. This antibiotic is excreted by feces and urine, mainly due to the poor absorption in the human intestine, ending up in wastewater. Additionally, the sewage sludge produced in wastewater treatment plants are widely used as fertilizer in agricultural soils, promoting soil pollution.
Adsorption is an effective technique to remove antibiotics from the environment, which favors the growth of studies on the use of low-cost and green bioadsorbents to remove antibiotics from soils. Previous studies demonstrated that cefuroxime adsorption was low in some soils (between 40-70%), and it could be improved adding sorbent materials. For this, in this work three bioadsorbents were added to various soils, to investigate their effect on cefuroxime adsorption in these soils. The bioadsorbents were pine bark, mussel shell and wood ash, which were added to the soils in doses of 12 and 48 t/ha. To carry out this study we used batch experiments, adding solutions with different antibiotic concentrations (0, 2.5, 5, 10, 20, 30, 40, 50 μmol L^{-1}) at 2 grams of each soil/sorbent mixture.
The results showed that when a bioadsorbent with a basic pH (wood ash or mussel shell) was added, adsorption increased in all cases in comparation with the soil without bioadsorbent. However, when the bioadsorbent with low pH (pine bark) was added, the increase in adsorption was significantly lower than in the case of the basic bioadsorbents, and even for some soils adsorption decreases compared with the soil alone. It shows that cefuroxime adsorption depends on the pH of the adsorbent, conditioning different sorption mechanisms. Desorption was very low for all samples, with the smallest found when the bioadorbents were added into soils. Both wood ash and mussel shell increase adsorption and decrease desorption for cefuroxime, suggesting that would be suitable bioadsorbents for remediation of soils polluted with that antibiotic.

4.04.P-Th250 Green Technology for Clarithromycin Sorption

Ana Barreiro[1], *Raquel Cela Cela-Dablanca*[1], *Manuel Arias-Estevez*[2], *Avelino Núñez-Delgado*[1], *Esperanza Alvarez-Rodriguez*[1] *and María J. Fernández-Sanjurjo*[1], *(1)Soil Science and Agricultural Chemistry, University of Santiago de Compostela, Spain, (2)Soil Science and Agricultural Chemistry, University of Vigo, Spain*

Removal technologies of persistent organic pollutants (POPs) are key in the efforts to reduce the spread and accumulation of these chemical compounds in the environment. The wide variety of POPs and consequently of their properties, represents a challenge in the pursuit of the most adequate removal techniques and is the cause of the highly diverse different approaches that are being tested, from very high to simpler technologies. Among the POPs, pharmaceutical products, such as antibiotics, are an important target for these removal process since there are widely spread in the environment. One of the paths is spreading on soils through animal slurries or sewage sludge used as fertilizers, with potential detrimental effects in both the environment and the human health. One technique that has gained increasing interest for antibiotic removal is the biosorption, which allows antibiotic retention using different types of bioadsorbents. The problem with some of these bioadsorbents materials is that they may be expensive when made intentionally for that purpose and not sustainable. The aim of our study is to analyse the sorption capacity of different low-cost by-products from the forest and food industry, to test their capacity to effectively adsorb clarithromycin. Batch type experiments were performed were seven different antibiotic concentration (2.5, 5, 10, 20, 30, 40, 50 µmol L^{-1}) were added to three by-products (wood ash, pine bark and mussel shell). The adsorbed and desorbed antibiotic concentrations were measured by means of HPLC. The results indicate that for the highest concentration of added clarithromycin, the ash showed the highest sorption capacity (92% of the added antibiotic), meanwhile pine bark and mussel shell adsorbed 71% and 67%, respectively. The minimum adsorbed was similar for both ash and pine bark (around 60%), while it was lower for the mussel shell (51%). Regarding clarithromycin desorption, for the highest concentration added, the released concentrations were below the detection limit for the mussel shell, while both ash and pine bark desorbed just 2%. All these by-products (especially wood ash) would be suitable green and sustainable bioadsorbents for the removal of clarithromycin, which could be relevant in the design of green technologies for antibiotics removal.

4.04.P-Th251 Clarithromycin Adsorption in Soils with and without Bioadsorbents

Raquel Cela Cela-Dablanca[1], Ana Barreiro[1], Manuel Arias-Estevez[2], Avelino Núñez-Delgado[1], María J. Fernández-Sanjurjo[1] and ***Esperanza Alvarez-Rodriguez****[1], (1)Soil Science and Agricultural Chemistry, University of Santiago de Compostela, Spain, (2)Soil Science and Agricultural Chemistry, University of Vigo, Spain*

Many studies have previously shown the presence of antibiotics in soils causing pollution. The increase of antibiotic consumption, followed by the poor absorption in the intestine and unappropriated techniques to remove these antimicrobials from wastewater and sludge in wastewater treatment plants contribute to this problem. After their incorporation in soils through wastewater irrigation and/or sewage sludge spread as fertilizer, antibiotics interact with the solid phase. The subsequent behavior of these antimicrobials depends on the soil characteristics and antibiotic physicochemical properties, and their persistence in the environment will be determined by different process, such as mineralization, degradation, volatilization, transport or adsorption. However, most of the antibiotics that reach the soils remain in the surface due to adsorption reactions. Hence, adsorption processes are of main relevance as regard antibiotics behavior in soils.

Clarithromycin is an antibiotic belonging to the macrolide group, which is characterized by the presence of one macrocyclic lactone ring. Clarithromycin is one of the most consumed antibiotics, and a significant amount of it is excreted by feces and urines after its ingestion. Several studies have found the presence of this antibiotic in rivers, surface and ground waters, in concentrations between 1 and 17 µmol L^{-1}.

Previous works have shown a rather low clarithromycin adsorption capacity for different soils (between 40 and 70%). The aim of this work is to explore the potential improvement of clarithromycin adsorption in soils by adding low-cost sorbents, thus aiding to prevent its entry into the food chain. For this, three bioadsorbents (pine bark, mussel shell and wood ash) were added individually to six soils, in doses of 48 t/ha. To carry out this work we performed batch experiments, adding antibiotic solutions in concentrations of 0, 2.5, 5, 10, 20, 30, 40, 50 µmol L^{-1} at 2 grams of soil without and with bioadsorbent (added at 48 t/ha).

The results showed that in most cases the highest adsorption occurred when soils were added with pine bark, followed by wood ash and mussel shell. In fact, adding mussel shell to the soils decreased adsorption. Finally, desorption values were always less than 10 µmol kg^{-1}, with pine bark associated to the lowest desorption. Overall, pine bark performed as the best option to increase adsorption, while mussel shell showed the lowest efficacy as soil amendment.

4.04.P-Th252 Determining Pharmaceutical Uptake by Wetland Plants to Assess Their Remediation Potential

Julie Layshock[1] and ***Marisa Almeida****[2], (1)Pacific University, (2)University of Porto, Interdisciplinary Centre of Marine and Environmental Research (CIIMAR), Portugal*

Natural treatment systems, such as constructed or natural wetlands, may be a solution for the purification of water from pharmaceutical pollution. Plants are an important part of wetland systems but pharmaceutical uptake in plant tissues is a poorly understood removal mechanism.

The aims of this research are to optimize and validate methodologies for analysis of pharmaceuticals in aerial and below-ground plant tissues in order to evaluate overall uptake. Grinding, extraction, and analysis methods will be optimized for roots, rhizomes, and stems of important wetland plants, *Juncus maritimus* and *Phragmites australis*. After optimizing methodologies, pharmaceutical uptake by the plants when exposed to these compounds in experiments simulating wetland environments will be evaluated. This research will help clarify the role of plants in removing pharmaceuticals from contaminated media so that wetland conditions, including the harvest or selection of plant species, may be optimized.

4.04.P-Th253 Adsorption of Ibuprofen, Tetracycline and Atenolol in Sand, Silt and Clay Fractions of Two Soils

Carlos García-Delgado*[1], Ana Isabel Ruiz[1], Olga Rodríguez-Díaz[1], Marco A. A. Jiménez-González[1], Enrique Eymar[2], Laura Delgado-Moreno[2] and Teresa Fresno[2], (1)Geology and Geochemistry, University of Madrid (UAM), Spain, (2)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain*

The presence of pharmaceuticals in agricultural soils is increasing because of the use of wastewater, sewage sludge, and organic fertilizers of animal origin. The physicochemical interaction between the pharmaceuticals and the soil governs the environmental fate of pharmaceuticals and their bioavailability. The aim of this work was to determine the role of the textural fractions (sand, silt, and clay) of two soils on the adsorption of ibuprofen (IB), tetracycline (TC), and atenolol (AT). These pharmaceuticals were selected because of their different chemical characteristics such as water solubility and pK_a values. Two agricultural soils (S and B) from Spain with the same textural classification (sandy loam) but different pH (7.44 and 8.44, respectively), organic matter (OM) content (1.39 and 0.77%, respectively) and mineralogy were used. Adsorption isotherms of the three compounds were performed with raw soils and their respective fractions of sand, silt, and clay. After the adsorption process, pH was determined in the suspension and the remaining concentration of pharmaceuticals was analyzed in the supernatant. The data were fitted to the Freundlich adsorption model ($Q_e = K_f C_e^n$). The pH values revealed that the major ionic form was the anion form of IB, the zwitterionic form of TC, and the cationic form of AT in the two soils and in all the fractions. The lowest adsorption took place for IB because of its anionic nature. The adsorption of the zwitterionic form of TC was higher than the cationic form of AT denoting that the cation exchange was not the only adsorption mechanism in soil and soil fractions, including clay. Soil S showed higher adsorption of IB, TC, and AT than soil B. This result can be related to the lower pH, higher OM content, and mineral composition. The adsorption of clay fraction was higher than silt and sand for the two soils and the three pharmaceuticals. The isotherms were of type L and S for IB, type L for TC, and type C and S for AT denoting different adsorption mechanisms in bulk soils and fractions. The mineral composition, OM, and cation exchange capacity were related to the adsorption properties of soil and soil fractions.

4.04.P-Th254 Degradation of Sulfamethoxazole by Immobilized Enzyme-Mediator Systems

*Sergio Zamora[1], **Carlos García-Delgado**[2], Begoña Mayans[1], Javier Guerrero[1], Laura Delgado-Moreno[1], Rafael Antón-Herrero[1], Jaime Cuevas[2] and Enrique Eymar[1], (1)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain, (2)Geology and Geochemistry, University of Madrid (UAM), Spain*

Antibiotics in wastewater have become an issue due to the low removal efficiency of conventional wastewater treatment plants. Sulfamethoxazole (SMX) is a widely used antibiotic in human and veterinary medicine. Laccase can degrade a broad spectrum of organic pollutants. This enzyme catalyzes the degradation of phenolic and non-phenolic compounds. However, industrial application of laccase is limited by its high price, continuous loss of enzyme due to its solubility, and low stability. The immobilization of the enzyme onto solid supports could prevent mentioned drawbacks. The aim of this study is to evaluate the degradation of sulfamethoxazole by a laccase-mediator system using immobilized laccase on two mesoporous materials, activated carbon (AC) and stevensite clay (ST) thermally treated at 500ºC, with two different redox mediators, syringaldehyde (SA) and concentrated olive- wastewater (OW). Laccase was immobilized by covalent binding using glutaraldehyde as the linker. Stevensite clay was pretreated by acid wash while no pretreatment was needed for activated carbon. Furthermore, the degradation of this antibiotic using laccase will be compared with other conventional chemical oxidation processes such as Fenton reactions. All the immobilized laccase-mediator systems degraded the antibiotic in a short period of time (5 minutes). AC-SA system achieved a 93% SMX degradation. The others biocatalyst-mediator systems degraded 48% (AC-OW), 50% (ST-SA) and 50% (ST-OW). Furthermore, OW has the potential of becoming a competitive redox mediator capable of achieving , a widely used redox mediator, depending on the carrier used. In advantage, most of the redox mediators used in enzyme catalyzed reactions are costly. OW presents a great advantage due to its waste condition. Fenton reaction degraded a similar amount of antibiotic as the enzyme-mediator systems, showing that the immobilized laccase-mediator systems produce similar SMX degradation than the advanced oxidation processes. This work demonstrates the usefulness of the biocatalyst-mediator systems studied to degrade SMX.

4.04.P-Th255 Absorption of Atenolol and Tetracycline in Different Organic Amendments

***Marco A. A. Jiménez-González**[1], Carlos García-Delgado[1], Laura Delgado-Moreno[2], Ana Isabel Ruiz[1], Enrique Eymar[2] and Teresa Fresno[2], (1)Geology and Geochemistry, University of Madrid (UAM), Spain, (2)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain*

In recent decades, the use of pharmaceutical for human and veterinary purposes has increased considerably. This fact has generated a marked increase in the presence of this type of compounds in wastewater, which is an important problem because some pharmaceuticals are recalcitrant. Consequently, pharmaceuticals usually are in sewage sludge and accidentally enter in agricultural soils as part of fertilization generating a big problem at trophic level, or leaching and contaminating groundwater. The goal of this work is to study different organic amendments as possible adsorbent of these compounds and minimize bioavailability or leaching. A total of four organic amendments were selected for the adsorption study of pharmaceuticals: biochar (B), hydrochar (HYD), compost (COM) and spent mushroom substrate (SMS). Tetracycline (TC) and atenolol (AT) were selected due to their common use and differences in water solubility and pKa. A general characterization of the organic amendments was carried out (pH, electrical conductivity, organic matter content, elemental composition...). Furthermore, different spectroscopic techniques were used to obtain more detailed information of the chemical structure: solid-state ^{13}C nuclear magnetic resonance (^{13}C-NMR), infrared (IR). For the absorption analysis, the isotherms were adjusted using Freundlich model. The results showed good absorption in all the organic amendments. In the case of TC, the SMS presented the highest absorption capacity (K_f=3025) followed by HYD (K_f=1305), COM (K_f=1035), and finally B presented the lowest absorption (K_f=608). The AT presented lower absorption than TC but for this compound B was the organic amendment with the highest absorption (K_f=239), then COM (K_f=189), HYD (K_f=110) and SMS (K_f=20). The different organic carbon nature of these organic amendments could show the different adsorption mechanisms for TC and AT and therefore, the different affinity of organic amendments by each compound. In conclusion, organic amendments can be a potential tool to control pharmaceuticals in the natural environment. Also, the differences in absorption capacity between the organic amendments maybe create new perspectives with the possibility of creating mixtures of various amendments to expand the richness and absorption potential.

4.04.P-Th256 Phytoremediation of Amr Drivers by Aquatic Plants: A Green Barrier to Combat Amr Spread

Kaniz Fatema Chowdhury[1]*, Rebecca H Hall*[2]*, Alan McNally*[2] *and Laura Carter*[1]*, (1)School of Geography, University of Leeds, United Kingdom, (2)University of Birmingham, United Kingdom*

There is a growing concern regarding antimicrobial resistance and its spread in the environment. Alongside the detection of chemicals, we also see the development of AMR in the aquatic environment following the release of wastewater and industrial effluents. Various drivers contribute to the spread of antibiotic-resistant bacteria and their antimicrobial genes (ARGs). Antimicrobials, heavy metals, and biocides are classed as AMR drivers and contribute towards a selective pressure resulting in the development of antimicrobial resistance. There is an urgent need to develop tools and processes to remove these drivers from the environment to challenge AMR spread. Aquatic phytoremediation is a recently adopted methodology to remediate contaminated matrices via sequestration and enhanced degradation of chemical pollutants in aquatic environments. An aquatic hyper-accumulator plant, *Lemna minor,* was selected to assess the potential for phytoremediation of common AMR drivers (metals, antibiotics, biocides). For the first time we assess the phytoremediation of AMR drivers in isolation and a combination. Under controlled laboratory exposure two metals (XX), two antibiotics (XX), and two biocides (XX) were used to assess potential combined competition on phytoremediation amongst chemicals of the same class and across different chemical classes. Mitigation measures to combat AMR are needed which account for chemical complexity in the natural environment and the fact that exposure does not occur in isolation to a single driver.

4.04.P-Th257 Reduction of Odors Emitted by Swine Manure Facilities with Bio-foam Cover Technology

Seung-Woo Jeong[1]*, Prakash Gautam*[2]*, Rabin K.C*[2] *and Subok Chae*[2]*, (1)Environmental Engineering, Kunsan National University, Korea, (2)Kunsan National University, Korea*

In this pilot-scale study for ammonia (NH3) reduction from swine facilities, bio-foam was produced by surfactant solution and ammonia-degrading microbes using automatic foam generation unit and sprayed onto the manure surface. We report that the bio-foam spraying significantly suppresses the release of NH3 from swine manure (located in the four different real swine manure storage facilities in Yongin city, South Korea) irrespective of the seasonal change. The bio-foam spraying system designed was as effective as the laboratory tests (previous study) in masking and degrading NH3, and complete manure coverage was achieved in 40-50 minutes. The applied bio-foam in this study was very dry (Hexagonal, foam quality; 99.0-99.2% and foam density 0.0080 g/mL), medium expansion and stable (half-life; 120 min) with foam bubble density of 25 bubbles/cm2 (small size bubbles). Furthermore, this study reduced NH3 significantly higher (90–100 %) compared to the control (without treatment; 25–43 %). Considering this evidence, the bio-foam has two major functions; i.e., bio-foam can act as a physical barrier to prevent early release of malodorous compounds into the atmosphere, and it ultimately degrades malodorous (bad odor gases) by the bacteria, after breaking the foam. In addition, surfactant foam may also serve as an effective medium for bacteria to spread evenly in manure pits.

4.04.P-Th258 Enhanced Rhizoremediation of a Kerosene-Contaminated Soil with a Mixed Bacterial Inoculant Combining Tactic Motility and Biosurfactant Production

Alicia Fernandez-Vazquez[1]*, María Balseiro-Romero*[1]*, Pol Martin*[2]*, Jose Luis Garcia*[1]*, Jose Carlos Castilla Alcantara Sr*[3]*, Rosa Posada*[1]*, Carmen Fernández-López*[4]*, Joaquim Vila*[5]*, Magdalena Grifoll*[5] *and Jose Julio Ortega-Calvo*[1]*, (1)Instituto de Recursos Naturales y Agrobiologia, Spain, (2)Department of Genetics, Microbiology and Statistics, Section of Microbiology, Virology and Biotechnology, University of Barcelona, Spain, (3)Instituto de recursos Naturales y Agrobiologia, Spain, (4)UCAM, Spain, (5)Genetics, Microbiology and Statistics, University of Barcelona, Spain*

Bioremediation is a main natural-based solution for the clean-up of polluted soils. Pollutant biodegradation is improved by stimulating the activity of the autochthonous microorganisms through the improvement of soil conditions (nutrient content, moisture, pH, etc.) (biostimulation); and/or through the addition of allochthonous microorganisms with specific metabolic traits (bioaugmentation). In heterogeneously polluted soils with organic xenobiotics, it is essential to guarantee the dispersal of the inoculants over the volume of soil and to promote the bioavailability of the pollutants, which will in turn enhance bioremediation efficiencies.

The aim of the present work was to design a rhizoremediation strategy for a kerosene-contaminated soil from a military base (South of Spain), based on the combination of both biostimulation and bioaugmentation in the presence of a model plant (sunflower, *Helianthus annuus*) and at the greenhouse scale (pots with 2 kg of soil). The bioaugmentation inoculant was a mixture of a motile strain (*Pseudomonas putida* G7), which is chemotactic towards sunflower root exudates, and a biosurfactant producing strain (*Bacillus subtilis* DSM10). This inoculant was designed to enhance the dispersion of the biosurfactant producer strain all over the soil volume in pots by chemotactically-mediated comobilization together with the *P. putida* G7 front.

The analysis of the kerosene residue through time showed that its degradation by the autochthonous microbial communities was more efficient in the presence of the plants, and it increased in the presence of both bacterial inoculants. This degradation enhancement was probably due to a pollutant bioavailability improvement provoked by the action of the plants and the surfactants produced by *B. subtilis* DSM10. A decrease in the surface tension of the soil-water extracts of the pots containing *B. subtilis* DSM10 corroborated that the strain was producing biosurfactants. The effect of *B. subtilis* DSM10 on kerosene degradation was only significant in the presence of *P. putida* G7, which is possibly attributable to the dispersal effect provoked by the combination of *P. putida* G7 and the plant.

These results would reflect the importance of achieving a homogenous distribution of the inoculants over the soil volume for efficient soil clean-up, as well as the enhancement of organic pollutant bioavailability, which is one of the mayor constraints of the remediation of soils polluted with organic xenobiotics.

4.04.P-Th259 Influence of Saponin on Pyrene Microbial Degradation in Different Pollutant Carbon Fluxes Relevant for Soil Bioremediation

Alicia Fernandez-Vazquez *and Jose Julio Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia, Spain*

The limited biodegradability of slowly desorbing contaminants must be taken into account when developing nature-based solutions (NBS) to soil pollution by polycyclic aromatic hydrocarbons (PAHs). The use of biosurfactants is a well-known strategy for promoting their biodegradation in polluted soils. Although the potential of microbial biosurfactants, such as rhamnolipids, is well known, fitogenic (i.e., plant-produced) surfactants, such as saponin, constitute a realistic alternative, considering sustainability and financial aspects of NBS. This non-ionic biosurfactant, with an excellent performance, low toxicity and wide presence in nature, contains a hydrophilic glycoside backbone and a lipophilic triterpene derivative, contributing to its excellent solubilization capacity for hydrophobic organic contaminants.

The present study seeks to investigate the influence of *Quillaja* saponin biosurfactant on biodegradation of ^{14}C-pyrene by the PAHs degrader *Mycobacterium gilvum VM552* under bioavailability restrictions. The experiments were carried out in three different exposure regimes of pyrene generating dissimilar carbon fluxes: supplied as crystals (high carbon flux), supplied by partitioning from loaded polydimethylsiloxane (PDMS- medium) and sorbed to a soil-soot mixture (low), where pyrene was strongly sorbed to soil and soot particles.

The results showed that saponin above and below its critical micelle concentration (0.5 g/L) promoted the biodegradation of pyrene, in different ways depending on the scenario. Significant solubilization and enhanced biodegradation of crystalline pyrene was observed. The enhancement was, however, not so efficient for pyrene-preloaded PDMS and pyrene sorbed into soil-soot mixture. This loss in the efficiency of biosurfactant promoting biodegradation could be explained by the decline in bioavailability and the adhesion of bacteria cells to PDMS surface and soil particles. Our study suggests that saponin can constitute a valid alternative in risk-minimizing strategies at different stages of the bioremediation processes.

4.04.P-Th260 Soil Enzyme Activity in Polluted Soils Treated with Waste-derived Technosols

Antonio Aguilar Garrido[1], Mario Paniagua López[1], Manuel Sierra Aragón[2], Francisco Javier Martínez Garzón[1], ***Ana Romero Freire[2]*** *and Francisco José Martín Peinado[1], (1)Departamento de Edafología y Química Agrícola, Facultad de Ciencias, Universidad de Granada, Spain, (2)Department of Soil Science and Agricultural Chemistry, University of Granada, Spain*

Metal mining causes severe pollution problems by releasing potentially hazardous elements (PHEs) into the soil-plant-water system, affecting its ecosystems functions and human health. This study evaluates the effectiveness of Technosols designed to remediate soils affected by the Aznalcóllar mine spill, one of the largest mining accidents in Europe. In particular, the remediation process is assessed by measuring soil enzyme activity (dehydrogenase, β-glucosidase, cellulase, acid phosphatase). Six Technosols (T1-T6) were made by mixing polluted soil (50-60%) and organic/inorganic wastes from mining (iron sludge, marble sludge, and carbonated waste from peatbogs), urban activity (composted sewage sludge, and vermicompost from gardening) and agro-industry (solid olive-mill by-product). The assay included two controls (polluted soil [PS], unpolluted soil [US]), each Technosol [T1-T6] and six treatments of the PS to which the Technosol (T1-T6) was added on top (R1-R6). After 2 months of controlled incubation, soil enzyme activities, soil properties (pH, EC and OC), and soluble and bioavailable PHEs concentrations were analysed. No changes in the different enzyme activities were found in the treatments (R1-R6). Two months were not enough to recover the low biological activity in the PS treated with the different Technosols on top (R1-R6). However, in Technosols (T1-T6) the biological activity in terms of dehydrogenase activity has been stimulated by far compared to the US. Especially in the Technosols containing solid olive-mill by-product (T1 and T4) or composted sewage sludge (T2 and T5) with more than 100 µg TPF g soil^{-1}, while in the US about 27 µg TPF g soil^{-1}. Likewise, β-glucosidase, cellulase, and acid phosphatase activity have increased in Technosols (T1-T6) with respect to PS control, but not in all cases they exceeded those given in US control. Although no changes in enzyme activity were observed, soil properties in PS treated with Technosols (R1-R6) have generally improved; in particular, pH rose to neutralisation and OC has increased by about 0.5%. Also, the solubility and bioavailability of Cd, Cu and Zn was reduced in R1-R6 soils, although there was an increase in the levels of soluble and bioavailable Sb and bioavailable As (not in soluble). Thus, these Technosols were effective in remediating soils polluted by sulphide mining as they recover soil properties, reduce mobility and bioavailability of some PHEs, and also promote biological activity.

4.04.P-Th261 Bioremediation of Polluted Soils with Petroleum Hydrocarbons by Four Spent Mushroom Substrates

Rafael Antón-Herrero[1], ***Carlos García-Delgado[2]****, Natalia Baena[1], Begoña Mayans[1], Laura Delgado-Moreno[1] and Enrique Eymar[1], (1)Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain, (2)Geology and Geochemistry, University of Madrid (UAM), Spain*

The remediation of polluted soils with petroleum hydrocarbons is a difficult and expensive task. The bioremediation of polluted soils is an attractive alternative to traditional techniques such as thermal desorption. The objective of this work was to assess the ability of four spent mushroom substrates (SMS) (*Lentinula edodes, Pleurotus ostreatus, Pleurotus eryngii* and *Agaricus bisporus*) to bioremediate a polluted soil from an oil refinery. This soil was sampled from a refinery in Huelva (Spain). Soil samples were mixed with SMSs at a rate of 10% in weight in reactors of 1L and incubated at 70% MWHC for 40 days at 20ºC in the dark. TPHs were extracted by microwaves using a mixture of acetone and n-hexane 1:1 (v/v). Fungal biomass was assessed by the ergosterol content. The ligninolytic activities determined were laccase, Mn-peroxidase and versatile peroxidase. Two enzyme activities were analyzed to assess the soil microbial activity, total hydrolase and dehydrogenase.

The soil was extensively colonized by *A. bisporus* and *P. eryngii*. In contrast, *P. ostreatus* and *L. edodes* showed low colonization. However, no significant differences in ergosterol were found between inoculated microcosms. The SMS of *A. bisporus* significantly enhanced the ligninolytic and microbial activity of the soil with respect to control soil. The biostimulatory effect of the other SMSs was low. The final concentration of TPHs was lower in the four amended soils than in the unamended soil. The SMS of *A. bisporus* increased 48% the degradation of TPHs with respect to control. The other SMS increased the degradation rate of TPHs 34% (*L. edodes*), 29% (*P. ostreatus*), and 12% (*P. eryngii*). However, the degradation effectivity of hydrocarbons was dependent on the aliphatic or aromatic nature and the long chain of the hydrocarbons and the SMS used. The light aliphatic and aromatic hydrocarbons were more degradable than the heaviest. No significant enhanced degradation was found for the aliphatic hydrocarbons >C35 or aromatic hydrocarbons >EC21. The bioavailability of the different fractions of TPHs was important. The SMS of *A. bisporus* was the most effective SMS to degrade aliphatic and aromatic hydrocarbons because of the ability of the fungi to colonize the soil and the biostimulating potential of this agricultural waste. This work demonstrates the usefulness of SMS, an abundant agricultural waste, to bioremediate polluted soils with TPHs and is the first step of a scaling-up procedure.

4.04.P-Th262 Green Bioremediation with White-Rot Fungi
Oksana Golovko[1] *and Malin Hultberg*[2]*, (1)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (2)Department of Biosystems and Technology, Swedish University of Agricultural Sciences (SLU), Sweden*
Efficient removal techniques are urgently needed to remove emerging contaminants (EC), such as pharmaceuticals from wastewater, in order to protect water resources. A major source of pollution of inland waters are effluent discharges from wastewater treatment plants (WWTPs) because the existing treatment processes do not efficiently remove EC. Bioremediation based on white-rot fungi (mycoremediation) is particularly promising in decontamination because of the nonspecific nature of the ligninolytic enzymatic system, which can degrade a wide range of EC. Direct use of a colonized mushroom substrate is one method of employing oxidative enzymes. From a practical perspective, this would be less resource-intense than downstream processing and purification of the enzymes. Furthermore, locally produced plant biomass, such as wetland biomass, could be used to propagate the fungal mycelium. Another option may be submerged fermentation for production of mycelium directly in wastewater. Thus, this research focuses on developing novel, circular and resource-efficient mycoremediation strategies.
In one study, laccase and manganese peroxidase produced from mushroom substrates colonized by *Pleurotus ostreatus* and other white-rot fungi were evaluated as a novel wastewater treatment method for removal of EC including sulfamethoxazole, erythromycin, azithromycin, fluconazole, trimethoprim, venlafaxine and its metabolite desvenlafaxine, tramadol, lidocaine, metoprolol and caffeine at environmentally relevant concentrations. The selected ECs were treated with suspensions of mushroom substrate with laccase activity ranging between 10-50 U/L.
Overall, removal efficiencies varied significantly between the studied ECs. This demonstrates potential for using mushroom substrate colonized by white-rot fungi for production of lignolytic enzymes which can be useful for removal of ECs from wastewater.

4.04.P-Th263 Biopiles Design for Mycoremediation of Soils Contaminated with Petroleum Hydrocarbons
Carlos García-Delgado[1]*, Rafael Antón-Herrero*[2]*, Begoña Mayans*[2]*, Laura Delgado-Moreno*[2]*, Sergio Zamora*[2] *and Enrique Eymar*[2]*, (1) Geology and Geochemistry, University of Madrid (UAM), Spain, (2) Agricultural Chemistry and Food Sciences, University of Madrid (UAM), Spain*
The production of mushrooms at an industrial scale generates large amounts of spent mushroom substrate (SMS). The storage and management of this organic waste cause environmental problems ending in landfills or being incinerated. This waste can be used for bioremediation as it contains a valuable microbiota to remediate contaminated soils with organic pollutants. The main objective of this work was to assess the bioremediation of contaminated soil with petroleum hydrocarbons (TPHs) by three SMS (*Pleurotus ostreatus, Pleurotus eryngii* and *Agaricus bisporus*) in biopiles. Contaminated soil was obtained from an oil refinery in Huelva (Spain). Two different soil managements were performed, one set of biopiles was built by soil amended with the *A. bisporus* SMS and the other set of biopiles by unamended soil. The biopiles were built by the disposition of a layer of soil, a layer of SMS, and finally, another layer of soil. The three treatments of each set of biopiles corresponded to each one of the three SMS tested. A control treatment without SMS was performed. Biopiles were prepared in 1 L cylindrical and transparent reactors. Moisture was controlled by periodical irrigation. Forced aeration was introduced in the biopiles by a pipette coupled to a pump. The biopiles were incubated for 60 days at 25ºC.
Soil moisture was higher for the soils amended with *A. bisporus* SMS than unamended soil, indicating the positive effect of SMS to keep the soil moisture in sandy soil. The enzymatic analysis showed that the highest activities were found in the inferior soil layers. The biopiles built with amended soil with *A. bisporus* SMS and an intermediate layer of *P. eryngii* showed the highest microbial activity. Anyway, all the biopiles with an intermediate layer of SMS reached a final concentration of TPHs significantly lower than the control, reaching up to 65% of TPHs degradation. In general, the inferior layers of soil reached higher TPHs degradation than the upper layers because of the higher moisture levels and microbiota activity. This work demonstrates that the three SMS evaluated enhanced significantly the removal of TPHs, demonstrating the usefulness of this abundant agricultural waste in the remediation of TPHs contaminated soils. The valorization of SMS for this purpose promotes the circular economy and the Green Deal of the European Union reducing the environmental and climate footprint of the food system.

4.04.P-Th264 Bacterial Benz(a)anthracene Catabolic Networks in Soils Are Influenced by HMW-PAHs as Co-substrates
Sara Nienke Jiménez-Volkerink[1]*, Maria Jordán*[1]*, David Singleton*[2]*,* ***Magdalena Grifoll***[1] *and Joaquim Vila*[1]*, (1)Genetics, Microbiology and Statistics, University of Barcelona, Spain, (2)Environmental Molecular Biotechnology Laboratory, Duke University, USA*
Polycyclic aromatic hydrocarbons (PAHs) are major environmental pollutants in a number of point source contaminated sites, where they are found embedded in complex mixtures containing different polyaromatic compounds. The application of

bioremediation technologies is often constrained by unpredictable end-point concentrations, enriched in recalcitrant high molecular weight (HMW)-PAHs, and by the formation of generally overlooked PAH transformation products. The aim of this study was to elucidate the microbial populations and potential interactions involved in the biodegradation of benz(*a*)anthracene (B*a*A) in a historically creosote-contaminated soil. The combination of DNA-SIP and shotgun metagenomics of ^{13}C-labeled DNA identified a member of the recently described genus *Immundisolibacter* as the key B*a*A-degrading population. Analysis of the corresponding metagenome assembled genome (MAG) revealed a highly conserved genetic organization unique within this genus, including novel aromatic ring-hydroxylating dioxygenases. The influence of other HMW-PAHs on B*a*A degradation was ascertained in soil microcosms spiked with B*a*A and fluoranthene (FT), pyrene (PY) or chrysene (CHY) in binary mixtures. Co-incubation of PAHs resulted in a major delay in the removal of the less soluble PAHs and an increased formation of benz(*a*)anthracene-7,12-dione (B*a*AQ), the ready oxidation product from B*a*A, which was associated to relevant microbial interactions. Our findings highlight that interacting microbial populations modulate the fate of PAHs when found in mixtures.

4.04.P-Th265 Bacterial Biodegradation Mechanisms to Mitigate the Risk Posed by Polar Transformation Products in PAH-Contaminated Soils

***Sara Nienke Jiménez-Volkerink**[1], Maria Jordán[1], Cristina Minguillón[2], Hauke Smidt[3], Joaquim Vila[1] and Magdalena Grifoll[1], (1)Genetics, Microbiology and Statistics, University of Barcelona, Spain, (2)Nutrition, Food Science and Gastronomy, University of Barcelona, Spain, (3)Laboratory of Microbiology, Wageningen University & Research, Netherlands*

Genotoxicity of PAH-contaminated soils can eventually increase after bioremediation despite effective PAH removal. This effect has been attributed to the formation and accumulation of polar transformation products, such as oxygenated PAHs (oxy-PAHs). The further biodegradation of these compounds has been described under certain biostimulation conditions; however, the underlying microorganisms and mechanisms remain to be elucidated. With the aim of understanding the mechanisms involved in the biodegradation of oxy-PAHs, we isolated a 9,10-anthraquinone (ANTQ)-degrading bacterial strain and obtained a 7,12-benz(*a*)anthraquinone (B*a*AQ)-degrading bacterial consortium. Sand-in-liquid microcosms inoculated with creosote-contaminated soil revealed the existence of a specialized ANTQ-degrading community, and *Sphingobium* sp. AntQ-1 was isolated for its ability to grow on this oxy-PAH. Combining metabolomic, genomic and transcriptomic analysis of strain AntQ-1 we comprehensively reconstructed the ANTQ biodegradation pathway. Specific mechanisms for oxy-PAH degradation were revealed, involving the cleavage of the central ring catalyzed by Baeyer-Villiger monooxygenases (BVMO). Essential genes for the ANTQ biodegradation pathway were encoded in megaplasmid *pANTQ-1*. Abundance of strain AntQ-1 16S rRNA and its BVMO genes in the sand-in-liquid microcosms correlated with maximum ANTQ biodegradation rates, supporting the environmental relevance of this mechanism. In the case of B*a*AQ, we also identified a specialized B*a*AQ-degrading subpopulation in the soil using sand-in-liquid microcosms and a B*a*AQ-degrading microbial consortium was obtained by enrichment in sand-in-liquid cultures with B*a*AQ as sole carbon source. The integration of data from metabolomic and metagenomic functional gene analyses revealed that the B*a*AQ metabolic pathway was probably initiated by BVMOs with identical genetic sequences to those encoded in *pANTQ-1*, indicating horizontal gene transfer phenomena. Our results demonstrate the existence of highly specialized microbial communities in contaminated soils responsible for processing oxy-PAHs. Also, they suggest that Baeyer-Villiger oxidations, infrequent during PAH-biodegradation, could be a relevant mechanism for the processing of oxy-PAHs in contaminated sites, thus contributing to mitigate the potential risk of their accumulation.

4.04.P-Th266 Complete Genome Sequence of *Penicillium brevicompactum* (CMG 72), a Polyethylene Microplastics Degrading Strain

***Ana Maria Paço**[1], Micael F.M. Gonçalves[2], Joao Pinto da Costa[3], Teresa Rocha-Santos[1] and Artur Alves[2], (1)Chemistry, University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (2)University of Aveiro, Portugal, (3)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal*

In recent years, there has been an exponential increase in the number of genomic sequences of fungi, which provide information about their genetic, physiological, and ecological diversity. It also shows the great potential of fungi to produce metabolites with pharmaceutical interest.

Penicillium species, for example, are very common fungal species and producers of several secondary metabolites and are widely studied and applied in different economic fields. Some of these species are also involved in the decomposition of compounds and have been used in biodegradation studies.

Penicillium brevicompactum is an example of a species that can produce an important compound, mycophenolic acid, and its propensity to biodegrade some polymers has also been demonstrated by some authors. In our group, its ability to biodegrade polyethylene microplastics has been studied and demonstrated.

Thus, the annotation of the genome of this fungus will allow the characterization of key genes associated with the biodegradation process, which would be useful in the screening of new microorganisms. Furthermore, the obtained genome would also help to unravel the enzymes and metabolites involved in the biodegradation process, since an annotated genome is essential for all other OMICs studies.

The DNA was extracted from the mycelium cultured in Potato Dextrose Broth, by the guanidinium thiocyanate method. DNA quality was checked with a Nanodrop, and the genome sequence was obtained using Illumina Novaseq. The generated raw sequence was assessed with fastQC and the assembly was done using SPAdes.

After assembly, the genome was analyzed, characterized, and annotated using different web-applications and bioinformatic programs.

The genome shows a total length of 31 099 894 bb, divided into 240 contigs, with a size >=500bp and the largest has a size of 1 505 776 bp. The assembly has a G+C content of 49.22% and 10 907 genes were predicted.

Genes were identified that encode enzymes or proteins already associated with biodegradation of plastics, as well as proteins involved in pathways related to the degradation of chemical compounds.

4.04.P-Th267 Insights into the Phytoremediation of Microplastics from the Aquatic Environment
Ula Rozman *and Gabriela Kalcikova, Faculty of Chemistry and Chemical Technology, University of Ljubljana, Slovenia*
Due to global plastic production, microplastic pollution is becoming a serious environmental problem. Therefore, there is enormous interest in methods that can limit microplastics in the environment. Currently, most approaches focus on implementing advanced technologies in existing wastewater treatment plants (e.g., membrane technologies, electrocoagulation), as they represent an important pathway for microplastics to enter the environment. However, microplastics can also enter the environment through other routes or be generated by fragmentation of larger plastic pieces in the environment. In this case, methods for *in situ* removal of microplastics are needed, and one of the promising options is phytoremediation. To date, several studies have documented the attachment of microplastics to the surface of aquatic macrophytes, but quantitative assessment of the amount of adhered microplastics to plant biomass and kinetic studies have not yet been performed. In this context, the aim of our study was to mathematically describe the adhesion of microplastics to plant biomass (duckweed *Lemna minor*) under different environmental conditions with pristine and aged polyethylene microplastics. The results showed that the maximum capacity for microplastics retention was reached after 24 h, with 2.76 ± 0.43 particles/mg and 0.84 ± 0.19 particles/mg being weakly and strongly bioadhered to the plant biomass, respectively. The experimental data were applied to different isothermal models, and the Radke-Prausnitz isotherm best described weak bioadhesion, while strong bioadhesion was best described by the Koble-Corrigan isotherm. Finally, the phytoremediation experiment was performed with pristine and aged particles, and the results showed that pristine particles adhered to a higher extent compared to aged particles. The results indicated that phytoremediation is possible and that its use can be beneficial in removing “fresh” microplastic pollution when microplastics are not yet covered by a biofilm that forms on their surface after aging in freshwaters.

4.04.P-Th268 Enzymes as Bioremediation Strategy Against Microplastics in soil, and its Effects on *L. terrestris*
***Cristina Palacios-Mateo*[1]*, Esperanza Huerta Lwanga*[2] *and Lars Blank*[3]*, (1)Maastricht University, Netherlands, (2)Wageningen University & Research, Netherlands, (3)RWTH Aachen University, Germany*
Microplastics are increasingly accumulating in agricultural soils worldwide, affecting biodiversity and soil health. For instance, Dr. Esperanza Huerta-Lwanga, previously reported the increased mortality of *Lumbricus terrestris* after exposure to PLA microplastics.
In order to reduce the amount of microplastic in soil, bioremediation strategies could be implemented. Through a collaboration between Maastricht University, RWTH Aachen and Wageningen University, the use of biotechnology was studied as a potential bioremediation strategy against polyester microplastics (PET, PLA, PBAT).
For this first stage of the research, enzymatical tests on polyester microplastics and films were performed in vitro at different conditions. The chosen enzymes were leaf-branch compost cutinase (LCC) and FAST-PETase. At the same time, ecotoxicology tests were performed on the effect of different enzyme concentrations on *L. terrestris*.
Our results showed degradation of the polyester substrates with no increased mortality on *L. terrestris* (compared to control tests), proving the potential of this technology in the fight against microplastics.
These preliminary tests could, therefore, set ground for further studies on the enzymatic or microbial degradation of microplastics on soil. Ecotoxicity on other soil organisms should also be analyzed further.
4.04.P-Th269 Comparison of the Remediation Potential of Selected Plant Species for Hexachlorocyclohexane (HCH) Contaminated Sites
Stanislava Vrchovecka*, Aday Amirbekov and Pavel Hrabák, Technical University Liberec, Czech Republic*
HCHs have been one of the most used pesticides during the last century. Although their use was banned, the remains of their production, processing and application represent the source of contamination. At present, 299 sites are known where these substances have been handled. Phytoremediation using plants and plant-associated microorganisms is one of the applicable methods to remove leaked HCH from the environment.
The four selected plant species (*Juncus effuses, Typha latifolia, Phragmites australis,* and *Alnus glutinosa*) were repeatedly exposed to either δ-HCH or technical HCH (tHCH) at three different concentrations (20; 200 and 1000 $\mu g. L^{-1}$) for three months. HCH isomers were determined in the growing substrate and plant biomass by an established method using GC/MS/MS.
The pesticide removal from the growing substrate is supported by the plants' presence in most cases. The removal intensity depends on the plant species, the concentration of chemicals and the type of treatment (δ-HCH or t-HCH). Alder trees provide the highest mean removal efficiency in both kinds of treatments. Followed by *J. effuses >T.latifolia > P.australis* in the case of the t-HCH. In the case of δ-isomer, the order is as follows: *J. effuses > P.australis > T.latifolia*. The influence of HCH concentration and kind of treatment is evident in all selected plants. The highest removal efficiencies were noticed by the concentration of 200 $\mu g.l^{-1}$ of δHCH and t-HCH treatment by *J.effuses*, *A.glutinosa* and *P. australis* after correction for the unplanted group. *T. latifolia* showed the highest pesticide removal in the group treated with 1000 $\mu g.l^{-1}$ of t-HCH and 200 $\mu g.l^{-1}$ of δHCH. Different trends were observed in the accumulation of HCH in roots and above-ground plant parts. Trans-isomerization was observed in the plant biomass in the δ-group. Isomers α and β were present in the highest concentration, especially in root tissue. The presence of chlorobenzenes as the main degradation product of HCH was observed in all biomass samples. The part of applicated pesticides was subject to degradation to unmonitored metabolites, volatilization or complete degradation. This part also depended on the plant species, concentration and the type of treatment.

4.04.P-Th270 Performance of the One and Two Year *Alnus glutinosa* seedlings in Contaminated Soil with Hexachlocyclohexane - Evaluation its Microbial Abundance in Soil and Rhizosphere

***Aday Amirbekov**, Stanislava Vrchovecka, Jakub Riha, Alena Ševců and Pavel Hrabák, Technical University Liberec, Czech Republic*

Hexachlorocyclohexane (HCH) is an persistent organochlorine pesticide consisting eight isomers (α HCH to θ-HCH)The effect of delta-isomer (δ-HCH) and technical hexachlorocyclohexane (t-HCH) on growth, physiological parameters and to microbial and fungal community was studied in different 1and 2-year-old alder seedlings.   veral sets of microcosm pot experiment with exposure to OCP will be performed in order to evaluate growth, differentiation and regeneration of plant tissues together with OCP bioaccumulation and transformation.. Changes in the hormonal system of alders were monitored as well. Most of the evaluated characteristics revealed significant differences between the treated and control groups. Furthermore, the presence of plants increased the remediation efficiency by 6.27 - 26.17 %, indicating the plant's role as a remediation accelerator, most likely through released exudates, and a positive effect on the soil microbiome. Higher remediation efficiency for biennial plants without pruning was expected due to higher root biomass, but unexpectedly higher efficiency was observed for annual plants after pruning than without pruning. In the presence of HCH, there was a decrease in Abscisic acid (ABA) and an increase in Jasmonic acid (JA). The intensity of change depended on the plant age. Similarly, Salicylic acid (SA) is increased in annual and decreased in biennial plants.

The amount of the lin genes in chemically treated group exceeds the amount of the lin genes in the control group, thereby proving that bioremediation took place in the rhizosphere of the plant.

The research findings could help us better understand the processes involved in removing pesticides from the soil. The mechanism of in-plant isomerization and the identification of metabolites should be the focus of future research.

4.04.P-Th271 Phytoremediation Potential of *Miscanthus x giganteus* in Organochlorine Pesticide Contaminated Soils Using Polysorbate 80 as a Mobilizing Agent

***Marigona Morina - Gashi**[1], John Clifton-Brown[2] and Rolf-Alexander During[2], (1)Institute of Soil Science and Soil Conservation, Justus Liebig University Giessen, Germany, (2)Justus Liebig University Giessen, Germany*

There are extensive land areas globally of pesticide-contaminated agricultural soils in need of remediation. In this global environmental challenge, phytoremediation stands as a sustainable, low-cost, biological remediation perspective. *Miscanthus sp.* is a C4 perennial rhizomatous grass and trials to evaluate its potential for phytoremediation of contaminated soils have been reported and are ongoing for sites in Asia and Europe. However, more research on the establishment of a phytoremediation technique for the removal of organochlorine pesticide (OCP) residues of agricultural soils is essential.

Knowing the slow degradation attribution and bioaccumulative nature of the OCPs as well as their low plant availability, the objective of this study was the evaluation of *Miscanthus x giganteus* (MxG) ability, in combination with polysorbate 80 - based microemulsion as a biodegradable mobilising agent, for dichlorodiphenyltrichloroethane (DDT) and hexachlorocyclohexane (HCH) uptake and remediation potential.

A first six-month greenhouse experiment for the optimization of DDT and HCH uptake was performed. The randomised block design consisted of a control group and three different treatments (T1 – no microemulsion was added, T2 – 0.1 % and T3 – 0.5 % microemulsion concentration). DDX and HCHs contamination concentrations in the treated groups were 765 µg/kg and 105 µg/kg respectively. These concentration levels were achieved by mixing an aged highly contaminated Georgian soil with soil obtained from a local site.

During this experiment, plant phenotypes such as shoot and root development, leaf colour diversity and biomass yield were recorded on weekly basis. These first preliminary results presented unexpected phenotypic significant differences in the plant growth between control and treated groups. Further research to identify possible factors other than OCP contamination, which could explain this outcome, is being conducted. To this end, an ongoing OCP spiked soil experiment will allow us to quantify the plant's fitness and OCP uptake when compared to the aged polluted Georgian soil. Results from chemical analysis on DDT and HCH uptake and translocation in the plant (root–to–shoot ratio) will be presented, and this will address the question of whether the surfactant has boosted the phytoremediation efficiency. Moreover, the fate of OCP accumulated in plants in regard to the transformation products of both DDT and HCH in soil and plant will be studied thoroughly.

4.04.P-Th272 Biodegradation of Organochlorines: Patterns in the Distribution of Biodegradative Functions and the Phylogenetic Origin of Bacteria

***Iva Dolinová**[1,2], Kristyna Markova[2], Jan Nemecek[2], Jakub Riha[2], Michal Strejcek[3], Jáchym Suman[3], Ondrej Uhlik[3] and Alena Sevcu[2], (1)Regional Hospital in Liberec, Czech Republic, (2)Technical University Liberec, Czech Republic, (3)University of Chemistry and Technology Czech Republic*

Organochlorines such as chlorinated ethenes (CE) remain to be widely distributed worldwide and, along with their toxic metabolites, still constitute a substantial environmental threat due to actual and/or potential contamination of air, soils or drinking water sources. Although physico-chemical treatment is often necessary at highly polluted sites, natural or substrate-enhanced bacterial degradation of CE and their metabolites in situ is gaining wide acceptance. The spatial distribution of bacteria that metabolize CE (e.g., *Dehalococcoides, Dehalobacter, Geobacter, Dehalogenimonas, and Desulfitobacterium*) is far from uniform at contaminated sites. Sensitive methods are required to monitor and guide bioremediation process as well as to enable linkage of this process with specific bacterial taxa. Our major goal is to understand patterns in the distribution of vital biodegradative functions and the phylogenetic origin of bacteria that perform these functions by employing metagenomics and epicPCR. In 2022, we have installed nanofibrous carriers of biomass in drilled wells at two highly polluted sites in Czechia to obtain bacteria with

CE degradation capability. We investigate the contribution of horizontal gene transfer to the distribution of CE degradation genes for reductive dehalogenase by relocating the nanofibrous carriers from contaminated to non-contaminated aquifer.

4.04.P-Th273 Testing Organic Amendment, *Populus nigra* Plantation and Bioinoculation on Mine Polluted Soil Material for Phytoremediation Optimization Purposes

Marc Romero-Estonllo[1]*, Judith Ramos-Castro*[2]*, Yaiza San Miguel del Río*[2]*, Ángeles Prieto-Fernández*[3]*, Beatriz Rodríguez-Garrido*[3]*, Petra Susan Kidd*[4] *and Carmela Monterroso*[5]*, (1)Edaphology and Agriculture Chemistry, University of Santiago de Compostela, Spain, (2)Department of Edaphology and Agriculture Chemistry, University of Santiago de Compostela, Spain, (3)Misión Biológica de Galicia sede de Santiago de Compostela, MBG-CSIC, Spain, (4)Instituto de Investigaciones Agrobiológicas de Galicia, IIAG-CSIC, Spain, (5)Department of Soil Science and Agricultural Chemistry, University of Santiago de Compostela, Cross-Research in Environmental Technologies (CRETUS), Spain*

Mine driven trace elements' pollution entails serious environmental risks and can cause an overall reduction in soil fertility. In the last decades, *in situ* techniques such as phytoremediation have become increasingly important as ways to tackle these negative impacts. The aim of this study was to test the individual and combined effects of different phytoremediation techniques. For this, 64 pots were prepared with mine polluted soils from a mine polluted site from the Phy2SUDOE network (SOE4/P5/E1021). In 4 of them the soil was left untreated, while in the remaining 60 pots compost was applied as an organic amendment in a 1:10 (w:w) ratio. No plant thrived in the bare mine soil. Three culture patterns (NP, P and PT: not planted, planted with *Populus nigra* and *P. nigra* planted in co-culture with *Trifolium repens*) with 4 inoculation patterns (NI, BAC, MYC and MIX: no inoculation, plant growth promoting rhizobacteria, mycorrhizae and the previous two mixed) were tested in the amended pots, obtaining a total of 12 different treatments (x5 replicates). After 110 days of plant development, the substrates were collected on the one hand and the plants on the other, separating them into roots, stems and leaves. In the substrates, physicochemical (pH, CEC_e, total C, total N, Olsen's P, pseudo-total and available elements) and microbiological (metabolic footprint: activity, richness and diversity) parameters were determined. Whereas in plants, observable biometric and phytopathological parameters (stem height, root depth, wilting, chlorosis, pests) were recorded and elemental composition was determined. Multiple 1-ANOVA tests were performed to verify the statistical significance of the differences between groups. The use of the amendment, *P. nigra* plantation and bioinoculation with rhizobacteria turned out to be the best techniques to reduce toxicity and improve soil fertility, as well as to increase the survivability and productivity of the plant itself. Metabolic footprint is markedly different between planted and non-planted soils, and between planted soils inoculated or not with bacteria, which suggests that plant growth regulates the configuration of a microbial community in which the inoculated bacteria thrive comparatively the better. Under the conditions of this study, the use of an organic amendment, a tolerant plant, and plant growth promoting rhizobacteria reduce environmental risk and corrects the infertility of soils impacted by mining activity.

4.04.P-Th274 Influence of Soil Water Content on Energy Crop Summer Rape (*Brassica napus* l.) Phytoremediation Potential

Inesa Kniuipyte[1]*, Austra Dikšaitytė*[2]*, Marius Praspaliauskas*[1]*, Nerijus Pedišius*[1] *and Jurate Zaltauskaite*[1,2]*, (1)Lithuanian Energy Institute, Lithuania, (2)Vytautas Magnus University, Lithuania*

Soil heavy metal pollution caused by industrialization and anthropogenic activities has become a global and widespread issue. Among the various approaches of heavy metal contaminated sites remediation in situ, phytoremediation technologies receive special attention. Soil moisture content variation with ongoing climate change will have an impact on plant biomass production and soil pollutant behavior, and it will affect phytoremediation. The purpose of the study was to determine how soil water content affects the ability of the energy plant summer rape (*B.napus* L.) to phytoremediate Cd-contaminated soil (1-250 mg kg^{-1}). Summer rape growth, Cd bioaccumulation and removal efficiency were assessed at optimal, reduced and elevated soil water contents (SWC). *B. napus* demonstrated strong resistance to Cd toxicity as well as the capacity to phytoextract Cd from the soil. While removal effectiveness was determined by rape growth and Cd soil concentrations, Cd accumulation in oilseed rape increased with Cd soil concentration. *B. napus* coped well with low and moderate Cd pollution, whereas high Cd soil pollution had a significant negative impact on plant growth , resulting in low Cd removal efficiency. Plant growth, Cd accumulation, and removal from the soil were influenced by SWC. Oilseed rapes grown in elevated SWC had higher biomass than those grown in reduced SWC, despite the fact that the adverse effect of Cd was more severe at higher SWC. Elevated SWC increased Cd bioaccumulation from soil, whereas reduced SWC resulted in decreased Cd bioaccumulation. The highest Cd removal efficiency is guaranteed by the optimal SWC, whereas a lack of or excess of soil water limits B. napus phytoremediation potential and prolongs removal process.

4.04.P-Th275 Development of a Green Electrochemical Degradation Method of ATMP in Water Using Cyclic Voltammetry (CV) on a Graphite Electrode

Duaa Tahboub[1]*, Detlef Diesing*[2]*, Klaus Kerpen*[3]*, Alexander Rostek*[4] *and Ursula Telgheder*[3]*, (1) Instrumental Analytical Chemistry, University of Duisburg-Essen, Germany, (2) Physical Chemistry, University of Duisburg-Essen, Germany, (3) Instrumental Analytical Chemistry, University of Duisburg-Essen, Instrumental Analytical Chemistry (IAC), Germany, (4) Environmental Microbiology and Biotechnology, Environmental Microbiology and Biotechnology, University of Duisburg, Germany*

The degradation of phosphonates in water is a crucial issue in environmental and analytical chemistry.
Aminotris(methylenephosphonic acid) (ATMP) is an anthropogenic chelating agent containing three $C\text{-}PO(OH)_2$ groups, widely used in industries and is found in surface water in large amounts. It can chelate with metal ions, increasing metal bioavailability and leading to eutrophication. Therefore, aminomethylphosphonic acid (AMPA) is a persistent metabolite of ATMP

biodegradation in nature and a hazardous compound that is responsible for several health risks. Electrochemical degradation (ED) is a promising technique in order to achieve full pollutant degradation prior to the analytical determination. The aim of this study is to develop a green CV method for ATMP degradation in water media. Accordingly, the degradation experiment is carried out in water in the absence of supporting electrolytes and then compared it to a solution containing supporting electrolyte. A pristine graphite electrode (working electrode) vs. Ag/AgCl electrode is employed for CV experiment without any modification steps or added chemicals. The oxidation potential of the ATMP is determined in both electrolytes (0.6 V) and the capacitance of double layer is also measured. ED of ATMP by long-term CV in water showed a significant decrease in the oxidation current along the long-term CV time period of around 60%. This decrease is assumed to be as a result of ATMP concentration drop during the ED experiment. Therefore, the formation of orthophosphate (o-PO_4) indicating a possible ATMP degradation was determined spectroscopically at 820 nm using a molybdenum blue reaction of a formation percentage of 12%. In this study, ATMP is considered as a model substance for phosphonates to investigate the reaction mechanism, degradation products in water media and to develop LC-MS analytical technique simultaneously with o-PO_4 determination in order to achieve a mass balance as a future work.

4.04.P-Th276 Carbonaceous Materials Production from Olive Pomace: Possible Valorization Pathways and Application for Remediation of Contaminated Water and Soil

*Gabriel F. Batista[1], **Silvana Teixeira Costa**[1], Ana P.F. Silva[2], Hélder T. Gomes[2], José F. Lustosa[1] and Zulimar Hernandez[1], (1) MORE- Laboratório Colaborativo Montanhas de Investigação, Portugal, (2) Centro de Investigação de Montanha (CIMO), Instituto Politécnico de Bragança, Portugal*

Portugal is one of the main producers of olives in the world, producing more than 1 million tonnes per year. The main use of the olive is for olive oil production, however, the two-phase system used in its production generates more than 600.000 tons of olive pomace (pasty, anaerobic and phytotoxic), a hard-to-deal residue with a lot of harmful potential to the environment. In this context, the industrial and agricultural sectors have been putting a lot of effort towards the valorization of this residue. One alternative is the production of carbonaceous materials, such as Biochar and Activated Carbon, by the pyrolysis process. These materials can be produced from residues, such as olive pomace, and their application is diverse, from soil remediation, soil conditioner to improve the growth environment of crops, adsorption of heavy metals to the decontamination of polluted waters and ecosystems.

The usual characterization of the carbonaceous materials prepared from residues has a high surface area, and stability, small bulk density, a strong adsorption capacity, weak electrical conductivity, porous structure, and is environmentally friendly and economical. Preliminary studies show that carbonaceous materials from olive pomace have similar characteristics, such as alkaline pH (≈ 9.5), high total C (around 68%) and low BET surface area (≈ 5 $m^2 g^{-1}$), and some methodologies can be employed to improve these properties, as chemical and physical activation.

Nowadays, our group is studying the optimization of new methodologies for the production of carbonaceous materials from the olive pomace, using slow pyrolysis (800ºC, 8-12 h) and activations techniques to pre-industrial scale. The produced carbonaceous materials are being tested on contaminant adsorption besides soil application, for water retention and enhancement of soil productivity. Promissory results to simulate the adsorption of contaminated wastewater are being obtained. Some carbonaceous materials were able to adsorb 99% pollutant in 30 minutes. The higher adsorption capacity and faster adsorption kinetics were obtained in the material with a higher surface area, as expected. This early test highlights the carbonaceous materials' potential to remove wastewater pollutants and different ecotoxic tests are carried out to evaluate the potential for freshwater decontamination in mountain rivers.

4.04.P-Th277 Molecular Biology Tools (Mbts) Coupled with Compound-specific Isotope Analysis (Csia) for the Monitoring of a Biological Remediation of an Aquifer Contaminated by Chlorinated Ethanes and Ethenes

***Ilaria Pietrini**[1], Giovanna Carpani[2], Massimiliano Baric[2], Lucia Poppa[3], Federico Villani[3], Guido Bonfedi[3], Marco Marchesi[4] and Luca Alberti[4], (1)-, Eni S.p.A., Italy, (2)Eni S.p.A., Italy, (3)Eni Rewind S.p.A., Italy, (4)Politecnico di Milano, Italy*

An aquifer contaminated mainly by chlorinated aliphatic hydrocarbons, both chlorinated ethanes and ethenes, was treated by Enhanced Natural Attenuation (ENA), as groundwater remediation intervention. In fact, these compounds may be subject to degradation by specific bacterial populations, whose presence on site had previously been determined through a targeted microbiological/molecular characterization. Considering the large extension of the Area to be treated and the differences in the type of prevailing pollutants, 4 different modules of intervention have been defined according to the chemical composition of the contamination i.e., predominance of one of the two classes of contaminants present in the area, chlorinated ethanes and ethenes. The activities were carried out through the injection within the saturated horizon of 2 different amendments, selected on the basis of the chemical composition of the contamination. Specifically, a solution of lactate and inorganic salts was used in 2 modules, while the remaining 2 modules were treated with a slow-release commercial product.

The injection activity lasted for one year, from spring 2021 until April 2022. The post-operative monitoring phase began in May 2022. In both phases, the monitoring was conducted integrating the chemical data (i.e. trend of the concentration of the target contaminants) with the molecular monitoring of the bacterial species most involved in the anaerobic biodegradation of chlorinated solvents, such as *Geobacter* sp. and *Dehalococcoides* sp., and of the genes corresponding to the key enzymes of the metabolic pathways involved (i.e. *rdhA_* involved in the degradation of 1,2-Dichloroethane; *tceA_*involved in the degradation step from Tetrachlorethylene to cis-Dichloroethylene; *bvcA* and *vcrA_*involved in the degradation step from Vinyl Chloride to Ethylene). The interpretation of the reclamation progress was strengthened by the results obtained from the CSIA (Compound Specific Isotope Analysis) isotope analyses conducted on the ^{13}C of the contaminants of interest. The overall results obtained will be, in fact, discussed by integrating the three types of data (i.e., chemical, molecular and isotopic) to promptly evaluate the effectiveness of the interventions in progress and highlight the different trends in the different modules. By combining these methods, a more rapid and precise estimation of the reclamation progress and the implementation of any corrective measures are reached.

4.04.P-Th278 BIOremediation SYStems Exploiting Synergies for Improved Removal of Mixed Pollutants

Michel Chalot[1]*, Lila Otero-Gonzalez*[2]*, Rocio Barros*[3]*, Blanca Velasco Arroyo*[3]*, Ales Lapanje*[4]*, Eduard Borras*[5]*, German Cavero*[6]*, Ana Paula Mucha*[7]*, Isabel Allona*[8]*, Arturo Redondo-Lopez*[9]*, Emmanuelle Vulliet*[10]*, Raquel Moreno*[11]*, Alfredo Pérez-de-Mora*[12]*, Ioanna Katsavou*[13]*, Jose Jimenez*[14] *and Marisa Almeida*[7]*, (1)UMR 6249 Laboratoire Chrono-environnement, University of Bourgogne Franche-Comté, France, (2)IDENER, Spain, (3)Universidad De Burgos, Spain, (4)Institut Jozef Stefan, Slovenia, (5)Acondicionamiento Tarrasense Associacion, Spain, (6)Blue Synergy Sl, Spain, (7)University of Porto, Interdisciplinary Centre of Marine and Environmental Research (CIIMAR), Portugal, (8)Universidad Politecnica De Madrid, Spain, (9)Universidad Politécnica de Madrid, Spain, (10)Institut des Sciences Analytiques, France, (11)Axia Innovation, Germany, (12)Tauw, Germany, (13)Exelisis, Greece, (14)Imperial College London, United Kingdom*

BIOSYSMO is a 48-month EU-action that will develop a computationally-assisted framework for designing and optimizing synergistic biosystems combining the required pathways and traits to achieve the most efficient degradation and sequestration of pollutant mixtures. These biosystems will comprise combinations of bacteria, fungi and plants containing the natural or engineered pathways required for pollutants degradation and identified based on a computationally-assisted analysis. BIOSYSMO will take advantage of the high natural microbial diversity by screening samples from polluted sites and locations affected by diffuse pollution to identify natural microorganisms already present and able to metabolize/transform the target pollutants. The search will be expanded to microorganisms previously identified and characterized by applying data mining tools to genomic and metagenomic data available in public repositories. The construction and optimization of synergistic biosystems will combine approaches based on 1) enhancing plant- microbe (bacteria, fungi) interactions to achieving combinations with improved pollutant uptake and/or degradation; 2) engineering bacteria, for improved degradation and bioaugmentation, and plants (poplar tree), for improved microbial colonization and pollutant uptake; 3) constructing artificial micro-structured consortia into aggregates and biofilms, containing all the required pathways for pollutant removal; and 4) applying bioelectrochemical systems (BES) as stand-alone or in hybrid systems. 5) biostimulating the native microbial communities to exploit natural traits that improve contaminant removal. The different key players will be identified and combined to formulate innovative biosystems with the assistance of genome-scale metabolic (GEM) models for elucidating and simulating the key metabolic pathways. The constructed biosystems will be applied in conventional (phytoremediation, biopile, biostimulation/bioaugmentation) and innovative (BES, hybrid BES-phytoremediation) bioremediation approaches optimized for the treatment of mixtures of pollutants in soil, sediments and waters.

4.05 Characterization, Testing and Assessment of Complex Substances (MCS, UVCBs & MOCS)

4.05.T-01 UVCB Substances: Characterization, Chemical Representation and Selection of Representatives for (Eco)toxicological Screening Purposes

Darina Gancheva Yordanova[1]*, Stela Kutsarova*[1]*, Louise Camenzuli*[2]*, Delina Lyon*[3]*, David Saunders*[4]*, Sandrine Sourisseau*[5] *and Ovanes Mekenyan*[1]*, (1)Asen Zlatarov University, Laboratory of Mathematical Chemistry, Bulgaria, (2)ExxonMobil, Belgium, (3)Concawe, Belgium, (4)Shell Global Solutions, Netherlands, (5)TotalEnergies, France*

People, animals and the environment can be exposed to various mixtures, including substances of unknown or variable composition, complex reaction products and biological materials (UVCBs). The toxicity potential of the latter has been growing toxicology concern for some years. One of the approaches for assessing the risks UVCBs pose to human and ecological receptors is through understanding their chemical identity. A methodology for UVCB characterization is developed to address this issue. The methodology allows for coding of structural information and generation of individual constituents, using a knowledge for generic substance identifiers, such as names of chemical classes, structural formulas, reaction steps, physicochemical properties, and/or spectral data. In some cases, the number of generated UVCB constituents is too large, which complicates their further (eco)toxicological assessment. Because of that, selecting a manageable number of constituents that represents the UVCB is necessary. Two types of representatives selections are applied depending on the user's goal. The first scheme is an endpoint non-specific selection. To this end, a special algorithm was developed to determine the minimal sample size of randomly selected structures that objectively represent the set of all generated UVCB constituents. The algorithm was further implemented as part of the methodology for UVCB characterization. The second type of selection of a representative sample is endpoint-driven. This is achieved by a novel approach based on hierarchical clustering taking into account different similarity criteria associated with the property under investigation. Finally, one structure is chosen from each obtained sub-group. The selected constituents from all small sets form an endpoint-specific representative sample that could be used for (eco)toxicological screening purposes instead of the whole UVCB. A hierarchical scheme for selection of UVCB constituents for biodegradation modelling is defined based on structural and degradation similarity between the structures. Specific chemical class of a target petroleum UVCB substance is used to analyse the behaviour of the proposed scheme. The scheme showed effective and mechanistically transparent grouping of the chemicals with similar characteristics and properly chosen representatives. Similar approaches for selection of endpoint-specific samples can be developed for other environmental, fate and human health endpoints.

4.05.T-02 Acute Aquatic Toxicity Testing with Isomer-Mixtures of Liquid Organic Hydrogen Carriers

Felix Irrgang[1]*, Yohan Seol*[2]*, Stefan Stolte*[2] *and Marta Markiewicz*[2]*, (1)Institute of Water Chemistry, Technical University Dresden, Institute of Water Chemistry, Germany, (2)Institute of Water Chemistry, Technical University Dresden, Germany*

Liquid Organic Hydrogen Carriers (LOHC) can contribute to decarbonisation of energy and transportation. Two promising candidates ivestigated in this work Benzyltoluene (BT) and Dibenzyltoluene (DBT) are already marketed as heat transfer fluids

and are technical isomer-mixtures, which gives these LOHC broad liquidus range and is highly desired. The hydrogenated counterparts (BT-12/DBT-18), are even more complex due to possibility of inclomplete hydrogenation.
DBT for instance is thus labelled as a UVCB compound by the European Chemicals Agency (ECHA). The difficulties in assessment of these mixtures are additionally exacerbated by hydrophobic nature (log Kow 5-10) and volatility (of BT and DBT). Passive dosing emerged in the last decade as a reliable method to test very hydrophobic compounds in limit as well as concentration-response tests. This was modified here to allow for polymer loading from pure liquid and viscous mixture of LOHC.
Acute *Daphnia magna* immobilisation and *Raphidocelis subcapitata* growth inhibition tests are performed as limit tests. In case of sufficient inhibition, dose-response tests are conducted and EC_{50} values are determined. The exposure concentrations are confirmed via GC/MS. We measured log Kow of these compounds and screened their modes of action using toxic ratios approach.
No effect in acute *Raphidocelis subcapitata* and *Daphnia magna* test was observed for BT-H12, DBT and DBT-H18. We speculate that this is due to very high hydrophobicity of the compounds and too short test duration. BT can be classified into acute category I according to GHS aquatic toxicity classification (EC50 below 1 mg/L). Although only a specific composition of the isomer mixture was tested here, the batch-to-batch differences in H2-lean starting materials are not expected to influence the toxicity to large extent as these compounds seem to baseline toxicants and isomers differ very little in hydrophobicity. The hydrogenated forms of LOHC are more hydrophobic than the starting H2-lean materials. Therefore, incomplete dehydrogenation leading to presence of (partially) hydrogenated compound in the H2-lean compound could theoretically increase (chronic) effects or bioaccumulation potential, as baseline toxicity is the most probable mode-of-action, and the overall water exposure will not significantly change with varying isomer composition.

4.05.T-03 Assessment of Acute and Chronic Ecotoxicological Effects of Aqueous Eluates of Stone Wool Insulation Materials

Esther Smollich[1]*, Eberhard Döbbeler*[2]*, Tina Müller–Geipel*[2]*, Lars Stratmann*[2]*, Christoph Koch*[3]*, Valentina I. Merkus*[4]*, Denis V. Okhrimenko*[5]*, Mette Solvang*[5]*, Milen Nachev*[2]*, Sonja Zimmermann*[2]*, Torsten C. Schmidt*[4] *and Bernd Sures*[2]*, (1)Deutsche ROCKWOOL, Germany, (2)Aquatic Ecology, University of Duisburg-Essen, Germany, (3)Department of Industrial Engineering, Technical and Environmental Chemistry, Ernst-Abbe-University of Applied Science Jena, Germany, (4)Instrumental Analytical Chemistry, University of Duisburg-Essen, Germany, (5)ROCKWOOL A/S, Denmark*

Currently, a number of crises, including the global climate crisis and energy supply shortages, affect people worldwide. To limit the anthropogenic climate change to 1.5 °C and to reduce the dependency on fossil fuels like gas for heating purposes, appropriate thermal insulation for buildings especially in temperate regions of the world is needed. Meanwhile, maintaining a high protection of ecosystems makes the ecotoxicological evaluation of all products, including construction materials, necessary. Construction materials often pose a challenge to standardized ecotoxicological testing due to limited water solubility and a complex composition, which is often variable within certain limits.
The test materials investigated in this study were stone wool fibres, which are used in thermal building insulation products and are considered inorganic UVCBs. We assessed the acute and chronic ecotoxicological potential of aqueous eluates of the stone wool fibres. These eluates have been studied with four test species, using standardized laboratory ecotoxicological tests for the following endpoints: acute bioluminescence inhibition (*Aliivibrio fischeri*), acute algae growth inhibition (*Desmodesmus subspicatus*), acute *Daphnia magna* immobilization, chronic *Daphnia magna* reproduction inhibition and chronic nematode growth and reproduction inhibition (*Caenorhabditis elegans*). In parallel, chemical analysis of the eluates was conducted to examine potential leaching of metals and organic substances from the test materials.
The laboratory testing revealed no acute or chronic ecotoxicological effects by the eluates of fibrous stone wool material, while high concentrations of milled test materials lead to some chronic effects on aquatic invertebrates. The chemical analysis showed no leaching of organic carbon from the test materials and a limited elemental leaching, with only two of 18 analysed elements detectable in the eluates. Based on our assessment within this study, aqueous eluates of stone wool fibres should not be considered as chemically hazardous to the aquatic environment. Our study presents a comprehensive test battery, that utilizes aqueous elution and subsequent chemical analysis and ecotoxicological testing with several species of different trophic levels to deepen the current knowledge on the environmental behaviour of an inorganic UVCB construction material.

4.05.T-04 Characterising the Environmental Fate and Behaviour of Diluted Bitumen Within Freshwater Systems

Scott L. J. Hepditch[1]*, Juan Manuel Gutierrez-Villagomez*[1]*, Tuan Anh To*[1]*, Qin Xin*[2]*, Nicole E. Heshka*[2]*, Heather D. Dettmen*[2]*, Gaëlle Triffault-Bouchet*[3]*, Richard Martel*[1]*, Jason M. E. Ahad*[4] *and Valerie S Langlois*[1]*, (1)Ete, Institut national de la recherche scientifique (INRS), Canada, (2)CanmetENERGY, Natural Resources Canada, Canada, (3)Centre d'expertise en analyse environnementale du Québec (CEAEQ), Canada, (4)Natural Resources Canada, Canada*

Extraction and transportation volumes of unconventional bitumen crude oil diluted with naphtha condensates (dilbit, a type of diluted bitumen) will see continued expansion as world reserves of conventional crude oils diminish. However, the environmental fate and behaviour of dilbit is still poorly understood, particularly in freshwater systems. To this end, we conducted spills of dilbit and conventional crude oils (for comparison) in both terrestrial and aquatic model systems to characterise chemical profiles over time and the subsequent embryotoxicity to a North American freshwater indicator species, the fathead minnow. Terrestrial spills of Cold Lake Blend dilbit or Conventional Heavy Blend (CHB) were conducted in large (1 × 0.6 m; H × D) soil columns with artificial precipitation to assess the chemical evolution of oil substituents within infiltrating water of an unsaturated zone. Leachate water contaminated with dilbit had 2- and 1.6-fold greater concentrations of BTEX and polycyclic aromatic compounds (PACs), respectively. Additionally, tracer tests showed that petroleum constituents of dilbit were transported 6 – 48 % faster in the infiltrating water. Malformations and expression of *cyp1a* in exposed fish were greatest prior to 34-days post spill. No differences in toxicity were observed between the two oil types, and toxicity could not be correlated to the petroleum contaminants measured (metals, BTEX, PACs, acid extractable organics fraction). Fresh surface water spills were conducted by spilling either Cold Lake Blend dilbit or a Medium Sweet Blend (MSW) within a large meso-scale spill tank. Concentrations of BTEX and PACs were higher in the MSW contaminated water. These higher concentrations correlated with greater sublethal toxic effects of malformations, reduced growth and heart rate in exposed fish. However, significantly greater lethality was observed for up to 2-weeks post-spill for the fish exposed to the water contaminated with dilbit, which could not be directly correlated to the petroleum contaminants analyzed. In conclusion, our studies demonstrated variance in the fate and behaviour of dilbit and conventional oils reflective of their chemical composition (*i.e.,* heavy versus light oil profiles). Further characterisation of the petroleum hydrocarbon classes causing toxic effects is necessary as some endpoints of our studies could not be directly correlated to those compounds most often assessed in oil toxicity literature.

4.05.T-05 Integrating UVCBs and Related Data into Open Chemical Knowledgebases
Emma Schymanski[1]*, Anjana Elapavalore*[1]*, Qingliang Li*[2]*, Paul Thiessen*[2]*, Leonid Zaslavsky*[2]*, Jian Zhang*[2] *and Evan Bolton*[2]*, (1) Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Luxembourg, (2) National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health, USA*
Although 20-40 % of chemical registries consist of Substances of Unknown or Variable Composition, Complex Reaction Products, and Biological Materials (UVCBs), integrating and exchanging information on UVCBs in open chemical knowledgebases is challenging. The integration of UVCBs into high resolution mass spectrometry (HR-MS) based identification workflows is also problematic. Often only a name or numerical identifier is provided in the registry listings, hindering comparison, merging and enumeration or mapping of potential component species either based on expert knowledge or (semi-) automated cheminformatics methods. Improved UVCB handling in major open chemical resources will help support the exchange of information between registries, researchers, and regulators, as well as supporting, *e.g.,* toxicological/environmental assessments and the integration of UVCBs into HR-MS-based workflows. PubChem (https://pubchem.ncbi.nlm.nih.gov/), a large open chemical database with over 112M compounds, 298M substances and contributions from over 884 data sources, have recently introduced “concepts” to specifically improve their handling of UVCB-like entities. An initial dataset of ~62K “concepts” was compiled from three large authoritative data sources with a high proportion of UVCBs (FDA GSRS, TSCA and ECHA). Close to 0.5M synonyms (names) were associated with these concepts, which were then used to form the basis for literature mining dictionaries and sets of regular expressions for pattern-based recognition of UVCBs among synonyms. This was validated over several collections. Since UVCBs of variable composition often form (or are expressed as) homologue series, this subset of UVCBs is particularly conducive to automated grouping methods and adaptation to HR-MS workflows. Thus, as a second step, the homologue grouping algorithm OngLai was run over the PubChemLite for Exposomics database (a subset of PubChem with environmentally and toxicologically relevant annotation) and connected to “concepts” using mappings to representative or component structures provided by depositors. Over 163 connections between chemical, homologue series and PubChem Concepts (often many concepts per series) were made; a select few were hand curated and processed so far as proof-of-concept exemplars. This contribution intends to show and discuss potential (and pitfalls) associated with UVCB handling in open resources to support environmental and toxicological use cases.

4.05.P Characterization, Testing and Assessment of Complex Substances (MCS, UVCBs & MOCS)

4.05.P-We299 A Tiered Assessment Framework for Ecological Risk Assessment of Substances of Unknown or Variable Composition, Complex Reaction Products, or Biological Materials (UVCBs)
Sandrine Estelle Deglin[1]*, J. Samuel Arey*[2]*, Marc Fernandez*[3]*, Delina Lyon*[4]*, Athena Keene*[5]*, Erin Maloney*[6]*, Philipp Mayer*[7] *and Rowena Raeburn*[8]*, (1)HESI, (2)Oleolytics, (3)Environment and Climate Change Canada, Canada, (4)Concawe, Brussels, Belgium, (5)Afton Chemical Corporation, (6)Shell International, Netherlands, (7)Department of Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark, (8)Afton Chemical, United Kingdom*
Complex substances such as multi-constituent substances (MCS) and UVCBs usually result from the industrial processing or extraction of natural substances (e.g., essential oils), or from chemical reactions (e.g., Coco Amidopropyl Betaine). Because of the variable and complex nature of source materials, and the potential variability inherent to production processes, these substances can contain many, sometimes uncharacterised, constituents whose concentrations may vary between batches.
The variation of substances between batches can make hazard data difficult to collect and interpret. In addition, testing the whole UVCB substance does not necessarily inform on the behaviour of its constituents, or reveal the presence of risk drivers. As a result, UVCB/MCS risk assessment presents unique challenges to product registrants and regulators alike.
To address these challenges, the UVCB Committee of the Health and Environmental Sciences Institute (a tripartite group including members of the academic, regulatory, and industry sectors) is building an exposure-based tiered approach considering specific types of easily accessible information (namely, Tier 0 information) that may be more suited to the characterization of the complex nature of UVCBs, to integrate it into a fit-for-purpose weight of evidence approach.
The practical use of this framework is highly dependent on the availability and ease of access of Tier 0 characterization and exposure data, as well as the possibility to easily determine whether a substance of interest could be assessed quickly, or whether it might require sophisticated analytical schemes.
We will present this new framework, as well as the progress made on the development of a pilot database of Tier 0 information containing about 100 UVCBs, and the creation of a high-throughput UVCB "complexity" evaluation scheme, and demonstrate how this new framework can help improve or evolve existing approaches to the prioritization and assessment of UVCBs.

4.05.P-We300 Tiered Approaches to Estimating Human Exposure to Mixture Components Via Inhalation and Dermal Absorption

***J. Mark Parnis*[1]**, *Alena Celsie[1], Trevor N Brown[2], Alessandro Sangion[3], Jon A. Arnot[3], James M Armitage[4], Li Li[5] and Donald Mackay[6], (1) Chemistry, CEMC Trent University, Canada, (2) Arnot Research and Consulting, (3) Arnot Research and Consulting, Canada, (4) AES Armitage Environmental Sciences, Canada, (5)School of Public Health, University of Nevada, USA, (6)Trent University Canada*

Assessing human exposure risk from chemical mixture components is challenging, primarily due to the fact that key physico-chemical properties of these components are different in the mixture compared with the pure substance. Therefore, a key area of interest is the rapid estimation of properties that determine the extent of chemical exposure from mixtures. this work, we have developed and/or tested various approaches to estimating vapour pressure and dermal permeation coefficients, two key properties associated with inhalation and dermal exposure, respectively.

We demonstrate that the vapour pressure of a mixture component can be estimated with increasing accuracy from (1) QSARS based on chemical structure (2) pp-LFERs based on Abraham solvation parameters and (3) COSMOtherm estimates based on activity coefficient estimation derived from quantum mechanics. Dermal permeation coefficients may be likewise estimated for mixture components with increasing accuracy by (1) COSMOperm, a dedicated activity-based model based on quantum mechanics, (2) QSARs based on chemical structure, and (3) log-linear models based on Abraham solvation parameters estimated from chemical structure-based QSARs.

The results demonstrate that inhalation exposure to chemical mixture components can be modelled with acceptable accuracy using exposure models such as RAIDAR-ICE and estimated vapour pressures from the above approaches. It is also demonstrated that dermal exposure is less accurately modelled due to the relatively poor performance of models for dermal permeation coefficient estimation, likely associated with the high uncertainty in the experimental data used to train these models.

4.05.P-We301 Screening Assessment of Endocrine Disruption Properties of a Large Portfolio of Petroleum-Related UVCB Substances

***Tim Verslycke*[1]**, *Ari S Lewis[1], Tatiana Manidis[1], Delina Lyon[2], Nicholas Synhaeve[2], George Hinkal[2] and Leslie J Saunders[2], (1) Gradient, USA, (2) Concawe, Belgium*

The European Commission (EC) developed its initial strategy for evaluating endocrine disruptors (EDs) over 20 years ago (COM(1999)706). Currently, the EC is in the process of adopting criteria for identifying EDs under different EU regulations and is considering an amendment to the EU's Classification, Labelling and Packaging (CLP) Regulation. In 2022, the EC proposed new ED hazard categories and criteria for the CLP of substances and mixtures; however, how substances and mixtures will be assigned to these categories and how this might impact other chemical regulations (*e.g.*, REACH) is yet to be determined. Regardless, the potential impact of this amendment to product value chains could be substantial, and there is a critical need for developing technically sound approaches to evaluate ED mechanisms and adverse effects, particularly for highly complex materials like petroleum UVCB substances.

In a first attempt to gather relevant ED information on petroleum UVCB substances, we compiled and evaluated information for a large selection of substances, considering the 2018 ECHA/EFSA guidance for the identification of EDs under the Biocidal Products Regulation or the Plant Protection Products Regulation. The identification of EDs under this guidance requires a rigorous weight-of-evidence analysis of "all available relevant scientific data," a resource-intensive evaluation that is not feasible to implement across a large chemical/product portfolio, like petroleum UVCB substances which may encompass many chemical entities. Therefore, we developed a stepwise, prioritization process: 1) identifying a list of substances of interest; 2) developing a search strategy to efficiently compile *in vitro*, *in silico*, and *in vivo* information related to estrogenic, androgenic, and thyroid pathways from database sources and the scientific literature; 3) employing a "heatmap" approach to visualize the compiled information across sources and pathways; and 4) identifying priorities, uncertainties, and data gaps, and recommending next steps.

Our findings illustrate the challenges associated with compiling ED information using the 2018 ECHA/EFSA guidance, especially for complex chemical portfolios with UVCBs and mixtures. We provide several recommendations and procedures to efficiently compile and evaluate ED information. Our approach can be applied to other chemical/product portfolios to support initial ED screening assessments to identify key data gaps and inform decision-making.

4.05.P-We302 Development of an IATA to Screen for Persistent, Bioaccumulative/Mobile, and Toxic Petroleum UVCB Constituents and Stable Degradation Products

***Irina Andreevna Dermen*[1]**, *Stela Kutsarova[1], Darina Gancheva Yordanova[1], Nadezhda Dimitrova[1], Louise Camenzuli[2], Delina Lyon[3], David Saunders[4], Sandrine Sourisseau[5] and Ovanes Mekenyan[1], (1) Asen Zlatarov University, Laboratory of Mathematical Chemistry, Bulgaria, (2) ExxonMobil, Belgium, (3) Concawe, Belgium, (4) Shell Global Solutions, Netherlands, (5) TotalEnergies, France*

There is increasing interest in replacing animal tests with computational methods to predict chemical (eco)toxicity. Because of the complexity of toxicity mechanisms, usually several endpoints need to be combined to adequately predict the toxic profile of chemicals. Integrated Approaches to Testing and Assessment (IATA) are based on the integration and translation of the data derived from multiple methods and sources. IATA can incorporate different types of information, such as (eco)toxicity data, computational model predictions, in chemico, in vitro, in vivo, etc. This information can be used to answer different questions in a specific regulatory context.

The current work shows the development of a method to screen persistent (P), bioaccumulative (B) or mobile (M), and toxic (T) constituents generated for petroleum UVCB substances and their predicted degradation products in amounts above 0.1%. For this purpose, an IATA screening the PBMT constituents and their stable degradation products has been developed. The architecture of the PBMT IATA is based on the execution of several layers, each of them providing specific information. The layers are metabolism, persistence, bioaccumulation, mobility and toxicity. Metabolism is the most critical layer as it is responsible for generation of degradation products and identification of those present in amounts above 0.1%. Therefore, the microbial metabolism simulator developed by the Laboratory of Mathematical Chemistry (LMC) has been used to simulate the biodegradation pathways. The PBT/vPvB and PMT/vPvM assessment combines experimental data from the OECD QSAR Toolbox and modelling results from various (Q)SAR models. The assessment criteria have been taken from the regulatory guidelines for PBT/vPvB assessment and the latest draft criteria for PMT/vPvM assessment. Finally, the classification layer provides overall classification for the constituents and their degradation products.

4.05.P-We303 CHANCES2 Project: Testing and in Silico Predicting Acute and Chronic Aquatic Toxicity of Highly Complex Mixtures

*Paul Thomas[1], Pascal Bicherel[1], **Floriane Larras**[1], Nicolas Delpit[2], Lise Mata[2], Mélanie Persillon[2], Marine Canton[3], Marina Thierry[3], Sylvain Antoniotti[3] and Aurelia Lapczynski[4], (1)KREATiS, France, (2)Laboratoires des Pyrénées et des Landes, France, (3)Institut d'Innovation et de Partenariats Arômes Parfums Cosmétiques, Université Côte d'Azur, France, (4)Research Institute for Fragrance Materials, USA*

Testing of Unknown or Variable Composition, Complex Reaction Products or Biological Materials (UVCB) poses a regulatory challenge and classical Water Accommodated Fraction (WAF) tests are often criticized as uninterpretable for risk assessment purposes. The CHANCES2 project (Compartmentalized Hazard Assessment for Natural Complex Extracted Substances (Type 2) aims to provide greater certainty in the environmental toxicology assessment of highly Complex Substances. The Type 2 Natural Complex Substances (NCS2) are UVCB of which less than 90% of the composition is known. NCS2s contain also a large fraction of semi-or non-volatiles, resins or waxes which makes them particularly difficult to analyze in the laboratory. Also, lack of information on their composition complicates application of alternative methods such as QSAR. Phase 1 of this project investigated the acute and chronic toxicity of galbanum resinoid to algae and daphnids using a "three block approach". Galbanum resinoid sample was first divided into 3 blocks (i.e., volatile, non-volatile, non-volatile non-soluble), displaying different chemical characteristics (e.g., monoterpene and sesquiterpene derivatives in volatile block vs. coumarin-sesquiterpene derivatives, ombelliferone and galbanic acid in the non-volatile one). Then, the experimental toxicity of the three blocks to algae and daphnids were assessed. Toxicity of the whole substance was between 10 and 100 mg/L. When fractionated into 3 blocks, the acute toxicity of volatile block was fairly high (between 1-10 mg/L). For the non-volitile block, no acute toxicity was observed. Neither acute nor chronic toxicity was observed for the non-volatile non-soluble block. Also, the results of the toxicity testing and the *in silico* predictions were compared. For the volatile block and the whole substance, the daphnids EC50 were described by the *in silico* predictions, explaining the observed toxicity. Those results evidence that aquatic toxicity of such complex substances can be modeled using appropriate methodology. To date all experimental WAF studies on the blocks have provided quality empirical results in agreement with the *in silico* predictions. Experimental data validate the prediction while the latter support and thermodynamically explain the empirical results from the studies. The project underlines the importance of combining experimental data with accurate *in silico* predictions. Those findings will be confirmed using another NCS2.

4.05.P-We304 Combining Whole UVCB Degradation Tests with Constituent Specific Analysis Can Yield Biotic and Abiotic Degradation Kinetics

***Heidi Birch**, Karen Scharling Dyhr and Philipp Mayer, Department of Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark*

Essential oils are UVCBs (Substances of Unknown or Variable composition, Complex reaction products or Biological materials), which contain volatile and hydrophobic constituents. This makes essential oils "difficult to test substances" that often fall outside the applicability domain of test guidelines, prediction models, and assessment schemes. The environmental testing of UVCBs is normally done by either a whole substance approach or by testing each main constituent separately. The former does not provide constituent specific information, whereas the latter is limited to those constituents that are included in the test.

We have recently proposed an approach that combines whole UVCB biodegradation testing and constituent specific analysis. Fully automated Solid Phase Microextraction (SPME) coupled to GC-MS is here applied directly on gastight test systems. Primary biodegradation kinetics are then determined as constituent depletion based on peak area ratios between biotic test systems and abiotic controls that serve as an experimental and analytical reference. Recently, we observed a decline of several lavender oil constituents in the abiotic controls, which challenged our approach and indicated abiotic degradation. The aim of the study was to separate and quantify biotic and abiotic degradation kinetics of UVCB constituents by the inclusion of an additional freshly spiked analytical reference.

Stream water was sampled in Jydebæk stream (DK) upstream (11.5°C) and downstream (13.5°C) of an effluent discharge point for the local wastewater treatment plant (WWTP). 15 mL stream water was added to 20 mL headspace vials (biotic test systems) and spiked with Lavender oil Barreme type at a test concentration of ≈ 50 µg/L. Spiked ultrapure water was used for abiotic test systems. Biotic and abiotic test systems were incubated at 12°C for 1-28 days. On each day of analysis, triplicate freshly spiked abiotic test systems were prepared and analyzed (SPME GC-MS/MS) along with triplicate incubated biotic and abiotic test systems.

Biodegradation kinetics were determined for most lavender oil constituents and were similar in upstream and downstream water. Linalyl acetate was unstable in the abiotic controls and hydrolyzed with a half-life of 4.4 days. Overall, the inclusion of freshly spiked controls allowed to separate and quantify biotic and abiotic degradation kinetics of the UVCB constituents.

4.05.P-We305 Screening for Persistence Using Whole Petroleum Substance UVCB Biodegradation Testing with Constituent Tracking

Delina Lyon[1]*, Mari Creese*[2]*, Andy Booth*[3]*, Jonas Gros*[4]*, J. Samuel Arey*[5]*, Leslie J Saunders*[1]*, David Saunders*[6]*, Lisbet Sorensen*[2]*, Louise Camenzuli*[7] *and Aaron Redman*[8]*, (1) Concawe, Belgium, (2)SINTEF, Norway, (3)Climate and Environment, SINTEF, Norway, (4)Independent Consultant, Germany, (5)Oleolytics, (6)Shell Global Solutions, Netherlands, (7)ExxonMobil, Belgium, (8)ExxonMobil Biomedical Sciences*

Petroleum substances (PS) are produced at very high tonnage levels – underlining the need to generate useful and appropriate chemical assessment information. Yet, it has proved extremely challenging to assess the biodegradability of PS due to their UVCB (Unknown, variable, complex reaction product, or biological origin) nature, since the individual constituents may have different partitioning behavior and fates. Typical regulatory biodegradation tests which are optimized for single constituent substances do not function well for PS UVCBs. Specifically, ready biodegradation tests (e.g., OECD 301 series) do not provide information on the biodegradability of individual constituents in PS, and biodegradation simulation tests (e.g., OECD 307-309) do not function well for PS as it is not possible to appropriately radiolabel the numerous individual constituents present in the whole substance. We have previously explored a new method for performing whole PS UVCB biodegradation assessment and the mapping biodegradation half-lives using two-dimensional gas chromatography (GCxGC) with peak tracking (SETAC-Europe 2022, 4.12.P-We213). Over the course of a marine biodegradation test, samples taken at several timepoints were extracted and analyzed by two-dimensional gas chromatography with a flame ionization detector (GCxGC-FID). Thanks to the improved separation of hydrocarbons afforded by the GCxGC technique, it is possible to monitor the biodegradation of individual peaks potentially representing several constituents and then to calculate primary biodegradation half-lives for those peaks. In this effort, about 1100 peaks were tracked, with less than 30 having primary biodegradation half-lives exceeding 40 days. The identity of the constituent(s) in the peaks with the longest half-lives were assessed using GCxGC with a mass spectrometer (MS). The ability to screen the biodegradability of so many constituents was previously only possible with QSAR. This approach can be used to assemble experimental data on groups of related constituents. It also provides data on constituents that would otherwise not have empirical data, as they are not commercially available and difficult to synthesize. The whole substance testing with peak-tracking approach as part of a weight-of-evidence presents a novel answer to the persistence assessment of PS UVCBs.

4.05.P-We306 Elution Model Hydrocarbon Block Method: A Computational Approach to Estimate Hydrocarbon Class and Carbon Number of GCxGC-FID Peaks of a Petroleum Substance UVCB for Environmental Risk Assessment

J. Samuel Arey[1]*, Sandrine Sourisseau*[2]*, Yves Verhaegen*[3] *and* ***Delina Lyon***[4]*, (1)Oleolytics, (2)TotalEnergies, France, (3)CONCAWE, Belgium, (4)Concawe, Belgium*

UVCBs (substances of Unknown, Variable composition, Complex reaction products, or of Biological origin), like petroleum substances (PS) pose a challenge for chemical hazard and risk assessment due to the complexity of the substance. One option for simplification of the composition of PS UVCBs, which may contain hundreds to thousands of constituents, is to group those constituents by carbon number and chemical class into what are called hydrocarbon blocks (HCB). Each HCB should be similar in structure and property. The HCB distribution of a PS composition can be determined by allocating the individual peaks from Comprehensive Two-Dimensional Gas Chromatography coupled to a Flame Ionization Detector (GC×GC-FID) to specific HCBs, termed the HCB method (HCBM).

Historically, the HCBM was performed by analytical experts, but this proprietary approach is difficult to replicate. A more computational and reproducible approach, termed the "Elution Model HCBM" is here presented. The elution model, as described in a recent publication (Arey et al., *ES&T*, accepted November 2022), uses an *in silico* approach to simulate the 2-D elution (retention time) pattern of petroleum substances in a GC×GC. To develop the Elution Model HCBM, the elution pattern of a hydrocarbon library of 15,495 individual chemical structures was simulated. The simulated elution patterns were interpreted as probabilistic information about chemical class and carbon number. A 2-D kernel density estimation (KDE) method was then used to determine the regions of the GC×GC chromatogram which approximately contain the constituents of each HCB. This analysis mapped HCB regions onto the GC×GC chromatogram, which then could be used to identify individual GC×GC-FID peaks and also quantify HCBs of real PS samples.

This first version of the Elution Model HCBM is designed to quantify HCBs through the statistical averaging of GC×GC-FID data, but it is not designed to be highly accurate for any individual analyte. The programmed approach is well-defined, and it is amenable to validation, peer-review, and extension. Improvements to the Elution Model HCBM are likely to arise through further testing of the elution model, the associated thermodynamic parameters, the KDE methodology, and the hydrocarbon library, particularly the polynaphthenic, polyaromatic, and naphthenic polyaromatic classes.

4.05.P-We307 Revalidating PetroTox for the Performance of Aquatic Hazard Assessment Using Revised Target Lipid Models

Tifany L Torralba[1]*, Christopher J Fanelli*[1]*, Richard F. Carbonaro*[2]*, Louise Camenzuli*[3]*, Aaron Redman*[4]*, Delina Lyon*[5]*,* ***Yves Verhaegen***[6]*, Joy A Mcgrath*[7] *and Thomas Parkerton*[8]*, (1)Mutch Associates, (2)Manhattan College, (3)ExxonMobil, Belgium, (4)ExxonMobil Biomedical Sciences, (5)Concawe, Belgium, (6)CONCAWE, Belgium, (7)Joy McGrath Consulting, (8)EnviSci Consulting*

Ever since its development in the early 2000s, *PetroTox* has been successfully used to estimate the distribution of complex petroleum hydrocarbon mixtures among interacting physico-chemical phases and their corresponding toxicity/environmental risk limits. With the emergence of new aquatic toxicity studies with hydrocarbons in recent years, a need to update the core *PetroTox* physico-chemical property and toxicity databases has arisen. A revalidation of *PetroTox* using up-to-date versions of these databases is presented in this work. Recent acute and chronic toxicity data were compiled for approximately three hundred unique hydrocarbons constituents across over 50 aquatic species. The empirical toxicity data were ranked based on reliability, then used to calibrate and evaluate the performance of different organism target lipid models (TLMs) for the prediction of toxicity endpoints. These endpoints are one of the key estimation components of *PetroTox*. The eight TLMs evaluated include partitioning to different types of lipids and lipid surrogates as well as more general target site, rather than lipid, models. The performance of the TLMs fits, and thus prediction of petrochemical toxicity, was evaluated showing the prediction errors among the TLMs were reasonable and very similar to each other, indicating that model selection in this case needed to include criteria other than performance, such as accessibility and practicality. Environmental risk limits (e.g., hazardous concentration for 95% species protection [HC5]) were recalibrated using the selected TLMs. Under a separate related project an updated ecotoxicity database for UVCBs (unknown or variable composition, complex reaction products or of biological materials) was developed. The *PetroTox* model was then revalidated utilizing this updated UVCB database and the newly selected TLMs. This revalidation was an iterative process between the recalibrated TLM and the re-validated *PetroTox* model to balance the variability of partitioning data for mono-constituents and UVCBs in the newly developed ecotoxicity database. This step was crucial to ensure internal consistency between the TLM and *PetroTox* models for regulatory acceptance. This revalidation provides further support to the technical robustness and applicability of PetroTox as an environmental modeling tool for the estimation of the toxicity of petroleum products to aquatic organisms.

4.05.P-We308 Evaluating the Impacts of Hydrocarbon Solvent Variability on Environmental Hazard and Persistence

***Christopher Prosser**[1], Craig Warren Davis[2], Louise Camenzuli[3], Anna Tancorra[4], Alexander T'Sas[4] and Yun Zou[4], (1)ExxonMobil, USA (2)Toxicology & Environmental Science, ExxonMobil Biomedical Sciences, (3)ExxonMobil, Belgium, (4)ExxonMobil*

Hydrocarbon (HC) solvents are a diverse group of petrochemical substances that are generally described as Unknown or Variable composition, Complex reaction products or of Biological materials (UVCBs) and may contain tens of thousands of individual chemical constituents. HC solvents are manufactured from petroleum feedstock following a number of processing steps including distillation, hydrogenation, and hydrodesulfurization. However, feedstock and manufacturing processes may differ across regions. As such, hydrocarbon solvent sold under the same trade name may be manufactured in different locations. Whil solvents sold under a trade name have to meet various company specific specifications (e.g. viscosity and pour point), the difference in manufacturer process and feedstock may result in subtle differences in composition. The goal of this work is to investigate compositional differences between three solvents from different manufacturing locations and compare each using a suite of environmental fate and hazard metrics. Three different solvents were selected (referred to as Aro, Iso, and Exo), each of which is manufactured in the US, EU and Asia (a total of 9 individual substances). Aro's are predominantly aromatics ranging from C11 – C13; Iso's are primarily isoparaffins and naphthenics ranging from C10 – C13, And Exo's are C11 – C15 containing paraffins, isoparaffins and naphthenics. The composition of each was evaluated with two-dimensional gas chromatography time-of-flight mass spectrometry (GC×GC-TOFMS), and subsequently modeled for aquatic hazard using PetroTox. Additionally, the bioavailable fraction was measured using BE-SPME and ecotoxicological assays were performed using *ceriodaphnia*. Finally, biodegradation testing was conducted using OECD 301F methodology. 2D GC showed that, hile the overall carbon distribution of each solvents type was consistent, there were some differences in relative percentage of carbon numbers and chemical class (e.g. relative ratio of isoparaffins to naphthenics). However, despite this Petrotox, Be-SPME and *Ceriodaphinia* ecotoxicolgical data all demonstrate a comparable hazard, and biodegradation rates were also comparable. This study demonstrate that while differences in feedstock and manufacturing process may lead to subtle differences in composition, substances sold under the same trade name in different geographies demonstrate comparable hazard and fate properties.

4.05.P-We309 Photomodification of Low-sulfur-fuel-oils: Investigations of Toxic Effects (POLITE)

***Benjamin Patrick de Jourdan**[1], Danielle A. Philibert[1] and Christoph Aeppli[2], (1)Huntsman Marine Science Centre, Canada, (2)Bigelow Laboratory for Ocean Sciences*

The changes in International Maritime Organization regulations regarding the lower limits of sulfur content in marine fuel oils have initiated the transition to a new generation of low sulfur fuel oils (LSFO). These new generation fuels are diverse, and their physical, chemical, and toxicological properties are less well understood compared to their traditional counterparts. Little is known about the photooxidation capacity of these LSFOs, or the toxicological significance of the range of photo-products they may form. The aim of this project is to improve the understanding of the photomodification potential of LSFOs using both Stage I American lobster larvae, and state-of-the-art analytical capabilities. Trials were conducted with an ultra-low sulfur fuel oil (ULSFO), a conventional heavy crude (CONV, sulfur content ~3.4%), and 12 different LSFOs selected from 49 LSFO products collected from the Australian Maritime Safety Authority (AMSA). Low energy WAFs were prepared and mixed either under the light for 18-hr irradiation or in the dark, and full spectrum light exposures were generated using an Atlas Solar Constant lamp. WAFs were characterized using a fluorometry, a solid phase microextraction coupled to a gas chromatography-flame ionization detection (SPME-GC-FID) instrument was used for biomimetic extraction (BE) measurements, and polycyclic aromatic hydrocarbons and total organic carbon were quantified using USEPA method 3510C/8270C and standard method 5310B. Irradiated and non-irradiated WAFs were prepared with loading rates of 0.01, 0.1, 1, and 10 g/L oil. There was a concentration dependent increase in BE values with increased loading, and irradiation lead to an increase in BE values for both oils. The increase in BE values mirrored the observed toxicity, with the irradiated 10g/L CONV sample having greater effect. WAFs with the AMSA LSFOs were prepared at 1 g/L under UV light and in the dark and were tested using only 100% strength solution of the WAF. For 11 of the 12 LSFOs tested, observed toxicity in the UV treated WAF was equal or greater than the WAF prepared in the dark. The LSFOs tested were more toxic than the ULSFO and CONV at the 1 g/L loading, and they showed a full range of immobilization response from 10 - 100%. The findings highlight the diversity in LSFO products on the market, and the data generated will be used to develop and validate models, to predict and assess the toxicity of these new generation fuel oils.

4.05.P-We310 Assessing the Toxicity of Oil Sands Process-Affected Water in Early Life Stage Wood frogs (*Lithobates sylvaticus*) using Biomimetic Extraction via Solid-phase Microextraction (BE-SPME)

Katelyn Stenner[1]*, Blake Danis*[1]*, Asfaw Bekele*[2]*, Neal Tanna*[3]*, Bonnie Drozdowski*[3]*, Frank Gobas*[4]*, Barry C Kelly*[5] *and Vicki Marlatt*[5]*, (1)Department of Biological Sciences, Simon Fraser University, Canada, (2)Imperial Oil, Canada, (3)InnoTech Alberta, Canada, (4)Resource & Environmental Management, Simon Fraser University, Canada, (5)Simon Fraser University, Canada*

Oil sands process-affected water (OSPW) is a by-product resulting from the extraction process of bitumen in the Canadian oil sands industry and is currently stored in large tailings ponds on site. OSPW is comprised of a mixture of various organic and inorganic constituents. e composition and toxicity of OSPW is influenced by its age, source, and location within tailings ponds. Due to OSPW's complex composition and known acute toxicity to a variety of aquatic life, this experiment is part of a multi-year study aimed to evaluating biomimetic extraction via solid-phase microextraction (BE-SPME) analytical technique for toxicity screening of OSPW. BE-SPME has recently been developed as a cost-effective tool for hazard assessment of the bioavailable organic components in OSPW. We investigated the potential lethal and sub-lethal effects of a range of dilutions of OSPW (80, 40, 20, 10, 5, 2.5 and 1.25%) in wood frogs (*Lithobates sylvaticus*) native to Alberta, Canada from pre-hatching embryonic stages through to metamorphosis. Mortality at 80% of raw OSPW and developmental delays at concentrations of 40% and 80% are evident. As well, low concentrations have significant incidences of deformities (scoliosis and hind limb malformations). In addition to BE-SPME measurements, speciated and total naphthenic acid (NA) concentration analyses of OSPW were conducted. BE-SPME and NA concentration data will be used to derive concentration-effect relationships for OSPW exposure in an environmentally relevant amphibian model. The results will be beneficial for future screening assessment of raw and remediated OSPW in the Canadian Oil Sands.

4.05.P-We311 Sensitivity of Aquatic Organisms to Aromatic and Medicinal Plant Essential Oils and Crude Extracts: A Meta-analytic Approach

Sandra Afonso*, University of Coimbra, Centre for Functional Ecology, Portugal*

Interest on plant-based products, especially extracts and essential oils, has increased over recent years due to their bioactive and biopestice properties. Plant products are generally thought to be safe, though plants can produce and accumulate a variety of toxic compounds, with various factors influencing their toxicity. Aquatic organisms can easily be exposed to the toxicological risks of plant-based products, but research exploring the extensive published ecotoxicological data is still limited.
This study aims to conduct a systematic review of published evidence on the acute/short-term and chronic/long-term toxicity of aromatic and medicinal plant (AMP) extracts and essential oils on aquatic organisms. We undertook a systematic literature search using multiple search paths and key words to locate all relevant studies addressing ecotoxicologial effects of extracts and essential oils on aquatic organisms that were published in English by November 2022. Studies were screened and inclusion/exclusion criteria allowed the selection of 595 studies in the review. Information on LC50 values was extracted, as well as on variables that might moderate the toxic effects (e.g. plant identity, functional group and origin, plant part, organism identity, functional group). Principal component analysis (PCA) will be carried out to identify the variables most strongly related with toxicity effects. A subset of studies (22) that address ecotoxicologial effects on both the standard species *Daphia magna* (or in alternative *Daphnia* sp.) and other aquatic organisms will be used in a meta-analysis to compare the sensitivity of aquatic organisms to that of *Daphia* sp.; the effect size is calculated as the response ratio R ($LC50_{AquatOrg}$ / $LC50_{Daphnia}$). Effect sizes will be sumarized using the random-effects model of meta-analysis; overall R > 1 or < 1 indicates lower or higher, respectively, sensitivity in aquatic species than *Daphnia* sp. Potential moderators of toxic effects will be tested using sub-group analyses. Sensitivity analyses will be carried out to assess the robustness of results to analysist decisions and fail-safe numbers will be used to assess robustness of the matrix to publication bias.
The methodological approach used makes available new and relevant information for the development of valid criteria for evaluating the effects of a substancial variety of commercialized AMP essential oils and crude extract on the aquatic environment.

4.05.P-We312 Cytotoxic and Molecular Effects of Soil Extracts from the Agbogbloshie Electronic-Waste Site on the Rainbow Trout RTgill-W1 and Human Caco-2 Cell Lines

Krittika Mittal[1]*, Ke Xu*[2]*, Jingyun Zheng*[2]*, Julius Fobil*[3]*, Stéphane Bayen*[2] *and Nil Basu*[2]*, (1)Natural Resource Sciences, McGill University, Canada, (2)McGill University, Canada, (3)University of Ghana, Ghana*

Electronic-waste (E-waste) sites are notoriously contaminated with complex chemical mixtures thus challenging environmental monitoring, management, and remediation activities. Additionally, there is increasing awareness that traditional whole animal based toxicity tests are resource-intensive, expensive and unethical. Given that E-waste sites are typically situated in low- and middle-income countries that tend to be poorly resourced, there is a need to develop more efficient techniques for application in such settings. The objectives were to: A) characterize cytotoxic effects of soil extracts on the rainbow trout RTgill-W1 and the human Caco-2 cell lines; B) measure gene expression changes in both cell lines, and calculate transcriptomic points of departure (tPODs); and C) compare the cytotoxicity and molecular results across both cell lines to determine if the tPODs are protective of *in vitro* LC50 values. Extracts were prepared from 35 soil samples collected at the Agbogbloshie E-waste site (Accra, Ghana).

Samples were classified as upstream (6), downstream (2), community (3), trade site (8), dump site (13), and burn site (3). The RTgill-W1 and Caco-2 cells were exposed in triplicate to concentrations equivalent to 9.38, 4.69, 2.34, 1.17, 0.59, and 0.29 mg dry weight of extract (eQsed)/ml. Many of the samples from the various site types caused a decrease in RTgill-W1 cell viability % at 9.38 eQsed/ml. For example, obvious cytotoxicity was measured in two upstream and two community samples (6.9 - 66%), five dump site samples (5.2 – 31.4%), and the eight trade site samples (2.2 – 53%). The most cytotoxic site to the RTgill-W1 cells was trade site #8 with an LC50 value of 0.5 eQsed/ml. Preliminary results from the first exposure to the Caco-2 cell line showed that it was less sensitive to the extracts with most sites causing little to no decrease in cell viability; For example, only trade site #8 decreased cell viability by 45% (though this was deemed to be the most cytotoxic sample for both the cell lines). Studies on molecular responses are underway. Differential gene expression upon exposure to these extracts will be measured by ultraplex RNA sequencing technology, from which tPODs will be determined for each site. This work is expected to support ongoing efforts in establishing the use of efficient alternative testing strategies with a focus on developing methods for environmental monitoring activities in contaminated sites at under-resourced locations.

4.05.P-We313 Liquid Organic Hydrogen Carriers (LOHCs) as Novel Carriers of Renewable Energies - Proactive Environmental Hazard Assessment

Yohan Seol[1]*, Marta Markiewicz*[1]*, Stephan Beil*[1]*, Felix Irrgang*[2] *and Stefan Stolte*[1]*, (1)Institute of Water Chemistry, Technical University Dresden, Germany, (2)Institute of Water Chemistry, Technical University Dresden, Institute of Water Chemistry, Germany*

Liquid Organic Hydrogen Carriers (LOHCs) are very promising vectors for hydrogen storage and transportation. LOHC systems consist of a pair of H_2-lean, typically (poly)cyclic aromatic compounds and H_2-rich form, (poly)cyclic aliphatic compounds. LOHCs have high gravimetric hydrogen storage capacity and can go through multiple hydrogenation/dehydrogenation cycles. Additionally, hydrogen can be stored in LOHC under ambient conditions. The scale of LOHC implementation can reach that of liquid fossil fuels if full replacement shall occur – in this scenario there is a high likelihood of release of LOHCs into the environment. Until now, the LOHC systems based on toluene and benzyltoluene are technically mature but there are some technological hurdles. Thus, it is of high interest to find potential LOHC, which allow for a similar performance but also with similar or better hazard profile. To avoid regrettable substitution (of fossil fuels or one LOHC system by another) a comprehensive hazard profile is crucial before widespread use. This study presents ready biodegradability screening as well as aquatic toxicity assessment of novel LOHC using *Raphidocelis subcapitata*, *Daphnia magna* and *Aliivibrio fischeri*. Due to structural similarity to known endocrine disruptors, this study also reports about estrogenic and androgenic potential. Toxic Ratio approach was used to evaluate whether LOHCs act as baseline toxicants (i.e., toxicity is driven by hydrophobicity). COSMO-RS and COSMOmic were used to predict soil partition coefficient and lipid membrane-water partition coefficient to understand the fate and bioaccumulation of the compounds. Lastly, a comparative hazard assessment was conducted including comparisons between different forms of the same carrier (H_2-lean vs H_2-rich forms) and between LOHCs and conventional energy sources (fossil fuels). Our results show that all tested LOHCs seem to be baseline toxicants. Most LOHC compounds are expected to be rather mobile in the soil environment and only H_2-rich LOHC forms are assumed to have a high bioaccumulation potential. Investigated monocyclic compounds were fully mineralized while bicyclic compounds were only partially degraded in the ready biodegradability test. Overall, tested LOHCs seem to have a similar level of environmental hazard to that of fossil fuel-based system. The research outcome will be of the highest interest to environmental scientists, LOHC developers, regulatory agencies, and the general public.

4.06 Complex Mixtures in Chemical Risk Assessment: Challenges and Opportunities

4.06.P-Th279 Assessment of Developmental Adverse Effects of Complex Real-Life Mixtures Using a Human Induced Pluripotent Stem Cell - Based 3D Bioassay

Andreas Treschow[1]*, Maria Valente*[2]*, Maria Margalef Jornet*[3]*, Solene Motteau*[4]*, Maria Koenig*[5]*, Marja Lamoree*[6]*, Jean-Philippe Antignac*[7]*, Beate Escher*[5] *and Anne Marie Vinggaard*[1]*, (1)Technical University of Denmark (DTU), Denmark, (2)National Food Institute, Technical University of Denmark (DTU), Denmark, (3)Vrije Universiteit Amsterdam, Amsterdam Institute for Life and Environment (A-LIFE), Netherlands, (4)Oniris, INRAE, France, (5)Department of Cell Toxicology, Helmholtz Center for Environmental Research (UFZ), Germany, (6)Amsterdam Institute for Life and Environment (A-LIFE), Section Environment & Health, Vrije University Amsterdam, Netherlands, (7)LABERCA UMR 1329 INRA, France*

Humans are exposed to an unknown number of chemicals from environmental and food sources. Traditionally, hazard identification and toxicological assessment is performed on single chemical level. This approach falls short in describing potential harmful effects of complex mixtures of unknown composition we are exposed to every day. The Green Deal Project "PANORAMIX" aims at determining the effects of chemical mixture extracts from real-life samples using human-relevant bioassays and to identify the mixture drivers. The mixtures investigated are extracts of mixtures of organic chemicals obtained from various pooled samples of water, fish, cow milk, human breast milk and serum (from adult and umbilical cord blood) collected from several European countries. e potential adverse effects of the extracts on development were assessed using the human induced pluripotent stem cells (hiPSCs)based 3D cardio-developmental PluriLum assay.

hiPSCs-derived embryoid bodies (EBs) mimicking the human blastocyst were exposed to above extracts during differentiation into cardiomyocytes. Reduction in expression of the cardiac-specific gene *NKX2.5* was quantified by the end of the differentiation regime using a luminescent reporter expressed alongside *NKX2.5*.

Exposure to some extracts of real-life samples negatively impacted the differentiation of EBs within non-cytotoxic levels, when compared to negative control. Cardiac-specific effects were observed in EBs exposed to surface and drinking water, as well as to human cord blood serum.
This work highlights how bioassay analysis of extracts from real-life samples can create value by shedding light on potential harmful exposures that is undetected in our exposome. By using assays such as the PluriLum, it is possible to monitor potential developmental adverse effects of complex chemical mixtures more closely, as well as compare contamination levels across the environment-human-food continuum.

4.06.P-Th284 Combining Polar Organic Chemical Integrative Samplers (POCIS) with Three Standard Bioassays to Evaluate the Impact of Chemical Mixtures in Surface Waters

Roberta Carafa[1]*, Jan De Lange*[2]*, Livia Gomez Cortes*[2]*, Montserrat Real*[1]*, Luisa Colzani*[3]*, Carola Forni*[4]*, Giulio Mariani*[2] *and Teresa Lettieri*[2]*, (1)AECOM, Spain, (2)European Commission Joint Research Centre (JRC), Italy, (3)Settore Laboratori -U.O.C. Laboratorio Regionale Area Ovest, Italy, (4)ARPA Lombardia, Italy*

Chemical risk assessment as deployed by the European Water Framework Directive (WFD) might not be sufficient to protect surface waters when considering the contribution of chemical mixture effects on the aquatic environment and subsequently on human health. The proposal of the WFD review has been launched by the Commission in 2022, with the final aim to improve the directive, also on the perspective of the objectives of the European Green Deal and the Circular Economy Action Plan. Main improvements might include sampling schemes with comprehensive exposure times as well as repeated peak concentration exposure time, spanning target analytes, and addressing the impacts of chemical mixtures. The present study is aiming to compare different screening methods, on wastewater treatment plant outflow waters, which combine polar organic chemical integrative samplers (POCIS) with a panel of mode of action (MoA)–specific toxicity bioassays. Two main classes of widely present and highly harmful compounds were investigated: (i) endocrine disrupting compounds using ERα-CALUX and Ligand-Binding Estrogen Receptor Assay (LiBERA) tests and (ii) pesticides using standard algae fluorescence inhibition test measured by pulse-amplitude modulated (PAM) fluorometry. The selected bioassays were tested with both (i) whole field extracts dilutions and (ii) reconstructed spikes test mixture dilutions, prepared with the most representative priority and emerging substances measured in the extracts. Effects measured in the whole extract tests were greater than effects measured in the reconstructed spike tests. Besides, the interference of toxic substances can mask the target MoA, e.g., killing ERα-CALUX cells before the maximum estrogenic agonistic effect is expressed. Practical considerations about the suitability of large-scale implementation of bioassays for monitoring the status of water bodies are provided in terms of required expertise and instrumentation, related costs, time needed to obtain results, limits of detection, etc. Combining passive sampler extracts with standard toxicity tests offers promising perspectives for ecological risk assessment and can be considered complementary to routine chemical analyses.

4.06.P-Th295 How Monitoring Data from the Information Platform for Chemical Monitoring (IPCHEM) Can Help Addressing Mixtures – Two Use Cases

Stephanie K Bopp[1]*, Antonio Franco*[2]*, Alberto Cusinato*[1] *and Alberto Pistocchi*[1]*, (1)European Commission Joint Research Centre (JRC), Italy, (2)Joint Research Centre, European Commission Joint Research Centre (JRC), Italy*

The Information Platform for Chemical Monitoring (IPCHEM) is a single access point where EU, national and regional authorities, and researchers can find and share information about where chemicals are found and at which concentrations. IPCHEM allows the user to discover, access and retrieve information on chemical occurrences across different media, such as air, water, soil, food and also in humans. The platform incorporates about 500 million concentration measurements for over 3000 substances. Data originate from regulatory monitoring and research consortia and is continuously integrated following defined quality criteria and harmonisation procedures.
Monitoring data are valuable in the assessment of combined exposures to multiple chemicals, as they allow looking at real-world combinations and exploring trends over time and space. In this poster, we illustrate two mixture studies using data from IPCHEM to illustrate possibilities to the regulatory and scientific community: **Chemical mixtures in the EU population**: in collaboration with the human biomonitoring project HBM4EU, typical mixture compositions at median and higher end exposures (95^{th} percentile) were explored based on human biomonitoring data representing internal exposure in the EU adult and children populations. Possible risks were calculated for the single substances and the mixtures using human biomonitoring guidance values. **Spatial distribution of pesticide concentrations at European level**: concentrations of 148 pesticide active substances in stream networks at European level were modelled from their estimated agricultural uses. The screening level model quantified pesticide concentrations in the same order of magnitude of the monitoring data used for benchmarking. The possible mixture risk to aquatic organisms was assessed using a Sum of Toxic Unit approach.
Further examples how monitoring data can support addressing policy and research questions are e.g., direct use in regulatory risk assessments, monitoring compliance and targeting intervention, risk/impact indicators, evaluating the impact of regulatory interventions.

4.06.T-01 Are Pesticide Mixtures at Realistic Environmental Concentrations Noxious to the Freshwater Microalgae *Raphidocelis subcapitata*?

Ana-Belen Muniz-Gonzalez[1,2]*, Isabel Campos*[3]*, Ana Ré*[4]*, Joana Pereira*[5]*, Fernando J. M. Gonçalves*[5]*, Irene Navarro*[6]*, Adrián de la Torre*[6]*, María de los Ángeles Martínez*[6] *and Nelson Abrantes*[7]*, (1)Physics, Mathematics and Fluids, UNED, Spain, (2)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (3)Environment and planning, University of Aveiro, Portugal, (4)Department of Environment and Planning, Department of Environment and Planning & Centre for Environmental and Marine Studies (CESAM), University of Aveiro, Portugal, (5)University of Aveiro, Portugal, (6)CIEMAT,*

Spain, (7)Department of Biology, University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal
Pesticides are intensively used in farming systems worldwide to ensure crop yields, and food safety, with values approaching 350,000 tons of active substances used annually in Europe. Pesticides reach not only to soil even pollute air, and water systems becoming a remarkable risk factor for non-target organisms living there. Albeit the harmful impact of pesticides has been widely documented, most of ecotoxicological studies are focused on single compounds ignoring the real case scenarios where mixtures of pesticides are commonly found in soil and aquatic systems. Developed within the framework of the H2020 SPRINT project (https://sprint-h2020.eu/) this study aimed to assess the impact of realistic PPPs mixtures concentrations on the growth rate of the microalgae *Raphidocelis subcapitata*. For this purpose, 11 case studies (CSS) across Europe and Argentina were selected and the concentration of pesticides (>200 active ingredients; a.i.) in water systems nearby agricultural fields was measured in each. Per CSS a mixture of 5 pesticides were defined based on the frequency of occurrence and risk quotient (RQ) calculated for each a.i., totalizing 11 distinct pesticide mixtures. Following the OECD test guideline 201, the microalgae was exposed to each mixture at 4 distinct concentrations: measured environmental concentration (MEC), predicted environmental concentration (PEC), 3*PEC and 5*PEC mixtures concentrations.
Of the total of 11 mixtures, 7 have already been tested (PT, SW, IT, CR, CZ, FR, and DE), with significant effects observed in 4 of them (CR, CZ, FR, PT) when exposed to the realistic concentration (MEC). At PEC concentration all mixtures significantly reduced algal growth. Given that all the pesticide mixtures tested contain three herbicides, this may explain the strong inhibition found due to their capacity to interact and modulate the correct photosynthesis of the microalgae. Considering that the MEC tested are generally lower than the lowest NOEC/EC50 values reported for each pesticide, our results reinforce the high risk of pesticide mixtures for aquatic systems, and the need to include more realistic approaches, both considering mixtures and testing environmentally relevant concentrations.

4.06.T-02 Indoor VOCs Levels in retail stores and Employee Personal Exposures in an urban city in Türkiye: Health Risk Assessment, I/O Ratios, and Seasonal Effects
***Fatma Nur Eraslan**, Özlem Özden Üzmez and Eftade Emine Gaga, Environmental Engineering, Eskişehir Technical University, Turkey*
This study was carried out in seven various workplaces (bakery, photocopy center, restaurant, hairdresser, dry cleaner, market, and hotel) where different activities were carried out. 43 volatile organic compounds (VOCs) were determined simultaneously in the indoor and outdoor environments of each workplace by passive sampling methodology. Furthermore, to determine the exposure concentrations of the people working in these workplaces, personal sampling was carried out. The sampling studies were repeated in the summer and winter seasons due to the importance of seasonal fluctuations in indoor and outdoor air pollution concentrations. Analyses of the samples were performed by a TD-GC-MS. As a result of the study, it was observed that the specific activities of the workplaces played an essential role in the concentrations of indoor VOCs in the study area. While the highest indoor VOC concentrations were measured at dry cleaners (926.045 $\mu g/m^3$-winter, 1014.1533 $\mu g/m^3$-summer) in both seasons, the lowest indoor VOC concentrations were measured at the hotel (95.25 $\mu g/m^3$-winter) and bakery (85.905 $\mu g/m^3$-summer). All indoor/outdoor ratios (I/O) in workplaces other than the bakery were obtained as > 1. This indicates that most workplaces had higher indoor VOC levels than the outdoor environment due to dominant indoor sources. Besides, for the bakery, photocopy center, restaurant, hairdresser, and hotel, winter indoor concentrations were higher than summer concentrations. The reason for this was that ventilation was reduced during the winter months. In addition to all these outcomes, personal sampling results revealed that most employees were exposed to TVOCs at higher levels than indoor levels. Furthermore, carcinogenic (LTCR) and non-carcinogenic health risks (HQ) due to VOC exposure were estimated using personal sampling results. The total LTCR values of all samples collected from 9 different employees from 7 different workplaces were above the acceptable limit of 1,0E-06 defined by USEPA. The total HQ values were found to be also above the reference value (1) defined by USEPA for the employees working in the photocopy center, restaurant, and hotel reception. The results showed that indoor activities at the workplaces were significant on indoor VOC levels as well as occupational health risks faced by the employees at the workplaces.

4.06.T-03 High-Throughput Effect-Directed Analysis Strategy to Study Thyroid Hormone System Disruptors in WEEE Contaminated Toy Material
***Naroa Lopez**[1,2], Maria Margalef Jornet[3], Peter Cenijn[3], Marja Lamoree[4], Timo Hamers[5] and Sicco Brandsma[6], (1)Plentzia Marine Station of Basque Country University (EHU/UPV), Spain, (2)University of the Basque Country (UPV/EHU), Spain, (3)VU Amsterdam, A-LIFE-Environment & Health, Netherlands, (4)Environment & Health, VU University, Netherlands, (5)Amsterdam Institute for Life and Environment (A-LIFE), Section Environment & Health, Vrije University Amsterdam, Netherlands, (6)Vrije University Amsterdam, Netherlands*
Plastic products often contain chemical additives (e.g., plasticisers, flame retardants, surfactants…) to improve and/or modify a specific property of the product. However, these additives are also known to be harmful to human health. Although regulation on certain additives exists within the European Union (EU), public concern has been raised about the possible presence of chemical additives in consumer products and plastic children's toys originating from waste electrical and electronic equipment (WEEE). High migration rates of certain additives have been reported in some commercially available toys by simulating the mouthing behavior of children as one of the most significant exposure pathways. The EU restricted the content of some chemicals in toys considering their endocrine disrupting potential. Thyroid hormones play a key role in the development and maintenance of a normal physiological state and a deficiency of such hormones can cause a neurodevelopmental effect. The aim of this study is to elucidate whether chemical mixtures of those polymeric toy materials and their saliva leachates operate as thyroid hormone system disruptors, and to adopt a high-throughput effect directed analysis (EDA) strategy to identify and confirm specific drivers. Saliva leaching experiments were performed in polymeric material from toys commercially available in the EU market. Saliva

and plastic extracts were assessed for their competitive activity with the thyroid hormone in the TTR-binding assay. Samples showing relatively high TTR-binding were later subjected to high-throughput effect-directed analysis (EDA). TTR-binding experiments showed a concentration dependent activity in all analyzed extracts. Components extracted directly from the plastic toys showed the highest TTR-binding capacity. Moreover, saliva leaching extracts from one particular toy appeared to have a non-negligible TTR-binding activity when compared to the others. Two TTR-binding active fractions stood out in all the fractionated plastic extracts. Saliva leaching extracts of one toy showed some minor active fractions as well. This study demonstrates that when using high throughput EDA is a good approach to unravel the potential activity drivers in complex mixtures.

4.06.T-04 Combining Algal Growth Inhibition, Flow Cytometry and Computational Approaches for Chemical Mixture Ecotoxicity Assessment

Théo Ciccia[1]*, Pascal Pandard*[2]*, Nastassia Urien*[1]*, Anne Bado-Nilles*[3]*, Leo Lafay*[1] *and Philippe Ciffroy*[1]*, (1)Laboratoire National d'Hydraulique et Environnement (LNHE), Electricité de France (EDF) R&D, France, (2)Institut National de l'Environnement Industriel et des Risques (INERIS), France, (3)Umr-I 02 Sebio, Institut National de l'Environnement Industriel et des Risques (INERIS), France*

Risk assessment of contaminants present in freshwaters is usually carried out according to 'single' compound approaches, assuming that ecosystems are exposed to only one chemical at the same time. Chemical substances are therefore evaluated one by one, independently of possible co-exposures with other compounds. However, ecosystems are generally exposed to chemical mixtures, leading to unknown ecotoxicological effects. In this context, the component-based approach (CBA) can be used when the components of a mixture are clearly defined and consists in predicting the ecotoxicological effects of a combination of substances based on the individual toxicity of each component present in the mixture by using models of joint action. Using the CBA, the present work aimed to assess the joint toxicity of several disinfection by-products (DBPs) in binary mixtures (with three different concentration ratios) on the microalgae *Raphidocelis subcapitata* through the evaluation of the microalgal population growth inhibition coupled with a flow cytometry (FCM) approach for subcellular effects. FCM is able to assess effects on the physiology and morphology of algal cells and thus provide information about the potential underlying causes of toxicity (mode of action) and interaction of the substances in a mixture. Determination of the interaction (additivity/synergism/antagonism) was achieved by comparison with a model of joint action.

We discuss here three binary combinations of substances, monochloroacetic acid (MCAA)-trichloroacetic acid (TCAA), MCAA-Bromochloroacetic acid (BCAA) and TCAA-BCAA. Additivity effects were observed for both MCAA-TCAA and TCAA-BCAA on *R. subcapitata*. In the case of MCAA-BCAA mixtures, only one mixture showed an additivity response, the other two resulting in significant synergistic effects on the growth inhibition endpoint. Additivity observed in most mixtures could be explained by the combined approach of algal growth inhibition and FCM. Indeed, similar effects were observed for each single substance on the physiological and morphological parameters tested, potentially meaning that the substances share the same molecular target in the microalgae in accordance to the CA model. However, further work on the MCAA-BCAA mixture will be needed to confirm and explain the observed synergetic effects. Finally, testing different concentration ratios by combination of DBPs allowed us to generalize the interaction of a specific mixture.

4.06.P Complex Mixtures in Chemical Risk Assessment: Challenges and Opportunities

4.06.P-Th281 Endocrine Disrupting Potential of Real-life Chemical Mixtures from Pooled European Environmental, Food and Human Samples

Yanying Ma[1]*, Maria Margalef Jornet*[2]*, Solene Motteau*[3]*, Maria Koenig*[4]*, Beate Escher*[4]*, Marja Lamoree*[5]*, Jean-Philippe Antignac*[3]*, Maria Valente*[1] *and Anne Marie Vinggaard*[1]*, (1)Technical University of Denmark, Denmark, (2)Vrije Universiteit Amsterdam, Amsterdam Institute for Life and Environment (A-LIFE), Netherlands, (3)Oniris, INRAE, France, (4)Helmholtz Center for Environmental Research, Germany, (5)Amsterdam Institute for Life and Environment (A-LIFE), Section Environment & Health, Vrije University Amsterdam, Netherlands*

Humans are not exposed to single substances, but rather to multiple chemicals simultaneously. Therefore, it is crucial to evaluate the impact of chemical mixtures on human health and encourage mixture risk assessment. Our aim was to evaluate the endocrine disrupting potential of real-life chemical mixtures extracted from pooled environmental, food and human samples.

Two OECD validated reporter gene assays, namely human estrogen receptor (hER; TG455) and human androgen receptor (hAR; TG458) transactivation assays, were used. Cytotoxicity was measured and concentrations inducing more than 10% of cell death were excluded. Chemicals were extracted from pooled samples collected from various European countries to get as close as possible to an average European chemical mixture in each matrix. Effects are reported as relative to maximum effect of positive control.

Wastewater (WW) and surface water (SW) showed hAR agonistic activity below a REF of 2 $L_{water}/L_{bioassay}$. Wild (FFW) and lean fatty fish (LFW) exhibited 2-fold higher hAR antagonistic activity compared to aquaculture fatty fish (FFA). Organic (OCM) and conventional cow milk (CCM), as well as human breast milk (HBM), exhibited hAR antagonistic activity below a REF of 2 $mL_{milk}/mL_{bioassay}$. The highest antiandrogenic potential was found in serum from adult females and in cord blood (IC_{10} values below 0.2 $mL_{serum}/mL_{bioassay}$).

The ranking of estrogenic potency of water samples was as follows: WW > Effluent > SW > Bottled water > Drinking water. FFW and LFW, but not FFA, also exhibited estrogenic activity. Cow milk samples showed ER agonistic effects as well, whereas no effect was observed in HBM. Both adult and cord blood serum samples showed significant ER agonist activity (EC_{10} values below 0.3 $mL_{serum}/mL_{bioassay}$).

Our work emphasizes the potential of *in vitro* reporter gene assays as useful tools to assess endocrine disrupting effects of real-life chemical mixtures. Our results indicate that endocrine disrupting activity appears in samples across the environment-food-human continuum. Future studies include the identification of the chemical mixture drivers in these samples by effect-directed analysis.

4.06.P-Th282 Food Packaging – Effects of Recyclable Plastic

***Erica Josefin Selin** and Johan Lundqvist, Swedish University of Agricultural Sciences (SLU), Sweden*

There is an increasing demand from society towards using recyclable materials in food packages. However, there are concerns that hazardous chemicals existing in the recyclable material may migrate into food and pose a health hazard for humans. To gain more knowledge about the potential hazards, effect-based methods, were used to understand the effects of known, unknown and mixtures of chemicals. The panel of effect-based methods included oxidative stress, xenobiotic metabolism and endocrine system effects in recycled plastic materials intended to be used in food packages. In total, migration of eight recyclable plastic materials was conducted using ethanol according to the European legislation, which then were tested at concentrations of 0.006 - 0.050 cm^2/mL. No effects were seen for oxidative stress or antagonistic estrogen response, while only one material induced xenobiotic metabolism. The plastic materials tested consisted of polyethylene and low-density polyethylene/linear low-density polyethylene, of which the former showed the effect. To summarize, an effect-based approach enables hazard assessment of chemicals within food packages, which is a valuable tool for ensuring safe use of these types of packing materials.

4.06.P-Th283 Risk Assessment of Mixtures of Antiandrogenic Chemicals Based on In Vitro Hazard And Human Biomonitoring Data

*Yanying Ma[1], Camilla Taxvig[1], Andrea Rodríguez-Carrillo[2,3], Vicente Mustieles[2,3,4], Lena Reiber[5], Anja Kiesow[5], Nathalie Michelle Löbl[1], Mariana F. Fernández[2,3,4], Tina V. A. Hansen[1,6], **Maria Valente**[1], Marike Kolossa-Gehring[5], Madlen David[5] and Anne Marie Vinggaard[1], (1)Technical University of Denmark, Denmark, (2)Instituto de Investigación Biosanitaria Ibs Granada, Spain, (3)University of Granada, Center for Biomedical Research (CIBM), Spain, (4)Consortium for Biomedical Research in Epidemiology & Public Health (CIBERESP), Spain, (5)German Environment Agency, Germany, (6)Department of Veterinary and Animal Sciences, University of Copenhagen, Denmark*

In our everyday life, humans are exposed to numerous chemicals steming from environmental sources, food, and consumer goods. Multiple component-based mixture studies have shown that chemical mixtures can induce effects greater than those induced by the single chemicals on many human health endpoints, including male reproductive health disorders, for which human androgen receptor (hAR) antagonism emerges as a key molecular initiating event. Mixture risk assessment (MRA) is commonly performed using *in vivo* rodent data and human exposure data from food intake or environmental exposure. Due to the lack of *in vivo* data for many chemicals, the questionable relevance of rodent data, and the risk of lacking the most relevant exposure sources, there is a need to explore alternative MRA approaches. In this case study we explored a methodology for MRA of antiandrogenic chemicals based exclusively on human-derived hazard and exposure data.

A comprehensive literature search was conducted to retrieve hazard and exposure data of 231 compounds previously reported as hAR antagonists. The ratio of human blood levels by hazard values (IC_{10} values for hAR antagonism), were used for deriving Risk Quotients (RQs) for each chemical. For a rough measure of cumulative risk, the Hazard Index (HI) was calculated by summing up the RQs estimated for each component of the mixture.

From the total of 231 substances, reliable data was retrieved for 61 chemicals. No chemical showed an individual RQ above 1. The HIs for the entire mixture were 0.32 and 0.98 based on mean and maximum exposure levels, respectively. The mixture risk drivers, i.e. the compounds that contributed the most to the HIs, included polychlorinated biphenyls (PCBs), phthalates, the UV filter benzophenone-3, perfluorooctanesulfonate (PFOS), methylparaben, some pesticides, and a polycyclic aromatic hydrocarbon metabolite.

The aim of the study was to assess whether combined exposure to antiandrogenic chemicals with direct action on the androgen receptor *in vitro* may have an impact on human health. Our approach has pinpointed compounds that contribute markedly to the HI, such as PCBs, phthalates, benzophenone-3 and PFOS. Moreover, the calculated HIs provide a basis for a better understanding of the extent to which the combined chemical load will potentially exhibit adverse antiandrogenic effects in humans.

4.06.P-Th284 Combining Polar Organic Chemical Integrative Samplers (POCIS) with Three Standard Bioassays to Evaluate the Impact of Chemical Mixtures in Surface Waters

***Roberta Carafa**[1], Jan De Lange[2], Livia Gomez Cortes[2], Montserrat Real[1], Luisa Colzani[3], Carola Forni[4], Giulio Mariani[2] and Teresa Lettieri[2], (1)AECOM, Spain, (2)European Commission Joint Research Centre, Italy, (3)Settore Laboratori -U.O.C. Laboratorio Regionale Area Ovest, ARPA Lombardia, Italy, (4)ARPA Lombardia, Italy*

Chemical risk assessment as deployed by the European Water Framework Directive (WFD) might not be sufficient to protect surface waters when considering the contribution of chemical mixture effects on the aquatic environment and subsequently on human health. The proposal of the WFD review has been launched by the Commission in 2022, with the final aim to improve the directive, also on the perspective of the objectives of the European Green Deal and the Circular Economy Action Plan. Main improvements might include sampling schemes with comprehensive exposure times as well as repeated peak concentration exposure time, spanning target analytes, and addressing the impacts of chemical mixtures. The present study is aiming to compare different screening methods, on wastewater treatment plant outflow waters, which combine polar organic chemical integrative samplers (POCIS) with a panel of mode of action (MoA)–specific toxicity bioassays. Two main classes of widely present and highly harmful compounds were investigated: (i) endocrine disrupting compounds using ERα-CALUX and Ligand-Binding Estrogen Receptor Assay (LiBERA) tests and (ii) pesticides using standard algae fluorescence inhibition test measured by pulse-amplitude modulated (PAM) fluorometry. The selected bioassays were tested with both (i) whole field extracts dilutions and (ii) reconstructed spikes test mixture dilutions, prepared with the most representative priority and emerging substances measured in the extracts. Effects measured in the whole extract tests were greater than effects measured in the reconstructed spike tests. Besides, the interference of toxic substances can mask the target MoA, e.g., killing ERα-CALUX cells before the maximum estrogenic agonistic effect is expressed. Practical considerations about the suitability of large-scale implementation of bioassays for monitoring the status of water bodies are provided in terms of required expertise and instrumentation, related costs, time needed to obtain results, limits of detection, etc. Combining passive sampler extracts with standard toxicity tests offers promising perspectives for ecological risk assessment and can be considered complementary to routine chemical analyses.

4.06.P-Th285 Cost-Effective and Effect-based Evaluation of the Wastewater Quality Using a Battery of In Vitro Bioassays
*Nikiforos A Alygizakis[1,2], **Kelsey Ng**[2,3], Niki Maragou[1], Sylvana Alirai[1], Peter Behnisch[4], Harrie Besselink[4], Peter Oswald[2], Ľuboš Čirka[2,5], Jaroslav Slobodnik[2] and Nikolaos Thomaidis[1], (1)National and Kapodistrian University of Athens, Greece, (2)Environmental Institute, Slovakia, (3)RECETOX, Masaryk University, Czech Republic, (4)BioDetection Systems, Netherlands, (5)Slovak University of Technology in Bratislava, Slovakia*
Wastewater treatment plants (WWTPs) represent a key point source of contaminants of emerging concern (CECs) into the environment. The continuous monitoring of performance of the WWTPs to avoid influx of contaminants to the ecosystems is therefore important. In this study, a battery of *in vitro* bioassays covering a wide spectrum of effect endpoints is proposed for wastewater monitoring (estrogenic, anti-androgenic, glucocorticoid, PPARγ receptor, PAHs, oxidative stress, and pregnane X receptor activities). The bioassays can act as an early warning system by addressing the mixture toxicity (combined adverse effect) of multiple contaminants. The battery was applied to 11 WWTP effluent samples from the Danube River Basin (DRB), Selection of WWTP was based on the dominant removal technology of the country and the size of population served by the plants. The results indicated that the treatment technologies adopted by the studied WWTPs are unable to remove efficiently certain groups of CECs that cause specific effects including estrogenicity, PAH activity, xenobiotic metabolism and oxidative stress. The measured signals were benchmarked against the effect-based trigger values (EBTs). A mitigation plan was proposed to the WWTP operators based on the extent of exceedance of EBTs. This study demonstrates that the effect-based monitoring battery is a complimentary tool to the chemical analysis approach for quality control of wastewater. A regular application of such time- and cost-effective bioanalaytical tools in the WWTPs of DRB is proposed to provide a 'safety net' for the aquatic ecosystems.

4.06.P-Th286 Effects of Bisphenols and Their Mixtures on The Estrogen Receptor Transactivation in Cultured Hera-hela-9903 Cells
*Handule Lee, Juyoung Park and **Kwangsik Park**, College of Pharmacy, Dongduk Women's University, Korea*
As the use of household chemical products increases, the risk of chemical mixtures also increases and a more precise evaluation of the mixture toxicity is required, but studies on mixture toxicity are not yet sufficient. In this study, the transcriptional activity of estrogen receptor (ER) was measured based on the OECD Test Guideline 455 for the 9 bisphenols including bisphenol A, bisphenol AF, bisphenol B, bisphenol C, bisphenol E, bisphenol P, BPS-MPE, bisphenol Z,and 2,4-BPS. As results, bisphenol A, bisphenol AF, bisphenol Z, bisphenol B, bisphenol C, and bisphenol E showed agonistic activity while BPS-MPE, 2,4-BPS, and bisphenol P showed antagonistic activity. For the mixtures toxicity of bisphenols, some of agonists and antagonists were mixed for binary and ternary combination : agonist/agonist, antagonist/antagonist, agonist/antagonist. The ER transcription activity for the mixtures were measured according to the test guideline and the results were compared to the predicted values obtained by full logistic model (FLM). As results, the parameters (Max, Min, EC50, and Hill slope) obtained from the concentration-response curves of the measured and the predicted were very similar. This result suggests that POD (point of departure) value of the bisphenols mixture can be obtained from in silico model without testing and it may be one of tools for the next generation risk assessment (NGRA).

4.06.P-Th287 Composition-Specific Th17 Responses Induced by Real-world Air Pollution and Amelioration by Vitamin D
***Drew Glencross**[1], Charlotte Cheadle[2], Tanapat Palaga[3], Tassanee Prueksasit[4], Ganjana Lertmemongkolcha[5], Catherine Hawrylowicz[2] and Ian Mudway[6], (1)School of Public Health, Imperial College London, United Kingdom, (2)Peter Gorer Department of Immunobiology, King's College London, Asthma UK Centre for Allergic Mechanisms of Asthma, United Kingdom, (3)Department of Microbiology, Chulalongkorn University, Thailand, (4)Department of Environmental Science, Chulalongkorn University, Thailand, (5)Faculty of Associated Medical Sciences, Chiang Mai University, Thailand, (6)School of Public Health, Environmental Research Group, Imperial College London, London, United Kingdom*
Individuals with chronic respiratory disease (e.g., asthma, COPD) are particularly susceptible to poor air quality, whilst serum vitamin D (VitD) is inversely associated with disease exacerbations. Ambient particulate matter (PM) composition is highly complex containing a significant organic component, including aryl hydrocarbon receptor (AhR) ligands. The AhR is an environmental sensor required for Th17 maintenance, though different ligands may have contrasting immunoregulatory roles. We hypothesised that real-world particulate matter (PM) contributes to Th17-type responses linked to severe respiratory disease by perturbing AhR signalling within DCs and CD4 T cells, that PM effects are composition-specific, and that VitD supplementation is protective.
Methods: Human monocyte-derived dendritic cells (DC) were stimulated with ambient real-world PM (10µg/mL) from London ($PM_{2.5}$, PM_{10}) and Thailand (urban/rural $PM_{2.5}$), or an endogenous AhR ligand (FICZ, 200nM), *in vitro* for 20 hours. Autologous memory CD4+ T-cells (Tm) were co-cultured with PM-exposed DC, with or without a selective AhR-antagonist (CH223191, 10µM), or 1,25-dihydroxyvitamin D (100nM) for 7 days. DC maturation and T-cell phenotype was assessed by flow cytometry and RT-qPCR.

London PM_{10} ($p<0.0001$) and $PM_{2.5}$ ($p<0.001$), but Thai $PM_{2.5}$ from Chiang Mai and Bangkok did not increased expression of DC maturation markers such as HLA-DR. Tm proliferation, Th17 frequency, d AhR expression, which was not restricted to the Th17 compartment, were increased by co-culture with both London and urban Thai PM pre-treated DCs. AhR antagonism in coculture reduced Tm proliferation (approx. 50%), IL-17A+ frequency and AhR target gene expression (cytochrome p450s, IL-22). FICZ-treatment and AhR antagonism in DCs had no effect upon DC/Tm phenotype. VitD treatment significantly reduced DC maturation, subsequent CD4 proliferation and Th17 responses.
PM pre-treated DC induce both T cell expansion and Th17-associated cytokine production, and these effects appear PM-source dependent. The AhR plays a role in T-cell expansion, but is not obviously linked to PM-induced effects on DC. Future organic compositional analyses of real-world PM samples linked to functional data may provide insight into PM driven signalling pathways. VitD significantly reduced PM-induced inflammatory responses, placing it as a promising therapeutic to mitigate against PM-induced inflammation.

4.06.P-Th288 In Vitro Comparative Metabolism of Chemicals that are Nominally a Gas
Daniel T Evans[1] *and Rory Mumford*[2]*, (1)Environental Fate and Metabolism, Smithers, United Kingdom, (2)Environmental Fate and Metabolism, Smithers, United Kingdom*
The requirement to perform *in vitro* comparative metabolism studies for pesticide active substances related to human health is defined by Commission Regulation (EU) No 283/2013, setting out the data requirements for active substances, in accordance with Regulation (EC) No 1107/2009 of the European Parliament and the Council concerning the placing of plant protection products on the market. *In Vitro* Comparative Metabolism (IVCM) is required to assess the potential toxicity of agrochemicals to humans; comparison is typically made between human microsomes, S9 fractions, or hepatocytes and the equivalent test system from the toxicological assessment species (rat, dog, mouse, rabbit).
The EFSA Plant Protection Products and their Residues (PPR Panel) working group has been focussing on how best to do this, and a scientific opinion was published in 2021. However, this does not address how to deal with chemicals that are nominally a gas, yet an IVCM study is requested by the regulatory authorities.
This presentation discusses the challenges of performing an *in vitro* comparative metabolism study on a ^{14}C-labelled water-soluble gas in relation to recovery, metabolism, and analytical challenges.

4.06.P-Th289 Induction of CYP1A1 by Benzo[a]pyrene and Phenanthrene in zebrafish hepatocytes
Beatriz Matos[1]*, Mário Diniz*[2]*, Vasco Branco*[3] *and* ***Marta Martins***[1]*, (1)MARE - Marine and Environmental Sciences Centre, NOVA School of Science and Technology, Portugal, (2)UCIBIO, REQUIMTE, Portugal, (3)Research Institute for Medicines, Faculty of Pharmacy, Universidade de Lisboa, Portugal*
Polycyclic aromatic hydrocarbons (PAHs) are persistent contaminants ubiquitously present in the environment. Anthropogenic activities, namely fossil fuel combustion are the main sources of these compounds.
Once in the aquatic environment, PAHs are hardly degraded owing to their physical-chemical properties and therefore persist and accumulate in sediment beds being available to cause harm to several organisms.
Many PAH compounds are procarcinogenic, thus requiring hepatic biotransformation to form reactive metabolites and exert toxicity. Cytochrome P450 monooxygenase system is responsible for phase I transformation in which those reactive metabolites are formed. The quantification of CYP1A1 subfamily members is a common and widely used biomarker of polycyclic aromatic hydrocarbon exposure.
One of the most important features of PAHs is that they always appear as complex mixtures but, nonetheless, research has focused mainly on the effects of single compounds. It was already proved that mixtures may trigger totally different toxicological effects on organisms since interactions between compounds may result in an unpredictable outcome compared to exposures to single PAHs. These unpredictable effects of the mixtures are not accounted for by environmental guidelines. Therefore, understanding the mechanistic features of PAH mixtures is a crucial research need.
The present work aimed to disclose the interaction effects of two PAHs, Phenanthrene and Benzo[a]yrene that have different carcinogenic potentials and chemical structures. Then, to assess CYP1A1 protein levels, ZFL cells were exposed to Phe (3-ring PAH) and B[a]P (5-ring and carcinogenic PAH) individually and in mixture with 1:1, 1:2 and 2:1 ratios for 24h in Danio rerio hepatocyte cell line (ZFL cells). CYP1A1 levels were determined by Western Blot.
Results for CYP1A1 protein levels showed higher increase for BaP than for Phe. Furthermore, in the case of the mixture, an even greater increase was observed, which may suggest synergistic interactions.
The results are in line with previous investigations since it is known that BaP is an AhR agonist that regulates primary activation by CYP1A1. The increased results for the mixture suggest that Phe, even though it is a non-carcinogenic PAH, may further potentiate the toxic effects when mixed with a carcinogenic PAH. It is therefore clear, that the environmental guidelines need to be revised taking into account the compositions of the mixtures.

4.06.P-Th290 Mixture Toxicity: Tannic Acid Impacts on Graphene Oxide and Pollutants Biological Effects
Romana Petry[1]*, James Moraes de Almeida*[2]*, Felipe David Crasto de Lima*[2]*, Diego Stefani Teodoro Martinez*[3] *and Adalberto Fazzio*[2]*, (1)Federal University of ABC, Federal University of ABC, Campus Santo André, Ireland, (2)Ilum School of Science, CNPEM, Brazil, (3)Centro Nacional de Pesquisa em Energia e Materiais, CNPEM, Brazil*
When released into the environment, nanomaterials interact with the present pollutants altering their bioavailability and resulting in a complicated mixture of toxicity effects. Biomolecular coronas formed upon the nanomaterials release, significantly affect this process, competing with pollutants for surface interaction sites or multiplying the possibilities of interactions. This work comprehends an ongoing project that aims to develop a theoretical-experimental approach to understand the interactions between

graphene oxide (GO) and environmentally relevant molecules (i.e., organic matter and pollutants) and their impacts on ecotoxicity during co-exposure scenarios. Tannic acid (TA) is an environmentally abundant polyphenol with applications in developing novel technologies, such as nanomaterial synthesis, and their functionalizations. We found that TA has a significant dose-dependent mitigation effect on GO's toxicity over Caenorhabditis elegans at environment-relevant concentrations. To understand the mitigation effects of TA, we integrated experimental characterizations techniques (i.e., Atomic Force Microscopy, Raman, and X-ray photoelectron spectroscopy) to assess changes in the morphology and surface chemistry of GO. In addition, computational methodologies were employed to analyze the interaction mechanisms and GO's surface modification by TA. We performed a multilevel study with different theory levels; reactive classical molecular dynamics enabled the exploration of the chemical and conformational changes of TA and GO, whereas ab initio calculations provided information regarding the electronic properties of the system, such as the most reactive sites and their interactions. Further, we evaluated the TA and GO toxicity effects on the atrazine pesticide for the biological model Zebrafish. We found that GO and TA increase the toxic sublethal effects of atrazine, delaying embryo hatching, while TA also potentiated cardiac edema formation. However, when GO and TA are both combined with atrazine, the toxicity potentiation effect was not observed. Due to this multiplicity of responses raised from the complex environmental biomolecular interactions, integrating experimental and computational approaches is essential to understanding mechanistic aspects of mixtures toxicity, especially regarding nano-bio interactions. Here, we present how computational methodologies may be applied in the evaluation of nano-bio interface at molecular level.

4.06.P-Th291 Sublethal Effect of an Environmentally Relevant Pollutant Mixture on Zebrafish Embryos

Ofir Azran, *Tom Topaz and Alon Daya, The Faculty of Marine Science, Ruppin Academic Center, Israel*

To measure the real extent of aquatic toxicity, there is a need to measure the actual toxicity effects of pollutant mixtures rather than single chemicals. Zebrafish (*Danio rerio*) play a key role in aquatic risk assessment throughout the globe, a procedure that usually involves exposing newly fertilized embryos to the desired pollutants at multiple concentrations. At the end of the exposure period, the toxicity is determined based on the outcome of the observations recorded, and the lethal dose (LC50/EC50) is calculated. Although effective, these experiments require excessive resources and are difficult to be used in a sustainable way. Therefore, cross-effective toxicity experiments, which accurately reflect aquatic toxicity while requiring manageable resources, are pursued. Furthermore, discovering sublethal effects of pollutant mixtures on the ecosystem is of high importance to protect and manage natural waters. The presented study aims to determine the actual toxicity of a pollutant mixture by establishing a feasible method for assessing sub-lethal toxicity of chemical mixtures on zebrafish embryos. Toxicity experiments are based on a pollutant mixture of 13 chemicals, derived from the Alexander micro-estuary, located in the eastern Mediterranean Sea. This representative mixture of pesticides and pharmaceuticals was established from a two-year study conducted in the Alexander estuary, a unique water body receiving municipal effluents and runoff from agricultural origins. This pollutant mixture, found to have a potential negative effect on the aquatic environment, is used in exposure experiments to zebrafish embryos and larvae. The experimental design aims to use small batches of embryos in a small range of concentrations with specific easy-to-find endpoints which reflect sublethal effects. The results are expected to reveal the real extent of the pollutant mixture toxicity to the Alexander estuarine ecosystem, while establishing an experimental design that will be easily implemented in additional aquatic environments.

4.06.P-Th292 Air Particulate Mixtures from a Midsized Tropical City of Brazil Impacted by Biomass Burning: Concentrations of Polycyclic Aromatic Hydrocarbons and In Vitro Toxicity

***Caroline Scaramboni*[1]**, *Roberta Cerasi Urban[2], Danielle Palma de Oliveira[3], Daniel Junqueira Dorta[1] and Maria Lucia Arruda de Moura Campos[1], (1)Department of Chemistry, Faculty of Philosophy, Sciences and Letters at Ribeirão Preto, University of São Paulo, Brazil, (2)Department of Chemistry, Federal University of Sao Carlos, Sao Carlos, Brazil, (3)School of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Brazil*

In this study, atmospheric particulate matter (PM) samples were collected at Ribeirão Preto, an agro-industrial municipality with ca. 700,000 inhabitants located within the sugarcane belt of São Paulo State (Brazil). Although the use of fire for agricultural practices have been legislated in the State, a large number of accidental/criminal fires still break out every year, mostly during the dry season. The aim of this work was to investigate the impact of biomass burning on human health in Ribeirão Preto by determining the concentration of polycyclic aromatic hydrocarbons (PAH), their nitrated (NPAH) and oxygenated (OPAH) derivatives in the atmospheric PM, and evaluating the cytotoxic and genotoxic activity of the PM organic extracts using *in vitro* tests. Fractionated PM (cut sizes: 18, 10, 2.5 and 1 µm) was collected in a sub-urban and an urban site, from January 2020 to July 2021 (n = 19). PAH and OPAH concentrations were higher in the dry season (2.59 ± 1.72 and 0.68 ± 0.69 ng m^{-3}, respectively) than in the wet season (0.28 ± 0.20 and 0.07 ± 0.06 ng m^{-3}, respectively), and correlated with fire *foci* number and with levoglucosan (a biomass burning marker), indicating that biomass burning is an important source of PAH and OPAH in the region. Conversely, no seasonal variability was observed for NPAH (dry: 0.48 ± 0.33 ng m^{-3} and wet: 0.50 ± 0.33 ng m^{-3}), which did not correlate with PAH and levoglucosan, indicating that other sources, such as vehicular, could be more important to the emission of NPAH. The mean of benzo(*a*)pyrene equivalent index in the dry season was larger than the unit risk established by the World Health Organization, corresponding to an average excess lifetime lung cancer risk of 12 cases per 100,000 people. HepG2 cells were exposed to different organic extracts of the finest fraction (< 1 µm) at the same concentration (1 m^3 mL^{-1}). The dry season extract decreased cell viability (MTT assay) by 36% after 72 h of exposure, while no cytotoxic effect was observed for the wet season extract. Significant DNA damage (comet assay) was observed in cells exposed to the dry season extracts for 4 and 24 h, with an increase of up to 3-fold compared to the negative control. No genotoxic effect was observed for the wet season extract. Our results indicate that there is a health risk associated to air particulate mixture mainly associated with biomass burning in the region of Ribeirão Preto.

4.06.P-Th293 Application of In Vitro New Approach Methodologies to Determine Whole Mixture-Based Relative Cancer Potency Factors

*Marcos Felipe de Oliveira Galvão[1], Ioannis Sadiktsis[2], Simone A. Pozza[3], Tetsushi Watanabe[4], Gisela Umbuzeiro[3] and **Kristian Dreij**[5], (1)Institute of Environmental Medicine, Karolinska Institutet, Sweden, (2)Department of Materials and Environmental Chemistry, Stockholm University, Sweden, (3)School of Technology – State University of Campinas, Brazil, (4)Department of Public Health, Kyoto Pharmaceutical University, Japan, (5)Institute of Environmental Medicine, Karolinska Institutet, Institute of Environmental Medicine, Sweden*

Air pollution and airborne particulate matter (PM) are classified as carcinogenic to humans, but these complex mixtures of multiple compounds makes quantitative risk assessment a challenge. Current strategies for cancer risk assessment of air pollution are based on a pollutant-by-pollutant approach. This is clearly a simplification which excludes the possibility of interaction effects and may misestimate the actual cancer risk. Whole mixture-based testing using in vitro new approach methodologies (NAMs) has been suggested to facilitate the hazard and risk assessment of complex environmental mixtures. We have addressed this issue by developing a NAM for whole mixture-based cancer risk assessment of air pollution. The overall aim is to combine state-of-the-art methods for analysis of chemical composition of urban, diesel and biomass burning PM with in vitro testing of PM samples in order to determine Mixture Potency Factors (MPFs) estimating the carcinogenic potency of whole mixtures. Our results so far show that MPFs based on whole mixtures better indicate cancer potency than looking at single pollutants. Moreover, that these MPFs are in good agreement with potency values based on published data from Salmonella mutagenicity and in vivo carcinogenicity studies. This research will develop an approach that can be used for assessment of total carcinogenic effects of air PM pollution both for larger city-wide and for smaller site-specific risk assessments. Ultimately, this in vitro NAM will improve the cancer risk assessment of airborne PM by including the obtained knowledge about whole mixture potencies in already established models for estimation of lung cancer incidence in polluted environments.

4.06.P-Th294 Source Apportionment and Health Impact of Atmospheric Particulate Matter in the City of São Carlos, Brazil

*Rita de Kássia Silva do Nascimento[1], Renata Rank Miranda[2], Mauro Almeida Lima[1], Jonatas Schadeck Carvalho[1], Fillipe Vieira Rocha[1], Valtencir Zucolotto[2] and **Roberta Cerasi Urban**[3], (1)Federal University of Sao Carlos, Brazil, (2)University of São Paulo, Brazil, (3)Department of Chemistry, Federal University of Sao Carlos, Brazil*

Particulate matter (PM) is one of the principal causes of health problems worldwide.[1] These harmful health effects are related to the different compounds that are present in PM, some of which have known toxic, mutagenic and carcinogenic effects. To evaluate PM_{10} sources and toxicity in lung cells, PM_{10} samples were collected in São Carlos, a city located in the state of São Paulo (south-eastern Brazil), with ca. 240,000 inhabitants, 200,000 vehicles and an economy based on sugarcane production and diverse industrial activities. PM_{10} concentrations ranged from 2.70–54.77 $\mu g\ m^{-3}$ (n = 47) values that were lower than the standard for 24h in Brazilian legislation, but the maximum value exceeded the limit recommended by the World Health Organization (WHO). Biomass burning plus secondary aerosols (40.7%) were the major sources of PM_{10}, followed by the burning of biomass and fossil fuels (23.8%), biogenic emissions (19.7%) and soil (15.8%). PM_{10}, Polycyclic aromatic hydrocarbons, and their nitrated and oxygenated derivatives, sugars, anhydrosugars and anions concentrations were higher in the dry season than in the wet season. This behaviour is explained by sugarcane burning and by reductions in precipitation levels, relative humidity, and air temperature. In 2016, 247,856 hectares of sugarcane plantations were burned to facilitate manual harvesting in the state.[2] Conversely, the sugar alcohol concentrations were higher in the wet season, and no seasonal variability was observed for cations. The mean benzo(*a*)pyrene equivalent index was greater than the unit risk established by WHO, corresponding to a mean excess lifetime lung cancer risk of 3.09 ± 4.23 cases per 100,000 people. Furthermore, exposure of A549 and MRC5 cells to PM_{10} extracts for 24 and 72 h indicated that reductions in cell viability (MTT assay) were time-dependent and not dose-dependent. Reactive oxygen species assay (fluorogenic probe: 2',7'-dichlorodihydrofluorescein diacetate) results were consistent with the reductions in cell viability observed for A549 cells, indicating that cell death likely occurs following oxidative stress. Our results indicate that although PM_{10} concentrations in São Carlos were not above the limits recommended by local legislation, there is a health risk associated with atmospheric particles.

4.06.P-Th296 Identification of Key Toxicants in Municipal Wastewater Receiving Water Environments: Application of Effect-directed Analysis with In-situ Bioassay Samples

***Yujun Tong**, Xinyan Wu, Fei Cheng, Huizhen Li, Yuan Liu, Weizong Li and Jing You, Jinan University, China*

Municipal wastewater is an important route for water pollution in urban environment. Conventional wastewater treatment processes often ignore the removal of contaminants of emerging concern (CECs), as a consequence, CECs may enter the receiving waters and threaten aquatic ecosystem security and even human health. Currently, water quality managements are mostly based on monitoring regular water parameters and limited number of priority pollutants, which may not be the main toxicity contributors in the mixtures. To identify bioavailable toxicants responsible for adverse effects from municipal wastewater receiving water and sediments, 10-d *in-situ* bioassays using tilapia and Asian clam were conducted in receiving waters of a municipal wastewater and adjacent urban waterways in Guangzhou, China. Two sites (the municipal wastewater receiving water (S1) and a sampling site in residential areas (S2)) that exhibited high toxicity to both organisms were selected for further effect-directed analysis (EDA) using the extracts of the biota samples and *in vitro* cell tests. Toxicity endpoints of the *in vitro* bioassays were selected based on adverse outcome pathways (AOP) and they showed the same toxicity trend as *in vivo* bioassays across sampling sites. Reversed-phase chromatography fractions of S1 and S2 were tested using *in vitro* bioassays, and the relatively hydrophobic fractions showed high responses on AOP26. Furthermore, target, suspect and non-target analysis of the toxicogenic fractions were conducting by GC-MS/MS and LC-Q-ToF-MS. Some pharmaceuticals and personal care products (PPCPs), current-use pesticides (CUPs) and industrial compounds were identified in tissue samples and contributed significantly to the toxicity related to AOP26.

4.06.P-Th297 A Vision for Safer Food Contact Materials and Articles: Public Health Concerns as Drivers for Improved Testing

Jane Muncke[1], *Thomas Backhaus*[2], *Anna-Maria Andersson*[3], *Scott Belcher*[4], *Justin Michael Boucher*[1], *Bethanie Carney Almroth*[2], *Birgit Geueke*[1], *Terrence J. Collins*[5], *Ksenia J Groh*[6], *Frank von Hippel*[7], *Jerrold J Heidel*[8], *Juliette Legler*[9], *Maricel Maffini*[10], *Olwenn Martin*[11], *John Peterson Myers*[12], *Angel Nadal*[13], *Cristina Nerin*[14], *Ana Soto*[15], *Leonardo Trasande*[16], *Martin Wagner*[17], *Laura N Vandenberg*[18], *Lisa Zimmermann*[19], *Martin Scheringer*[20] *and Robert Thomas Zoeller*[18], *(1)Food Packaging Forum Foundation, Switzerland, (2)University of Gothenburg, Sweden, (3)Rigshospitalet, Denmark, (4)North Carolina State University, (5)Carnegie Mellon University, (6)Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (7)University of Arizona, United States, (8)Commonweal, (9)Utrecht University, Netherlands, (10)Independent Consultant, United States, (11)Arts and Science, University College London, United Kingdom, (12)Environmental Health Sciences, (13)Universidad Miguel Hernández de Elche, (14)University of Zaragoza, (15)University of Santiago de Compostela, Cross-Research in Environmental Technologies (CRETUS), Spain, (16)Department of Pediatrics, New York University, (17)Norwegian University of Science & Technology, Norway, (18)University of Massachusetts Amherst, (19)Food Packaging Forum, Switzerland, (20)Institute of Biogeochemistry and Pollutant Dynamics, Switzerland*

Food contact materials (FCMs) are used to make food contact articles (FCAs) such as food packaging and food processing equipment, and they are ubiquitous in today's globalized food system. The chemical composition of FCAs is diverse and can be highly complex. Chemicals migrate from FCAs into foodstuffs, but current regulatory requirements are ineffective for protecting public health from hazardous food contact chemicals (FCCs) because they focus only on the individual starting substances used to make FCMs, and because they only assess genotoxicity as proxy for carcinogenicity. As a consequence, the non-intentionally added substances (NIAS) migrating from finished FCAs as complex mixtures are largely ignored. The current practice also implies that FCAs widely present on the market today are a source of hazardous chemicals and mixtures contributing to highly prevalent non-communicable diseases (NCDs) worldwide.

Based on the work with the Food Packaging Forum's Scientific Advisory Board, we propose here our vision of a novel approach for establishing the safety of FCCs in finished FCAs, thereby addressing (1) the overall migrate (i.e. mixture of all migrating FCCs), including unknown and/or untested NIAS, and (2) focusing testing efforts on those NCDs that are increasingly prevalent in the human population and that are associated with chemical exposures. We group these relevant NCDs into the Six Clusters Of Disease (SCOD) concept.

We envision an improvement of the current status quo of FCC testing by establishing cost-effective, rapid testing of all finished FCAs for their impacts on all relevant NCDs, as defined by the SCOD. Future research must focus on development of in-vitro assays that are sufficiently robust, relevant, and sensitive, and that are based on mechanistic information linked to the SCOD, for example from Adverse Outcome Pathways and the Key Characteristics of Toxicants concept. Taken together, this vision for a novel approach offers a significant improvement to the status quo because it offers better protection of public health by contributing to the prevention of NCDs that are associated with all chemical exposures from FCAs, including mixtures containing unknown NIAS.

4.06.P-Th298 Predicting the Chemical Properties and Exposure of Mixtures Using QSPRs and PPLFERs

Trevor N Brown[1], *Jon A. Arnot*[1], *Alessandro Sangion*[1], *Alena Celsie*[2] *and J. Mark Parnis*[3], *(1)Arnot Research and Consulting, Canada, (2)Queens University, Canada, (3)Trent University, Canada*

Developing a better understanding and improved predictive tools for mixtures has been identified as a key research need in the field of chemical risk assessment. Poly-parameter Linear Free Energy Relationships (PPLFERs) are a well-established tool in environmental chemistry for predicting partitioning and transport properties of chemicals. PPLFERs are composed of system parameters which characterize the solvation environment in which partitioning takes place, and solute descriptors which characterize the chemical of interest. Quantitative-Structure Property Relationships (QSPRs) have previously been developed for PPLFER solute descriptors and system parameters which allow them to be applied to a wide range of liquid mixture phases. A new model for predicting the Vapor Liquid Equilibrium (VLE) of mixtures has been developed based on a modification of the log-linear co-solvency model of Yalkowsky with the solute descriptors and system parameters of the mixture components as inputs. This new VLE model is then used as an input for a new model for predicting the skin permeability (K_P) of mixtures applied to human skin. The K_P model also accounts for penetration enhancement effects that can be attributed to partitioning. The models are applied to assess two different mixture exposure scenarios, a petrochemical spill and application of skin cream to the skin. These tools have been made available as a part of the freely available on-line Exposure And Safety Estimation (EAS-E) Suite platform (www.eas-e-suite.com).

4.06.P-Th299 Chronic Metal-organic Mixture Toxicity: Quantitative Reappraisal and Identifications of Data Gaps

Charlotte Nys[1], *Karel Viaene*[1], *Koen Oorts*[1], *Marnix Vangheluwe*[1], *Violaine Verougstraete*[2], *Hugo Waeterschoot*[3] *and Karel De Schamphelaere*[4], *(1)ARCHE Consulting, Belgium, (2)Eurometaux, Belgium, (3)Chemicals Management, Eurometaux, Belgium, (4)Ghent University - GhEnToxLab, Belgium*

In the Chemicals Strategy for Sustainability, the EU Commission calls to systematically integrate the issue of combined exposure into chemical risk assessments. Ecological risks of chemical mixtures have predominantly been studied within broad substance groups, (e.g., metals, pesticides), while chronic effects of metal-organic mixtures have rarely been assessed. The metal-organic

mixture project within the Metals Environmental Exposure Data Program (MEED) aims to provide scientific evidence on effects of metal-organic mixtures. As a first step, a literature review and quantitative reappraisal of chronic mixture toxicity of metals and organic chemicals was conducted. The null hypothesis was that metals and organic chemicals act independently from each other, i.e., that the Independent Action (IA) model is an accurate predictor of mixture toxicity, and that it is on average more accurate than the concentration addition (CA) model.
Overall, focusing on the period 2007-early 2022, we identified only 4 chronic metal-organic mixture toxicity studies (13 individual experiments) that were of sufficient quality and relevance to be included into the systematic quantitative reappraisal. Those studies were dominated by tests with algae and with Cu, with limited other species and metals tested. Among these few studies, IA performed somewhat better than CA in predicting metal-organic mixture toxicity (lowest root mean square error), whereas CA was generally the most conservative (i.e. overestimates mixture effects more than IA). At low effect levels (10% mixture effect), CA performed relatively well, albeit some experiments suggested quite strong synergisms. However, these synergisms were unreliable and/or observed at unrealistic exposure concentrations (based on monitoring data reported in the Waterbase environmental monitoring database). In fact, most identified chronic metal-organic mixture studies were conducted outside of environmentally and/or regulatory relevant mixture concentrations, which means that it is not appropriate to draw any meaningful or general conclusions with respect to our central question whether IA is a better model to predict metal-organic mixture toxicity than CA, and how protective CA would be on average. Hence, there is a need to investigate metal-organic mixture toxicity at environmentally and regulatory relevant concentrations, with appropriately sensitive species and endpoints.

4.06.P-Th300 A Proposed Higher Tier Refinement for Lagomorphs Exposed to a Dual Active Plant Protection Product Applied to Cereals

Andrea Milne, *Blue Frog Scientific, United Kingdom*

Higher tier refinements are often required in order to pass mammal risk assessments for single-active pesticide products, and the complexity of these refinements often increase when products contain more than one active substance. This work describes risk assessment of a pesticide product containing two active substances, which is applied in the early growth stages of cereals. The screening and Tier 1 risk assessments of the individual active substances performed according to EFSA/1438/2009 indicated a long term risk to the indicator species "large herbivorous mammal (lagomorph)" from one of the active substances in the product, and also from the combined long-term risk assessment. Refinement options that addressed not only the individual substance risk, but also the combined risk were therefore required. Refinement of the focal species and diet were performed via publicly available literature sources. Refined exposure calculations were then performed for each active substance before performing a refined combined assessment. The result was that both the individual and the combined assessments met the long term TER criteria. The presentation of this information is relevant as it demonstrates the relevance of using a variety of literature data to refine pesticide product risk assessments as a potential alternative to field studies.

4.06.P-Th301 The Aquatic MixTox Tool for Risk Assessment of Plant Protection Products and the Related FAQ Document

Sabine Duquesne[1], *Marcus Hillebrand*[1], *Alf Aagaard*[2], *Signe Pedersen*[2], *Manuela Trobej*[3], *Christoph Gassner-Schneckenleithner*[3], *Mathilde Hauge Skarsjø*[4], *Mathilde Zorn*[5] *and Mascha Rubach*[5], *(1)German Environment Agency, Germany, (2)Danish Environmental Protection Agency, Denmark, (3)Austrian Agency for Health and Food Safety, Austria, (4)Norwegian Food Safety Authority, Norway, (5)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands*

In the EU aquatic risk assessment the authorisation of a plant protection product with more than one active substance requires a risk calculation considering the toxicity of the mixture. A scheme and background information are provided in the EFSA Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters (EFSA Journal 2013;11(7):3290; AGD).
The authors developed the i.e., an Excel-based calculation tool composed of different worksheets that provides a calculator and user guidance following the scheme of the AGD. It is intended to support a relatively complex process by harmonising the assessment and facilitating the delivery of appropriate and consistent risk calculations. The tool has been available to all European pesticide risk assessment stakeholders including EU Member States since early 2021 and was presented at SETAC 2022 (Hillebrand et al., 2022). An updated version has been released in December 2022.
In addition to the tool itself, a new FAQ document is also available that complements the excel spreadsheets. This living FAQ document includes recommendations on several issues that emerged during developing the tool. It informs on the lessons-learned and goes where necessary beyond the advice provided in the AGD. The various issues detailed in the FAQ document include currently clarifications on; 1. the (mixture) assessment of metabolites, 2. the combination of different FOCUS Steps for different assessment steps of the AGD scheme, 3. the inclusion of chronic mixture toxicity and 4. the driver assessment.

4.06.P-Th302 Evidence from In-situ Bioassays and Suspect Analysis Distinguished Region-specific Aquatic Toxicity Characteristics Across China

Yujun Tong, *Huizhen Li, Fei Cheng, Yuanyuan Pei and Jing You, Jinan University, China*

Aquatic environment presents a combined pollution status with complex mixtures, which hindered accurate assessment of ecological risk using methods based only on chemical analysis or laboratory toxicity tests. Alternatively, *in-situ* bioassays measure the stresses suffered by aquatic organisms in real environments and may provide more environmentally-relevant results. Two native species (pelagic Chinese rare minnow and benthic Asian clam) were applied for 10-d *in-situ* bioassays in three basins with economic gradience in China, including the Pearl River, Taihu Lake and Poyang Lake basins. Eventually, aquatic risk in these regions was prioritized using a weight-of-evidence method, with chemical residues (98 target and 942 non-target contaminants) and in situ biological effects (survival and enzymatic activities) as lines of evidence. Survival of the tested organisms was significantly reduced at all sites, while significant spatial variability was noted for various enzymes. A diversity of chemicals was detected in aquatic environments, showing region-specific patterns. The combination of exposure and effect data showed that both water and sediments in the highly developed Pearl River basin had the highest ecological risk, while high risk was also shown in the sediments of the agriculture-dominated Poyang Lake basin. The results of risk assessment in different economic zones show the generality of the *in-situ* bioassay method, and emphasize that biological effects should be considered when conducting risk assessment.

4.06.P-Th303 The Long-term Ecological Effects of Single Antibiotics and Their Mixtures on Freshwater Ecosystems

Dailing Wu[1]*, Kaisheng Yao*[2]*, Markus Hermann*[2] *and Paul van den Brink*[1]*, (1)Wageningen University & Research, Netherlands, (2)Aquatic Ecology and Water Quality Management, Wageningen University & Research, Netherlands*

The wide and large use of antibiotics all over the world increased the residue concentrations of antibiotics in environments, where the organisms are exposed continuously to mutiple antibiotics. However, the knowledge about the effects of chronic exposure of antibiotics on aquatic ecosystems and the effects of their mixtures is sparse. Hence, in this study, we conducted an indoor microcosm experiment to mimic real aquatic ecosystems to investigate the effects of long-term exposure to antibiotics on aquatic ecosystems. Sulfamethazine (SMT) and tetracycline (TC) were selected as representative antibiotics which were applied to tested microcosms with different concentrations (SMT: 0.1 ug/L, 1.0 ug/L and 10 ug/L; TC: 1.5 ug/L, 15 ug/L and 150 ug/L) and combinations. After 28 days (4 weeks) of exposure, the results showed that the concentration of green algae was lower in the two higher concentration treatments of both STM and TC compared to the control until the end of the experiment while no significant difference between the different treatments was observed in the mixture treatments. For the zooplankton community, their abundance and diversity were significantly affected by the antibiotics and their mixture. The total abundance of zooplankton in all highest concentrations of three different treatments (SMT, TC and mixture) increased substantially in the first 7 days or first 14 days, followed by a decrease until the end of the experiment. Moreover, the microbial degradation didn’t present significant differences in the first 14 days but showed significant effects of the treatments after 28 days of exposure. The abundance of macroinvertebrates (*Asellus aquaticus*, *Gammarus pulex*, *Physella sp*. and *Planorbis sp*.) didn’t show a clear significant treatment related difference during the experiment period but the food consumption by them indicated that in the SMT treatments food consumption was higher in the highest concentration (10 ug/L) than that in the lowest concentration (0.1 ug/L) ($p < 0.05$). The results from this study showed that the selected antibiotics pose long-term effects on aquatic ecosystems, and The mixture of the antibiotics resulted in different effects than the individual antibiotics, which will be studied in more detail the coming months.

4.06.P-Th304 Which Organic Substances Occur Most Frequently in Hazardous and Environmentally Relevant Binary Mixtures with Metals in European Freshwater?

Franz Marius Schmitt[1]*, Maria Laura De Donno*[2]*, Karel Viaene*[3]*, Charlotte Nys*[3]*, Koen Oorts*[3]*, Marnix Vangheluwe*[3] *and Karel De Schamphelaere*[1]*, (1)Ghent University - GhEnToxLab, Ghent, Belgium, (2)Animal sciences and aquatic ecology, Ghent University, Belgium, (3)ARCHE Consulting, Belgium*

Ecological risks of chemical mixtures are predominantly assessed within a single compound group rather than simultaneously accounting for different groups of chemicals. Few studies are available describing the chronic mixture toxicity of metals and organic pollutants and most of these studies have been conducted at concentrations that have neither environmental nor regulatory relevance. This study aims to prioritize organic substances that potentially pose a aquatic mixture risk in binary pairs with metals. The analysis was based on monitoring data from the European Environmental Agency Waterbase. 16 metals considered in this prioritization had all been identified previously as inorganic substances potentially contributing to aquatic mixture risks. All organic substances with an individual CAS number, present in the Waterbase, were included in the analysis (598). 418 PNECs were derived from NORMAN’s PNEC database, 29 from the Swiss Ecotox Center water quality parameters database, 84 PNECs were calculated using the Envirotoxdatabase.org database. 68 compounds were excluded because no PNEC could be found in any of the consulted databases, leaving 531 compounds for the analysis. 512 organics were measured together with at least one of the 16 metals. To priority-rank the organic substances, we calculated the percentage of mixtures at risk – based on the Hazard quotient (HQ = PEC/PNEC) – for each metal-organic pair. This percentage was calculated by dividing the number of samples showing risk (sum HQ > 1) where both the organic and metal contribute at least 10% to the risk by the number of samples where both compounds were measured together. The number of metals (out of 16) for which % mixture risk was >10% (priority) were counted and ranked in decreasing order. The (preliminary) top priority organic compounds belonged to various substance groups with different modes of action such as pesticides (imidacloprid), pharmaceuticals (diclofenac), Industrial chemicals (PAHs, Bisphenol-A). This prioritization identified realistic metal-organic mixtures driving the risk to aquatic communities in the field based on PNECs. It is possible, though, that this prioritisation may be somewhat biased to include more organic substances for which high assessment factors have been used in deriving their PNECs. Further laboratory test will be conducted to test the occurrence of mixture interactions between metals and organic substances in some of these identified priority mixtures.

4.06.P-Th305 Analysis of the Contribution of Surfactants to Mixture Toxicity in French Rivers

Nathalie Briels[1]*, Charlotte Nys*[1]*, Karel Viaene*[1]*, Frederik Verdonck*[1]*,* ***Erin Maloney***[2]*, Chiara Maria Vitale*[3] *and James Dawick*[4]*, (1)ARCHE Consulting, Belgium, (2)Shell International, Netherlands, (3)Procter & Gamble, Belgium, (4)Innospec Limited, United Kingdom*

Surfactants are used in many industrial applications as well as in “down-the-drain” household cleaning and personal care products. Their high production volumes and use can lead to concentrations in local water bodies that potentially exceed threshold values. A recently published monitoring study reported detection of several surfactants in French surface and waste waters, with some exceeding predicted no effect concentrations, indicating that these substances might require further attention. In the environment, chemicals mostly occur in complex mixtures. The objective of the current study was therefore to assess the potential risk of surfactants in French river basins based on their relative contribution to complex mixture effects, rather than on single-compound effects. Surface water monitoring data were gathered from two databases and data from 234 water samples with 995 targeted chemicals (including 13 surfactants) from 80 locations in France were used in the mixture analysis. For each chemical, the effect concentration (hazardous concentrations for 5% of species, HC5) was collated from a specific database or if needed, calculated from ecotox data in the EU REACH registration dossier. To characterize mixture toxicity, hazard indices (HI) were calculated for each mixture by summing hazard quotients (HQ = measured environmental concentration/HC5) of each mixture constituent. The highest number of surfactants quantified in the same sample was six and linear alkylbenzene sulfonates were the most frequently quantified surfactants in the monitoring dataset (84% of samples). Most surfactants were found at low concentrations, with only laurylpyridinium demonstrating exceedance of the HC5 value. Specific evaluation of this data, however, demonstrated that the HC5 generated for this substance was below the quantification limit, artificially increasing the HI. According to the concentration-addition model assumption, the mixture toxicity was unaffected when surfactants were excluded from the mixture. Overall, this study demonstrates that surfactants are unlikely to significantly contribute to the mixture toxicity in surface water systems. Furthermore, it highlights that the choice and quality of the threshold value is critical for the conclusion of the risk assessment.

4.06.P-Th306 Precision Environmental Health: A Framework For Identifying Chemical Components of Concern in Natural Rivers

Xiaojing Li[1]*, Jiarui Zhou*[1]*, Timothy Williams*[1]*, Tobias Schulze*[2]*, Martin Krauss*[3]*, Yaohui Bai*[4]*, Meng Qiao*[5]*, Liang-hong Guo*[6] *and John Colbourne*[7]*, (1)School of Biosciences, University of Birmingham, United Kingdom, (2)Department of Effect-Directed Analysis, Helmholtz Center for Environmental Research, Germany, (3)Department of EffectDirected Analysis, Helmholtz Center for Environmental Research, Germany, (4)Key Laboratory of Drinking Water Science and Technology, Reseach Centre for Eco-Environmental Sciences, China, (5)Key Laboratory of Drinking Water Science and Technology, Research Centre for Eco-Environmental Sciences, China, (6)Institute of Environmental and Health Sciences, China Jiliang University, China, (7)Michabo Health Science, United Kingdom*

In a natural river, hundreds to thousands of chemicals co-exist as complex mixtures, which pose potential health threats to aquatic organisms and humans. Identifying and evaluating the effect of each chemical component in the environment is undoubtedly an insurmountable challenge to ecotoxicological studies and an unrealistic approach to identifying the harmful component driving the mixture effect at environmentally relevant concentrations. Thanks to the advancements in "omics" technologies and machine learning algorithms, subtle variations in biomolecular levels can be captured for extracting the biomolecular signatures of chemical exposure from the systematic profiles in a toxicogenomic study.

Here, we propose the **Precision Environmental Health** framework to establish the associations between the chemical components within the environmental mixture and their co-responsive biomolecular signatures. Our framework re-invents the use of sentinel organisms to identify **putative molecular key events (mKEs)** activated by the chemical components within the environmental mixtures and associated with potential hazards. The framework relies on gene orthologs within conserved pathways of toxicity among animals to enable cross-species extrapolation for the early diagnosis of the potential hazards of chemical pollution, even when chemicals are present at environmental, usually sublethal, concentrations.

We conducted a case study with local-scale sampling along the Chaobai River as a proof of concept. By exposing the ecotoxicological model species (*Daphnia*) to the ambient river samples, the changes in gene expressions reveal the overall biochemical and physiological/metabolic responses to chemical pollutants. With network analysis and multi-block correlation analysis, chemical components with potential hazards are identified and suggested by the functionally conserved pathways enriched in the associated putative mKEs. This case study demonstrates that the chemical components of concern are identified based on establishing links between bioactive chemicals within mixtures and the perturbations of functional pathways under the Precision Environmental Health framework.

4.06.P-Th307 Sensitivity of Different Phytoplankton Species to Chemical Activity of Mixtures

Talles Oliveira[1]*, Sebastian Abel*[2]*, Elin Lindehoff*[3]*, Clare Bradshaw*[4] *and Anna Sobek*[2]*, (1)ACES, Stockholm University, Sweden, (2)Environmental Science, Stockholm University, Sweden, (3)Linnaeus University, Sweden, (4)Stockholm University, Sweden*

Chemical activity is a thermodynamic concept based on the chemical's energetic state. Under equilibrium, the measured activity is the same in all phases regardless of the quality of the phase. Therefore, the natural variability in lipid composition among species might modulate the total amount of HOCs in the cell, but not impact the chemical activity. Still, some phytoplankton species are more sensitive than others to HOC mixtures. This project aims to further investigate the sensitivity of different phytoplankton species to chemical activity. Saturated solutions of acenaphthene, fluorene, phenanthrene and fluoranthene were prepared in methanol and combined to produce mixtures in a range of chemical activities (0.008 – 0.13). Chemical activity and passive dosing were integrated into an algae toxicity test, where silicone was loaded with the PAH mixture serving as a donor to the system. The effect of growth inhibition on six phytoplankton species (*Rhodomonas salina*, *Phaeodactylum tricornutum, Heterocapsa triquetra, Monoraphidium minutum*, *Prymnesium parvum and* Picocaryote species). Both medium and biota samples were analyzed through LC and GC-MS methods for exposure confirmation. Biota samples were collected for total lipids and lipid profiling. The results from *Rhodomonas salina* show that the concentrations of PAHs in the algae, except fluorene, increased proportionally with increased chemical activity. Individual PAHs contributed similarly to the exposure (25 ± 5 % to the total chemical activity), which indicates the efficiency of the passive dosing method. Chemical activity and the growth inhibition followed a dose-response curve. As a result, the effect on single cells is reflected in the population growth. The effective activity that causes 50% effect was 0.067. Based on this endpoint, *R. salina* would be considered more tolerant than *Daphnia magna* (Ea50 = 0.036), and more sensitive than the marine diatom *P. tricornum* (Ea50 = 0.14), to chemical activity. The remaining phytoplankton species have been exposed to the same mixture and the next step is to determine the activities in both medium and biota. This study provides confirmatory evidence that the chemical activity concept can be used to assess the mixture effects of Hydrophobic Organic Chemicals (HOCs) on the toxicity test. This is an ongoing experiment, and the sensitivity of the other phytoplankton species and lipid characterization are being evaluated for further comparisons.

4.06.P-Th308 The Effects of Long-term Exposure of Bio-ozone Treated Wastewater Treatment Plant Effluent on the Structure and Functioning of Freshwater Microcosms

Paul van den Brink*, Myrthe van Venetië, Lara Schuijt, Koen van Gijn, Alette Langenhoff and Dailing Wu, Wageningen University & Research, Netherlands*

Freshwater ecosystems are constantly subjected to various anthropogenic pressures, such as pollution of pharmaceuticals and personal care products. These substances enter the systems via effluent of wastewater treatment plants, as these are not yet designed to remove the substances. The aim of this study was therefore to investigate whether long-term exposure (6 weeks) of 8 different exposure solutions (wastewater tratment plant effluent treated with bio-ozone processes) affects the structure and function of the aquatic freshwater ecosystem in an outdoor microcosm experiment, focussing on several invertebrate populations. The experimental set-up contained 100 microcosms filled with approximately 58 L of water (29 L supply basin water and 29 L of 1 of the 8 exposure solutions), sediment and organisms. In total 9 different treatments were added to the microcosms (one control group and 8 different exposure solutions (wastewater, spiked wastewater, wastewater treated with bioreactor processes and wastewater treated with ozonation processes)). The micropollutant concentrations in the wastewater is probably too low to have a significant negative effect on the structure and functioning of freshwater ecosystems, although the increase in algae could be a direct effect of nutrient addition through the wastewater or an indirect effect due to a reduction in grazing pressure. Furthermore, the ozonation processes is more effective in removing micropollutants from the wastewater in comparison with the bioreactor processes. Here, a higher ozonation intensity also seems to be more effective. Lastly, the results give an indication that the ozonation processes in some cases produce other toxic by-products that negatively affects the structure and functioning of the freshwater aquatic ecosystem. It is recommended to conduct further research into the possible formation of toxic by-products due to ozonation processes and their effect on the aquatic ecosystem.

4.06.P-Th309 Wastewater Monitoring Based on an Epidemiological Method for Assessing Environmental Mixture Risks of Anti-Tuberculosis Drugs

Wei-Yu Chen[1]*, Yi-Fang Chen*[2] *and Hsin-Mei Huang*[1]*, (1)National University of Tainan, Taiwan, (2)Kaohsiung Medical University, Taiwan*

The environmentally relevant concentration of antimicrobial agents can be monitored by surveying or predicting the infected population in communities. Our study proposed real-time environmental monitoring based on epidemiology for assessing environmental mixture risks of anti-tuberculosis (TB) drugs, isoniazid (INH), rifampicin (RMP), and ethambutol (EMB). The trends of environmentally relevant concentration are decreasing in 2020 – 2030. The EMB has the highest residues in the environmental releases, whereas the INH was the lowest. For the mixture toxicity threshold, the no-observed effect concentration (NOEC) of RMP+EMB and INH+RMP+EMB mixture exposure are not observed from daphnia (*Daphnia magna*) acute immobilization test, whereas the LOECs is 70 mg L^{-1} and 76.26 mg L^{-1}, respectively. The NOEC was 26.25 mg L^{-1} and 112.5 mg L^{-1} to INH+RMP and INH+EMB, respectively, higher than the NOEC of individual anti-TB drugs, indicating the antagonistic effects of INH+RMP and INH+EMB. The approach of combination index was used to examine the mixture toxicity in response to levels of immobilization. RMP+EMP range from 1.27 – 1.33, showing moderate antagonism. Other binary mixtures are higher than the RMP+EMP that presented antagonism, and the ternary mixture tends to be a nearly additive effect when exposing high concentrations of anti-TB drugs. The predicted environmental concentration was used to calculate the environmental exposure risk of anti-TB drugs in individuals and mixtures would decrease from 2020 to 2030; risk quotients were lower than 1, indicating no environmental risk concerns.

4.06.P-Th310 Effect Based Monitoring of the Effluent of a Public Wastewater Treatment Using Cyanobacteria *Microcystis Aeruginosa*

Warich Leekitratanapisan *and Karel De Schamphelaere, Ghent University - GhEnToxLab, Belgium*

Public wastewater treatment plant (WWTP) effluents are a major source of organic micropollutants (OMPs) released into surface water. This could pose an impact on the aquatic ecosystem. Screening-level environmental risk assessment is a tool to identify problematic compounds as well as hot spots of contamination. However, the drawback could arise from the lack of measured effect data and analytical methods of detection for these chemical cocktails as well as transformation products. To minimize these issues, the effect-based method is a holistic approach, which captures the toxicity of the whole chemical mixture. In Flanders, Belgium, more than 30 public WWTP effluents are at risk according to the calculated sum of PNEC-based risk quotients and toxic units of three biological quality elements (sumRQ-PNEC, and sumTUs of algae, crustacean, and fish >1) based on 5-year OMPs monitoring data by Flemish Environment Agency. In this study, we selected 18 high-predicted environmental risks to conduct effect-based monitoring using cyanobacteria *Microcystis aeruginosa* for validation of ERA. The effluents were concentrated using OASIS HLB cartridges and their toxicity was tested based on OECD201. The growth inhibition of cyanobacteria was pre-screened at a relative enrichment factor (REF) of 10. All WWTP extracts inhibited the cyanobacteria growth obyf more than 10% and four of them had growth inhibition of more than 50% at a REF=10. The results of the pre-screening test exhibited a moderate to high correlation with the sum of RQ-PNEC and TU algae (Pearson's r of 0.59 and 0.74, respectively). The results support the usefulness of environmental risk assessment to identify the problematic sites posing environmental risks. For future work, we are planning to identify the main contributors to the toxicity of cyanobacteria using effect-directed analysis (EDA). The EDA approach will be done by utilizing the fractionation process, and toxicity testing in complement with chemical analysis to narrow down the problematic chemical mixtures.

4.06.V Complex Mixtures in Chemical Risk Assessment: Challenges and Opportunities

4.06.V-01 Effect Based Monitoring in Ecosystems Potentially Affected by Power Plants

*Ines Lacchetti[1], **Mario Carere**[1], Walter Cristiano[2] and Laura Mancini[1], (1)Environmental and Health, Italian Institute of Health, Italy, (2)University of Torino, Italy*

Power plants for regasification of liquefied natural gas (LNG) have been proposed with the aim to satisfy the energy demand. However, it is necessary to control the potential emissions, releases and losses of chemical pollutants in the ecosystems where these plants are located. In the context of the Health Impact Assessment an ecotoxicological monitoring has been recommended for preventing the possible adverse effects on the ecosystems and human health. Effect Based Methods (EBM) will be applied to this aim in marine waters and sediments, but also in surface waters and soils located in the proximity of the pipelines for the gas furnitures. EBM are key tools for the detection of the effects caused by chemical mixtures and contaminants which are not included in the legislation. The EBM that are suggested are both *in vivo* and *in vitro* bioassays, and will cover several endpoints, including genotoxicity and embryotoxicity. Furthermore, such methods will be performed in the phases of scoping and monitoring of the health impact assessment. EBM will play an important function in the early warning system and, at the same time, they will play a screening role for further chemical analyses. We consider that applying monitoring based on EBM to gather information on the status of the ecosystems potentially affected by the impacts of LNG regasification power plants, can help to protect the ecosystems and the health of the population living in these areas.

4.07 Environmental Risk Assessment of Organic and Inorganic UV filters

4.07.P-Mo322 Assessing Environmental Hazard of Sunscreen Formulations for the Development of Safe(r) and Sustainable by Design Products

***Alberto Katsumiti**[1], Vanesa Benito[2], Blanca Motos-Pérez[3], Irene Zaldivar[3] and Felipe Goñi de Cerio[2], (1)Biotechnology, GAIKER Technology Centre, Spain, (2)Biotechnology, GAIKER Technology Centre, Basque Research and Technology Alliance, Spain, (3)Advanced Dispersed Particles S.L., Spain*

Every year, tons of sunscreen end up in the ocean raising emerging concerns regarding the risks to the environment. In sunscreen formulations, UV filters, either organic or inorganic, are major active ingredients present at high concentrations. Some of these UV filters are known to cause harmful effects on marine organisms. For this reason, several authorities have banned specific UV filters and are now supporting the development of more eco-friendly, safer and approved alternatives. In this context, the objective of this work was to assess the environmental hazard of different organic and inorganic UV filters to support the development of Safe(r) and Sustainable by Design (SSbD) sunscreen formulations. In this work, we tested the organic filter ethylhexyl methoxycinnamate (EHMC) and the mineral filters ZnO, nano-ZnO, TiO_2, US (ZnO, TiO_2, SiO_2), UT (TiO_2, SiO_2) and UTM (FeOOH, Fe_2O_3, Fe_3O_4, TiO_2, SiO_2). For it, we carried out the acute ecotoxicological tests: luminescent bacteria test, microalgae growth inhibition test and the *Artemia sp.* nauplii immobilisation test. In addition to that, inorganic filters were characterised using SEM-EDX, DLS and ICP-MS for particle's dissolution in marine water (MW). Based on the SEM-EDX analysis, ZnO and nano-ZnO samples showed irregular particles of 211.1 to 287nm and 79.10 to 87.89nm respectively. TiO_2 samples showed spherical particles of 175.8 to 181nm in size. US, UT and UTM were composed of irregular particles of 158.2 to 738.5nm. DLS analysis showed that all samples aggregate and showed negative surface charge in MW. ICP-MS analysis indicated that predominantly samples containing Zn were less stable in MW. Luminescent bacteria test showed that EHMC was the most toxic UV filter tested, followed by nano-ZnO, ZnO and the UV filter mixture US. The microalgae growth inhibition test indicated that all UV filters tested inhibited cell growth. The *Artemia sp.* nauplii immobilisation test showed that EHMC was the most toxic UV filter tested, followed by nano-ZnO, ZnO and the UV filter mixture US. As conclusions, results indicated that ZnO and nano-ZnO are important contributors to the toxicity of inorganic UV filters, being nano-ZnO more toxic than ZnO. Taken together, results indicated that toxicity of UV filters was as follows: EHMC>nano-ZnO>ZnO>TiO_2>US>UTM>UT. Thus, in the SSbD context, safe(r) sunscreen formulations should avoid EHMC and Zn in their formulation.

4.07.P-Mo323 Primary and Ultimate Biodegradation of Benzophenone-type UV Filters Under Different Environmental Conditions and the Underlying Structure-biodegradability Relationships

*Lale Carstensen[1], Stephan Beil[2], Hilmar Börnick[3], **Marta Markiewicz**[2] and Stefan Stolte[2], (1)Technical University Dresden, Institute of Water Chemistry, Germany, (2)Institute of Water Chemistry, Technical University Dresden, Germany, (3)University of Applied Sciences Dresden, Germany*

Although benzophenone-based (BP) UV filters are widely used in different branches of industry information about their biodegradation under environmentally relevant conditions is scarce. We investigated ten common BP-based UV filters, sharing the same basic structure and differing only in their substituents, with respect to their primary and ultimate biodegradability. The primary biodegradation of the selected BPs was studied in river water at environmentally relevant concentrations (1 µg/L) while varying specific, crucial environmental conditions. Moreover, their ultimate biodegradation was examined according to OECD guideline 301 F. The range of applied complementary test procedures allowed to correlate the biodegradability of BPs to their structural features. Thereby, test conditions (aerobic, suboxic, supplementation of nutrients) seem to have a minor influence on

the biodegradation potential of the studied BPs. Commonly used ultimate biodegradability tests, according to OECD guideline 301, offer a rapid option for the identification of readily biodegradable derivatives, such as BP-1 and BP-3, or inherently biodegradable compounds, such as BP, BP-4 and BP 7. Complementing these approaches with methods that also provide structural details, such as LC-MS/MS, may provide additional knowledge about the primary (though not ultimately biodegradable) derivatives. Concerning the structural dependence of the biodegradability of BPs, features such as hydrophobicity or the prevalence of certain functional groups were not the determining factors. Instead, the substitution pattern plays a crucial role. This hypothesis was supported by docking simulations showing systematic differences in the orientation of BPs within the active site of a cytochrome P450 enzyme. The basic structure BP and derivatives that carry substituents on only one of the two rings, such as BP-1, -3, -4, and -7, can be readily biodegraded (> 50%) within 28 d. One exception is BP-10, which is very heterogeneously substituted on both rings and thus different orientations within the active site of CYP 450 are possible.
This oral presentation provides an insight into the aquatic persistency of various BPs, which is highly relevant for the environmental hazard assessment of this class of substances.

4.07.P-Mo324 UV Filters in the Environment: Using Market Research Methods to Fill Exposure Data Gaps
Andrea Carrao[1]*, James C Coleman II*[1] *and Harshita Kumari*[2]*, (1)Kao USA, (2)University of Cincinnati, James L. Winkle College of Pharmacy*
A growing number of scientific and media articles have investigated the impact of sunscreen active ingredients (ultraviolet (UV) filters) on environmental health. While the effects of UV filters in the aquatic environment are well researched, environmental exposures are often understudied. Consumer sunscreen usage habits directly influence the amount of sunscreen products, and subsequently UV filters, released into the environment. These habits also directly impact environmental exposure assessments of UV filters.
Traditional market research tools, such as online surveys and clinical studies, can be repurposed for scientific research thus informing challenging environmental safety questions. These methods can be used to address data gaps in environmental exposure assessments, particularly when normal product use results in direct release to the environment, as is the case with typical sunscreen products. Results from a recent large-scale online consumer survey will be presented as well as several key learnings. In addition, a home usage study designed to measure consumer sunscreen usage over a four-week period will be presented along with results from a sunscreen rinse-off study conducted in human volunteers. Taken together, these data will help refine exposure assessments of UV filters, making it possible to predict more realistic environmental concentrations. This research is critical to understanding the real environmental impact of UV filters.
Sunscreen products protect consumers from the harmful effects of solar radiation. Therefore, it is important to ensure environmental risk management decisions regarding UV filters in sunscreens are well-informed and do not unnecessarily result in reduced availability of a significant form of sun protection.

4.07.T-01 Review of Fate, Exposure, and Effects of U.S. Sunscreens in Aquatic Environments and Implications for Sunscreen Usage and Human Health
Charlie Menzie*, Ecological Sciences, Exponent*
Concerns have been raised about the potential toxicity of sunscreens to a variety of marine and freshwater aquatic organisms, particularly corals. At the same time, there are concerns that people will use less sunscreen as a result of environmental concerns. An ad hoc committee of the National Academies of Sciences, Engineering, and Medicine reviewed the state of the science on the use of the active ingredients in sunscreens (UV filters) currently marketed in the United States. This review was conducted to provide information useful for future application in ecological risk assessments with an assessment of available information on UV filter fates, exposure, and effects. Based on their review, the committee recommended that ecological risk assessments for sunscreen active ingredients used in the United States be conducted by U.S. Environmental Protection Agency. The report also includes review of the potential human impacts that could result from changes in availability of certain UV filters for use in sunscreens, in order to inform management of both human and ecosystem health. This presentation will describe the committee's findings, conclusions, and recommendations related to this issue, as well as the priority knowledge gaps to fill to inform higher tiered risk assessments. The presentation will include discussion of the intersection of aquatic chemistry, environmental toxicology, ecology, and epidemiology to understanding the potential for risks from UV filters and implications to human health for changes in sunscreen use.

4.07.T-02 Spatial and Temporal Investigation of Concentrations of Organic UV Filters in Seawater from The Florida Keys, USA
Carys Louise Mitchelmore[1]*, Andrew Heyes*[2] *and Michael Gonsior*[3]*, (1)Chesapeake Biological Laboratory, University of Maryland Center for Environmental Science, (2)Chesapeake Biological Laboratory, (3)University of Maryland Center for Environmental Science*
Despite concerns regarding the impact of UV filters contained in sunscreens to corals there is limited or no information available on the environmental concentrations of these chemicals in seawater from coral reefs in Florida. Previous studies from other locations have found spatial and temporal variations in concentrations, for example, lower concentrations with depth in the water column, distance from the shoreline and in times of lower recreational activity. Researchers have hypothesized that concentrations are higher in the microlayer yet there is limited or no data to support this. To address these knowledge gaps seawater samples from multiple sites (i.e. beach and reef locations) in the Florida Keys, USA were analyzed for 13 organic UV filters. At recreational beach locations multiple sites (and replicate samples) were assessed for concentrations in the microlayer and surface seawater at two distances from the shoreline. A temporal assessment was conducted with samples collected early in the morning,

mid-afternoon and late in the evening. At reef locations sites (and samples) seawater both surface and seawater collected at coral depth were analyzed. UV-filters were measured using LC-ESI-MS/MS techniques in both the dissolved and particulate fractions. Numerous UV filters were detected in seawater with the highest concentrations present in the sites closest to the beach correlating with the level of recreational activity. UV filters were present at significantly lower concentrations in samples taken further from the beach and in early morning and late evening samples. A number of UV filters were present in higher concentrations in the microlayer samples compared with the corresponding surface water samples. A number of UV filters were detected in seawater collected both at coral depth and the surface, although both were at much lower concentrations compared to beach samples. This study provides insight as to the environmentally relevant concentrations in seawater samples at beaches and coral reefs in the Florida Keys. Furthermore, the spatial and temporal assessments provide data that are essential for developing probabilistic marine exposure models and environmental risk assessments.

4.07.T-03 Model Simulations of UV Filter Exposure to Marine and Freshwater Organisms
Brenna Kent[1]*, W. Martin Williams*[1]*, Todd Gouin*[2]*, Raghu Vamshi*[1]*, Scott Dyer*[3]*, Nicola Hefner*[4]*, Eva Klingelmann*[5]*, Sascha Pawlowski*[6] *and Amelie Ott*[7,8]*, (1)Waterborne Environmental, (2)TG Environmental Research, United Kingdom, (3)LeTourneau University, United States, (4)DSM Nutritional Products, Switzerland, (5)Symrise AG, Germany, (6)GBP/RA, BASF SE, Germany, (7)Cosmetics Europe, Belgium, (8)International Collaboration on Cosmetics Safety*
Sunscreens are vital in preventing skin cancer by absorbing harmful UV-A and UV-B light. Questions have been raised regarding the potential impact of specific UV filter ingredients in aquatic systems. Given the lack of robust and high-quality monitoring data to characterize UV filter concentrations in water and sediment under the diverse conditions in which sunscreens are used, a modeling framework is being developed to evaluate the behavior and exposure concentrations of different UV filter ingredients under high exposure beach scenarios. The modeling framework consists of several levels ranging from simplistic dilution-based estimates to more complex 3-dimensional circulation models. Hydrodynamics play an important part in UV filter dispersion; therefore, scenarios and sites identified for benchmarking model performance represent a variety of aquatic environments, including highly-flushed, semi-flushed, and more static waterbodies. Rarely do monitoring studies record information on all input parameters required for model setup; thus, certain inputs are based by necessity on assumptions. In particular, site-specific information necessary to estimate UV ingredient emissions is often unavailable, including the specific sunscreen products used, consumer application and reapplication patterns, and swimming behavior with respect to time in water and extent of immersion in water. To account for the uncertainties around these inputs, the UV ingredient emission estimate is addressed in a probabilistic manner. The modelling framework was applied to different sites for benchmarking and ultimately scenarios were created to represent various environmental conditions where UV-filters are used to evaluate potential ecological risk. This presentation describes the framework, comparisons of model predictions to monitoring data for three study sites, and the development of model scenarios to evaluate the potential exposure of UV filter ingredients under a diverse range of highly populated beach environments.

4.07.T-04 Developing Relevant and Reliable Toxicity Assays in the Scleractinian Coral *Acropora cervicornis*
Dorothy-Ellen Abigail Renegar[1]*, Iain Davies*[2] *and Carys Louise Mitchelmore*[3]*, (1)Dept. of Marine and Environmental Science, Nova Southeastern University, (2)PCPC (Personal Care Products Council), (3)Chesapeake Biological Laboratory, University of Maryland Center for Environmental Science*
Coral reefs are unique ecosystems supporting a significant diversity of marine life in tropical regions. Coral reefs and associated organisms are directly or indirectly negatively impacted by a combination of stressors including a diverse array of chemical contaminants. Additionally the impacts of chemical contaminants can be enhanced when combined with co-stressors, including UV radiation and those relating to climate change, such as ocean warming and acidification. Recently, concerns have been raised regarding the impact of UV filter constituents contained in sunscreens and other products. However, clear assessment of the environmental risk of chemical contaminants to scleractinian corals is hampered as there are currently no standard test protocols for corals (i.e., OECD, US EPA), and it is unclear how representative other standard test species (i.e. marine invertebrates and algal species) may be, given the complexity of the host-symbiont-holobiont system. Toxicity tests with corals have been conducted but the lack of a standard methodology has limited comparisons between studies and highlighted concerns on data reliability and quality. Building upon experiences conducting coral and other cnidarian toxicity tests with numerous chemical contaminants of diverse physical-chemical properties we provide guidelines and discuss considerations moving forward on designing standard toxicity tests for scleractinian coral species. Factors include choice of test species and life-stage, specific test designs and replication requirements, inclusion of appropriate parameters for quality control (i.e. water quality, health assessments and appropriate negative and positive controls), timing of exposures, analytical verification, and finally the choice of appropriate biological endpoints for acute and chronic assessments to provide reliable and statistically appropriate measurements. The flow-through exposure system and methodology which was developed based on these principles was tested with two positive controls (copper and diuron) and UV filters in acute and chronic exposures. Analytical verification in each replicate confirmed that reliable and reproducible concentrations in expected ranges (based on nominal dosing) were achieved, water quality parameters remained within guidelines, and coral health was maintained throughout the 21-day duration for chronic tests.

4.07.P Environmental Risk Assessment of Organic and Inorganic UV filters

4.07.P-Mo325 Experimental and Predicted Aquatic Ecotoxicity of Suncare and Rinse-off Products
Ludovic Faravel[1]*, Pascal Bicherel*[2]*, Floriane Larras*[2]*, Paul Thomas*[2]*, Laure Giamberini*[3] *and Carole Cossu-Leguille*[3]*, (1)University of Lorraine, France, (2)KREATiS, France, (3)University of Lorraine, France*

Over the last 10 years, cosmetic industry have grown to become one of the largest sectors using chemical substances in the world and is still growing. After use, residues of cosmetic products may end up in the aquatic environment despite the treatment of water in wastewater treatment plants. Consequently, they may represent a potential risk for organisms in the aquatic environment and their impact needs to be evaluated.The objective of this study was therefore to determine the aquatic ecotoxicity of cosmetic rinse-off and suncare products, to find out whether the products on the market or in development can present a risk for the aquatic environment. The results obtained will then help in the development of a predictive tool determining the toxicity of cosmetic products, which are mixtures of at least 15 different ingredients.
To meet these objectives, a battery of bioassays, where the ISO and OECD standards will be used for the various tests, was set up. Several species representative of different levels of the food web of the freshwater and marine aquatic environment were selected. These included primary producers: *Pseudokirchneriella subcapitata* and *Phaeodactylum tricornutum*, a primary consumer: *Daphnia magna,* a decomposer: *Aliivibrio fischeri* and secondary consumers: *Danio rerio* and *Hydra attenuata.* In addition to these tests, an OECD 301F biodegradability study modified to include analysis and supplementary parameters, will also be conducted to determine the extent of biodegradability of each finished product. These tests thus allow both acute and chronic toxicities as well as persistency of the tested cosmetic products to be assessed. Finally, *in silico m*odelling studies are used to predict the toxicity of mixture and these are compared with the experimental data.
The results obtained showed that the most sensitive organisms are *P. subcapitata* and *A. fischeri* for the solar products and *P. tricornutum* for the rinse-off products. Despite this, the tested products show low toxicity to the aquatic environment, with EC50 values above 30 mg/L for acute tests and above 20 mg/L for chronic tests. These will be compared with iSafeRat® water accommodated fraction model developed by the ecotoxicologist of KREATiS. Further studies will be conducted and compared to various toxicity prediction models for mixtures to assess their validity.

4.07.P-Mo326 Commercial Sunscreens Modulate the Gene Expression on *Physella acuta* Adults: Acute and Medium-term Exposure

Ana-Belen Muniz-Gonzalez[1] *and Jose-Luis Martinez-Guitarte*[2]*, (1)University of Aveiro & Centre for Environmental and Marine Studies, Portugal, (2)UNED, Spain*

The growing incidence of ultraviolet (UV) radiation has increased the concern and hence the use of sunscreens with special attention in spring and summer seasons. Therefore, UV filters (UVFs) presence in the environment has grown over the years, becoming one of the main emergent pollutants, mainly due to their inefficient removal in wastewater treatment plants (WWTPs). In this line, recreational activities such as sunbathing/swimming act as sources of UVFs to aquatic systems worldwide. The impacts of UVFs on aquatic organisms have been widely evaluated, mainly for marine environments, with single UVF exposure altering coral bleaching, physiological and biochemical responses on mussels or the endocrine system of fishes. However, these approaches are very far from real scenarios since sunscreens are composed of a mixture of different UVFs plus multiple chemical compounds for moisture, odour, etc. Therefore, in this work, three commercial sunscreens (SC1, SC2, SC3) were selected to study their impact on aquatic invertebrates, trying to mimic environmental conditions. Due to their lower flow, rivers tend to present higher concentrations of UVFs, partly due to the absence of tides. So, *Physella acuta*, an aquatic snail with a high capacity to live in adverse conditions and spread worldwide, was selected as a novelty organism for future toxicity test guidelines. The adults of *P. acuta* were exposed at 10 mg/L of each sunscreen for 7 days, and samples were collected at 24h and 7 days and frozen for the subsequent RNA extraction. The effects of the sunscreens were analyzed by Real-time PCR employing an array, including 42 genes related to essential metabolic pathways. The results showed a stronger response with downregulation after longer exposure, mainly in genes related to detoxification, redox, and stress response. Comparison between times showed mainly upregulation at 7 days of exposure respect to 24h, so *P. acuta* could need more time to respond concerning other aquatic invertebrates. There is a difference in the response to each commercial sunscreen, showing the lower toxicity in the case of SC1. To sum up, for the first time, the impact of commercial sunscreens on aquatic invertebrates at the sub-organismal level was evaluated. New biomarkers have been tested and proven their utility for future aquatic toxicology risk assessment. Furthermore, *P. acuta* has proven to be an effective sentinel organism for evaluating the effects of UVFs in freshwater systems.

4.07.P-Mo327 Screening Thyroid Hormone Disruption of Several Organic UV Filters and their Mixtures with Rat Pituitary (GH3) Cells

Ah-Reum Jo[1]*, Ba Reum Kwon*[2]*, Eun-Jin Kim*[2]*, Yeonju Nam*[2]*, Juyeon Choi*[2]*, Yujin Park*[2]*, Eunhye Kim*[2]*, Gowoon Lee*[2] *and Kyungho Choi*[2]*, (1)School of Public Health, Seoul National University, Korea,(2)School of Public Health, Seoul National University of Science and Technology, Korea*

Organic ultraviolet (UV) filters are suspected of adverse endocrine effects on humans and aquatic ecosystem. Avobenzone (AVB), diethylamino hydroxybenzoyl hexyl benzoate (DHHB), homosalate (HS), octocrylene (OC), octyl-methoxycinnamate (OMC, same as EHMC), and octisalate (OS) have been widely used as active ingredients in many sunscreen products, and have frequently been used in combination to enhance UV protection. However, their endocrine disruption, especially thyroid hormone (TH), is little understood. We screened thyroid disruption effects of major UV filters and their mixtures using rat pituitary (GH3) cells.
Six UV filters (AVB, DHHB, HS, OC, OMC, OS) were selected among frequently used organic filters. Then their mixture combinations were decided based on toxicity and usage pattern of the filters. Ten mixtures with 5 binary and 3 ternary combinations were chosen, which include combinations of UV filters with the same directions of thyroid hormone changes in zebrafish (Danio rerio), and another two binary combinations with high usage. After 48 hours of exposure, a NOAEL (no observed adverse effect level) of each UV filter was determined based on gene transcription in GH3 cells. Concentrations of

binary combinations were decided at x1/8, x1/4, x1/2, x1, x1.5, and x2 NOAEL, and those of ternary combinations were x1/27, x1/9, x1/6, x1/3, x1, x1.5, and x3 NOAEL.
After single exposure, organic UV filters significantly changed transcription levels of thyroid-relating genes in GH3, which included *Tshβ*, *Trhr*, and *Dio2* genes. In mixtures, most of them showed similar effect directions — up-regulation of *Trhr* gene and down-regulation of *Tshβ*, *Trα*, *Trβ*, *Dio1*, and *Dio2* genes — although examples with opposite thyroid-disrupting responses *in vivo* were found. AVB+OMC, DHHB+OC, OC+OMC, AVB+DHHB+OMC, AVB+HS, and OMC+OS mixtures caused significant transcriptional changes at ≤ x1 NOAELs, suggesting additivity or greater-than-additive effects.
In conclusion, the results from our study demonstrate that UV filters commonly used in marketed sunscreens may alter thyroid function either alone or in combination. Further studies are warranted to validate our observation and to understand the mixture effects of chemical exposure *in vivo*.

4.07.P-Mo328 Presence and Environmental Risk Assessment of Organic UV Filters in Coastal Waters of the Iberian Peninsula
*Sandra Mozas Blanco[1], Judit Kalman[1], Gerard Quintana[2], Silvia Diaz-Cruz[2], Andreu Rico[3], Isabel López[3], Salome Martinez Morcillo[4], Miguel Motas[5], Unax Lertxundi[6], Jose Luis Rodriguez-Gil[7,8], Gorka Orive[9], Osvaldo Santos[10] and **Yolanda Valcarcel Rivera**[1], (1)Rey Juan Carlos University, Spain, (2)IDAEA-CSIC, Spain, (3)IMDEA Water Institute, Spain, (4)University of Extremadura, Spain, (5)University of Murcia, Spain, (6)Araba Psychiat Hosp, Spain, (7)University of Manitoba, Canada, (8)Experimental Lakes Area, Canada, (9)NanoBioCel Group, Laboratory of Pharmaceutics, School of Pharmacy, University of the Basque Country, Spain, (10)University of Lisbon, Portugal*
Organic UV filters are increasingly used in different personal care products to protect against UV radiation. These substances have been receiving increasing attention due to their possible behaviour as endocrine disruptors and, therefore, could pose a risk to human health and the environment. They enter the aquatic environment mainly through bathing activities but can also be discharged from wastewater treatment plants and illegal dumping. Monitoring their presence in different environmental matrices, including coastal water/beaches, is essential to assess their exposure and potential risks and propose actions for their proper management. The objective of this study was to identify and quantify the presence of 21 UV filters in coastal areas of the Iberian Peninsula, which may be especially vulnerable during summer due to the high tourist pressure, to determine their environmental risk and detect “hot spots” where adverse effects on biota resulting from chronic exposure could be expected. Sixteen samples were collected along the Portuguese coast (Lisbon and Algarve) and 30 on the Spanish one: 18 in Cádiz and 12 in the Mar Menor (Murcia) in July and August 2021, during the peak tourism season. Sample analysis was performed using high-performance liquid chromatography coupled to tandem-mass spectrometry. Hazard was characterized using chronic toxicity data to calculate their Hazard Quotients (HQ). Measured concentrations and HQs were mapped to highlight Hot spots. Out of the 21 UV filters analysed, only 5 were found above the limit of detection: BP4, OC, BP3 and two of its metabolites BP1 and DHMB (BP8). BP4 was present in almost all samples (89%), followed by OC (35%) and BP3 (30%), while both metabolites were barely detected (3%). UV filters were detected in 43 sampling sites out of the 46 investigated. Samples collected in Mar Menor had the greatest variety of compounds per sample while the rest contained at least one of them. The highest total concentrations of UV filters were found in samples from Arcos beach (954 ng/L) in Lisbon, La Barrosa (607 ng/L), and Villanitos beach (1088 ng/L) in Mar Menor. Moderate (46%) and high (54%) risk was found for OC, while the others showed no or low risk, BP3 reached moderate risk in only 2%. No risk was estimated in any area for BP4 despite being the substance that appeared in the highest concentration in all the samples (633 ng/L). This study has been funded by Rey Juan Carlos University through “Bridge Projects”.

4.07.P-Mo329 Development of Toxicity Test Protocols for Corals
***Guido Gonsior**[1] and Maren Dill[2], (1)Aquaculture, Ecotox, Marine Science, GG BioTech Design GmbH, Homberg, Germany, (2)GG BioTech Design, Germany*
The risk assessment which is generally performed for any registration of chemical products did not cover corals in the past. First research on the effects of UV-filters started. However, for the generation of reliable and comparable toxicity endpoints it is essential to develop a standard toxicity test protocol. For risk assessment larvae or nubbins (branch tips consisting of several polyps) can be used. Beside acute testing also long-term tests using growth parameters can be performed under lab conditions. First studies showed that in case of extended test durations to 1-2 months, some coral species could be suitable to fulfil validity criteria according to OECD 239 (Water-Sediment *Myriophyllum spicatum* Toxicity Test) to generate robust and reproducible data. Endpoints could be assessed on growth rates and yields based on fresh weight, polyp number or total length of corals.
We present data showing that tests with focus on coral growth parameters can be established and can assist in risk assessment of chemicals on corals.

4.07.P-Mo330 Benzotriazole Ultraviolet Stabilizers Induce Toxicity in Early-Life Stage Fish Through Aryl Hydrocarbon Receptor Activation
***Hunter Johnson**[1], Justin Dubiel[1], Andreas Eriksson[2], Zhe Lu[3], Jon Doering[4] and Steve Wiseman[1], (1)University of Lethbridge, Canada, (2)University of Jyväskylä, Finland, (3)University of Québec À Rimouski, Canada, (4)Louisiana State University*
Benzotriazole ultraviolet stabilizers (BUVSs) help counter degradation and discoloration of plastic materials caused by UV radiation. Because BUVS’s are ubiquitous in aquatic environments and biota, there is concern for the health of fishes. Studies suggest that certain BUVSs might cause toxicity by dysregulating the aryl hydrocarbon receptor (AhR) causing early life-stage toxicity in fishes. However, little is known about relative potencies of these chemicals as AhR agonists or about differences in sensitivity of phylogenetically diverse fishes to BUVSs that are AhR agonists. Therefore, the first objective of this study was to assess the toxicity of the three BUVSs - 2-(benzotriazol-2-yl)-4-methylphenol (UV-P), 2-(Benzotriazol-2-yl)-4-methyl-6-prop-2-

enyl-phenol (UV-9), and 2-[3-(2H-benzotriazol-2-yl)-4-hydroxyphenyl]ethyl methacrylate (UV-090) – using embryotoxicity assays with zebrafish (*Danio rerio*) and to assess the potency of each BUVS for activation for the zebrafish AhR2, using an *in vitro* luciferase reporter gene (LRG) assay with COS-7 cells transfected with the AhR2 of zebrafish.   bryos exposed to BUVS by use of microinjection experienced mortality in a dose-dependent manner, with UV-P being the most potent BUVS with a median lethal dose (LD50) of 4772 ng/g-egg, which is less potent than TCDD, the prototypical AhR agonist. Compared to TCDD, relative potencies of UV-P, UV-9, and UV-090 were 0.0005, 0.0002, and 0.00004, respectively. The order of potency based on activation of the zebrafish AhR2 was UV-P > UV-9 > UV-090, which agrees with the embryotoxicity assay. The second objective was to assess species differences in sensitivity to AhR2 activation by each BUVS, by use of the *in vitro* AhR2 activation bioassay. There were interspecies differences in sensitivity to activation of the AhR by BUVSs. For UVP, the range of sensitivity was 6.4-fold, with zebrafish being the most sensitive species and brook trout being least sensitive. Fo UV9, the range of sensitivity was 2.6-fold, with zebrafish being most sensitive and lake sturgeon be least sensitive. UV-9 failed to activate the AhR for northern pike, white sturgeon, and brook trout. UV-090 did not activate the AhR in any species. This research gives valuable insight on the toxicity of BUVSs and can help guide objective assessment of risks posed by BUVS that have AhR agonistic properties.

4.07.P-Mo331 Thyroid Hormone Disruption by Exposure to Mixtures of Major Organic UV Filters in Zebrafish (*Danio rerio*)
***Ba Reum Kwon**[1], Ah-Reum Jo[2], Yeonju Nam[1], Eun-Jin Kim[1], Juyeon Choi[1], Eunhye Kim[3], Yujin Park[3], Gowoon Lee[1] and Kyungho Choi[3], (1)Environmental Health Sciences, Seoul National University of Science and Technology, Korea, (2)School of Public Health, Seoul National University, Korea, (3)School of Public Health, Seoul National University of Science and Technology, Korea*
Organic UV filters have been developed and applied to numerous products including cosmetics and sunscreens, to protect skin and products. Many sunscreens are manufactured with multiple UV filters in combination to maximize photoprotection of the products. Growing body of evidence supports negative impacts, including endocrine disruption, of organic UV filters. Nevertheless, little is know about the mixture interaction of UV filters. In the current study, avobenzone (AVB), diethylamino hydroxybenzoyl hexyl benzoate (DHHB), homosalate (HS), octocrylene (OC), octinoxate (OMC), and octisalate (OS) were chosen as target filters, and thyroid endocrine disrupting effects were evaluated for their mixtures using embryo-larval zebrafish (*Danio rerio*). First, no observed adverse effect level (NOAELs) were determined for each UV filter, based on thyroid hormone level (TH) changes following 5 day exposure after fertilization. Then, embryo-larval zebrafish were treated with binary or ternary combinations of a fixed-ratio dilution series, e.g., x1/8, x1/4, x1/2, x1, x1.5, x2 NOAEL. Thyroid hormone levels decreased following exposure to AVB+OMC (TSH, T3) and AVB+DHHB+OMC (TSH, T4, T3), at ≥1xNOAEL. Exposure to OMC+OS significantly reduced TSH at ≥1xNOAEL, and T3 even at <1xNOAEL of OMC and OS, e.g., x1/8 NOAEL, demonstrating concentration additive effect on the thyroid system. Significant regulatory changes of *sult1 st5* or *ugt1ab* genes, which are responsible for TH metabolism and elimination, were observed by AVB+OMC, AVB+DHHB+OMC, and OMC+OS exposure, supporting the decreased thyroid hormone levels observed in the fish following exposure to the mixtures. Overall, our observation demonstrates that exposure to organic UV filter mixtures could impair normal thyroid function possibly through increasing hepatic THs elimination by *sult1 st5* and/or *ugt1ab* genes. Further studies on commn mixtures of UV filters should be carried out.

4.07.P-Mo332 A Reliable Method for Testing Acute Toxicity of UV Filters and Related Chemicals Towards Adult Corals
***David Brefeld**[1], Valentina Di Mauro[1], Matthias Kellermann[1], Samuel Nietzer[1], Mareen Moeller[1], Laura Henriette Lütjens[2], Sascha Pawlowski[2], Mechtild Petersen-Thiery[3] and Peter Schupp[1], (1)Environmental Biochemistry, University of Oldenburg, Germany, (2)GBP/RA, BASF SE, Germany, (3)BASF Personal Care and Nutrition, Germany*
Coral reef ecosystems are in decline due to global and local anthropogenic stressors. At coastlines with high touristic activity, the direct influx of organic and inorganic UV filters might be a significant local stressor for reef-building corals. However, the degree to which UV filters exhibit toxic effects towards corals is highly discussed and the use of various testing methods led to controversial results.
For this reason, we have developed a test method that can reliably assess the acute toxicity of UV filters and related chemicals to reef-building corals. The test is designed as a semi-static setup, has a duration of 96 hours, and includes a negative and positive control ($CuCl_2$), plus a solvent control if necessary. The stony coral *Montipora digitata* was chosen as test species, since it exhibits adequate sensitivity to different chemicals, including UV-filters, and has a planar morphology allowing rapid creation of uniform discs (approx. 10 mm in diameter). The tests on coral fragments are carried out in artificial seawater to which different concentrations of the test substance have been added. To maintain the desired concentration of the chemical (> 80% of nominal), a water exchange is carried out after 48 hours. Accompanying analytics (ICP & UPLC-MS) are used to confirm exposure concentrations, and water parameters are measured to monitor water quality.
Endpoints indicating the toxicity of the tested chemical include bleaching, inhibition of photosynthetic efficiency and mortality / tissue loss. All endpoints are measured at the beginning and at the end of the experiment so that changes can be tracked on an individual basis. Predetermined validation criteria are used to evaluate the negative and positive control.
The testing system was successfully used with four different chemicals: Benzophenone-3 (BP-3), Copper-II-Chloride ($CuCl_2$), 2,4-Dichlorophenoxyacetic acid (2,4-D) and Dimethylformamide (DMF), giving reproducible results which are presented.
The setup and workflow of the testing method was aligned with existing toxicological test protocols for other aquatic organisms (e.g., ISO 6341) and is reproducible in a standard laboratory setting. Therefore, the method can serve viable for ring testing and subsequent standardization under ISO, DIN and/or OECD guidelines.

4.07.P-Mo333 Spatial Analysis on the Distribution of Sunscreen Use Patterns from Consumer Surveys Across the United States

*Raghu Vamshi[1], **Brenna Kent**[1], Scott Dyer[1] and Andrea Carrao[2], (1)Waterborne Environmental., (2)Kao USA*

Information on consumer use patterns is an asset in understanding the qualitative and quantitative parameters of product usage across any geography. This is particularly relevant for consumer product use since such data is lacking, especially on a local scale to better understand the relevance from an environmental exposure perspective. Within consumer products, information on sunscreen usage is of special interest because of recent concerns about the toxicity of certain UV-filters. Sunscreen products contain chemicals that act as UV-filters, essential in preventing skin cancer by absorbing harmful UV radiation. However, there are concerns about the potential risk of some UV filter chemicals in aquatic environments. A survey across the United States (US) and Canada on sunscreen use by consumers provided a wealth of information on consumer usage behavior such as, application frequency, quantity of product, and swimming location (pools, lakes/rivers, oceans, etc.). Additionally, the survey data contained geographic relevance at a zip/postal code level, which is the most spatially detailed ever collected. Spatial analysis of the sunscreen use survey data provided insights into the per capita use, proximity to beaches and discharge to wastewater treatment plants – helping understand the environmental exposure to surface waters. Similarly, use quantity and direct exposure to ocean waters was examined. Further, the analysis also explored proximity of consumer use sources to exposure in aquatic environments. This spatially refined use information was extrapolated to adjust with national sunscreen use across the US and compared against wider data on temperature, cloud cover and UV index. The spatial and statistical analysis provided quantitative end points to correlate the relevance of sunscreen use to potential environmental risk. This research illustrates how consumer survey data about sunscreen habits and practices at a fine spatial scale can be used to better understand local environmental exposure concerns. The more refined understanding can better guide science-based risk management decisions for consumer products.

4.07.P-Mo334 Occurrence and Potential Impacts of Organic UV Filters in *Acropora cervicornis* from the Florida Reef Tract

***Dorothy-Ellen Abigail Renegar**[1], Andrew Heyes[2], Michael Gonsior[3], Ellen R Skelton[4], Megan Kennedy[4] and Carys Louise Mitchelmore[5], (1)Dept. of Marine and Environmental Science, Nova Southeastern University, (2)Chesapeake Biological Laboratory, (3)University of Maryland Center for Environmental Science, (4)Nova Southeastern University, (5)Chesapeake Biological Laboratory, University of Maryland Center for Environmental Science*

Organic UV filters have been detected in seawater, typically in the ng to µg/L ranges, with some UV filters also found in biota highlighting uptake and a potential environmental risk from exposure. However, despite scientific and societal concern, there are a limited number of studies that have measured UV filter concentrations in seawater near coral reefs and even fewer that have examined the presence of UV filters in coral tissues. The studies demonstrating the presence of UV filters in coral tissues did not provide information on the health of the corals sampled or an overall health status of corals at the collection sites. Some laboratory exposure studies have suggested detrimental effects of UV filters on coral development and consequences to coral reproduction. This study is designed to address the knowledge gap between environmentally relevant UV filter exposures and effects on a key element of coral health, namely reproductive health. The levels of UV filters in matched seawater and coral tissue samples collected from various reef nursery sites in Florida was assessed. Correlations between the UV filter concentrations observed and reproductive health (fecundity) were made in the endangered staghorn coral (*Acropora cervicornis*), a keystone species in the Florida reef tract and throughout the Caribbean. This is the first study to provide data regarding UV filter concentrations in corals in the continental United States, as well as the first to examine the potential effects of environmental UV filter exposure on coral fecundity. The insights gained will provide critical support for regulatory policies and management decisions concerning UV filters, as well as create a foundation for future research in this new and emerging field of coral toxicology.

4.07.V Environmental Risk Assessment of Organic and Inorganic UV filters

4.07.V-01 Aquatic Risk Assessment of Product-Released Engineered Nanomaterials (PR-ENMS) From Personal Care Products

***Mbuyiselwa Moloi**[1], Raisibe Lehutso[2], Mathapelo Seopela[3], Dana Kühnel[4], Mariana Erasmus[5], Paul Oberholster[5] and Melusi Thwala[6], (1)205 Nelson Mandela Drive, University of the Free State, South Africa, (2)CSIR, South Africa, (3)Chemical Sciences, University of Johannesburg, South Africa, (4)Helmholtz Centre for Environmental Research, Germany, (5)University of the Free State, South Africa, (6)Science Communication & Strategic Partnerships, Academy of Sciences of South Africa, South Africa*

Majority of studies thus far have used pristine engineered nanomaterials (ENMs) or in silico approaches to establish the environmental nanotechnology risks, approaches which may over- or under-estimate the risk of product-released ENMs (PR-ENMs). This study determined the environmental exposure of titanium dioxide and zinc oxide nanoparticles (nTiO2, nZnO) PR-ENMs and their toxicity to aquatic organisms due to their high application as UV filters in personal care products. The inorganic UV filters were released from products using environmentally realistic methods and characterised with a suite of physico-chemical analytical techniques. Toxicity was assessed using Daphnia magna (acute immobilisation test and reproduction test), Raphidocelis subcapitata (growth inhibition test) and Danio rerio (fish embryo tests); organisms chosen to represent micro-, macro-invertebrates and fish communities. Considerable release of nTiO2 (from sunscreen), and nZnO (from baby cream) from the products occurred, additionally, nZnO released Zn^{2+} ions. The released ENMs were needle-shaped (nTiO2) and angularly shaped (nZnO), with the sizes of 33.1±1.2×11.6±0.5 and 109.6±6.6×55.7±3.9 for nTiO2 and nZnO respectively. The toxicity was prevalent on all the tested organisms with lower order organisms (microorganisms) exhibiting relatively higher toxicity than higher order organisms (fish). PR-nTiO2 was growth inhibitive to microalgae by 80% at the highest concentrations while the

effects were mild (average 50% immobilisation) on *Daphnia magna*. PR-nZnO and Zn2+ induced higher toxic effects on *D. magna* (EC50s were 10.47% and 14.63% for nZnO and Zn2+, respectively) relative to PR-nTiO2.The same was true for *R. subcapitata*. The effects of both UV filters were mild on the survival of fish embryo but
comparable in inducing morphological malformations in the embryo. The results point to considerable risk to the aquatic organisms from PR-ENMs' environmental exposure. Thus, the determination of environmental exposure and effects in actual aquatic environments is required in reducing the probable risks of PR-ENMs. Now, more than ever, risk mitigation should be the integral part of product development and manufacturing.

4.08 Exposure and Effect Assessment of Ionic and Ionizable Organic Chemicals

4.08.T-01 Hazard and Fate Assessment of Permanently Charged Compounds

Marta Markiewicz[1], *Marcin Smiglak*[2] *and Stefan Stolte*[1], *(1)Institute of Water Chemistry, Technical University Dresden, Germany, (2)Poznan Science and Technology Park, Adam Mickiewicz University Foundation, Poland*

Most of studies concerning Ionic and Ionisable Organic Compounds (IOCs) pertain to acids/bases or their simple inorganic salts (halides or alkali metals), where in fact only one entity needs to be considered (the other being H^+ or Na^+, K^+, C^-, I^- etc.). Many pharmaceuticals, surfactants or PFAS are such examples. There is however a broad group of substances – known as ionic liquids (ILs) – where both the anion and the cation can be of environmental relevance. We looked into most important issues in environmental impact assessment of such substances using the example of ILs which can be used in crop protection as so called Systemic Acquires Resistance inducers (SAR inducers).

As expected, transforming a neutral compound into its simple ionic derivative (acid or K-salt) has mitigating effect on toxicity, while replacing the counterion with more hydrophobic entity vastly increases toxic potency. Within the set of investigated structural analogues EC_{50} values spanned over five orders of magnitude.

In assessment of ready biodegradability (most widely used for screening-level assessment) high biodegradability levels can be obtained even if one of the ions is persistent depending on the distribution of carbon between the ions. We suggest that in case of ILs, if anion and cation are amendable to biodegradation, they should be assessed both together and separately in the form of inorganic salt of the anion and the cation. The extent of biodegradation of both entities should also be assessed using specific analytical method.

Lack of experimental data does not allow for assessing the accuracy of K_{oc} predictions by COSMO-RS for tested ILs. HPLC method for screening log K_{oc} values of ILs was shown to deliver variable results so that validation using higher tier data is necessary.

In a broader context the question arises of how ILs will behave when released in the environment and what are the implications for hazard assessment. We have shown that both ions contribute to toxicity and biodegradability. Additionally, one ion can mask lack of the biodegradability of the other if test based on sum parameters is used without analytical verification.

We expect ILs to behave like separate ions in the environmental where other ions are abundant. In the same time, we believe that explicit attention should be paid to both the anion and the cation. Moreover, many experimental methods have too narrow a range to handle ILs or lack experimental verification.

4.08.T-02 Assessment of Methods for Determining the Membrane-water Partition Ratio for Surfactants

Steven Droge[1], *Nina Jansen*[1], *Elin Barrett*[2], *Adriana C. Bejarano*[3], *Jens Bietz*[4], *Kristin A Connors*[5], *James Dawick*[6], *Marc Geurts*[7], *Geoffrey Hodges*[8], *Eoin Kearney*[9], *Mark Miller*[9], *Sabrina Wilhelm*[10] *and Diederik Schowanek*[11], *(1)Environmental Risk Assessment, Wageningen Environmental Research, Netherlands, (2)Unilever R&D, United Kingdom, (3)Shell Global Solutions, (4)Clariant Produkte, Germany, (5)Procter & Gamble, (6)Innospec Limited, United Kingdom, (7)Nouryon Chemicals B.V., Netherlands, (8)Unilever - Safety and Environmental Assurance Centre, United Kingdom, (9)Department of Chemistry, Durham University, United Kingdom, (10)BASF Personal Care and Nutrition GmbH, Germany, (11)Procter & Gamble, Belgium*

Surfactants are often classified as difficult to test chemicals (Guidance Document on Aquatic Toxicity Testing of Difficult Substances and Mixtures), which may lead to uncertainty in chemical assessment. A key factor hampering adequate chemical fate modelling is that octanol-water partition coefficients (Kow) are often highly uncertain for surfactants, and poorly representative of the interaction energy of ionic surfactants with soil and tissue matrices. The phospholipid membrane-water partition ratio (Kmw) is a promising alternative chemical descriptor for surfactants instead of Kow, as it relates to partitioning into a critical cellular component and accounts for ionic interactions. Kmw can be determined by several experimental methods using artificial phospholipid material as unilamellar liposomes, bilayer coated silica, HPLC columns, or cells. Consistent Kmw values have been measured for a variety of surfactants. Also promising computational approaches to calculate Kmw have been evaluated. The overall aim of the study is for a systematic evaluation of three experimental methods and three computational approaches to determine Kmw for a diverse set of surfactants, covering nonionic, anionic, cationic, and zwitterionic structures. Based on this assessment, we aim to further establish confidence in the Kmw approach for different types of surfactants, provide guidance on the most cost-effective assay for specific surfactant classes, calibrate computation approaches, and make a next step towards standardization of validated test protocols. Here we present the initial phase of the work comparing experimental methods and molecular dynamics simulations for nonionic and anionic surfactants, using HPLC columns with Immobilized Artificial Membrane coated silica (IAM-HPLC), Solid-supported lipid membranes (SSLM), and unilamellar liposomes in dialysis systems. The data set provides relevant data to derive first tier estimates on bioaccumulation, and most likely also on baseline toxic potential.

4.08.T-03 A Food Web Bioaccumulation Model for Pharmaceuticals in Aquatic Ecosystems
Jiaqi Wang, MSc[1]*, Jan A.J. Hendriks*[1] *and Ad M. J. Ragas*[2]*, (1)Radboud University, Netherlands, (2)Environmental Science, Radboud University, Netherlands*
With increasing medical and veterinary use, pharmaceuticals have been detected as emerging pollutants in global water bodies. The continuous inflow of pharmaceuticals into the environment potentially imposes adverse effects on aquatic ecosystems and human health. Food web models in aquatic ecosystems (water-algae-daphnid-fish-bird/mammal) are useful tools to estimate potential exposure across trophic levels to pharmaceuticals. However, many pharmaceuticals are ionisable, and food web models accounting for ionisation are rare. Therefore, the present study aimed to develop a food web bioaccumulation model for pharmaceuticals in aquatic ecosystems and evaluate its performance.
The model was established based on the OMEGA bioaccumulation model, combining both mass balance and allometric theory to predict the bioaccumulation of chemicals throughout the food chain. Default values for parameters are obtained as functions of chemical properties (octanol-water distribution coefficient; D_{OW}) and biological traits (body mass). The sorption capacity of the organism for ionised pharmaceuticals compared to water (K_{BW}) was estimated through existing polyparameter linear free energy relationships (pp-LFERs), taking electrostatic effects into account. Model performance was subsequently evaluated by comparing estimated pharmaceutical concentrations in different trophic levels with measurements.
Two sets of results were computed. With K_{BW}s related to octanol as a function of D_{OW}, concentrations in organisms were lower than those estimated based on pp-LFERs. The difference was mainly attributed to the partitioning of acids (negatively charged) to serum albumin (positively charged lysyl- or arginyl residues) and the partitioning of bases (positively charged) to phospholipids (negatively charged phosphate). The model tends to underestimate concentrations of basic pharmaceuticals in algae. This may indicate that other processes such as ion-trapping and/or adsorption on cellulose surfaces may be important for basic pharmaceuticals, which are currently not included in the model. The present study is the first to develop a food web accumulation model that explicitly accounts for ionisation. The developed model will ultimately estimate the accumulation of pharmaceuticals in birds and mammals. Therefore, it will be possible to screen pharmaceuticals in terms of their potential to cause secondary poisoning.

4.08.T-04 Disentangling the Mechanisms Driving Accumulation and Elimination of Perfluoroalkyl Acids (PFAA) Using Toxicokinetic Modeling in Knock-out Mice
Fabian Christoph Fischer[1]*, Sophia Kozart Ludtke*[2]*, Sangwoo Ryu*[3]*, Emily Kaye*[3]*, Angela Slitt*[3] *and Elsie Sunderland*[1]*, (1)Harvard University, (2)Earth & Planetary Sciences/Environmental Science & Public Policy, Harvard University, (3)University of Rhode Island*
Perfluoroalkyl acids (PFAA) are the most studied chemicals within the broad family of per- and polyfluoroaklyl substances (PFAS) and have been detected in virtually all humans. Elevated PFAA concentrations in specific tissues such as the liver have been linked to adverse human health outcomes such as non-alcoholic fatty liver disease. However, mechanistic studies investigating the importance of specific tissue binding, transport and reabsorption mechanisms, and excretion for PFAA are scarce, resulting in a limited ability to constrain physiologically-based toxicokinetic (PBTK) models that could simulate tissue-specific accumulation and disease risks. Here, we develop and evaluate a multi-compartment PBTK model using temporal concentrations of PFAA measured in blood, excreta, and tissues sampled from mice after a single intravenous administration. The importance of albumin, fatty-acid binding proteins (FABPs), and organic-acid transporter proteins (OATPs) to internal PFAA distribution is evaluated using mice with specific biomolecules knocked out. The PBTK model accounts for: (1) blood flow to and from organs; (2) binding to tissue components (e.g. albumin, FABPs); (3) passive diffusion through membranes (permeability); (4) active transport by membrane transporters (e.g., OATPs); (5) enterohepatic circulation and tubular reabsorption; and (6) excretion via feces and urine. Chemical transport data are derived from *in vitro* cell assays and partitioning experiments and physiological model parameters are based on literature data. Preliminary simulations suggest unbound PFAA in all tissues to decrease with increasing carbon chain length (hydrophobicity). Retarded elimination is supported by strong binding to albumin and phospholipids and reabsorption from the liver and kidneys back into the bloodstream. Simulations that include active transport mediated by OATPs can explain higher tissue:blood ratios compared to those based only on membrane permeability. Further feedback loops between model simulations under varying input parameters and elimination experiments with knock-out mice will gradually identify the mechanisms driving PFAA accumulation and elimination in mammals. The findings will prioritize processes to be investigated in humans to clarify the link between the internal distribution and adverse health effects of PFAS.

4.08.T-05 Role of Bioavailability and Protein Binding of Perfluoroalkyl Substances in Cell-based Bioassays for Quantitative In Vitro to In Vivo Extrapolations
Weiping Qin[1]*, Luise Henneberger*[2] *and Beate Escher*[3]*, (1)Cell toxicology, Helmholtz Center for Environmental Research, Germany, (2)Cell Toxicology, Helmholtz Center for Environmental Research, Germany, (3)Department of Cell Toxicology, Helmholtz Center for Environmental Research, Germany*
Ubiquitous per- and polyfluoroalkyl substances (PFAS) pose a risk to human health. New approach methods (NAM) support risk assessment of PFAS but require quantitative *in vitro* to *in vivo* extrapolation (QIVIVE). The quantification of freely dissolved concentration (C_{free}) is a bottleneck of QIVIVE, since PFAS not only partition to lipid but also bind to protein, thereby reducing the bioavailability of PFAS, which results in C_{free} being lower than the nominal concentration (C_{nom}).
A method based on C18-coated solid phase microextraction (C18-SPME) fibers was developed to study the binding of four anionic PFAS (perfluorooctane sulfonate (PFOS), perfluorooctanoate (PFOA), perfluorobutanoate (PFBA), perfluorohexane sulfonate (PFHxS)) to bovine serum albumin (BSA) as a function of concentration, as well as their partition constants to medium,

cells and blood plasma. These parameters were used to predict C_{free} of PFAS in both cell bioassay and plasma by a concentration-dependent mass balance model (MBM). Anionic PFAS were found to bind to BSA in a concentration-dependent manner, including specific and non-specific binding. log $K_{specific}$ were derived from the specific saturable binding of PFAS to BSA and used to calculate the distribution ratio between plasma and water ($D_{plasma/w}$) by MBM with the volume fractions of protein (VF_{prot}) and lipid (VF_{lip}) in plasma.
As exemplary *in vitro* bioassay, a reporter gene assay indicating activation of the peroxisome proliferator-activated receptor gamma (PPARγ-GeneBLAzer) was chosen, and blood plasma levels were collected from literature for occupational exposure and the general population. A simple approach for QIVIVE is the ratio of concentrations (C_{nom} or C_{free}) in human blood to that in the bioassays. The QIVIVE_{nom} ratios were of concern for PFOS (22.7) and PFOA (1.96) for occupational exposure and were up to thousands of times higher than the QIVIVE_{free} ratios due to the strong binding affinity to proteins and large differences in protein contents between human blood and bioassays.
This study demonstrated that C18-SPME is a versatile method to quantify C_{free} and partition constants of PFAS under highly diverse conditions and over many orders of magnitude in concentrations. MBM can be used to estimate the C_{free} for more high-throughput *in vitro* assays from Tox21 database if more partition constants of PFAS are available in the near future.

4.08.P Exposure and Effect Assessment of Ionic and Ionizable Organic Chemicals

4.08.P-Mo335 Investigating the Role of Biotransformation in the Toxicity of Ionizable Organic Compounds, Using LC-HRMS – Zebrafish Embryos Exposed to Ibuprofen as a Case Study
Eleni Panagopoulou[1]*, Dimitrios E. Damalas*[1]*, Eleni Aleiferi*[1]*, Vasiliki Tzepkinli*[1]*, Mona Schweizer*[2]*, Lone Kundy*[2]*, Heinz Köhler*[2]*, Rita Triebskorn*[2]*, Peter Von der Ohe*[3] *and Nikolaos Thomaidis*[1]*, (1)National and Kapodistrian University of Athens, Greece, (2)University of Tuebingen, Germany, (3)German Environment Agency, Germany*
Pharmaceuticals as well as their transformation products are highly detected in the aquatic environment and may bioaccumulate in aquatic organisms causing adverse effects. Ibuprofen (IBU) is a commonly used nonsteroidal anti-inflammatory (NSAID) drug which has been reported in aquatic environments. Many pharmaceuticals belong to the group of ionizable organic chemicals (IOCs) and their properties appear to be affected by the pH of the surrounding medium. However, the influence of pH values on the toxicity of IOCs hasn't been extensively evaluated in risk assessment studies.
The zebrafish embryo (ZFE) has emerged as a powerful alternative model organism, which is widely used in ecotoxicological research studies for evaluating the potential effects of xenobiotics on aquatic organisms.
The scope of this study was to assess the influence of the different pH values of the test medium on the uptake, bioaccumulation, biotransformation as well as toxicity of IBU in ZFE. Another goal was to identify the potential bio-TPs of IBU and to determine their concentration. Our overall objective was to investigate whether using biotransformation data complementary to the internal concentration (C_{int}) of the parent compound, could provide a holistic toxicity interpretation at different pH values of the exposure medium.
Fish embryo toxicity test (FET) with ZFE was conducted at three pH values and the LC_{50} values of IBU were determined. For the extraction of IBU in ZFE samples, organic solvents were added, and a bead-beating homogenization process was followed. The extracts were analyzed by RPLC and HILIC, in both positive and negative ionization modes, using LC-HRMS. A target-screening approach was followed for the identification of IBU, whereas identification of tentative bio-TPs was performed through in-house developed suspect and non-target screening workflows.
The pH-dependent toxicity of Ibuprofen was investigated, highlighting the importance of including the pH as a factor in toxicity studies. Concerning biotransformation, more than 10 bio-TPs were identified and a potential biotransformation pathway of IBU was proposed. It turned out that biotransformation greatly contributes to the C_{int} of the parent compound and may affect its toxicity. Therefore, biotransformation should be thoroughly investigated in toxicokinetic studies, complementary to C_{int}, for a holistic interpretation of the toxicity of IOCs.

4.08.P-Mo336 The Use Of Toxicokinetic Models To Improve The Understanding Of Internal Concentration For Ionisable Organic Chemicals In Fish
Jacob-Joe Collins[1]*, Alessia Giorgis*[2]*, Dawei Tang*[3]*, Leonardo Contreas*[4]*, Tymotheusz Pietrenko*[4]*, Patrik Engi*[4]*, George Fitton*[5] *and* ***Bruno Campos***[4]*, (1)School of Biosciences, University of Birmingham, United Kingdom, (2)Unilever R&D, United Kingdom, (3)Safety and Environment Assurance Centre, Unilever - Safety and Environmental Assurance Centre, United Kingdom, (4)Unilever, United Kingdom, (5)Unilever Research, United Kingdom*
Regulatory frameworks for assessing chemical safety have had historically a reliance on *in vivo* testing. However, the global regulatory landscape is experiencing an evolution in thinking around the use of animal testing. Hence, data requirements are also changing towards the use of more New Approach Methodologies (NAMs) based on mechanistic knowledge from *in silico*, computation and *in vitro* sources. This trend towards the use of *in vitro* based NAMs in safety decisions is dependent on the availability of robust Physiologically Based Kinetic (PBK) models in order to support a better understanding of the relationship between the internal and external concentrations of chemicals through *in vitro* to *in vivo* extrapolations (IVIVE). To enable this, there is a compelling need to develop and build confidence in *in-silico* models such as toxicokinetic (TK) models that can be used to support the risk assessment of these chemicals.
While TK models are already available, they are focussed mainly on neutral organic chemicals. Yet, there are a large number of chemicals which have the potential to ionise in the aquatic environment and their potential impacts on organisms are often poorly characterised. Hence, TK models specifically designed for ionisable chemicals are needed to allow for the prediction of the internal concentration that is likely to elicit toxicity in the organism. In this study, we evaluate the potential applicability of a one-

compartment TK model for fish species, where physicochemical descriptors such as the pK_a and D_{ow} (octanol-water partition coefficient corrected for the pH) alongside with species traits such as the lipid fraction, could improve its performance and result in a better prediction of the relationship between the internal and external concentrations in fish species for ionisable compounds. This study will build on existing TK models by bringing more realism and expanding their applicability domain including ionisation. Furthermore, it will support the understanding of the mechanisms of uptake and elimination in fish and the main drivers underpinning them.

4.08.P-Mo337 Solid-Phase Microextraction Elucidates the Binding of Perfluoroalkyl Acids (PFAA) to Surrogate Biomolecules Relevant to Their Distribution in Humans

Sophia Kozart Ludtke*, Fabian Christoph Fischer and Elsie Sunderland, Harvard University*

Perfluoroalkyl acids (PFAA) are anthropogenic chemicals that have been associated with adverse human health effects like liver and kidney diseases following exposure to contaminated drinking water, food, and other sources. Despite their importance, factors controlling PFAA accumulation in human tissues and interactions with biomolecules (e.g., proteins, lipids) are still poorly understood. Binding affinities to biomolecules can be quantitatively described by empirically measured partition coefficients. This presentation will report newly measured partition coefficients for PFAA with varying carbon chain lengths (C3-C11) and functional groups (e.g., carboxylic and sulfonic acids) to biomolecules and biofluids suspected to be drivers of tissue accumulation in humans using a solid-phase microextraction (SPME) method with C18-coated fibers. Factors experimentally tested at chemical concentrations ranging from typical human exposure levels to high doses administered in mammalian toxicity tests include concentrations of human serum albumin (HSA), fatty-acid binding proteins (FABPs), bile, globulin, and casein. Preliminary fiber-water experiments showed high reproducibility and linear binding over the tested concentration range, with equilibrium achieved in < 48 hours for all tested PFAA. PFAA with longer carbon chains (greater hydrophobicity) were generally associated with higher binding to biomolecules. Perfluorinated sulfonates sorbed more strongly to proteins than their corresponding carboxylic acids. Sorption to bile showed the opposite trend, suggesting that enterohepatic circulation might be of higher relevance for perfluorinated carboxylic acids. These partition coefficients can broadly inform physiologically-based toxicokinetic (PBTK) models to help advance understanding of the driving binding mechanisms for organ-level PFAA distribution and accumulation. As a next step, the SPME method will be applied to compare the binding of PFAA to human tissues (e.g., liver, kidneys) sampled in Cohort studies to “model tissues” constructed as combinations of surrogate biomolecules and their respective partition coefficients.

4.08.P-Mo338 Developing Mass Balance Models for Simulating Indoor Fate and Human Exposure to Ionic and Ionizable Organic Chemicals Released Indoors

Lauren Hughes[1]*, Li Li*[2]*, Alessandro Sangion*[1] *and Jon A. Arnot*[1]*, (1)Arnot Research and Consulting, Canada, (2)School of Public Health, University of Nevada, Reno*

People spend most of their time in indoor environments where they are exposed to a wide array of neutral, ionic, and ionizable organic chemicals (IOCs). Humans directly ingest, inhale, or apply chemicals to their bodies in the form of pharmaceuticals and consumer and personal care products (PCPs). Chemicals released indoors can accumulate in dust and on surfaces and volatilize in indoor air. Humans subsequently encounter these chemicals indirectly through inhalation, indirect dermal contact, and mouthing-mediated (i.e., hand-to-mouth or object-to-mouth) ingestion of dust or residues. Mass balance chemical fate models are important tools for human health assessments and for elucidating, quantifying, and comparing pathways of exposure. Such models have been developed, applied, and evaluated for several classes of neutral organics for which intermedia partitioning behaviour can usually be well characterized. However, many organic chemicals used in indoor environments are ionic or ionizable, and the charged species of such chemicals may behave differently from their neutral forms. The RAIDAR-ICE model combines an indoor multimedia mass balance chemical fate model with a human exposure and physiologically-based biokinetic (PBK) model. This integrated and holistic approach enables modeling human external and internal exposures to chemicals in various indoor compartments (e.g., air, dust, and indoor surfaces) through multiple near-field exposure routes (e.g., inhalation, ingestion, and dermal exposure). RAIDAR-ICE has been revised to more explicitly quantify the indoor fate and transport of and exposure to IOCs. Partitioning of IOCs is calculated using distribution ratios, and indoor media are characterized as containing both organic and aqueous components. Here, the RAIDAR-ICE model is applied in a case study for consumer and occupational exposures to select IOCs. The calculated dust and air concentrations, as well as human intake rates and biological concentrations are compared to monitoring data (where available) and the model performance is discussed. The relative importance of explicitly considering dissociation for IOCs in human exposure estimation is highlighted.

4.08.P-Mo339 Toxicological Properties of Imidazolium-Based Surface-Active Ionic Liquids (Im-SAILs); A Case Study using the Brackish Water Shrimp, *Palaemonetes africanus*

Kafilat Adebola Bawa-Allah[1] *and Magaret Sivapragasam*[2]*, (1)University of Lagos, Nigeria, (2)Biotechnology, QUEST International University Malaysia, Malaysia*

Imidazolium-based surface-active ionic liquids (Im-SAILs) are cationic surfactants having long hydrophobic alkyl chains. They exhibit unique aggregation behaviour and are being explored for use in oil recovery and other biotechnological applications. This class of surfactants are believed to be environmentally friendly with low toxicity. However, studies to assess the toxicity of SAILs have been largely short-term acute toxicity studies using microorganisms. In the present study, we investigated the acute and sublethal toxicity of three Im-SAILs to a macroinvertebrate, *Palaemonetes africanus,* using laboratory bioassays. The shrimp is a brackish water shrimp able to tolerate varying salinity conditions. Toxicological tests were conducted using reconstituted water with a salinity of 5‰. The 96hr LC_{50} acute toxicity index of the three Im-SAILs assessed; 1-methyl-3-octylimidazolium tetrafluoroborate, 1-Decyl-3-methylimidazolium tetrafluoroborate, and 1-dodecyl-3-methylimidazolium tetrafluoroborate against the species were 18.52 mg/l, 18.17 mg/l and 3.93 mg/l respectively. The sublethal effects of the Im-SAILs on the shrimps were assessed by determining the levels of oxidative stress enzymes and substrates of oxidative stress after a 14-day exposure to sublethal concentrations. The results showed that the Im-SAILs did not induce sublethal toxic effects in the exposed shrimps. Results from the present study have established that Im-SAILs can be acutely toxic to macroinvertebrates. This indicates a need to regulate the application of Im-SAILs in the biotechnological process and maintain environmental concentrations below toxic levels. These can be achieved through regulatory testing and the establishment of environmentally safe limits for Im-SAILs.

4.08.P-Mo340 Why pH Matters in Cell-based in vitro Bioassays

Luise Henneberger[1], *Jenny Braasch*[1], *Julia Huchthausen*[1], *Maria Koenig*[2], *Audrey Ogefere*[1] *and Beate Escher*[2], *(1)Cell Toxicology, Helmholtz Center for Environmental Research, Germany, (2)Department of Cell Toxicology, Helmholtz Center for Environmental Research, Germany*

The speciation of ionizable organic chemicals (IOCs) is dependent on the pH-value of their environment. As different chemical species may exhibit different degree of toxicity towards living cells or whole organisms, the toxicity of IOCs is typically pH-dependent. In this study we measured the pH-dependence of cytotoxicity and activation of oxidative stress response for 11 (7 basic, 1 acidic and 3 multifunctional) IOCs with at least one acidity constant (pK_a) between 6.5 and 9. The pK_a values of all test chemicals were quantified using UV-metric or potentiometric titration. For the toxicity tests the AREc32 reporter gene assay based on genetically modified MCF7 cells was used. In general, cytotoxicity increased with increasing fraction of neutral or net-neutral (zwitterionic) species, which is in line with previously published data for organisms like daphnia and algae. The basic IOCs showed increasing cytotoxicity and activation of oxidative stress response with increasing pH, while toxicity slightly increased with decreasing pH-value of the medium for the acidic chemical benzothiazolone. For the multifunctional chemicals labetalol and cetirizine toxicity increased with increasing fraction of the zwitterionic species. The activation of oxidative stress response showed less dependence on the pH value of the medium for the majority of the test chemicals. For labetalol the measured cytotoxicity could be explained by baseline toxicity and did therefore correlate with the liposome-water distribution ratio $D_{lip/w}$ (pH). For all other test chemicals reliable $D_{lip/w}$ (pH) were missing and no in-depth analysis was possible. The diprotic base 1H-Imidazole-1-propanamine showed decreasing cytotoxicity and activation of oxidative stress response with decreasing fraction of the dicationic species. This effect cannot be explained by baseline toxicity as the dication is expected to have much lower membrane affinity compared to the cationic and neutral species. This also indicates that pH-dependence of toxicity in cell-based bioassays may not easily be predictable by QSAR models.

4.09.A Mechanistic Effect Modelling for Regulatory Environmental Risk Assessment: From Molecules to Landscapes

4.09.A.T-01 Compound-specific Toxicokinetics and Physiological Response Patterns of two Target and one Non-Target species

Clara Isis Römer[1], *Roman Ashauer*[2,3], *Juliane Hollender*[4,5], *Beate Escher*[6,7], *Kristin Hofer*[2], *Pouria Sadeghi-Tehran*[2], *Michel Muehlebach*[2] *and Anke Buchholz*[2], *(1)Syngent Crop Protection AG, Switzerland, (2)Syngenta Crop Protection, Switzerland, (3)Department of Environment and Geography, University of York, United Kingdom, (4)Environmental Chemistry, Environmental Chemistry, Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (5)ETH Zürich, Institute of Biogeochemistry and Pollutant Dynamics, Switzerland, (6)Department of Cell Toxicology, Helmholtz Center for Environmental Research, Germany, (7)Geosciences, Eberhard Karls University Tübingen, Germany*

Insecticides play an important role in preventing or reducing insect damage to crops and ensuring yield quality and quantity of crops. Targeted pest species, as well as non-target species, live in agricultural ecosystems and insecticide research and development aim to optimize selectivity. Physiological traits, such as feeding behaviour and biotransformation, can influence the toxicokinetics (TK) and thus present a lever to optimize species selectivity. It is unknown how target and non-target species differ in these physiological traits. TK of insecticides need to be understood independently of the toxicodynamics, i.e., insecticidal effects.

Five test compounds were investigated that range in lipophilicity (LogP 1.43-3.57) and are made up of scaffolds or fragments from known insecticides yet being insecticidally inactive. Single *Spodoptera littoralis* (pest) larvae were exposed to test compounds on soybean leaf discs by feeding and surface contact. Food consumption and transformation into faeces were recorded by image analysis. *Myzus persicae* (pest) mixed age populations were exposed by oral uptake in a sachet feeding assay. Continuous feeding was captured by honeydew excretion. *Chironomus riparius* (non-target) larvae were exposed actively and passively in water solutions (OECD guideline). Body residues, and excreted compounds were quantified as a function of time during the exposure and a follow-up depuration phase. Parent compounds and putative metabolites were separated by liquid chromatography and detected by mass spectrometry. A TK-model was built and parameterised to quantify uptake, biotransformation, and elimination rate constants. The exposure did not disturb continuous food consumption, nor excretion of exposed *Spodoptera* larvae and *Myzus* population in experiments. No disturbance in movement of exposed *Chironomus* larvae was observed. Body residues differed significantly between species and across compounds, quantified by differences in uptake, biotransformation, and elimination rate constants.

The bespoke bioassays enabled the measurement of body residues in target and non-target species to build species TK models. Knowledge about TK across these species could be used to achieve maximum effectiveness against pests at minimum environmental impact. Thus, this new knowledge on selectivity constitutes an important building block for sustainable food production and environmental safety.

4.09.A.T-02 Physiologically Based Gonadotropic Axis Kinetic Model in Female Zebrafish (Danio Rerio) Exposed to Two Azole Fungicides (Prochloraz and Imazalil)

***Tu-Ky LY*[1]**, *Julie De Oliveira[2], Karyn Le Menach[3], Edith Chadili[2], Hélène Budzinski[3], Nathalie Hinfray[2] and Rémy Beaudouin[4], (1)INERIS, France, (2)Ineris, Ecotoxicology of Substances and Environments, France, (3)UMR CNRS EPOC Universite Bordeaux / UMR 5805 EPOC, France, (4)Ineris, Experimental Toxicology and Modeling, France*

The reproductive function of vertebrates relies on the delicate dialogue between the gonads and the hypothalamus-pituitary complex defining the gonadotropic axis (i.e. hypothalamic-pituitary-gonadal axis, HPG axis). Its disruption by endocrine disruptors (ED) is well known and focuses mainly on several endpoints leading to an alteration of reproductive and developmental functions. Therefore, predicting the bioaccumulation of an ED is a key point to understand its underlying mechanism with the HPG axis. Physiologically based toxicokinetic (PBTK) models are useful tools to easily predict the bioaccumulation of a substance in an organism and enable a mechanistic approach.

Within the GinFiz project (APR EST ANSES n°2020/01/133), zebrafish was selected to study the alteration of the HPG axis. Also, two azole fungicides: prochloraz (PCZ) and imazalil (IMZ), were chosen for their well-known ED properties. Thus, this work aims to elucidate the kinetic profiles of PCZ and IMZ in the fish to understand their bioaccumulation and to translate their toxic effects into the HPG axis in the fish. To start with, the PBTK model predicted every data point available (i.e. internal concentrations in several fish organs) within a 3-fold range and 92% within a 2-fold range. Thereafter, the HPG axis was successfully integrated into the PBPK model and enabled the prediction of the physiological kinetics of steroid hormones, luteinizing hormones, and vitellogenin. This model will allow the investigation of the toxic effect of these two azole fungicides on the HPG axis in female zebrafish, such as steroid hormone balance.

4.09.A.T-03 Is Considering a Physiologically Based Toxicokinetic Module in a GUTS Model Really an Added Value or Not?

***Sandrine Charles*[1]**, *Dominique Lamonica[2], Jérémie Bruset[3], Ophelia Gestin[4] and Christelle Lopes[5], (1)UMR CNRS 5558, University Claude Bernard Lyon 1, France, (2)Agence Comptable, Université Claude Bernard Lyon 1, France, (3)University Lyon, France, (4)University of La Rochelle, France, (5)Umr Cnrs 5558, University of Lyon, France*

In the current Anthropocene, environmental pollution is a global problem that is inextricably linked with rapid industrialization and urbanization. Pollution hampers the environment sustainability and ecosystem services. The decline in environmental quality, because of pollution, is evidenced by a loss of vegetation, a loss of biological diversity, and excessive amounts of harmful chemicals in all compartments of the biosphere. As a result, the impact of chemicals on human health is today recognized as coming from contaminated air, soil, and water, via direct (e.g., ingestion) or indirect (trophic chain) exposure routes. Therefore, a holistic approach is an urgent need to remove the pollutants in a drastic way. Preserve the survival of living organisms in the face of chemical contamination is today among the biggest challenges of regulatory bodies, pollution and contamination of natural resources adversely affecting livelihood of all species. Nevertheless, could Europe really move towards zero pollution, in line with the ambition of the European Green Deal? If it is now several decades since concentration-response or effect models are used to estimate x% lethal or effective concentrations (LCx or ECx), mechanistic effect models (MEMs) were recently recognized of high potential to make risk assessment of chemicals more ecologically relevant than current standard practices [1]. MEMs consider the underlying mechanisms of how chemicals affect individual life history traits, linking the exposure concentration to the internal damages it causes (toxicokinetic), that in turn translate into a reduced fitness (toxicodynamic). MEMs belong to the so-called toxicokinetic-toxicodynamic (TKTD) models. Among TKTD models, the one dealing with survival, entitled GUTS for General Unified Threshold model of Survival [3] is already considered as ready-to-use for environmental risk assessment by regulatory bodies [3]. Nevertheless, the TK part of GUTS is oversimplified considering organisms as a whole and characterizing uptake and elimination by one single parameter k_d (dominant rate constant). Based on recent advances in the development of physiologically based toxicokinetic models [4], we present here an innovative extended GUTS model including a multi-compartment toxicokinetic model. This physiologically based TKTD model (namely PBGUTS) will presented in this talk from a case where gammarids were exposed to zinc and cadmium environmental concentrations.

4.09.A.T-04 Physiologically-Based Kinetic Models for Bird Species and Application to Fluopyram

***Stephan Schaller*[1]**, *Vanessa Baier[1], Colin G Scanes[2], Audrey Bone[3], Markus Ebeling[4], Thomas G Preuss[4], Johannes Witt[4] and David Heckmann[4], (1)esqLABS, Germany, (2)Department of Poultry Science, University of Arkansas, (3)Bayer AG - Crop Science Division, (4)Bayer AG - Crop Science Division, Germany*

Physiologically-based kinetic (PBK) models are effective tools for designing toxicological studies and conducting extrapolations to inform hazard characterization in risk assessment by filling data gaps and defining safe levels of chemicals. Toxicity testing in birds is performed as a requirement for pesticide registration by regulatory authorities (Regulation (EC) No 1107/2009), and PBK models have the potential to interpret such data mechanistically and to extrapolate to different exposure scenarios. PBK models represent the body as a network of interconnected compartments linked via blood flow. After an oral, dermal, or inhalation exposure to a compound, its absorption, distribution, metabolism, and excretion processes are simulated by means of ordinary differential equations, allowing to simulate time-concentration curves in target organs.

The aim of the present work was to develop a generic whole-body PBK model for male and female birds, for three bird species, chicken (*Gallus gallus*), duck (*Mallard duck*), and bobwhite quail (*Colinus virginianus*). The reproductive system includes ovary, oviduct, egg white and yolk compartments to predict detailed concentrations in eggs. For the model development several partitioning coefficient (PC) calculation methods were explored. The developed PBK models were then qualified (validated) against available *in vivo* data. Finally, models were documented and scored following international guidance documents from WHO, EFSA, and OECD.

Simulations of tissue time-concentration (PK profile) curves were run for the ten chemicals chloramphenicol, deltamethrin, florfenicol, ivermectin, melamine, midazolam, monensin, itraconazole, salinomycin, and fluopyram (with metabolite fluopyram-benzamide). Insights into the outcome for the fluopyram use case chemical will be provided in the presentation, where multiple exposure scenarios were evaluated on their impact on egg concentrations.
In order to assess the performance of the models, an analysis of the overall data points against the model predictions as a "goodness of fit" criterion was done. The models were evaluated within a range of -three and -tenfold to account for variability from the *in vivo* studies. The performance analysis was conducted for each chemical by comparing all observed *in vivo* data by species. The overall accuracy of the model predictions across the chemicals analyzed was found to be species- and compound-specific.

4.09.A.T-05 Reproductive Toxicity in Birds Predicted by DEB-TKTD Modelling
***Thomas Martin*[1]**, *Barbara Bauer[2], David Heckmann[3] and Andre Gergs[3], (1)RIFCON, Germany, (2)Rifcon, Germany, (3)Bayer AG - Crop Science Division, Germany*
Toxicokinetic-toxicodynamic models based on dynamic energy budget theory (DEB-TKTD models) can predict sublethal toxic effects at the organism level. However, relatively few studies have used DEB-TKTD models to predict impacts of pesticides on bird and mammal species. This lack of case studies was highlighted as a key obstacle to the use of DEB-TKTD models in ERA by the recent draft EFSA guidance document on ERA for Birds and Mammals. We used DEB-TKTD modelling to mechanistically predict the effects of fluopyram on the weight of bobwhite quail (*C. virginianus*) *hatchlings* and 14-day old chicks following parental exposure via the diet. We assumed that some of the chemical is transferred from the mother into eggs. The model was calibrated to a novel experiment in which eggs were injected with benzamide (the metabolite of fluopyram found in a study on laying hens) at various concentrations. Effects on embryo growth, survival, and yolk utilization were measured during incubation. Model calibration tested three physiological modes of action (pMoAs) – stress on maintenance costs, growth costs, or reserve mobilization – as well as two TK assumptions: that benzamide exposure of the embryo begins upon injection or starts with yolk absorption on day eight. The experimental data showed reduced embryo growth as well as reduced yolk utilisation with increasing benzamide concentration. The choice of pMoA was thus clear, as this pattern could only be matched by selecting stress on reserve mobilization. The fitted model closely matched data for all endpoints. It was then used to predict effects on hatchling weight and 14-day chick weight (normalised to percentage reduction vs controls) in an independent dataset, in which bobwhite quail females were exposed to fluopyram via diet, and hatchling and chick weights were monitored (OECD 206 study). To infer benzamide concentration in the egg resulting from parental exposure we used a physiologically-based TK model. Data were well matched by predictions, with 87.5% of all data points predicted to within one standard deviation. The results show that DEB-TKTD models calibrated to embryo data can predict effects at hatching and at later life-stages. This study also demonstrates value of calibrating to multiple endpoints to determine the correct pMoA. Finally, this study provides a much-needed case study in which the effects of a pesticide on a bird species relevant to ERA were accurately predicted by a DEB-TKTD model.

4.09.B Mechanistic Effect Modelling for Regulatory Environmental Risk Assessment: From Molecules to Landscapes

4.09.B.T-01 Modelling Temperature-Dependent Life-Cycle Toxicity of Thiamethoxam in Chironomus Riparius Using a DEB-Based TKTD Model
***Josef Koch*[1]**, *Silke Claßen[1], Daniel Gerth[1], Tido Strauss[1], Maxime Vaugeois[2] and Nika Galic[3], (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Syngenta Crop Protection, (3)Syngenta Crop Protection, Switzerland*
Thiamethoxam (TMX) is a systemic neonicotinoid insecticide, which is used to protect crops against insect pests. In a recent ecological risk assessment released, the US EPA identified potential concerns primarily from chronic TMX exposure to freshwater aquatic invertebrates. Chironomids were identified as one of the most sensitive taxa. Given the use of TMX in different regions, the toxicity of TMX to the chironomid life cycle at variable environmental temperatures needs to be considered in risk assessment but is not yet well understood.
In this study, we developed a quantitative mechanistic effect model for *Chironomus riparius*, to simulate the species' life history under dynamic temperatures and exposure concentrations of TMX. Laboratory experiments at both constant and dynamic conditions of temperature and TMX exposure were performed for model calibration and validation. The larval dry weight and survival over time, the time to emergence, and the reproduction (as mean egg mass size) were assessed as endpoints. The model design was based on the state-of-the-art mechanistic approach of combining the Dynamic Energy Budget (DEB) theory with toxicokinetic-toxicodynamic (TKTD) modelling. Different assumptions about the size-dependency of *damage* dynamics were explored to adequately reproduce the experimental data. Furthermore, multiple hypotheses about which processes and parameters should be corrected for temperature were tested.
The results showed concentration-dependent effects of TMX on the chironomids' life cycle, including slower growth, later emergence, smaller egg masses, and higher mortality rates with increasing concentrations. Besides an expected acceleration effect on the organisms' growth and development, higher temperatures further increased the adverse effects caused by TMX. With some data-informed modelling decisions (most prominently the inclusion of a size-dependency that makes larger animals more sensitive than smaller ones), the model was parametrised to convincingly reproduce the calibration data. Furthermore, the calibrated model also delivered adequate fits to independent data, which had been collected specifically for validation purposes. While the approach of combining DEB with TKTD modelling has been tested before with other species-toxicant combinations, this study is among the first to rigorously investigate the combination of toxic stress and temperature-dependency with tailor-made extensive experiments.

4.09.B.T-02 Comparing Dynamic Energy Budget Parameters and Traits of Birds for the Extrapolation of PPP Exposure Impacts across Species

Erik B Muller[1], *Benoit Goussen*[1], *Jonathan D. Maul*[2], *Richard Brain*[2] *and Nika Galic*[3], *(1)ibacon, Germany, (2)Syngenta Crop Protection, (3)Syngenta Crop Protection, Switzerland*

A major challenge in Environmental Risk Assessment is to evaluate the implications of the results from standard toxicity tests with a limited number of species in the context of species diversity. This is especially an issue with Plant Protection Products (PPP) as potential toxic agents, as a wide variety of organisms is bound to become unintentionally exposed as a result of field applications, while there is little experimental information that can help in estimating the potential impacts of PPP exposure on non-target organisms. In order to bridge this knowledge gap, we use Dynamic Energy Budget (DEB) theory, which is a cohesive, process-based bioenergetic framework describing the rates at which organisms acquire resources from their environments and use the energy and nutrients therein for growth, maintenance, development and reproduction. The dynamic equations of the theory are universal, with taxon-specific modular modifications, and differences among species are essentially differences in parameter values. Although the standard animal DEB model has only 11 core parameters and 4 state variables, these quantities can be used to calculate over 250 traits, implied properties and other derived quantities, such as maximum size, respiration rate and maximum reproduction rate, even if experimental information about those quantities is lacking. In the theory, sub-lethal effects of toxicants are expressed as quantitative changes in energy flows or life history trait values, known as Physiological Modes of Action, which lead to alterations in organismal performance, e.g., reductions in growth and/or reproduction. Accordingly, DEB theory promises a prospect to project known toxic impacts of PPPs on a few dedicated species to other species that are not involved in toxicity testing. The present study focusses on 72 North American birds that may inadvertely be exposed to PPPs. Within the DEB framework, we compare the bioenergetic parameters, traits and derived quantities of those birds with species that are routinely used in reproduction toxicity tests, namely Mallard, Bobwhite Quail and Zebrafinch, and describe the extent to which the latter species are representative of the former, with the ultimate aim to make informed projections of toxic impacts across bird species.

4.09.B.T-03 A Population Model to Assess the Combined Effects of Ionising Radiation and Chemicals on Wildlife

Jordi Vives i Batlle, *Belgian Nuclear Research Centre, Belgium*

A conceptual population model is presented to study the combined effects of ionising radiation and chemical pollutants on wildlife. The model is based on first order, non-linear logistic differential equations combining mortality, morbidity and reproduction phenomena with life history data and ecological interactions. The model includes adaptation as a possible mechanism in order to be able to simulate theoretically potential priming effects at low levels of radiation or chemical concentration. Radiation and chemical-induced damages are represented by a ‘repairing pool’ mediating between healthy, damaged, adapted and irrecoverable individuals. Damages to population, fecundity and the repairing pool are represented by a linear-quadratic function combining radiation dose and chemical concentration terms. The endpoints of the model are repairable damages (morbidity), impairment of reproductive ability and mortality.

The governing equations of the model are presented and discussed. The model is evaluated with a mixed radiation/arsenate scenario and model simulations illustrate the combined effect of radiation and chemical pollutants upon the sustainability of a hypothetical population, including the influence of adaptation, as well as the capacity of radiation and chemical toxicity to prime for each other, given the assumption that the repair of both radiation and toxicity damages share the same mechanism. A sensitivity analysis of the model illustrates the effects of combining radiation dose and chemical concentration on self-repairing and reproductive ability for the population, exploring cases of antagonism and synergism by varying the relevant model parameters.

This model provides a conceptual framework to assess synergistic effects of mixed radiological and toxic exposures at the population level, suggesting the possibility of a practical regulatory model. The output can be used to inform ongoing debates on the robustness of protection benchmarks in wildlife risk assessment. Future research will enable to draw conclusions about the most restrictive mixed exposure situations in terms of effects to the population, once existing uncertainty in some of the toxicity model parameters has been addressed. It is essential to improve the model with lessons learned from well-established approaches for chemical risk assessment, signalling the direction of future investigations.

4.09.B.T-04 Modelling the Effect of Resource Competition and Feeding Stress on Individual and Population Level Responses in Two Freshwater Shredders

Niamh O'Connor[1], *Philip Warren*[1], *Andreas Focks*[2] *and Lorraine Maltby*[1], *(1)University of Sheffield, United Kingdom, (2)Institute of Mathematics, University of Osnabrueck, Germany*

Ecological functions are performed by populations of species but toxicity endpoints are derived from single-species toxicity tests. Population responses to individual-level effects can be mediated by other ecological effects such as intraspecific competition for resources. Increasing competition reduces the amount of food available to individuals, affecting their acquisition of energy. For more ecologically relevant ERA, there is a need to extrapolate from individual-level effects to population-level responses to stress, understanding how competition for food affects population-level responses to chemical stress and how this differs between species. *Gammarus* and *Asellus* are freshwater invertebrates that play an important role in the decomposition of leaf litter and nutrient cycling. DEB IBMs for *Gammarus pseudolimnaeus* and *Asellus aquaticus* were used to simulate population-level responses to individual feeding stress (reduced feeding rate) and competition for food. The effect of feeding stress on individual-level responses was compared between *ad libitum* (f = 1) and conditions of a reduced resource (f = 0.5) at the end of 365 days. Population level responses (change in Biomass production) were simulated over 20 years. Sensitivity to feeding stress increased with decreased resource availability. *Asellus* was more tolerant of decreased availability of food. A 50% reduction in feeding rate resulted in 77% effect on the mean dry weight of individuals for *Gammarus* and a 70% effect for *Asellus* when feeding *ad libitum*.

When the functional response was reduced to 0.5, the effect on Biomass increased to 95% for *Gammarus* but to 81% for *Asellus*. This difference between species was found with Long term population level responses, with a variable resource, where a 50% reduction in feeding resulted in a 35% reduction in the production of biomass for *Asellus* but a 68% reduction for *Gammarus*. Starvation tolerances were the same for both species but simulated *Asellus* had a shorter time to maturity and more reproduction cycles per year, increasing the population tolerance to stress. Individual level effects are not representative of population level responses and their effects on ecosystem functions are affected by food availability caused by competition. The magnitude of effects differed between the two species studied. Life history traits, particularly reproductive cycles affect species' sensitivity to stress at the individual and population level.

4.09.B.T-05 Normal Operating Ranges (NOR) as a Measure to Analyse Arthropod Abundance Variability in Landscape Simulations

Leonhard Urs Bürger[1] *and Andreas Focks*[2]*, (1)Systems Science Group, Institute of Mathematics, Germany, (2)Institute of Mathematics, University of Osnabrueck, Germany*

Arthropod population numbers can change significantly from year to year and season to season due to various factors, like weather or (sub-)annual life cycles. Assessing declining abundances of species therefore proofs difficult. Knowing the amplitude of naturally occurring variances in the ecosystem is thus key to assess a potential decline due to newly introduced stressors. Basing such analyses solely on field data would require extensive field studies over a period of years. Additional usage of simulations enables the assessment to be carried out over a longer timeperiod, and additionally to account for e.g. changing weather conditions. We used the individual- based ALMaSS landscape simulation model of Topping et al. (2003), and here implementation of the Bembidion beetle species by Bilde and Topping (2004) to simulate beetle population abundances in a Danish agricultural landscape. ALMaSS simulates landscapes with real past weather data and dynamic crop management while the Bembidion model simulates individual beetles with their livestages and interactions with the landscape and other beetles. To analyse the variablility of seasonal abundance numbers, Normal Operating Ranges (NOR) are calculated. The concept of NOR describes the possible range of a measurand (e.g. population numbers) being usually oberseved in a certain period and (eco-)system. It should thus be described as a tolerance interval convering a defined share of the data with a certain confidence. Abundance data of 130 simulations (30 years each, excluding 10 years of a 'burn-in' period) was overlayed for each day of the year and used for daily abundance NOR calculations for all beetle livestages. Results show clear seasonal changes for each development stage that match expected abundance patterns. Such statistical NOR calculations based on simulation results apear as useful way to analyse the variability of species abundances, if the used model is capable of simulating relevant species traits and phenomenas and their variabilities. The use of the NOR concept might be used to analyse stressor impacts, develop in-field verifiable protection goals or the impacts of a changing climate in the future.

4.09.P Mechanistic Effect Modelling for Regulatory Environmental Risk Assessment: From Molecules to Landscapes

4.09.P-Th311 Physiologically-based Kinetic Models for Bird Species - A Case Study with Fluopyram

Stephan Schaller[1]*, Vanessa Baier*[1]*, Audrey Bone*[2]*, Markus Ebeling*[3]*, Thomas G Preuss*[3] *and David Heckmann*[3]*, (1)esqLABS, Germany, (2)Bayer AG - Crop Science Division, (3)Bayer AG - Crop Science Division, Germany*

Fluopyram (FLU) is a fungicide and nematicide used in agriculture to control fungal diseases. In birds, it is mainly metabolized to its benzamide metabolite (FLU-benzamide). The purpose of this study was the model-based evaluation of the toxicokinetic properties of FLU in chicken (*Gallus gallus*), mallard duck (*Anas platyrhynchos*) and in bobwhite quail (*Colinus virginianus*) by simulating and extrapolating egg concentrations in different exposure scenarios. Knowing the egg concentrations in the bird reproduction studies is important for understanding the mechanism that underlies the effects of FLU in these studies. A physiologically-based kinetic (PBK) model of FLU was built using the generic bird PBK models developed with the Open-Systems-Pharmacology Suite (OSP Suite with PK-Sim® and MoBi®). The PBK model includes the physiology (e.g., blood flow rates, organ weights) of both the chicken and bobwhite quail and FLU-specific parameters were fitted to residual data in chickens. To characterize metabolization of FLU, *in vitro* measurements of chicken and quail metabolism have been included into the model. To investigate egg concentrations in a non-constant exposure scenario, a pulse of exposure was simulated, opposed to the controlled quail reproduction studies using constant exposure over multiple months, which is often unrealistic when estimating effects in the environment. The pulsed exposure was based on a DT50 that was derived from residue data on insects for FLU. The model was able to predict FLU and its FLU-benzamide metabolite in tissues and eggs. The overall performance of the chicken model was very good and 96% of the simulated data points were within the 3-fold range of the observed data. Overall, toxicokinetic properties were comparable between chicken and quail, despite differences in *in vitro* metabolism. This is explained by blood-flow limitation of liver metabolism. Uncertainties related to data gaps on species-specific properties such as the unbound fraction of compound in plasma, extrahepatic metabolism and active renal excretion remain.
The PBK model predictions are relevant for assessing concentrations that could lead to possible adverse effects on the bird's reproductive performance and offspring. Due to the separation of species- and compound-specific parameters, PBK models are generally well-suited for species extrapolation, as presented in this study.

4.09.P-Th312 Application of Quantitative Structure-Activity Relationships (QSAR) For Physiological-Based Toxico-Kinetic (PBTK) Feed-To-Fillet Transfer Modelling of Contaminants in Feed to Atlantic Salmon

Cathrin Veenaas[1]*, Rudolf Hoogenveen*[2]*, Marco J. Zeilmaker*[2] *and Marc H.G. Berntssen*[3]*, (1)Institute of Marine Research, Norway, (2)National Institute for Public Health and the Environment, Netherlands, (3)Norwegian Institute of Marine Research, Norway*

The European Union has set maximum residue levels for undesirables in feed ingredients and food from animal origin, in order to protect animal health and consumer safety. Physiological-Based Toxico-Kinetic (PBTK) transfer modelling of contaminants from feed to animal food products is an essential component for harmonization of legislation of undesirables throughout the food production chain. Several PBTK models for the prediction of transfer of specific compounds or compounds groups in Atlantic salmon fillet exist already. However, these are largely based on *in-vivo* experimental data. Following these models, the current project aims to develop a generic *in-silico* feed-to-fillet transfer model for feed contaminants by merging *in-silico* methods with the existing PBTK salmon models.
To achieve this, quantitative structure-activity relationships (QSAR) are used for the model parametrization by relating molecular descriptors to the key model parameters. In addition, selected experimental parameters are considered as covariates. One of the key model parameters is the uptake rate. A literature search was conducted to obtain a database of gut absorption efficiencies that is used as a basis to train the model. Different modelling approaches, such as partial least squares (PLS) or machine learning algorithms are used and compared regarding their predictive power.
Preliminary results show that the chemical structure alone can not account for the uptake rate, but experimental parameters need to be taken into account. In addition, main factors of uncertainty that were identified are the limited data availability and as well as biological variability.
The generation of a generic feed-to-fillet model would allow for quick assessment of potential accumulation of feed contaminants in salmon fillet and greatly facilitate assessment of food safety.

4.09.P-Th313 Toxicokinetic and Toxicodynamic Modelling for Non-Monotonic Fluoxetine Toxicity in *Caenorhabditis elegans*

Merel van der Most[1] *and Nico van den Brink*[2]*, (1)Toxicology, Wageningen University & Research, Netherlands, (2)Division of Toxicology, Wageningen University & Research, Netherlands*
With increasing antidepressant prescriptions worldwide, a growing number of organisms is exposed to these pharmaceuticals in the environment. Antidepressants are neuroactive compounds and can therefore induce sensitive behavioural effects that could also propagate effects at a population level. Dose-response relationships of antidepressants sometimes shown non-monotonic patterns. Theories explaining non-monotonicity link to both toxicokinetic and toxicodynamic processes. Therefore, our study aims at developing a toxicokinetic/toxicodynamic (TK/TD) model for the toxicity of the antidepressant fluoxetine in *Caenorhabditis elegans* to gain a better mechanistic understanding of the dose-response relationship over time. Behavioural experiments with a wide range of fluoxetine concentrations were conducted to study the response for three different endpoints: general activity, feeding and chemotactic behaviour. Mono-, bi- and tri-phasic non-linear regression models were applied to test for non-monotonicity. Following this, 24 hour uptake, metabolism and elimination experiments were conducted for fluoxetine and its active metabolite norfluoxetine. A TK/TD model was developed with three compartments: the medium, *C. elegans* and its food source *E. coli*. Results of the behavioural experiments show non-monotonic dose-response relationships for both chemotaxis and activity. Activity was tracked over a 24 hour time period and we observed stabilization of the behavioural effect at 100 mg/l, a recovery at 10 mg/l, but a gradual continued increased effect at 10 ng/l. Results of the uptake, elimination and metabolism experiments demonstrated a rapid uptake of fluoxetine that was further increased when *E. coli* were present. The internal concentration of fluoxetine decreased after 5h (clean medium) or 10h (with *E. coli* present) under constant exposure, likely because of an increasing detoxification rate over time. This could be a reason for the recovery or stabilization of the effect at later time points. These first results indicate possible explanations for non-monotonic responses to fluoxetine, but they can be better interpreted with a TK/TD model. During the conference, we aim to present the results of the TK/TD model. Future experiments will also focus on repeated exposure, to see how both the TK and TD aspects of the model will develop in a more environmentally relevant exposure scenario.

4.09.P-Th314 Evaluating TK Compartmental Models Performance as Predictors of Internal Concentration in Environmentally Relevant Species

Jacob-Joe Collins[1]*, George Fitton*[2]*, Patrik Engi*[3]*, Tymotheusz Pietrenko*[3]*, Alessia Giorgis*[4]*, Joe Reynolds*[3]*, Bruno Campos*[3] *and Claudia Rivetti*[5]*, (1)School of Biosciences, University of Birmingham, United Kingdom, (2)Unilever Research, United Kingdom, (3)Unilever, United Kingdom, (4)Unilever R&D, United Kingdom, (5)Unilever - Safety and Environmental Assurance Centre, United Kingdom*
The large number and variety of chemicals in use today presents a major challenge in determining environmental safety for chemicals while minimizing the generation of new animal toxicity data. One proposed strategy for advancing the pace of environmental risk assessment is to use new methods which allow for higher throughput, including *in silico* and *in vitro*, which are generally referred to as New Approach Methodologies (NAMs). However, NAMs require robust toxicokinetic models, which allow the conversion between internal (at target site) and external (water) levels of chemicals in environmentally relevant species. *Daphnia magna* is a key model organism for ecotoxicology. However, quantitative toxicokinetic data for invertebrates, including *D. magna* are limited, resulting in a lack of robust Physiologically based kinetic / quantitative In Vitro to In Vivo Extrapolation models for invertebrates. Current models are chemical specific – derived by fitting individual chemical data, with restricted application to other chemicals.
This work addresses the current quantitative approach limitations. *D. magna* toxicokinetic study data were collected from 14 studies across 26 chemicals. The *D. magna* study data were standardized and combined with a *P. promelas* and *O. mykiss* specific dataset, containing a further 23 studies across 39 different chemicals.
A cross-species compartment-model based evaluation framework was developed using already well-established modelling concepts. Given the proposed cross-species evaluation framework, we show that concentrations are better predicted in *D. magna*

than in *fish*. This could suggest the simple model is unable to capture the uptake dynamics of a more complicated system like the fish whilst being able to capture the simple diffusion of the chemical into the *D. magna*. Further analysis of the *D. magna* prediction errors suggests that species performance differences are likely driven by the reliance on the octanol-water partition coefficient of the chemical, independent of time-course assumptions and physiological differences between the organisms. Our study shows the ability to generate robust predictions to support environmental safety decisions, not only for *D. magna* but any organism with minimum data requirements, with significant implications for next generation environmental risk assessments.

4.09.P-Th315 A Framework For Algae Modelling in Regulatory Risk Assessment
***Cecilie Rendal**[1], Johannes Witt[2], Thomas G Preuss[2] and Roman Ashauer[3], (1)Syngenta, United Kingdom, (2)Bayer AG - Crop Science Division, Germany, (3)Syngenta Crop Protection, Switzerland*
The use of ToxicoKinetic-ToxicoDynamic (TKTD) modelling in European regulatory risk assessment of plant protection products is rapidly gaining momentum, especially following the endorsement of the European Food Safety Authority (EFSA) in the 2018 opinion on TKTD modelling for use in risk assessment. This document outlines the regulatory context, the general model requirements, and the readiness of a series of established individual models for use in aquatic risk assessment [1]. Despite the fact it does not have a toxicokinetic (TK) component, the Weber et al. model of 2012 for green micro-algae is one of three TKTD models for primary producers that is discussed in the report. The model, also referred to as the SAM-X model, was designed for use in risk assessment of plant protection products (PPPs) to account for the effects of time-variable concentrations. However, the step-by-step workflow to link exposure profiles to risk assessment decisions via algae TKTD modelling has not yet been made clear. We here revisit the SAM-X model to present a modelling framework developed in accordance with the EFSA guidelines for regulatory submissions. We here demonstrate the power of TKTD modelling for use in Tier 2C risk assessment for algae. Based on the generation of a calibration and validation dataset, we were able to simulate over 11 thousand standard OECD TG 201 algae growth inhibition tests. Adhering strictly to the format of the standard test we changed only the concentrations – replacing constant exposures for time-variable exposures defined by FOCUS model outputs. Our implementation of the moving time window neatly avoids any of the issues caused by longer exposure times in algal cultures, such as over-crowding and nutrient stress. This permits us to assess the effects of long exposure profiles without introducing the unwanted complexity of multiple stressors at lower tiers of the risk assessment. We found that the moving time window approach is consistent with risk assessment under tier 1 for cases where the RAC is exceeded for three consecutive days. However, for peaks where RAC is exceeded for shorter durations, the approach offers a suitable refinement option for tier 2C. Our implementation of this modelling framework for the case study chemicals chlorotoluron and isoproturon demonstrated examples of both low risk and high risk for example FOCUS profiles.

4.09.P-Th316 Calibration and Validation of Algae TKTD Modelling for Risk Assessment
*Johannes Witt[1], **Cecilie Rendal**[2], Thomas G Preuss[1], Ian Sims[2], Roger Baetscher[3], Sibylle Eck[1], Jack Rumkee[2], Emily Scorgie[4], Roman Ashauer[3] and Eric Bruns[5], (1)Bayer AG - Crop Science Division, Germany, (2)Syngenta, United Kingdom, (3)Syngenta Crop Protection, Switzerland, (4)Syngenta, Netherlands, (5)Environmental Safety, Bayer AG - Crop Science Division, Germany*
Advances in ToxicoKineticToxicoDynamic (TKTD) modelling have made refinement with models an increasingly recognized option for risk assessors. One of the few TKTD models available for plant species is the SAM-X algae model that, when properly calibrated and validated, can predict algae responses to time variable concentrations of a target compound. The data generation for calibration and validation of this model, however, is not straight-forward. The European Food Safety Authority's (EFSA) opinion on TKTD modelling for use in risk assessment states that "…the largest drawback for implementing [the algae model] in pesticide risk assessment is that the flow through setup used in the existing example and needed to simulate long term variable exposures of pesticides to fast growing populations of algae has not yet been standardised, nor has the robustness of the setup been ring tested." The overall conclusion in the report is that the model therefore, is not yet ready for use in risk assessment. The present work is a direct response to the comments made by EFSA, and we here aim to demonstrate an explicit example of how time-variable data generated from seven laboratories can be used to calibrate and validate the SAM-X model. Further, we aim to demonstrate how we, following the guidance from EFSA, can use modelling to simulate OECD style experiments to extrapolate to longer exposure profiles using the moving time window framework. is modelling exercise is an answer to the comments to the algae model in the EFSA report on TKTD modelling. We provide a thorough evaluation of the data generation methodology, and we scrutinize the robustness of the data throughout the modelling framework – from the early stages of model calibration to the later steps of validation and extrapolation to longer and more realistic exposure profiles.

4.09.P-Th317 An R package for Calibration, Validation, and Effect Endpoint Calculation of Toxicokinetic-Toxicodynamic Models
***Nils Kehrein**, Andre Gergs, Thomas G Preuss and Johannes Witt, Bayer AG - Crop Science Division, Germany*
Toxicokinetic-Toxicodynamic (TKTD) modelling is increasingly used in European regulatory risk assessments of plant protection products, after publication of EFSA's scientific opinion on TKTD modeling. This creates a need for software that allow for quickly and smoothly going through the whole workflow required for regulatory submissions: from model calibration and validation, over effect calculation for exposure scenarios, up to calculation of the respective regulatory endpoints such as LP50 and EP50 values.
We developed an R package that implements the whole workflow for *Lemna*, GUTS and DEB models. Our goal is to ease the handling of TKTD models for scientific as well as for regulatory use cases. Importantly, the workflow implementation is independent of a specific model, thus all TKTD models are handled uniformly. In addition, the intuitive workflows can be extended to use custom models implemented by users of the package.

The model equations are implemented as C code which makes the package computationally efficient and decreases computation time by more than a factor of 1000 compared to pure R code.
We intend to publish the package as Free and Open Source Software to further foster the prosperity of TKTD modeling.

4.09.P-Th318 How to Include Temperature in Mechanistic Effect Models

Annika Mangold-Doring[1]*, Andreas Focks*[2]*, Paul van den Brink*[1] *and Egbert van Nes*[1]*, (1)Wageningen University & Research, Netherlands, (2)Institute of Mathematics, University of Osnabrueck, Germany*

Temperature is a natural variable, never constant under field conditions. And as global climate change continues, extreme temperature events are expected to increase in frequency. Therefore, prospective environmental risk assessment needs to consider the potential influence of those changing temperature conditions on pesticides' toxicity. For this, the variation of temperature should be considered in mechanistic or process based models like toxicokinetic-toxicodynamic (TKTD) models for chemicals. There are two different ways to include the influence of temperature on chemical effects. Firstly, temperature can be interpreted as a modulating factor, influencing the TKTD processes of the chemical. Secondly, temperature can be approached as an individual stressor, in addition to the chemical stress. Even though in reality, it might be a combination of both, looking at these two different approaches separately will help to understand the mechanisms of the combined stressors, chemicals and temperature. Temperature has been successfully included in TKTD models as a modulating factor via the Arrhenius equation, however, with limiting applicability regarding temperature conditions outside of the thermal tolerance of the organism.
To explore how to include those extreme (i.e., stressful) temperatures, we developed a module that allows to include temperature as a separate stressor in TKTD models for chemicals. We translated the damage model as used for chemical effects in the General Unified Threshold model of Survival (GUTS), to a damage model for the effects of temperature. We will present the assumptions and mathematical approach of this model and test its performance to predict experimental data. Furthermore, we implemented the new temperature damage model in the mixture GUTS framework to assess the survival of combined exposure to a temperature and a chemical stressor.

4.09.P-Th319 Has GUTS-RED Still Too Many Parameters? Comparing Data Explainability and Parameter Robustness of GUTS Variations for Arthropods

Leonhard Urs Bürger[1] *and Andreas Focks*[2]*, (1)Systems Science Group, Institute of Mathematics, Germany, (2)Institute of Mathematics, University of Osnabrueck, Germany*

The General Unified Threshold Model of Survival (GUTS) of Jager et al. (2011) managed to unify many existing toxicokinetic-toxicodynamic (TKTD) models into a consitent framework to analyse stressor impacts on individual survial based on laboratory test data. Using the full GUTS model requires internal concentrations, making its usage unfeasible in many cases. Two reduced GUTS variations (GUTS-RED-SD & -IT) emerged as models of choice to analyse standrad ecotoxicological data sets, covering only external stressor concentration and animal survival. These reduced models use four parameters to “learn” the link from external stressor to death from data by using an internal “damage” as substitute for actual stressor concentrations. Data explainability is good in many use cases, making GUTS ready to be used for regulatory risk assessment according to EFSA (2018). However, resulting parameter values tend to correlate strongly with each other and are thus neither interpretable in their absolute values nor robust. Robustness could be defined as when parameter values emerge from similar datasets with identical or very similar values., When refitting GUTS to slightly altered input data, the fits look comparable, while often using a completely different set of (absolute) parameter values. With a robust set of parameters the values would not change significantly when the datasets are near comparable.
Performance in terms of model accuracy and parameters robustness of the two GUTS-RED models is therefore compared to other variations of GUTS. Potential variations include for example using the external concentration directly as dose metric for the death mechanism. Other variations are generated by fixing individual parameters in the model. Parameter robustness is quantified by refitting the model to resampled datasets. All considered GUTS variations are compared based on data for different pesticide stressors and arthropod species to identify the most suitable GUTS variations concering data explanation and robustness. First results suggest that varations with three parameters reach a comparable model accuracy, while showing a higher robustness and better model selection parameters like the Akaike information criterion.

4.09.P-Th320 DEB Modelling of Anuran Amphibians for Setting a Normal Operating Range for Metamorphosis Duration

Carlo Romoli[1]*, Benoit Goussen*[1]*, Erik B Muller*[1]*, Joachim Kleinmann*[2]*, Adric D. Olson*[3]*, Lennart Weltje*[4] *and Pernille Thorbek*[2]*, (1)ibacon GmbH, Germany, (2)BASF SE, Germany, (3)BASF Corporation, (4)Ecotoxicology, BASF SE, Germany*

Amphibian tests, required by EFSA (OECD TG 231, 241, 248) are aimed at characterizing the thyroid axis, which is known to affect metamorphosis in amphibians. However, metamorphosis in amphibians is well known to be a plastic process and amphibians change rate of metamorphosis in response to various environmental stressors. This means the speed of metamorphosis from tadpole to froglet is a trade-off between fast development and size of the froglet. Specifically for anuran species that depend on fish-free, and hence often non-permanent water bodies, metamorphosis is necessary to be completed before the water body dries up. In such cases the tadpole trades the risk of death due to lacking the necessary adaptations to live on land when the pond is dried up against a small size at metamorphosis and co-occurring selective drawbacks (e.g. higher risk of desiccation or being predated upon).
EFSA has used models to assess the normal operating range (NOR) of natural dynamics, e.g. for honeybees. Here, we use an adapted DEB model to assess the normal operating range of plastic processes under different environmental conditions.
Mechanistic modelling is gaining importance in the field of ecology and ecotoxicology. Models based on the dynamic energy budget (DEB) theory are becoming the standard for the assessment of stressors on sublethal endpoints (e.g., size, mass, etc.).

However, the currently available DEB models for amphibians are not suitable for this purpose as they lack a specific treatment of the metamorphosis process and adaption. Consequently, they cannot simulate the plasticity regarding various stressors. Here we propose a robust and general model that can describe amphibian metamorphosis within the DEB framework by incorporating modules inspired by the DEB modelling of holometabolic insects (that also undergo metamorphosis). This implementation allows the qualitative and quantitative description of the size changes of the tadpoles under normal conditions and the effects that stressors may have in modifying development. We show examples of model calibrations for anuran species native to Europe and for the African clawed frog, *Xenopus laevis*, a species widely used in laboratory testing.

4.09.P-Th321 Building Dose-Response Relationships from Standard Rat Toxicity Studies With DEB-TKTD Models
Karel Viaene[1]*, Karel Vlaeminck*[2]*, Roman Ashauer*[3]*, Nika Galic*[3]*, Andre Gergs*[4]*, Trung-Hieu Mai*[5]*, Thomas G Preuss*[4] *and Pernille Thorbek*[5]*, (1)ARCHE, (2)Ghent University, Belgium, (3)Syngenta Crop Protection, Switzerland, (4)Bayer AG - Crop Science Division, Germany, (5)BASF SE, Germany*
Most studies used for setting endpoints for wildlife risk assessment of small mammals are performed primarily for human toxicology, where the aim is to set no observed effect levels (NOEL). Approaches based on dose response curves (DRC) are currently the standard for analysing such studies e.g., the recently updated benchmark dose (BMD) approach guidance by EFSA. However, in order to determine an accurate NOEL, the design of these studies is skewed towards more replicates at low doses rather than including more, higher doses, which would benefit the application of DRC. Additonally, DRC approaches have inherent limitations: they are applied to only one endpoint, only for the most relevant time point and extrapolation is based purely on a statistical relationship, disregarding any links with underlying mechanistic hypotheses or theories.
Dynamic Energy Budget (DEB) models, coupled with Toxicokinetic-Toxicodynamic models (DEB-TKTD), are recognized as an novel tool for risk assessment. DEB-TKTD models approach toxicity from a physiological/metabolic perspective, which allows better quantitative predictions due to a mechanistic understanding of toxicity. The DEB-TKTD framework allows simultaneous calibration on multiple endpoints over time (typically survival, growth and reproduction), which increases the biological relevance of the toxicity predictions and could lead to more robust effect levels based on data for low dose levels in the toxicity studies. The aim of this study is to explore whether DEB-TKTD modelling can be used to establish dose-response relationships for use in risk assessments and highlight their advantages over DRC approaches.
Existing (sub)chronic toxicity studies (i.e., 90-day and 2-generation studies) on the rat (*Rattus norvegicus*) were used to parameterize a DEB-TKTD model. Control treatments were used to calibrate the physiological (DEB) part of the model. After accounting for the effect of toxicant-induced reduction of feeding, the most appropriate physiological mode of action (PMoA) was determined. Growth and reproduction data in the treatments were used to derive the most approriate PMoA. Finally, effect levels for the studies were derived using both the DEB-TKTD model and the BMD approach and the accuracy and uncertainty of both approaches were compared. The outcome of this comparison is used to discuss the advantages and challenges of both approaches as a tool for environmental risk assessment.

4.09.P-Th322 Analysis of Sublethal Effects of Pyraclostrobin in Mysid Shrimp (A*mericamysis Bahia*) Using a DEB-Based TKTD Model
Josef Koch[1]*, Natalie Carmen Dallmann*[1]*, Kim Rakel, MSc Ecotoxicology RWTH University*[1]*, Tido Strauss*[1]*, Lennart Weltje*[2] *and Pernille Thorbek*[3]*, (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Agricultural Solutions - Ecotoxicology, BASF SE, Germany, (3)BASF SE, Germany*
Pyraclostrobin is a widely used fungicide from the class of strobilurins. In this study, we refine the chronic risk assessment for aquatic invertebrates, by using a quantitative effect model for pyraclostrobin and mysid shrimp (*Americamysis bahia*). At its core, the effect model represents a DEB model which is complemented by a TKTD module, accounting for lethal and sublethal effects. Experimental data from one acute and two chronic studies were used to calibrate and validate the model. Besides effects on survival, both chronic studies showed effects on growth and reproductive output of the mysids. For the unstressed DEB model, a model entry for *A. bahia* in the *Add-my-Pet* online repository served well, since it matched the experimental control data with high accuracy. Survival effects were modelled using a stochastic death model, whereas sublethal effects were captured best using a linear effect-above-threshold assumption for both the energetic costs for somatic maintenance and the costs for creating new eggs. While the sublethal effect data used for the model validation were adequately reproduced by the model with a slight tendency to effect overestimation, effects on survival were clearly overestimated by the model. This discrepancy, however, follows directly from a mismatch between the calibration and validation data originating from different studies. Nevertheless, considering the consistent overprediction of adverse effects, the model is conservative.
In a final step, we used the model to simulate the life cycle of mysids with realistic exposure profiles using a moving-time-window (MTW) approach. This method allows identification of the most adverse exposure window per profile, resulting from a critical combination of endpoint-dependent life-stage sensitivity and timing and magnitude of exposure. We then determined exposure multiplication factors that would result in a 10% effect on the most sensitive endpoint (here: reproduction) in the most critical window of each profile (EP_{10}). All EP_{10}-values for the relevant scenarios were above 10, indicating low risk for the proposed application pattern, including some additional risk mitigation measures such as drift reducing nozzles and/or buffer zones. In summary, we were able to demonstrate that a combination of laboratory experiments and mechanistic effect modelling can be used to aid environmental risk assessment in a meaningful way.

4.09.P-Th323 What Mechanistic Effect Models Can and Cannot Tell Us About the Variability in the Real World
Nika Galic[1]*, Roman Ashauer*[1]*, Andre Gergs*[2]*, Mattia Meli*[3]*, Stephan Partsch*[4]*, Thomas G Preuss*[2] *and Pernille Thorbek*[5]*, (1)Syngenta Crop Protection, Switzerland, (2)Bayer AG - Crop Science Division, Germany, (3)ADAMA, France, (4)FMC*

Agricultural Solutions, Germany, (5)BASF SE, Germany
Mechanistic effect models (MEMs) are increasingly used to support ecological risk assessments of plant protection products (PPP). The European Food Safety Authority (EFSA) has been supporting the developments of these important tools by providing several scientific opinions as well as public reviews of specific mechanistic effect models. Most recently, EFSA issued an opinion on background variability, based on the honey bee colony model BEEHAVE, an important aspect providing context for determining acceptable effects from exposure to PPPs. Models are in many cases calibrated and validated to represent average system behaviour and are thus not designed to make predictions on the variability of system behaviours. The exciting possibility to apply MEMs to determine normal operating ranges requires a thorough understanding of the variability implemented and observed in MEMs, namely its causes, its ranges, and how it compares to empirical observations as well as a definition of relevant spatial and temporal scales. Finally, a model's defined domain of applicability needs to be considered. It is currently still unclear how much variability can and should be represented in mechanistic effect models relative to what is observed in empirical systems as well as how well models can explain observed variability. To this end, we investigated models used within the PPP risk assessment arena, that accounted for sources of variability and that were validated with empirical data from lab and field experiments. We found that variability in control conditions was caused more often by parameters based on observed data and rarely by generic stochastic implementations. Model output generally showed less variability than the empirical data used for validation and the difference was especially visible when field data were used. Models were also successfully applied to explore the causes of variation in empirical data. As recommended by EFSA in their Scientific Opinion on good modelling practice, it is important to assess whether a given problem lies within a model's domain of applicability. Furthermore, there are other methods available which have been used for uncertainty analysis and probabilistic risk assessment (e.g., WEBFRAM, EUFRAM). In summary, when setting normal operating range of an empirical system then empirical data, MEMs, and non-mechanistic probabilistic methods should all be evaluated.

4.09.P-Th324 Endocrine Disruption: How to Perform a Hazard Assessment with Population Models?
***Alice Tagliati**[1], Charles Hazlerigg[1], Thomas G Preuss[2] and Laurent L.-M. Lagadic[2], (1)Enviresearch, United Kingdom, (2)Bayer AG - Crop Science Division, Germany*
Regulation 1107/2009 states that agrochemicals identified as Endocrine Disruptors (EDs) are banned for use in the EU. The ED identification criteria defined in Commission Regulation (EU) 2018/605 rely upon a hazard assessment. For non-target organisms, to be identified as an ED a substance must result in an adverse effect on a population as the result of an endocrine-mediated mechanism. Critically, adverse effects are commonly reported on individuals (e.g. fecundity in Fish Short Term Reproduction Assay) and so a method is required to extrapolate from the organism level to that of the population. Population modelling is one such method, however, ECHA-EFSA (2018) state that "…*generally these models are more suitable for risk assessment purpose…*" but provide no guidance on how such a method should be used in the context of EDCs.
We present the results of two modelling approaches that are consistent with the concept of a hazard assessment. In one, we do not consider exposure at all, effectively performing a sensitivity analysis on ED-relevant endpoints at a range of effect magnitudes over a period of 10 years. For this, we used three fish population models, the endpoints sex ratio, fecundity, fertilisation rate, growth and behaviour, with a range of effect magnitudes of 10, 20, 50 and 90%. We performed modelling for each endpoint individually and in combination. In the second, exposure is taken into account using regulatory fate models to predict concentrations in the environment following the proposed use of a product. In this instance, we identify an effect-threshold, above which effects are imposed and below which no effects are imposed. This threshold was based on the lowest NOEC from all available ED-relevant studies with the substance. This is still a hazard assessment, but the threshold is not 0 as in the first approach. This makes more use of the available data on a molecule and its proposed use and is justified for regulatory use as the Regulation 1107/2009 states that "*negligible exposure*" is acceptable.
We propose that these two modelling approaches could be used in conjunction with one another: the first method based on simple look-up tables as a screening assessment and the second method as a higher tier refinement making full use of the substance-specific data package.

4.09.P-Th325 Simulating Life-Cycle Toxicity in Chironomus Riparius With Realistic Dynamic Exposure Profiles and Variable Temperatures Using a Moving-Time-Window Approach
***Natalie Carmen Dallmann**[1], Josef Koch[1], Tido Strauss[1], Maxime Vaugeois[2] and Nika Galic[3], (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Syngenta Crop Protection, (3)Syngenta Crop Protection, Switzerland*
Insecticides are applied to treat many crops all over the world. Freshwater aquatic invertebrates are often identified at risk regarding exposure to insecticides from agricultural runoffs, with chironomids identified as one of the most sensitive taxa. To better quantify the chronic toxicity of a neonicotinoid insecticide in chironomids, we calibrated an individual-level mechanistic effect model for *Chironomus riparius*, which accounts for both time-varying temperature and insecticide concentration.
We used this recently developed model to simulate *C. riparius*'s life cycle with realistic exposure profiles and variable temperatures using a moving-time-window (MTW) approach. In this approach, a species' life cycle is repeatedly simulated, each time with a slightly shifted starting point in the exposure profile. This method is particularly relevant when the life cycle of a test organisms is shorter than existing exposure profiles used in risk assessment. It allows to determine the most adverse exposure window, resulting from a critical combination of (endpoint-dependent) life-stage sensitivity and (timing and magnitude of) chemical exposure. Besides the individuals' survival, their growth, time until emergence, and potential reproduction were assessed as endpoints. While the duration of each life-cycle simulation is typically set to a fixed length (mimicking a real-life experiment), in this study, the durations were corrected to account for temperature-dependencies in physiological rates, i.e., the time window corresponded to a physiological state, rather than the length of a regulatory experimental study. This resulted in

shorter windows at higher temperatures. Furthermore, while MTW simulations have so far been used in automated routines to seek out exposure multiplication factors (EMFs) resulting in a pre-defined effect strength, analogous to summary statistics like EC_X, recent research has raised concerns to this approach in cases where non-monotonous relationships exist between EMFs and the endpoint of interest. Therefore, in this study we created comprehensive EMF–effect profiles for each endpoint to determine critical EMFs in a more robust way.
With this study, we have contributed to the further development of the MTW approach, which is a highly valuable approach for ecological risk assessment of agricultural chemicals.

4.09.P-Th326 Environmental Risk Assessment at Landscape Level – Open Questions
Roman Ashauer[1]*, Andre Gergs*[2]*, Nika Galic*[1]*, Mattia Meli*[3]*, Stephan Partsch*[4]*, Thomas G Preuss*[2]*, Pernille Thorbek*[5] *and Carola Schriever*[5]*, (1)Syngenta Crop Protection, Switzerland, (2)Bayer AG - Crop Science Division, Germany, (3)ADAMA, France, (4)FMC Agricultural Solutions, Germany, (5)BASF SE, Germany*
Environmental risk of pesticides depends on the landscape under consideration. Through ecological modelling at landscape-scale we can devise holistic strategies for how to manage agricultural landscapes to optimize across ecosystem services whilst considering all relevant factors. What is unclear is how protection goals can be operationalized for decision making in a landscape level risk assessment.
Landscape level risk assessments require definition of the baseline scenarios against which the impact of an added stress factor like pesticides can be measured, including: spatial and temporal scale, landscape structure and composition, land use, natural factors (soil, weather, flora and fauna, habitat structures and sizes), agronomic practices, land management, risk mitigation and crops. Other stressors, natural and man-made, as well as their intensities and durations, need to be clarified. To some degree these baseline scenarios could be generalized, which means we would not need infinite numbers of scenarios for all combinations of species, crops and landscapes.
Ecological consistency needs to be maintained in the definition of scenarios, for example as to the type of plant communities potentially in the vicinity of fields where a certain crop could be grown or which data sets for soil, water bodies, land-use and climate are appropriate. Combined spatially distributed exposure and ecological modelling could track the exposure experienced by organisms and inform effect models predicting population dynamics. Baseline scenarios could also represent organic farming practices to compare with conventional farming or integrated pest management approaches. Endpoints for environmental risk assessment at landscape scale would differ from lower tiers but it is not clear which ones are meaningful and how they should be assessed.
There is an opportunity to use landscape level environmental risk assessment to also explore different agronomic management options, including non-pesticide related options (e.g. tillage vs. no till), the effectiveness of different mitigation options, alternative agricultural practices and landscape management options. Most importantly, landscape level risk assessment enables a more realistic and ecologically relevant risk assessment, for example by considering effects of other stressors (e.g. diseases, agronomic practices, land management). It may be possible to introduce landscape level risk assessments in a stepwise manner.

4.09.P-Th327 Assessing Ecological Risk from Mercury Exposure Across the South Florida Landscape from the freshwater Everglades to Coastal Marine Waters
Darren G Rumbold*, Florida Gulf Coast University, USA*
Mercury (Hg) was first recognized as a problem in Florida's freshwater Everglades in the late 1980s. The first fish consumption advisory was issued in 1989. It did not take long, however, to recognize that the problem extended beyond the freshwater marshes out through the estuaries and into south Florida's coastal waters. The first advisory for marine waters, issued in 1991, urged individuals to limit their consumption of sharks. Over the next 30 years, research on Hg biogeochemistry focused mainly on the freshwater Everglades. Several ecological risk assessments (ERAs) done during this period focused exclusively on the freshwater system, primarily because of the concern that efforts to restore the Everglades could worsen the problem. Hg levels have declined in certain areas of the Everglades but hotspots remain with tissue residues in 2021 still exceeding 3 ppm in some fish and 7 ppm in some reptiles. Much of the system remains under limited or no fish consumption advisories. Moreover, declines have not been observed in the marine environment with over 60 species of recreational or commercially important fish species currently under advisories. Hg concentrations as high as 4.5 ppm have been reported in sharks and as high as 42 ppm in feathers from nestlings and 96.5 ppm from adult ospreys (*Pandion haliaetus*). This presentation synthesizes data from both state-run monitoring programs and academic studies to characterize the risk to various taxa (e.g., fish, birds, reptiles, mammals) across south Florida's landscape using three lines of evidence (LOE): 1: based on fish-tissue Hg concentration as the media of exposure; 2: based on tissue residues within the ecological receptors and, 3: based on eco-epidemiological wildlife surveys. Together these LOEs suggest that biota in certain regions of south Florida continue to be exposed to levels of Hg that pose a threat. While eco-epidemiological wildlife surveys of Hg impact on health were the most direct method to assess risks, they were rare. Government agencies frequently monitor Hg in various media (often in support of consumption advisories for human health protection); however, they traditionally do not explicitly look for effects. Unfortunately, without improved estimates of the frequency of these sublethal responses and the probability of ecological mortality, risks go underappreciated by resource managers who may view any uncertainty as justification for taking no action.

4.09.P-Th328 Food and Density Dependence in *Chironomus riparius* (Diptera: Chironomidae): Laboratory Experiments To Inform Population Modelling
Tido Strauss[1]*, Jana Gerhard*[1]*, Daniel Gerth*[1]*, Josef Koch*[1]*, Maxime Vaugeois*[2] *and Nika Galic*[3]*, (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Syngenta Crop Protection, (3)Syngenta Crop Protection, Switzerland*

For ecological risk assessment of anthropogenic stressors, individual-based population models are an effective tool to extrapolate from effects observed on individuals in laboratory experiments to populations exposed under field conditions, integrating different environmental influences on the physiology and population dynamics of a species.
In addition to many dynamic environmental parameters, the capacity of populations in the field is often determined by density-dependent processes, which must be implemented and parameterised for a realistic simulation of population dynamics. However, mechanisms driving density depence in populations are not always known. Here we present results on the study with the dipteran species *Chironomus riparius*, for which density dependence experiments were conducted in the laboratory. Data on the impact of different food concentrations and larval densities on developmental rate, hatching success, reproductive performance, and larval mortality were collected. Experiments with different food quantities per individual were used to reflect the effects of fluctuating food supply in the environment as well as exploitative competition between individuals, while direct density-dependent interactions were analysed with experiments where food availability per individual was held constant, but systems contained different densities of individuals.
The experimental results were used to parameterise an individual-based population model for *Chironomus riparius*, whose physiological dynamic energy budget (DEB) module had previously been calibrated with laboratory data. This population model, which is also a sub-module of the ecosystem model STREAMcom, was then validated using field data at the population level. The lack of robust data on population regulation and relevant loss rates of larval and adult stages in the environment are often the biggest data gaps in population modelling of non-target organisms in the field. Reducing the uncertainty in the processes of density-dependent development and mortality rates will facilitate calibration of the remaining data gaps and help increase confidence in applying such population models to more realistic environments, such as aquatic outdoor mesocosm studies, for ecological risk assessment.

4.09.P-Th329 DEB-IBM-Based Population Modelling of the Non-biting Midge *Chironomus riparius* (Diptera: Chironomidae)

***Jana Gerhard*[1]*, Josef Koch[1], Maxime Vaugeois[2], Nika Galic[3] and Tido Strauss[1], (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Syngenta Crop Protection, (3)Syngenta Crop Protection, Switzerland*

Population models are powerful tools for predicting species population dynamics for different environmental scenarios under consideration of natural and anthropogenic stressors, and have been increasingly used in ecological risk assessment, often coupled with TKTD effect models.
Here we present a model concept for simulating populations of a species of non-biting midges, *Chironomus riparius,* with the aim of extrapolating ecotoxicological laboratory data to field scenarios. This concept combines individual-based models (IBMs), based on physiological dynamic energy budget (DEB) modules and complemented by toxicokinetic-toxicodynamic (TKTD) effect models for lethal and sublethal processes, driven by dynamic environmental conditions. The core of the model is an individual DEB-TKTD model that has been calibrated for individual life cycles using laboratory tests at different temperatures. This population model is also a sub-module of the ecosystem model STREAMcom, which simulates benthic macroinvertebrate communities in lentic and lotic water bodies and is currently used to model communities in aquatic mesocosms.
In developing such complex models, simplified assumptions have to be made about the relevant processes in population dynamics to be represented in a model concept. In addition to external factors such as weather conditions and food availability, population dynamics relevant processes such as feeding behaviour, larval background mortality, and adult loss rates in the field due to dispersal or predation need to be considered. While physiological modules or effect models such as the TKTD model GUTS are at least conceptually easy to parameterise with laboratory data, it is much more challenging to quantify relevant processes at the population or ecosystem levels, such as density-dependent growth and reproduction, or food availability, which ultimately determine the dynamic capacity of the population throughout the year.
We present a modular model framework for a *Chironomus riparius* population model and discuss strategies for model structure development and parameterisation, also in the context of available field data for calibration and validation. We also present model analysis and discuss how those can be used to inform model development.

4.10 New Approaches, Methodologies and Policies in Environmental and Human Health Risk Assessment

4.10.P-Tu354 Characterization of Microplastics in Beach Sediments Points to the Need for a Precautionary Approach to Plastic Use

***Ebin Johnson*[1]*, Ashwini Suresh Kumar[2] and George Kuttiparichel Varghese[2], (1)Civil Engineering, National Institute of Technology Calicut, India, (2)National Institute of Technology Calicut, India*

Data on the harmful effects of microplastics (MP) are not fully available and there is a need to control the microplastic pollution. Characterization of microplastics helps in understanding the impacts of these emerging pollutants on the environment and helps in executing the most effective reduction measures. It is important to formulate and adopt suitable environmental forensic techniques to track the pollution. Environmental forensics helps in identifying the pathways and sources of pollution which is required for implimenting the control strategies. Existing frameworks on sampling and analysis of plastics and MP in marine environment were studied in detail. Field investigations were carried out on the coast of Kerala, India, following the existing guidelines with appropriate improvisations to respond to the specific requirements of forensic application. From the analyses results and the experience gained from the site sampling, forensic site investigation protocol was devised for MP contaminated site. The forensic investigation strategy developed was capable of tracking down the sources of a significant portion of MP sampled from the strandline. From the forensic analysis carried out on the MP sampled from Kerala coast, various sources of MP that are either least useful or can be easily eliminated were identified. A microplastic pollution control strategy targeting the easily addressable sources is expected to be more efficient, both in terms of resources spent and public acceptance. The protocol developed in the study helps to regulate the MP pollution by applying precautionary principle.

4.10.P-Tu355 Importance Of Precautionary Approach In Massive Firework Display Releases- A Case Study From Kerala, India

*Bindu A. Gopalakrishnan[1], **PREM Mohan**[2] and George Kuttiparichel Varghese[2], (1)CIVIL ENGINEERING, National Institute of Technology Calicut, India, (2)National Institute of Technology Calicut, India*

Fireworks displays (FWD) which are an integral part of many festivals, releases highly hazardous and toxic chemicals to the atmosphere resulting in air pollution leading to severe risks to human health and the ecosystem. The final deposition of these elements on soil and subsequent migration to the subsurface and to groundwater aggravates the issue. It is important to conduct forensic studies to fix the share of FWD to the air quality deterioration during festival seasons and to analyse the illegal use of banned chemicals in the fireworks. A precautionary approach is important in the forensic analysis of such environmental crimes. The air quality due to various activities of the festival, including the massive fireworks display during 2019 episode of *Thrissur Pooram*, a world-renowned festival of Kerala, India, where millions of people gathering to witness the festivities, is taken as a case study to analyse the impacts of FWD releases and other festival related activities. In addition to the monitoring of the parameters PM, SO_2 and NOx, chemical speciation of the air samples was carried out to check the presence of banned chemicals in these samples. High concentrations of PM_{10}, SO_2, NO_x and metals were observed in the air on these days compared to the normal values for the city on non-festival days. alysis of air samples collected after 18 hours of FWD showed a declining trend for the pollutants. The elements that have shown significant increase in concentration after the FWD- Al, B, Ba, Ca, Fe, K, Li, Mg, and Zn- are the ones used in fireworks as colourants, fuel, oxidiser, chlorine donor, etc. Si e the vehicular traffic and all other commercial activities were stopped in the nearby area during the festival days, and there is no industry in the locality that could have contributed these metals, it is reasonable to report that it is contributed by the FWD and the soil particles. Sb, Li, Hg, As, Pb, Ba and strontium chromate found in the analysis were chemicals banned for use in fireworks by the Honourable Supreme Court of India. Hence these metals can be considered as the indicators of blatant violations of the orders issued by the Court and of the precautionary principle. Safety of the people is very important as hundreds of thousands of people assemble to witness the festivities. The study points to the need for research to generate new and economic formulations for fireworks that are green and safe, strictly adhering to the precautionary principle.

4.10.P-Tu356 A Forensic Investigation of a Contaminated Land at Kerala, India

*Lakshmi Priya[1], George Kuttiparichel Varghese[2] and **irfan Khursheed Khursheed Shah**[3], (1)Civil Engineering, National Institute of Technology Calicut, India, (2)National Institute of Technology Calicut, India, (3)Environmental Science, Higher Education, J&K Government, India*

Contamination of the natural environment has been viewed more seriously ever since its impact on human health became clear and quantifiable. This has lead to multitudes of legislations getting enacted in different countries for conserving and protecting the natural environment. An underlaying principle of most of these legislations is ‘polluter pays’. However, to make the polluter pay for the damages caused to the environment, the responsibility needs to be fixed to the satisfaction of the country’s legal system. Environmental forensics provides with a systematic scientific approach for fixing liability in a pollution episode. In this study, the forensic investigation of a contaminated land, Kuzhikandam, Ernakulam district of Kerala, India is reported. The major industries operating near the site were identified. The samples were collected from the site according to the guidelines provided by Unites States Environmental Protection Agency. The samples collected from the site as well as the industrial outlets were analysed to check the presence of heavy metals and organic compounds. The concentration of heavy metals and organic compounds at the contaminated site were higher than the corresponding background soil concentrations indicating the site to be highly contaminated. The presence of DDT (Dichlorodiphenyltrichloroethane) was found in the samples from the site. Iron, Nickel, Copper, Zinc, Chromium and Lead were found in the site as well as in the outlets of the industries, indicating that they may be contributed by any of the identified industries. Similarly, Endosulfan and HCH (Hexachlorocyclohexane) was found at the site. The sampling results of site were also compared with world shale average. All contaminants except for Zinc and Lead were lower than the world shale average. The extent of contamination and possible sources of contamination are identified. The results of the investigation can be used for assigning remediation liability among the polluters.

4.10.T-01 The Application of the Precautionary Principle in European Union Waste and Chemicals Regulation From a Material Circulation Perspective

***Mirella Miettinen**[1] and Joonas Alaranta[2,3], (1)Law School, University of Eastern Finland, Finland, (2)Registry of the Board of Appeal of the European Chemicals Agency, (3)University of Eastern Finland, Finland*

Both the EU waste and chemicals regulations are based on the precautionary principle (PP). The main objective of the chemicals regulation is to protect human health and the environment from the risks posed by hazardous chemicals. The modern waste regulation promotes, among other things, the recovery of waste. These material circulation aims have recently been reinforced by the introduction of ambitious circular economy (CE) targets. Balancing between the material circulation objectives and the safety objectives is the main dilemma of the precautionary regulation of the material circulation.

We examined the role of the PP in balancing the material circulation objectives and the safety objectives in EU waste and chemicals regulation. We analysed the relevant case law, discussed the role of scientific uncertainty in the precautious regulation of risks, and proposed a classification of risk problems in the CE.

The European Court of Justice (ECJ) and the General Court have applied the PP in several cases concerning restrictive measures on hazardous chemical substances. This has led to, for example, allowing the identification of substance as a Substance of Very

High Concern under REACH in the existence of uncertainties as regards the determination of safe level of exposure to that substance. In waste regulation, the ECJ has pointed out that special precaution must be taken as regards the potentially hazardous nature of the production residues that are intended to be recovered.
Application of the PP involves deliberation on a range of normative dimensions, for example, the determination of the chosen level of protection. Risk problems of the CE, classified as simple, complex, uncertain, ambiguous and purely hypothetical, also include diverse values on how to deal with a specific risk. The PP does not apply to purely hypothetical risks, nor does it apply to simple risk problems. Our analysis highlighted uncertainties related to decision-making in ambiguous risk problems. They may result from complexity or weak knowledge about the underlying phenomena, leading to interpretative ambiguity, but also to the need to balance different values (normative ambiguity) and environmental impacts in the decision-making.
The dilemma can only be solved by balancing risks and benefits and reconciling different objectives through an analysis that gives due weight to different types of risk problems and their associated uncertainties and ambiguities in an inclusive discourse.

4.10.T-02 Uncertainty and precaution in waste management: experimental assessment of the variability generated by waste sampling for classification and disposal
***Giovanni Beggio**[1], Michele Cattelan[2], Alberto Pivato[1], Francesco Trevisan[2] and Gianvittore Vaccari[2], (1)University of Padua, Italy, (2)Veneto Acque S.p.A.*
In the field of waste management, decisions made upon uncertain characterization data could lead the involved actors to be improperly charged, e.g., for incorrect waste classification. This forces waste managers to adopt overprecautionary measures influencing significantly the economic sustainability of their projects. To address this trend, in determining whether legal limits are exceeded, environmental forensics should take into account the data uncertainty upon which decisions are made. Uncertainty can be quantified by the variability (i.e., variance) of data generated by the materials characterization process. It is now recognized that this variability is mainly determined by the performed sampling procedures, while a minor role is played by the consolidated analytical techniques. A powerful tool to assess the total variability is represented by the so-called Replication Experiments (RE). By replicating the sampling performance in “fully nested experiments”, RE allow to calculate the value of the generated total variance together with its components (i.e., sampling and analysis), through nested ANOVA perfomed according to the applied experimental design. Whether these experiments are often included in QA/QC procedures for goods production, no examples can be found in the scientific literature about the application of RE on waste characterization.
As first of his genre, this work shows and discusses the results of a RE applied to evaluate the efficiency of the sampling phase defined within a characterization plan aimed at classification of mineral industrial waste. The case history is related to a remediation and disposal, funded by Veneto Region, of about 44,000 tonnes of waste of unknown origin, illegaly stored in a 11,200 m^2 former industrial building located in the province of Padova, NE Italy.
The total variability of the majority of the investigated parameters was generated by spatial variability, thus supporting the criteria applied for the classification of waste in different, spatially grouped, lots. Sampling variability contributes could be acceptable for most parameters measured in the solid samples with one exception (Mn), while eluates showed rather higher values, mainly in terms of DOC.
These results provide forensic scientists a scientifically sound tool to better interpret possible non compliance judgments, based on single concentration values, derived from the analysis of the materials investigated during subsequent investigations.

4.10.T-03 Vinyl Chloride Enhances High Fat Diet-Induced Proteome Alterations in the Mouse Pancreas Related to Metabolic Dysfunction: Implications for Individual Susceptibility
***Yue Ge**, Maribel Bruno, Maliha Nash and Brian Chorley, U.S. Environmental Protection Agency*
Alterations in physiological processes in pancreas have been associated with various metabolic dysfunctions and can result from environmental exposures, such as chemicals and diet. It was reported that environmental vinyl chloride (VC) exposure, a common industrial organochlorine and environmental pollutant, significantly exacerbated metabolic-related phenotypes in mice concurrently fed high-fat diet (HFD) but not low-fat diet (LFD). However, little is known about the role of the pancreas in this interplay, especially at a proteomic level. The present study was undertaken to examine the protein responses to VC exposure in pancreas tissues of C57BL/6J mice fed LFD or HFD. We demonstrated that VC-induced pancreas proteome changes were largely linked to metabolic processes in the pancreas that can contribute to diabetes and other facets of metabolic syndrome, such as insulin production and beta cell proliferation e.g., decorin, insulin-like growth factor-1, periostin, phosphorylated protein kinase B (pAKT) and phosphorylated glycogen synthase kinase 3 β. In addition, pancreatic proteins altered by HFD were also augmented by VC exposure compared to mice fed LFD. This result suggested that VC exposed mice might be more sensitive to adverse impacts of HFD. These data suggest that environmental toxicant exposures, such as occupational exposures to VC, may lead to individual susceptibility to adverse metabolic consequences in the pancreas due to dietary choices.

4.10.T-04 Characterizing Genetic Susceptibility in Populations Vulnerable to Pesticide Exposures
***Marissa B Kosnik**[1], Philipp Antczak[2] and Peter Fantke[3], (1)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Dübendorf, Switzerland, (2)Centre for Molecular Medicine, Germany, (3)Technical University of Denmark (DTU), Lyngby, Denmark*
Interactions between environmental factors and genetics underlie the majority of chronic human diseases. However, connecting chemical exposures and genetic susceptibility to assess how chemicals exert variable effects in a population is a challenge. Therefore, new approach methodologies (NAMs) are necessary to determine the role of genetic variability in chemically-induced adverse outcomes to protect vulnerable populations in chemical risk assessment. To assess molecular mechanisms of individual susceptibility to chemicals, we formed a dataset of chemicals, points of genetic variability (single nucleotide polymorphisms,

SNPs), and diseases using toxicity pathways. These Pesticide-SNP-Disease linkages describe genetic variants that chemicals may act on to lead to variable outcomes in a population. A geospatial analysis was done at the country level globally and refined to the county level in the United States (US) using pesticide application data for 491 chemicals. Based on where pesticides were applied, we identified SNPs implicated by those pesticides in our dataset. Many SNPs were implicated by multiple pesticides meaning these SNPs may represent important points for genetic susceptibility to adverse outcomes in the general population. While many of the same diseases were implicated by multiple pesticides, we found that different SNPs were implicated in different diseases. For example, of the 149 SNPs cypermethrin implicated in Alzheimer's Disease and Parkinson Disease, 80% were only implicated in one disease and not the other. Further, the toxicity pathways implicated by cypermethrin differ. This describes how, depending on the SNPs present in an individual, different diseases may develop following the same pesticide exposure. Therefore, using our dataset, SNPs and toxicity mechanisms important in individual susceptibility to specific diseases can be prioritized in different geographic regions based on pesticide use. Finally, we assessed our results against US disease incidence reported in the Global Burden of Disease. For Alzheimer's Disease and Parkinson Disease, we found that more SNPs implicated in our dataset correlated to greater disease incidence reported in a US state. While many exposures likely contribute to disease outcomes, our framework represents a promising NAM to predict genetically vulnerable populations in different regions based on where chemicals are used to help inform individual susceptibility in human health risk assessment.

4.10.P New Approaches, Methodologies and Policies in Environmental and Human Health Risk Assessment

4.10.P-Tu357 Exploring the Correlation Between Anthropogenic Contamination, Methylation Variation, and Adverse Health Effects in Olfactory Bulb Tissues

Raj Rathnam[1,2]*, Ayesha Babbrah*[1,3]*, Melanie Engstrom Newell*[1,4]*, Katherine B Henke*[3]*, Erin M Driver*[3,5]*, Devin A Bowes*[1,5,6] *and Rolf Halden*[1,5,7]*, (1)Arizona State University, (2)Biodesign Institute, Arizona State University, (3)Center for Environmental Health Engineering, Arizona State University, (4)Environmental Health Engineering, Arizona State University, (5)OneWaterOneHealth, Arizona State University Foundation, (6)School for Engineering of Matter, Transport and Energy, Arizona State University, Tempe, (7)Global Futures Laboratory, Arizona State University, Tempe, AZ*

Introduction of anthropogenic contaminants (which include pollutants such as smoking, microplastics, and occupational pollution) into the body has called for more study on the biological effects of this exposure. Inhalation, a potential entrance pathway for pollution, can damage tissues in the olfactory system and the brain, leading to potential neurodegeneration. Contaminant exposure can affect many biological processes in the cells of these tissues, one of these being epigenetic modification through methylation. Methylation is a modification of DNA which plays a role in gene expression and cell differentiation. Variation of this process is evidenced to cause a variety of adverse health outcomes such as cancer and neurodegeneration. There are a variety of factors that are linked to influencing these epigenetic changes, including exposure to aforementioned contaminants and medical comorbidities. However, little is known about the relationship between anthropogenic contamination and epigenetics in olfactory bulb tissues, and the significance of this relationship to neurodegeneration. This study aimed to investigate the relationship between anthropogenic contamination exposure and methylation variation in olfactory bulb tissue. The overarching hypothesis for this work was that patients with greater occupational or residential exposure to these environmental contaminants will show altered methylation signatures as compared to controls. Olfactory bulb tissue samples from individuals with diverse demographic and occupational backgrounds and associated epidemiological data were provided by a partnering university and pre-classified as either cancerous or healthy. The samples are dissociated and DNA is extracted. DNA concentration is quantified and each sample's methylation signature is profiled using Infinium MethylationEPIC BeadChip array on Illumina. These signatures are then referenced with the aforementioned background of each individual to explore any potential correlation. This exploratory study aimed to investigate the relationship between environmental exposures to anthropogenic chemicals and their impact on adverse human methylation signatures. Such a correlation could shed light on the long-term effects of environmental contamination on olfactory tissue, specifically through the epigenetic and neurodegenerative lenses. Anthropogenic contamination concerns could encourage early screenings and detection for neurodegeneration and other diseases.

4.10.P-Tu359 Geographic Disparity in Asthma Hospitalizations: The Role of Environmental Air Pollution

Sonia Munoz *and Carlos Mazariegos, Environmental Toxicology, Texas Tech University*

Public community health is an to community air quality. Annually, costs from air pollution-related illnesses are estimated at $150 billion and result in more than 100,000 premature deaths in the United States alone. The spatial distribution of Lubbock County, Texas, United States, is associated with hospitalizations caused by asthma due to environmental pollution factors. This current dynamic creates geographic disparities, specifically among industrial and residential sites. The proximity of residential areas to manufacturing sites is associated with an increased risk of respiratory distress due to airborne toxins. The population health related to asthma in Lubbock County is documented in public health records, thus serving as an indicator of the local environmental air pollution. Characterization and regulation of human and environmental health criteria are identified by the United States Environmental Protection Agency (US EPA) criteria for air pollutants. These pollutants are crucial for the determination of permissible pollutant levels. This study will utilize the Emission Weighted Proximity Model (EWPM) to measure the total quantities of pollutants from industrial facilities within Lubbock County and correlate the results to the Toxic Release Inventory (TRI) to investigate the line exposure of off-target residential areas in Lubbock County. rrent analyses are underway. Environmental air pollution, as a neighborhood-level factor, must be studied and evaluated to properly characterize and assess pollution-related hospitalizations related to asthma within the community. Exposure assessment is needed to address and minimize these hospitalizations related to asthma. Reduction of air pollution is a key foundation of economic growth, public health awareness, and the future development and well-being within the community. Additionally, the reduction and prevention of air pollution is vital to the conservation of air as a natural resource.

4.10.P-Tu360 Morphological Transformation and Phenotypic Plasticity of Normal Human Breast Epithelial Cells after 40-Week Exposure to Low-Dose Cadmium

Katelyn M. Polemi, *Anagha Tapaswi, Jade Schroeder, Rachel K. Morgan, Laurie K. Svoboda, Dana C. Dolinoy and Justin A. Colacino, University of Michigan, Ann Arbor*

As of 2021, breast cancer is the most commonly diagnosed cancer worldwide with the 5th highest mortality rate of any cancer in the US. Breast tumors are highly heterogeneous resulting from the acquisition of morphological alterations and cancer hallmarks including stemness and cellular plasticity. Roughly 80-85% of cases occur in women with no family history of the disease indicating how heavily lifestyle and environmental factors play in the disease. Cadmium (Cd) is a naturally occurring toxic heavy metal and a known lung carcinogen, however, its role in breast cancer remains controversial. *In vitro* studies have shown that breast cells exposed to Cd are malignantly transformed through estrogen receptor independent mechanisms. Here we investigate the role of long term (40-week) low dose Cd (0.25uM and 2.5uM) exposure on cancer-associated morphological alterations and cellular plasticity. Cell Painting, a high content image-based assay for morphological profiling, was used to measure cellular morphology of the cells in an unbiased manner every 10 weeks starting with week 0 through week 40. Hoechst, Concanavalin A, Syto14, Phalloidin, MitoTracker, and Wheat Germ Agglutinin (WGA) were used to stain DNA, endoplasmic reticulum, cytoplasmic RNA, actin, mitochondria, and golgi/plasma membrane, respectively, and fluorescence intensity was quantified using CellProfiler software. Using immunofluorescence, we also quantified expression of Keratin 8 and Keratin 14, markers of luminal and basal cells, respectively in treated and control cells. During image processing, the nuclear-cytoplasmic ratio and nuclear size were each separately categorized as “high” if it exceeded the 90th percentile among all cells imaged and all others categorized as “low”. Within the population of cells exposed to 2.5uM Cd for 30 weeks, there are 3-times the number of cells categorized as having a higher than average nuclear-cytoplasmic ratio compared to the control. Additionally, week 30 cells exposed to 2.5uM Cd were 3-times more likely to be in a higher category for nuclear size. Studies have shown that an increased nuclear-cytoplasmic ratio and larger nucleus have been associated with breast malignancy. After 36 weeks of 2.5uM Cd exposure, Keratin 14 intensity significantly decreased compared to control. Our analysis shows transformation of MCF10A cellular morphology at week 30 with the physiologically relevant dose of Cd exposure 2.5uM.

4.10.P-Tu361 Application of Precautionary Principles in Environmental Crime Reconstruction

Bindu A. Gopalakrishnan[1] *and George Kuttiparichel Varghese*[2], *(1)Civil Engineering, National Institute of Technology Calicut, India, (2)National Institute of Technology Calicut, India*

In the analysis of environmental crimes, scientific uncertainty is a key factor preventing concrete actions for protecting the environment. However, the adoption of precautionary principle requires taking preventive action in the face of scientific uncertainty. It also involves a shift in the “burden of proof” to the proponent of a project if there is an adverse environmental consequence. This study explains how Crime Reconstruction (CR) technique, involving the steps of recognition, identification, individualization and reconstruction, can be employed in environmental crimes and how, along with the conventional steps of crime reconstruction, the elements of precautionary principle can be applied in the various stages of reconstruction.

While giving clearance for a project, conditions are specified by the granting authority on the type and quantity of polluting emissions permitted. A violation of this condition constitutes an offence, and can be *recognized* as an evidence of the crime considering the precautionary principle. In the *identification* stage of CR, the characteristic properties of an item recognised is compared with that of the standard objects in order to classify them. In a multi-party pollution case, the violation of the emission standards by any unit is an indication of its involvement in crime. The characteristics of the pollutant exceeding the limits also helps in apportioning the criminal liability.

The releases from every industry will surely have its own signature components which makes it different from others. Review of the environmental clearance documents detailing the raw materials of production and their sources along with the processes of the industry will give some clue about the possible signature evidences. If it is able to find out that evidence among the identified set of evidences, the role of a particular industry can be *individualised* and their relative contribution to the pollution scenario can be assessed more precisely. The identification and individualization analyses of physical evidence and the conclusions drawn from them are important ingredients in a final reconstruction. In this stage, a set of actions such as data collection, conjecture, hypothesis formulation, its testing and theory formation are to be performed to achieve a successful reconstruction. Here a critical analysis of the deviations from the approved environmental clearance conditions will be useful.

4.10.P-Tu362 Investigating Chemical Exposures as Drivers of Phenotypic Plasticity in Normal Human Breast Tissue via High Content Imaging

Jade Schroeder, *Anagha Tapaswi, Katelyn M. Polemi and Justin A. Colacino, University of Michigan, Ann Arbor*

Breast cancer is the most diagnosed cancer, as well as the primary cause of cancer death in women worldwide. Of the different breast cancer subtypes, triple negative breast cancer (TNBC) is particularly aggressive and is associated with poor prognosis. Black women are two to three times more likely to be diagnosed with TNBCs than white women. BRCA1 mutations are thought to be drivers of 10-20% of TNBC, however etiological drivers remain unclear for women without these polymorphisms. Recent experimental evidence suggests that basal-like TNBCs may derive from luminal cells which acquire basal characteristics through phenotypic plasticity, a new hallmark of cancer. Whether chemical exposures are drivers of phenotypic plasticity in breast cancer is poorly understood. To address this research gap, we developed a high content immunocytochemistry assay using normal human breast cells to test whether chemical exposures can impact luminal/basal plasticity by unbiased quantification of keratin 14

(KRT14), a known basal-myoepithelial marker; keratin 8 (KRT8), a known luminal-epithelial marker; Hoechst 33342, a DNA marker; and phalloidin, a marker of the cell cytoskeleton. A cell line established from healthy tissue from a donor to the Susan G. Komen Normal Tissue Bank was exposed for 48 hours to three different doses (0.1µM, 1µM, and 10µM) of eight ubiquitous chemicals (Arsenic, BPA, BPS, Cadmium, Copper, DDE, Lead, and PFNA) with documented exposure disparities in US Black women in triplicate. Automated fluorescence image quantification was performed using Cell Profiler software, and a random-forest classifier was trained to classify individual cells as KRT8 positive, KRT14 positive, or hybrid (both KRT8 and KRT14 positive) using Cell Profiler Analyst. We saw significant dose-dependent increases of hybrid populations in response to BPA as well as low dose effects of PFNA. The increase in hybrid populations expressing both KRT14 and KRT8 is indicative of a phenotypically plastic progenitor-like population in line with known theories of carcinogenesis. Work is ongoing to test effects in cell lines from diverse individuals to identify consistent trends or interindividual differences in response. These results further elucidate the relationship between chemical exposure and breast phenotypic plasticity and highlight potential environmental factors which impact TNBC risk.

4.10.P-Tu363 Monitoring of Insect Traces in Japanese Bioaerosols using NGS
Hitoshi Iwahashi Dr., *Gifu University, Gifu, Gifu, Japan*
Studies on bioaerosols have primarily focused on their chemical and biological compositions and their impact on public health and the ecosystem. However, most bioaerosol studies have only focused on viruses, bacteria, fungi, and pollen. To assess the diversity and composition of airborne insect material in particulate matter (PM) for the first time, we attempted to detect DNA traces of insect origin in dust samples collected over a two-year period. These samples were systematically collected at one-month intervals and categorized into two groups, PM2.5 and PM10, based on the aerodynamic diameter of the aerosol particles. Cytochrome-c oxidase I (COI) was the barcoding region used to identify the origins of the extracted DNA. The airborne insect community in these samples was analyzed using the Illumina MiSeq platform. The most abundant insect sequences belonged to the order Hemiptera (true bugs), whereas order Diptera were also detected in both PM2.5 and PM10 samples. Additionally, we inferred the presence of particulates of insect origin, such as brochosomes and integument particles, using scanning electron microscopy (SEM). This provided additional confirmation of the molecular results. In this study, we demonstrated the benefits of detection and monitoring of insect information in bioaerosols for understanding the source and composition. Our results suggest that the PM2.5 and PM10 groups are rich in insect diversity. Lastly, the development of databases can improve the identification accuracy of the analytical results.

4.10.P-Tu364 NGS analysis of biological traces extracted from bioaerosols
Junko Takahashi, *Graduate School of Information, Production and Systems, Waseda University, Japan*
Bioaerosols are atmospheric particles with a biological trace, such as viruses, bacteria, fungi, and plant material such as pollen and plant debris. In this study, we analyzed the biological information in bioaerosols using next generation sequencing of the trace DNA. The samples were collected using an Andersen air sampler and separated into two groups according to particulate matter (PM) size: small (PM2.5) and large (PM10). Amplification and sequencing of the bacterial 16S rDNA gene, prokaryotic internal transcribed spacer 1 (ITS1) region and DNA sequence of a plant chloroplast gene (*rbcL*) were carried out using several sets of specific primers targeting animal and plant sequences. Lots of bacterial information was detected from the bioaerosols. The most abundant bacteria in several samples were of the Actinobacteria (class), Alphaproteobacteria, Bacilli, and Clostridia. For the animal detection using internal transcribed spacer 1, only uncultured fungi were detected in more than half of the hits, with a high number of *Cladosporium* sp. in the samples. For the plant identification, the ITS1 information only matched fungal species. However, targeting of the *rbcL* region revealed diverse plant information, such as *Medicago papillosa*. In conclusion, traces of bacteria, fungi, and plants could be detected in the bioaerosols, but not of animals using our primers.

4.10.P-Tu365 Soil's Organic Carbon Influence on the Dermal In Vitro Bioavailability of Parent and Alkylated PAHs in Former Gasworks Soils
Alison Williams-Clayson[1], *Chris Vane*[1], *Darren Beriro*[1], *Matthew Jones*[2] *and Russell Thomas*[3], *(1)British Geological Survey, United Kingdom, (2)University of Nottingham, United Kingdom, (3)WSP, United Kingdom*
Polycyclic aromatic hydrocarbons (PAH) pose a potential risk to human health, specifically when former contaminated industrial sites are reused to create places for people to live and work. Dermal contact with contaminated soil is one of the exposure pathways, and accounts for 5.5% of the total exposure in a residential site. The estimated risk is calculated using 13% of the total concentration in deterministic exposure models, this value is uncertain and is based only on benzo[*a*]pyrene (B[a]P). PAH are complex mixtures, many of the individual compounds behave in different ways to B[a]P, in particular the behaviour of alkylated PAH is unknown. Alkylated PAHs are potentially a greater problem on sites where oil is the main contamination source, studying their behaviour alongside parent PAH in real-world samples means that this research can relate to a wider range of contamination scenarios.
This research investigates 30 parent PAH and 21 alkylated PAH *in vitro* dermal bioavailability against selected soil properties from *Rock-Eval*(*6*) pyrolysis and particle size analysis to understand factors affecting parent and alkylated PAH release from former gasworks soils. The *in vitro* dermal bioavailability of 51 PAH were calculated from dermal diffusion cell experiments. Extractions of the applied soil, artificial skin, and receptor solution of five gasworks soils at three-time steps were quantified using GC-MS/MS. Total concentrations of B[a]P in these five soils ranged from 13.54 to 160.49 mg/kg, above the generic assessment criteria for residential land use. The samples include characterised soil reference material and real-world samples from a range of gasworks sites where different processes have operated and a detailed understanding of the site history has been obtained. Dermal bioavailability data will be presented to show differences between parent and alkylated PAH, this data will be

compared with physical and chemical properties to determine tentative cause effect relationships affecting the release individual compounds. This research is important to landowners, remediation companies, consultants, and regulators as it provides a new line of evidence for reducing uncertainties in site specific risk assessment of the chronic exposure of carcinogenic chemicals in soils on previously developed 'brownfield' land.

4.10.P-Tu366 BMD Analysis of Multiple Endpoints in Human Health Risk Assessment: Current Practice and Challenges

Lily Wang, *Todd Blessinger, Allen Davis and Jeff Gift, U.S. Environmental Protection Agency*

Human health risk assessment often evaluates multiple endpoint variables in order to form a comprehensive picture of the toxicity effects of an environmental chemical or toxicant. Benchmark dose (BMD) modeling is a flexible method that takes the shape of the dose-response curve and important measures of uncertainty and variability in the data into account. While BMD modeling is an improvement over previous (e.g., NOAEL) methods, existing BMD models are designed to evaluate single or independent endpoints, not multiple related endpoints simultaneously. Therefore, development of an advanced BMD approach for efficient analysis of multiple related endpoints could be beneficial to risk assessment. This presentation will present our research in univariate, ordinal and multivariate analysis of multiple endpoints including simultaneous analysis of multiple correlated endpoints using environmental chemical toxicity data. Our results demonstrate that multivariate BMD approaches produced comparable and stable BMDLs in a single analysis, with less variability and more robust estimation of adverse health outcomes. In addition, this presentation will also include the major approaches that are currently used in multivariate modeling of multiple endpoints for human health risk assessment, and the challenges in applying these models, such as model choice and model averaging, clustered, Bayesian versus likelihood or frequentist methods, and the analysis of aggregate versus individual data.
(The information in this Abstract has been subjected to review by the Center for Public Health and Environmental Assessment and approved for presentation. Approval does not signify that the contents reflect the views of the Agency, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.)

4.10.PC New Approaches, Methodologies and Policies in Environmental and Human Health Risk Assessment

4.10.P-Tu358 Measurement and modelling strategies for a study of health effects caused by urban ultrafine particle concentrations

Carmen Wolf, PhD[1], *Tobias Pohl*[2], *Astrid Manders*[3], *Ulf Janicke*[4], *Florian Pfäfflin*[5], *Volker Diegmann*[5], *Barbara Hoffmann*[6], *Pascale Haddad*[6], *Hicran Altug*[6], *Konradin Weber*[2], *Ana Maria Todea*[7], *Heinz Kaminski*[7] *and Christof Asbach*[8], *(1)Institut für Energie- und Umwelttechnik e. V. (IUTA), Germany, (2)Hochschule Düsseldorf, Germany, (3)TNO, Netherlands, (4)Ing.-Büro Janicke, (5)IVU Umwelt GmbH, Germany, (6)Heinrich Heine University, Germany, (7)IInstitut für Energie- und Umwelttechnik e. V. (IUTA), Germany, (8)Institute of Energy and Envionmental Technology e.V. (IUTA), Germany*

Ultrafine particles (UFP, D_P < 100 nm) can be formed directly e.g. by combustion processes or secondarily in the atmosphere by mostly photochemical processes from gaseous precursors. Due to their small size, they can penetrate deep into the lung and reach the alveolar region. From there, they may be translocated into other organs, where they may cause inflammatory reactions. It is assumed that organ damage and chronic diseases e.g. of the lung and the cardiovascular system or a weakening of the immune system are promoted by persistent inflammations. However, the health effects of UFP have not yet been fully elucidated. Knowledge gaps concerning long-term effects of UFP exposure are mainly due to the scarcity of corresponding epidemiological studies, which in turn are a result of the lack of high-resolution UFP concentration maps.
Furthermore, the effect of UFP has to be separated from that of of other pollutants that are partly correlated with UFP like PM_{10}, NO_2 or Black Carbon concentrations as well as noise has not yet been conclusively clarified.
The project KoPilot aims at filling the knowledge gap by designing measuring and modelling concept for an epidemiological study. The goal of KoPilot is to develop and experimentally test a measurement and modelling strategy for UFP that allows for the distinction of health effects of UFP and the abovementioned co-exposures. Modelling and measurement activities in this pilot study will focus on a limited urban area within Düsseldorf, Germany.
The first question to be answered is how the UFP concentration data, required for epidemiological studies of long-term exposure, can be determined accurately and validly so that personal exposure can be approximated as closely as possible. The second question is how effects from UFP can be separated from other confounders.
The measuring and modelling concept will be presented and discussed at this conference in view of their validity and knowledge gaps for future epidemiological studies.

4.10.V New Approaches, Methodologies and Policies in Environmental and Human Health Risk Assessment

4.10.V-01 Association Between Mercury Levels and Human Reproductive Health: A Cross-Sectional Study

Magda Carvalho Henriques[1], *Joana Santiago*[2], *Bárbara Guerra-Carvalho*[2], *David Fadista Carrageta*[3], *Filipa Bento*[4], *António Patrício*[4], *Susana Loureiro*[5], *Mário Oliveira*[4], *Margarida Fardilha*[6], *Pedro Fontes Oliveira*[2] *and Maria Teresa Herdeiro*[2], *(1)iBiMED - Institute of Biomedicine, University of Aveiro, Portugal, (2)University of Aveiro, Portugal, (3)University of Porto, Portugal, (4)Hospital Infante D. Pedro, Portugal, (5)CESAM & Department of Biology, University of Aveiro, Portugal, (6)Department of Medical Sciences, University of Aveiro, Portugal*

Infertility is defined as a disease of the reproductive system characterized by the failure to achieve a clinical pregnancy after 12 months or more of regular unprotected sexual intercourse. Infertility rates have decreased worldwide, and some studies showed that lifestyle and environmental risk factors (e.g., exposure to chemicals) may be responsible for this decline. Mercury (Hg) is one of the most prevalent contaminants in the environment, generated by anthropogenic activities. Hg exposure has been associated with human reproductive health decline since subjects with unexplained infertility had higher total Hg (THg) levels in hair, blood, and urine than fertile ones and high THg levels were associated with longer time-to-pregnancy and adverse reproductive outcomes such as spontaneous abortions, and increased rates of menstrual disorders. Our main goal was to evaluate if Hg exposure affects the reproductive health of cohort from the Aveiro region (Portugal) using non-invasive matrices. For that, eligible women and men were recruited at Centro Hospitalar do Baixo Vouga (Aveiro, Portugal). A detailed questionnaire regarding sociodemographic, diet, lifestyle and reproductive data was completed, and samples of hair, saliva, urine, semen, placental tissue, and umbilical cord were collected. Semen samples were processed according to World Health Organization standards. THg levels in hair from both men and women, as well as in placental and cord tissues samples were quantified by atomic absorption spectrometry after thermal decomposition of the sample using the Advanced Mercury Analyzer (AMA-254, LECO), while urine metabolomic profiling was performed by nuclear magnetic resonance (NMR) spectrometry. Our study demonstrated Hg bioaccumulation in biological samples from male and female participants living in the Aveiro region. A significant positive correlation was found between THg levels in hair and all matrices analysed, reinforcing the feasibility of the use of human hair to assess Hg exposure. Moreover, significant positive correlations between THg levels in men's hair and the percentage of sperm tail defects and the teratozoospermia index were found. Regarding metabolomic analysis, we showed that lifestyle and Hg exposure modifies several metabolites related with glycolysis metabolism. Finally, this study demonstrated that lifestyle habits seemed to play a role in Hg exposure, but further investigations are necessary.

4.11 Progress in Knowledge of Rare Earth Elements

4.11.P-Tu367 Rare Earths and Yttrium in Tissues and Shells of Bivalves from the Danube River and its Tributaries

Keran Zhang[1]*, Anna Lena Zocher*[2] *and Michael Bau*[2]*, (1)CritMET – Critical Metals for Enabling Technologies, School of Science, Constructor University Bremen, Germany, (2)CritMET – Critical Metals for Enabling Technologies, School of Science, Contractor University Bremen, Germany*

Due to their numerous applications in various high-technology products and processes, Rare Earths and Yttrium (REY) have become microcontaminants in freshwater systems. Recent toxicological studies demonstrated that REY represent toxicities for aquatic organisms under laboratory conditions. Nevertheless, their biogeochemical behaviour, especially their uptake by aquatic organisms is still poorly understood.

Here, we report on the concentration and distribution of REY in the shells of four different mussel species, in the tissue and shells of three *Anodonta anatina* mussels, and in the respective ambient waters from the Danube River and some tributaries. The shells were grouped according to their sizes and then meticulously cleaned, while the soft tissues were dissected and lyophilized. All samples were acid-digested and preconcentrated prior to ICP-MS measurements. Analytical quality was monitored by analysing the certified reference materials JLs-1 and BCR-668 for shells and tissues samples, respectively.

Size dependency of the REY concentration in shells was only observed for *Corbicula* shells, corroborating previous observations from the Rhine River. Shale-normalized REY patterns are similar for all shells and tissues, and they are slightly middle REY-enriched. Compared to the respective 0.2 µm-filtered ambient water, the biological samples show REY concentrations that are between three to five orders of magnitude higher, revealing significant bioaccumulation of REY. The observed preferential uptake of light REY relative to heavy REY is due to more stable complexation of HREY with dissolved ligands. Despite significant anthropogenic Gd enrichments in ambient water, there are no positive Gd anomalies in the biological samples, suggesting biounavailability of the Gd-based contrast agents present in the waters of the Danube River.

4.11.P-Tu368 Toxicity of REE Along the Food Chain Microalgae-Daphnia in a 14-Day Nanocosm

Chantal K.E. van Drimmelen[1]*, Andrew Hursthouse*[2] *and Susanne Heise*[3]*, (1)Ecotoxicology, University of Applied Science Hamburg, Germany, (2)University of the West of Scotland, United Kingdom, (3)Hamburg University of Applied Sciences, Germany*

While it is impossible in the lab to reflect the variability of responses and extent of interactions in natural systems to e.g. contaminant stressors, cosm-experiments can be set up that feature more than one species and run longer compared to single species bioassays. In order to find out, how rare earth elements (REE) impact the dynamics of organisms nanocosms were set up featuring two biological species from two trophic levels: e water flea *Daphnia mag*na and its food organism, the microalgae *Raphidocelis subcapitata*. Our nanocosms consisted of PET-cups with characterized sediment (Lufa 2.2) and M4 media without EDTA. They were spiked with environmentally and anthropogenically relevant nominal concentrations of La or Gd (1, 10, 100 and 1000 $\mu g\ L^{-1}$) and ran for 14 days. The experiment was repeated at least 5 times. Monitored endpoints comprised parameters such as death rate, reproduction rate, and population count, according to the guidelines of the single-species tests. Our hypothesis was that reproduction of *D. magna* would be a more sensitive endpoint after REE exposure compared to growth rate of *R. subcapitata*, and that the heavy REE gadolinium would be more toxic than lanthanum, in agreement with previous studies we had done. The nanocosms were analyzed over a course of 14 days using a sacrificial method. Preliminary results indicated that differences between effects under La and Gd exposure were not significant, probably due to the high variability in the nanocosms. In detail, reproduction of the daphnia was not significantly affected by the REE, meaning that this part of the hypothesis can be falsified. There was however, a clear trend for a delay of the onset of reproduction of daphnids between the control on one side, and La and Gd on the other. The growth rate of the algae also appeared to be impacted by REE. Analysis of data is being carried out and will be presented during the conference.

4.11.P-Tu458 Assessing Individual and Ternary Mixture Ecotoxicity of Three Rare Earth Elements for Tomato and Durum Wheat in Soil, using Total, Bioaccessible and Tissue Concentrations as Dose

Taylor A Vanderyagt and ***Beverley A. Hale****, University of Guelph, Canada*

Rare earth elements (REEs) comprise 17 elements of the lanthanide series plus Yttrium and Scandium, found in minerals worldwide in a range of concentrations. Due to similar physicochemical properties including luminescent and catalytic features, REEs have become crucial to a wide range of modern technologies such as green energy applications, hybrid vehicles, manufacturing industries; all accelerating in demand on a global scale. Despite increasing exploitation and documented REE pollution, REEs remain data-poor metals with concerns raised about their toxicological potential especially for terrestrial environments. For singular exposures, toxicity has been determined for some REEs but quantitative understanding of mixture ecotoxicity and interactions of REEs is limited. The objective of this work was to determine toxicity thresholds for terrestrial plant endpoints for singular and ternary mixture REE exposures, using low effect levels most relevant to risk assessment (EC10, EC20) and two agricultural species (Tomato and Durum Wheat). Toxic effect concentrations for tomato and durum wheat were determined for three REEs, Cerium, Neodymium, and Europium, in singular and ternary mixture exposure doses. Singular thresholds revealed Ce as the most toxic element, with all REE thresholds (EC10) ranging from 23- 596 mg/kg^{-1} based on total soil concentrations. Assuming concentration addition (CA), ternary mixture exposures were found to be both less than and more than additive among the 18 combinations of species and endpoint per the three REEs, compared to the sum of toxic units (ΣTUs) derived from single metal thresholds ("toxic units"). This was true whether dose was expressed as total or bioaccessible soil REE concentrations. However, when REE dose was expressed as internal concentrations (tissue), ternary mixture endpoint responses were found to be more similar to that of singular exposures, i.e. responses were additive or slightly less than additive. Internal tissue concentrations may serve as a better predictor of toxicity compared to external concentrations for both singular and mixture exposures, in that internal concentrations reveal at which level of plant exposure (soil, plant interface with soil, biotic ligand) REE interactions occur.

4.11.T-01 Rare Earth Elements binding to goethite: experimental and modeling investigations

Muhammad Muqeet Iqbal[1]*, Keran Zhang*[2]*, Mélanie Davranche*[3]*, Rémi Marsac*[4]*, Aline Dia*[5] *and Khalil Hanna*[6]*, (1)University of Rennes 1, Geosciences Rennes, France, (2)CritMET – Critical Metals for Enabling Technologies, School of Science, Constructor University Bremen, Bremen, Germany, (3)Geosciences Rennes, France, (4)Géosciences Rennes, France, (5)University of Rennes 1, France, (6)Ecole Nationale Supérieure de Chimie de Rennes, Rennes, France*

Rare Earth Elements (REE) are not only considered as high-technology components but also as emerging contaminants when released into ecosystems. However, there is a lack of comprehensive investigations on their mobility, environmental fate and transport in geochemical settings. REE can bind to the surface of minerals such as goethite, which can alter their fate and transport. Here, we have thoroughly examined the adsorption of the entire REE group with goethite via batch experiments at environmentally relevant geochemical conditions, over a wide range of pH and varying REE concentrations. As typically encountered for cations, REE binding increased with increasing pH values. Results from the experiments showed that at low pH values there is a stronger adsorption for middle REE (MREE) as compared to light REE (LREE) or heavy REE (HREE). Conversely, at higher pH values HREE are preferentially complexed. These two distinct complexation processes likely arise due to two different types of binding sites: (i) a larger number of weak sites that prefer HREE occurring on the major faces of goethite particles, and (ii) a smaller number of strong sites that primarily complexed MREE and occur at the termination of the goethite particles. A Surface Complexation Model (SCM) based on CD-MUSIC approach has been developed for goethite, which successfully predicted both sorption edges and sorption isotherms. These results have strong implications for an accurate assessment of the transport behavior of REE in natural systems.

4.11.T-02 How does the pH-dependency of the Colloid Structure Affect Rare Earth Elements Mobility in the Environment?

Yasaman Tadayon[1]*, Mélanie Davranche*[2]*, Julien Gigault*[3] *and Delphine Vantelon*[4]*, (1)University of Rennes 1, France, (2)Geosciences Rennes, France, (3)TAKUVIK CNRS, UniversitÈ Laval, France, (4)SOLEIL synchrotron, France*

Rare earth elements (REE) are used extensively for the manufacture of high-tech products, which drives up demand for and spread of these elements. As a result, questions have been raised about their impact on the environment. The ability of rare earth elements to bind to solid surfaces, particularly colloids is expected to mainly controls the REE mobility and transport between the various environmental compartments. Given their ubiquity and the rise of their concentration in natural in response to climate change, we are particularly interested in colloids composed of organic matter (OM) and iron (Fe). Recent research revealed that they are made up of Fe nano-oxides fractally organized into primary and secondary aggregates complexed with OM molecules or linked to larger OM colloids. The reactivity of these colloids is governed by this organization and the resulting surface site availability. In this study, our objective is to investigate how pH affects the binding of REEs by these colloids and their subsequent mobility in the environment. The Fe-OM colloids were synthesized by OM titration with Fe(II) solution at pH 6.5.Rare earth elements (whole group, from la to Lu) adsorption experiment by colloids were performed on a range of REE/Fe molar ratios at pH 6 and 4 and ionic strength of 0.05 mol L^{-1} (NaCl).

The results demonstrated that REE are mainly bound to the OM part of the Fe-OM colloids and that their mobility is controlled by the OM response to the pH conditions. At pH 6, small organic molecules are solubilized with their REE loading, REE mobility is no more controlled by the Fe-OM colloids mobility but also by the strong solubilization of these small organic molecules. By contrast at pH4, Fe-OM colloids bound lower amount of REE (4.4 m g-1 against 12 mg g-1 at pH 6), but aggregated. The major part of REE stay soluble in solution but that bound to Fe-OM colloids is expected to be immobilized by the colloid settlement or by the colloids trapping in soil and sediment porosity.

4.11.T-03 Effects of Sub-Chronic Exposure of Model organism Daphnia magna to Rare Earth Elements La and Gd

Edith Guadalupe Padilla Suárez[1]*, Marion Revel*[2]*, Giovanni Libralato*[3]*, Marco Guida*[4] *and Susanne Heise*[2]*, (1)Biology, University of Naples Federico II, Italy, (2)Hamburg University of Applied Sciences (HAW), Germany, (3)Department of Biology, University of Naples Federico II, Italy, (4)University of Naples Federico II, Italy*

Rare earth elements have become a vital resource in the technology we use in our everyday life. The increase in their use has led to studies focusing also on their effects on the environment, recognized as emerging contaminants. Many studies have focused on the acute effects of these elements on model organisms, however, one of the challenges remains in simulating a more realistic exposure that can give more information about the sub-lethal effects. For this reason, a non-standard test design was elaborated where the model organism *D. magna* was exposed for 7 days to two rare earth elements La and Gd to assess their individual toxicity.

The aim was to assess the mortality and sub-lethal effects such as feeding rate, somatic growth, and maturity. Test organisms were exposed to a series of concentrations ranging from 0.5 to 5 mg/L for both elements and fed daily with green algae *Raphidocelis subcapitata*.

The results obtained for the mortality are expressed as the daily LC_{50} values, which decreased with the increasing length of exposure. The value for La ranged from 5.42 mg/L to 1.08 mg/L for 2 days and 7 days of exposure, respectively, and for Gd from 3.67 mg/L to 1.38 mg/L. For all of the values obtained, Gd had a lower value, which indicates that in the conditions of exposure, it has a higher toxicity than La. Regarding the feeding rate, none of the La concentrations had a significant impact compared to the control ($p>0.5$). In contrast, exposure from 1 mg/L of Gd led to a significant decrease in the feeding compared to the control ($p<0.5$). In the somatic growth, both elements, significant inhibition of growth was observed for concentrations equal to or higher than 1 mg/L. Moreover, the lowest concentration of exposure (0.5 mg/L) of La induced a higher rate of feeding and a slight increase in size, in comparison to the control. As for the maturity, the results are expressed in terms of the EC_{10}, corresponding to 0.45 and 0.42 mg/L for La and Gd, respectively, and the EC_{20}, corresponding to 0.54 and 0.50 mg/L for La and Gd respectively. These results highlight the importance of focusing on sub-lethal endpoints for toxicity as the concentrations to cause mortality are higher and these endpoints can tell us more about potential negative effects on the population caused by more environmentally relevant concentrations.

4.11.T-04 Rare Earths Increasingly in the Picture – But Where Do They Rank Among Other Metals Regarding Ecotoxicity and Occurrence in the Environment?

Nele Deleebeeck*, Andreas Fettweis, Laura Lefèvre and Michiel Claessens, Arcadis Belgium, Belgium*

Now that rare earths are increasingly being investigated, it is of utmost importance to compile all existing and newly generated information in order to update PNECs for use in environmental risk assessments. For instance, at the time of first submission of the REACH dossiers for various rare earth substances, little long-term or chronic ecotoxicity data were available for aquatic organisms, resulting in a high assessment factor for PNEC derivation and PNECs typically in the 0.1-1 µg/L range. In the meantime, long-term or chronic aquatic ecotoxicity data are increasingly becoming available and have learnt so far that such data do not necessarily bring a substantial improvement of the aquatic PNEC (< factor 5). At the same time, results from monitoring campaigns measuring rare earths in the environment are increasingly becoming available. Comparison of rare earth measurements in the aquatic environment with most recent PNEC values could give an idea of the potential for these elements to cause harm in actual water bodies. Even more important – keeping in mind the future requirement under REACH to demonstrate safe use taking into account potential mixture toxicity – is to get an idea of where the rare earths would rank among other metals when comparing their potential contribution to toxicity resulting from combined exposure. This could be done, as a screening approach, by calculating how much of the potential toxicity when assuming concentration addition would be explained by rare earths in environmental samples for which measurements of rare earths as well as other toxic or harmful metals are available. However, the unavailability of rare earth concentration measurements in large compilations of environmental monitoring data such as Waterbase hampers this exercise. Therefore, in this exercise, an attempt was made to link sampling locations for which rare earth concentration measurements are reported in recent scientific literature to sampling locations in Waterbase for which concentration measurements for other metals are available. This should be considered as a screening approach that gives a rough idea of where the rare earths could rank among the other metals. The results of this exercise could find application in the preparation for the mixed exposure assessment which will be imposed in the near future under REACH.

4.11.P Progress in Knowledge of Rare Earth Elements

4.11.P-Tu367 Rare Earths and Yttrium in tissues and shells of bivalves from the Danube River and its tributaries

Keran Zhang[1]*, Anna Lena Zocher*[2] *and Michael Bau*[2]*, (1)CritMET – Critical Metals for Enabling Technologies, School of Science, Constructor University Bremen, Bremen, Germany, (2)CritMET – Critical Metals for Enabling Technologies, School of Science, Contractor University Bremen, Germany*

Due to their numerous applications in various high-technology products and processes, Rare Earths and Yttrium (REY) have become microcontaminants in freshwater systems. Recent toxicological studies demonstrated that REY represent toxicities for aquatic organisms under laboratory conditions. Nevertheless, their biogeochemical behaviour, especially their uptake by aquatic organisms is still poorly understood.

Here, we report on the concentration and distribution of REY in the shells of four different mussel species, in the tissue and shells of three *Anodonta anatina* mussels, and in the respective ambient waters from the Danube River and some tributaries. The shells were grouped according to their sizes and then meticulously cleaned, while the soft tissues were dissected and lyophilized. All

samples were acid-digested and preconcentrated prior to ICP-MS measurements. Analytical quality was monitored by analysing the certified reference materials JLs-1 and BCR-668 for shells and tissues samples, respectively.
Size dependency of the REY concentration in shells was only observed for *Corbicula* shells, corroborating previous observations from the Rhine River. In detail, reproduction of the daphnia was not significantly affected by the REE, meaning that this part of the hypothesis can be falsified. There was however, a clear trend for a delay of the onset of reproduction of daphnids between the control on one side, and La and Gd on the other. The growth rate of the algae also appeared to be impacted by REE. Analysis of data is being carried out and will be presented during the conference.

4.11.P-Tu369 Toxicity of rare earth elements on human health
***Antonios Apostolos Brouziotis**, University of Naples Federico II, Italy*
Rare earth elements (REEs) are metals including the 15 lanthanides together with Yttrium and Scandium. China is the leading country in their exploitation and production. REEs are applied in several sectors like agriculture and medicine. Its application is necessary for the production of several technological devices, while they are used also as additives on diesel fuels. This extended use of REEs has raised concerns about their hazardness. This research belonging to PANORAMA project (grant n. 857989) focuses on the toxicity of REEs on both human and environmental health. We investigate the toxicity of REEs on three different levels: i) the human biomonitoring by analyzing the REE-content in human samples; ii) the ecotoxicity of REEs by elaborating ecotoxicity trials; iii) the environmental background of REEs by analyzing the REE-content in environmental samples. This presentation focuses on the procedure and results concerning the human biomonitoring. The occupational exposure of car mechanics to REEs was investigated. Urine and hair samples of workers were collected from two workshops, in Avellino and Lake of Como. REE levels were determined by ICP-MS. LOD and LOQ values for the instrument and matrices were determined before the sample analysis. The urines of Avellino workers contained significantly higher levels of REEs, creatinine and 1-hydroxypyrene, but REE levels in hair samples were not significantly different between the two groups. Two methods for preparing human urine samples were validated. According to a literature review of ours concerning the toxicity of REEs on human health, there are several ways of exposure to REEs and they have been associated with several diseases like anemia or endomyocardial fibrosis. REEs can be bioaccumulated in human body and cause several implications. More studies about their toxicity should be elaborated as their environmental concentration is increased overtime.

4.11.P-Tu370 Does diffusion through soil control accumulation of REEs by plants roots or DGTs?
*Luba Vasiluk[1], Bianca Pereira[2], Amanda Pellegrino[3] and **Beverley A. Hale**[1], (1)University of Guelph, Canada, (2)Golder Associates Inc., Canada, (3)MTE Consultants Inc., Canada*
Despite the recent interest in assessing the risks associated with REEs, data on their bioaccessibility and bioavailability in soils are still relatively scarce. Diffusive gradients in thin films (DGT) are an *in situ* technique were used to measure Ce, Nd and Eu availability during prolonged deployments in an REE-amended black garden soil for comparison to accumulation of REES by durum wheat (*Triticum durum* var. 'Kyle') and tomato (*Solanum lycopersicum L.*). The DGT attempts to mimic the accumulation of REEs by plant roots by providing a zero sink with high affinity for REEs. For all three REEs tested, a sigmoidal equation described the relationship between soil REE concentration and the rates of REE accumulation by DGTs, and of uptake by plant roots.
The results of these studies show that accumulation by DGT was faster and similar for Nd and Eu, but slower for Ce. It was demonstrated that durum wheat and tomato had comparable rates of accumulation for Ce and Nd and was about half of that estimated by DGT. Accumulation of Eu by durum wheat increased with soil REE concentration at about half the rate for tomato,

which was more comparable to DGT accumulation of Eu. Rates of accumulation by DGT and by plant correlate if diffusive limitation controls the plant accumulation. However, maximum accumulation rates for plants were up to 10-fold greater than those for DGT, for all REEs tested. The greater plant accumulations suggest that REEs' availability for plant root uptake does not only depend on diffusion of REE through the soil as measured by DGTs. Plants can also explore larger soil volumes for REEs uptake than DGTs which are subject to diffusion limitations. The results also suggest that durum wheat can take up Ce and Nd slightly more efficiently from soil even at lower REEs concentrations than tomato. The results suggest that even though Ce, Nd and Eu have similar ionic radii, they differ in affinity for plant roots, and thus the actual dose at a plant's biotic ligand does not depend only on diffusion of REEs through soils.

4.11.P-Tu371 The Influence of Temperature Rise on the Impacts of Dysprosium to Adults and Sperms of the Species Mytilus galloprovincialis

Carla Leite[1]*, Tania Russo*[2]*, Alessia Cuccaro*[3]*, Gianluca Polese*[2]*, Amadeu M.V.M. Soares*[3]*, Carlo Pretti*[4]*, Eduarda Pereira*[5] *and Rosa Freitas*[3]*, (1)Department of Biology, University of Aveiro, Aveiro, Portugal, (2)University of Naples Federico II, Italy, (3)Department of Biology & CESAM, University of Aveiro, Aveiro, Portugal, (4)University of Pisa, Italy, (5)Department of Chemistry & LAQV-REQUIMTE, University of Aveiro, Aveiro, Portugal*

The need for sustainable products has led to the increasing use of rare earth elements (REE) due to their unique properties. Dysprosium (Dy) is widely used in magnets, motors, electrical vehicles and nuclear reactors, being considered a critical element due to its economic importance and high supply risk. However, the increasing use of this element contributes to the enrichment of anthropogenic REE in aquatic systems. Nevertheless, the information on the potential toxicity of Dy is limited. Furthermore, nowadays, it is of utmost importance to consider climate change factors, such as ocean warming, since the risk of negative impacts derived from increased surface water temperature is predicted to be high to very high for bivalves. Moreover, the effects of pollutants can be amplified when combined with climate change factors. Thus, this study aimed to assess the effects of Dy (10 µg/L) in the species *Mytilus galloprovincialis* under actual (17 ºC) and predicted warming conditions (21 ºC). For this, histopathological and biochemical alterations were evaluated in adult mussels, as well as physiological alterations in sperm. A multivariate analysis showed three distinct groups, separating non-contaminated mussels at 17 ºC, non-contaminated mussels at 21 ºC and contaminated mussels at both temperatures. The first principal component (PCO1) separated on opposite sides mussels under stressful conditions from non-contaminated ones at the control temperature (17 ºC). Dy-exposed mussels were strongly correlated with increased histopathological injuries and sperm motility while non-contaminated mussels under 21 ºC showed a close association with higher lipid peroxidation levels and electron transport system activity. This study demonstrated that although Dy and increased temperature induced negative impacts on mussels, the combination of both stressors did not have an additive effect. Eventually, the tested stressors, specially Dy, at a long-term, may have consequences on mussels' reproduction capacity as well as their growth, abundance, and survival.

4.11.P-Tu372 A biotic ligand model for acute toxicity of gadolinium on Daphnia magna

Marion Revel[1,2]*, Andrew Hursthouse*[2] *and Susanne Heise*[1]*, (1)Hamburg University of Applied Sciences (HAW), Germany, (2)University of the West of Scotland, United Kingdom*

The lanthanides (Ln) are a 15-element group that includes gadolinium (Gd). Because of the rising demand of Ln in contemporary technologies, they are now considered as emerging pollutant. Ln toxicity experiments persist to be challenging because of their complicated chemical speciation. The amount of free ion metal concentration in the water is decreased by the metal's complexation and precipitation with organic and inorganic substances. Free ion metals are most likely to interact with organisms by binding to ligands in membranes and causing physiological damage.

A biotic ligand model (BLM) takes metal speciation and interactive or competitive processes among metals for receptors into account in order to forecast the element's toxicity for a specific organism. This experimental setup's goal was to develop a first draft of a biotic ligand model for the acute toxicity of Gd for *Daphnia magna*. Acute daphnid tests lasting 48 hours were conducted in accordance with OECD 202 protocol to determine the stability constants of the cations and *D. magna* biotic ligand. Using a camera system, the *D. magna*'s mobility was assessed every 8 hours for 48 hours. In order to establish a link between cation concentration and the evolution of survival, only one cation's concentration was changed for each experiment. The combination of the Toxicokinetic-Toxicodynamic model (TK-TD) and the traditional BLM permitted the calibration of the model. Current results show a strong impact of Ca^{2+} and Mg^{2+} on Gd toxicity in contrast to that observed for K^+ and Na^+. The stability constant calculations are currently in progress.

4.11.P-Tu373 Toxicity and biodistribution of chronic dietary and waterborne of La and Gd in Daphnia magna

Marion Revel[1,2]*, Chantal K.E. van Drimmelen*[1,2]*, Andrew Hursthouse*[2]*, Frederika Misikova*[3]*, Susanne Heise*[1] *and Edith Guadalupe Padilla Suárez*[4]*, (1)Hamburg University of Applied Sciences (HAW), Germany, (2)University of the West of Scotland, United Kingdom, (3)University of Pardubice, Czech Republic, (4)Biology, University of Naples Federico II, Italy*

The wide use of Rare earth elements (REE) in agriculture, medicine or new techhnology has led to an increase in aquatic systems While the acute toxicity of these elements is increasingly known, there has been limited research on chronic toxicity, and none of these have looked at the impact of diet-borne metal toxicity. As a result, the goal of this work was to assess the toxicity and biodistribution of two REEs, lanthanum and gadolinium, on *D. magna* after chronic waterborne and food exposure. The waterfleas were exposed for 21-days to either La or Gd under four different conditions; (i) The control, in which *D. magna* was exposed to clean media and fed with non-contaminated algae (Ctr), (ii) Dietary exposure (D): Ln exposure through diet (contaminated algae) with *D. magna* grown in clean media, (iii) Waterborne exposure (W): Ln exposure through the medium (0.5 mg/L), and (iiii) combined exposure (DW): Ln exposure through both the contaminated microalgae as diet and the spiked media.

Every day, the organisms were fed, mortality and reproduction were checked. At the end of the 21 days of exposure, the daphnids were dried for 48 hours at 40°C. Dried samples were adhered with double-sided tape to the edge of glass slices in order to study metal biodistribution by X-ray fluorescence spectrometry (µXRF). After 21 days of exposure, no mortality was recorded regardless of the treatment. La combined exposure delayed the first brood by 1.13 ± 1.26 days and Gd dietary and combined exposures led to a decrease of 15.8 ± 13.2 and 21.9 ± 17.9 neonates by living organisms respectively. Lanthanum seemed to uniformly accumulate in the gut regardless the condition of exposure. Gd accumulated in the hindgut after dietary exposure. Waterborne exposure permitted a more diffused biodistribution in the tissues of the organisms while the combined exposure led to a diffused distribution of the metal in tissues and in the intestinal tract. These findings highlight the relevance of dietary exposure for long-term toxicity.

4.11.P-Tu374 Chaoborus punctipennis larvae to monitor rare earth elements contamination in lakes from two mining area

Virginie Ricard-Henderson[1]*, Dominic E. Ponton*[2]*, Marc Amyot*[2] *and Maikel Rosabal*[3]*, (1)Biologie, UQAM, Canada, (2)Groupe interuniversitaire en limnologie et en environnement aquatique (GRIL), University of Montréal, Canada, (3)Groupe interuniversitaire en limnologie et en environnement aquatique (GRIL), University of Québec à Montréal, Canada*

Over the last decades, the mining exploration of Rare Earth Elements (REE) for high-technology industry has quickly increased, which leads to their diffusion and accumulation in aquatic environments as emergent contaminants. The use of sentinel species to assess REE contamination in such ecosystems is necessary for the development of ecological risk assessment tools. *Chaoborus punctipennis* larvae have been proposed as candidates to reflect the level of lake contamination of Cd, Se and Ni, but we do not know about their potential use for REE contamination. We aimed to evaluate the usefulness of these larvae to inform us of the REE distribution in lake water as well as to identify the environmental factors that can modulate the bioaccumulation of these contaminants. To do that, water and larval samples of *C. punctipennis* were collected between 2019 and 2021 from 15 lakes located in the Rouyn-Noranda (Quebec) and Sudbury (Ontario), two Canadian mining regions. The concentrations of organic matter, major cations, anions and metals including REE were measured in 0.45 µm - filtered water to estimate metal speciation. Also, REE concentrations in larvae were determined by ICP-MS/MS. Depuration experiments (72h) and adsorption essays were conducted in parallel of REE measurements. Our results show spatial heterogeneity of REE concentrations in the studied lakes with significant concentration gradients (maximum [REE]/minimum [REE] ratio) in water (La: 273; Ce: 232) and in whole-body bioaccumulation (∑ETR: 151; La: 654; Ce: 487). According to our results, depuration is not a necessary step in this species for all the REE. The percentages of REE measured as adsorbed on *C. punctipennis* varied from 47% (Ce) to 75% (Pr), being globally higher than those internalized. For the relationship between water concentration and bioaccumulation, significant correlations are observed between REE concentrations in water and those in larvae when REE free ion concentrations (and not total REE concentrations) are considered. These results show that chemical speciation plays an important role in the bioavailability of REE in lakes. Improved relationships are observed when different competing factors (e.g., Al, Fe) are included in such regressions. This information provides a better understanding of REE interaction with aquatic organisms, which is essential for monitoring studies of REE given their increased used in new technologies.

4.12 Reducing Marine Pollution and the Role of Ocean Governance on the Road to Sustainability

4.12.T-01 Assessing Characteristics, Uses, and Potential Environmental Impact of Plastic Remediation Technologies

Giulia Leone[1]*, Ine Moulaert*[2]*, Lisa Devriese*[2]*, Ine Pauwels*[3]*, Matthias Sandra*[2]*, Peter Goethals*[4]*, Gert Everaert*[5] *and Ana I Catarino*[2]*, (1)Ghent University, Belgium, (2)Flanders Marine Institute, Belgium, (3)Research Institute for Nature and Forest, Belgium, (4)University of Ghent, Belgium, (5)Ocean & Human health, Flanders Marine Institute, Belgium*

Plastic pollution is a global environmental issue. Remediation technologies to prevent or clean up plastic pollution are currently being deployed in households, on land, freshwater, and marine ecosystems. However, there is a critical need to classify, assess and regulate these technologies. In this study, we reviewed the scientific literature and web on plastic remediation technologies, created an overview of these devices, and investigated their characteristics (e.g., field of application, targeted plastic size). Following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, we conducted, on the electronic database Scopus, a systematic literature review on plastic remediation technologies. In addition, using similar search terms, we have performed a non-systematic Google search. From the systematic review, we observed a growing interest on plastic remediation technologies demonstrated by 34 out of 61 scientific studies published in the last three years. Of these 61 publications, 55 discussed plastic clean-up technologies. By merging the results of the systematic and non-systematic reviews, we created an overview of 124 plastic clean-up and prevention technologies with 29 of their key traits. Similarly to the result of the systematic review, the interest is currently on plastic clean-up technologies, which represent 93.5% of the technologies listed in our overview. Although clean-up technologies can have multiple fields of application, our results indicate that 60% of the 124 technologies, can be used in inland waterways, indicating that the attention is, to date, on the collection of plastic before it reaches the open ocean. Based on these results, we investigated the strengths, weaknesses, opportunities, and threats (SWOT) of this group of technologies. Our SWOT analysis indicates that regulations are needed when deploying a clean-up system, especially due to the environmental effect of these technologies on ecosystems. Despite the challenges, plastic clean-up technologies offer fundamental opportunities, from the more evident removal of plastic waste to raising awareness of plastic pollution, creating new job opportunities, and collecting data. Plastic remediation technologies are essential elements in the fight against plastic pollution. Therefore, their regulation is imperative to ensure a balance between the benefits and the potentially negative consequences.

4.12.T-02 An Effect Assessment of Chemical Contaminants from the Salmonid Aquaculture Industry

Aoife Parsons*, Rosa Helena Helena Escobar Lux, Ann-Lisbeth Agnalt and Ole Bent Samuelsen, Havforskningsinstituttet/Institute*

of Marine Research, Norway
Sea lice are naturally occurring parasitic copepods that feed on the mucous, blood and skin of both wild and farmed salmonid fish. In high numbers, they can reduce the general health and welfare of their hosts, cause significant economic losses to commercial salmonid farms and negatively affect wild salmonid populations. Consequently, the salmonid aquaculture industry relies on several Veterinary Medicinal Products (VMPs) to control sea lice infestations with treatments are administered topically or via medicated feed. Their discharge from open fish net pens and subsequent accumulation in different marine compartments, has raised significant concerns about their potential to negatively impact the marine environment.
The aim of this work was to comprehensively assess the sensitivity of aquatic species to six key anti-sea lice VMPs used in the Norwegian salmonid farming industry, including azamethiphos [AZA], deltamethrin [DELTA], hydrogen peroxide [H_2O_2]), emamectin benzoate [EB], diflubenzuron [DIF] and teflubenzuron [TEF]. We carried out an extensive literature search in order to collate acute and chronic toxicity data for each of the selected VMPs. We subsequently compared the sensitivity of marine and freshwater species and finally estimated up-to-date predicted no effect concentration (PNEC) for both surface water and sediment compartments.
The findings of our literature search highlight that there has been extensive research into the acute toxic effects of many anti-sea lice VMPs. For example, we found 70, 299, 84 90 and 37 short-term reliable $L(E)C_{50}$ values reported in the literature for AZA, DELTA, H_2O_2, EB and DIF, respectively. These $L(E)C_{50}$ values represented 18, 64, 43, 30 and 14 different aquatic species, with crustaceans and insects generally the most commonly represented taxonomic group. There was no obvious difference in the overall sensitivity of marine and freshwater species, though differences in the taxonomic groups represented in each dataset may have biased these findings. Limited chronic toxicity data was available for all of the selected VMPs. Using the collated data, PNECs were estimated using the traditional deterministic method and the probabilistic method using species sensitivity distributions (SSDs). The estimated PNECs can be incorporated into future environmental risk assessments evaluating the risks anti-sea lice VMPs pose to the marine environment around aquaculture facilities.

4.12.T-03 An Effect-based Toolbox for Petroleum Toxicity Testing Evaluated for Hazard Assessment
***Sarah Johann**[1], Richard Ottermanns[2], Ionan Marigomez[3], Xabi Lekube[3], Urtzi Izagirre[4], Manuel Soto[5], Kari K. Lehtonen[6], Raisa Turja[6], Bjørn Munro Jenssen[7], Tomasz Maciej Ciesielski[8], Dag Altin[9], Henner Hollert[10] and Thomas-Benjamin Seiler[11], (1)Department Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (2)Environmental Biology and Chemodynamics, RWTH Aachen University, Germany, (3)Department of Zoology and Animal Cell Biology, Research Centre for Experimental Marine Biology and Biotechnology & Science and Technology Faculty, University of Basque Country, Spain, (4)UNIV BASQUE COUNTRY, Spain, (5)Plentzia Marine Station, University of the Basque Country (UPV/EHU), Spain, (6)Finnish Environmental Institute, Finland, (7)Department of Biology, Norwegian University of Science & Technology (NTNU), Norway, (8)Norwegian University of Science & Technology (NTNU), Norway, (9)Research Infrastructure SeaLab, Norwegian University of Science & Technology (NTNU), Norway, (10)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (11)Directorate, Hygiene-Institut des Ruhrgebiets, Germany*
After an oil spill, physical-chemical complexity of oil in addition to unique spill site-specific factors result in a variety of hazard scenarios for the exposed biota. Information about the oil toxicity is needed, which can often not be derived from quantified individual oil constituents due to unknown compounds and mixture effects. Effect-based methods (EBMs) can complement chemical analysis to assess the toxicity and hazard and predict future consequences for oil-exposed biota. EBMs can even be used for post-spill biological monitoring. Methods combining a huge set of biological effect data for a comprehensive toxicity evaluation often include the transformation of data by normalization to a maximum induction or reference site, which reflects the dimension of the biological relevance only marginally.
Hence, the aim of the present study was to evaluate a set of different EBMs for three petroleum products of varying processing degree in one common context. Toxicity assays of one crude oil and two refined petroleum products were performed with and without the addition of a chemical dispersant. Biological effect data of 12 different species/cell nes with a range of endpoints were included. Small scale *in vitro*-based methods (e.g. receptor actictivation) as well as methods using whole organisms of a broad range of developmental stages (from early embryo to adults) and salinity regimes as well as a set of biomarkers (e.g. enzyme acitvity) were included in the analysis leading to, e.g., a set of 41 endpoints for the crude oil. Data from all biological endpoints were individually transformed into effect classes between 1 and 5 ranging from no (1) up to high effect (5). The classification system combined mathematical approaches and expert judgement to account for the dimension of biological response and relevance. Weighting factors were introduced to distinguish between well-established and rather uncertain endpoints. Multivariate Principal Component Analysis (PCA) was performed with classified effect data.
Based on the PCA, a petroleum-specific bioassay battery providing EBMs being sensitive endpoints for the hazard assessment of oil contamination is suggested. A special advantage of the current study is the use of identical oil batches and shared sample preparation protocols allowing a large conformity and hence a joint evaluation. The suggested bioassay battery can be applied for monitoring programs and for the hazard assessment of e.g. new fuel types.

4.12.T-04 Ecotoxicological Effects of Marine Scrubbers' Discharge on Multi-domain Microbial Communities At Molecular Biodiversity Test Endpoints
***Savvas Genitsaris**[1], Natassa Stefanidou[2], Leonidas Ntziachristos[2], Meritxell Gros[3], Elisa García-Gómez[3], Mira Petrovic[3] and Maria Moustaka-Gouni[2], (1)National and Kapodistrian University of Athens, Greece, (2)Aristotle University of Thessaloniki, Greece, (3)Catalan Institute for Water Research (ICRA), Spain*
Exhaust gas cleaning systems (scrubbers) on-board vessels discharge effluent water with high concentrations of potentially toxic substances, including Polycyclic Aromatic Hydrocarbons (PAHs) and metals, and have acidifying and eutrophying properties that

synergistically can affect biota and ecosystem health. The increased shipping traffic in Eastern Mediterranean, especially near busy port areas, may increase pressures caused by scrubber discharges in the seawater. Microbial communities in marine systems are the first responders to exogenic stresses, such as pollutant surges, and certain members can absorb the pulses via biodegradation pathways, or others can magnify the outcomes via bioaccumulation to higher trophic levels. We performed mesocosm experiments to examine the responses of the multi-domain marine microbial communities of two coastal areas in Eastern Mediterranean, with variable trophic states (polluted and unpolluted), to different scrubber influxes. High-throughput metabarcoding targeted the bacterioplankton and unicellular eukaryotic assemblages, including phytoplankton and protozooplankton, to reveal community structural shifts; and random metagenomic sequencing aimed to provide insights into the functional strategies employed by microbes towards stressor alleviation. The results point towards variable community responses of the prokaryotic and microeukaryotic water-partitions, with shifts in biodiversity and composition. Among bacteria, a proliferation of Operational Taxonomic Units (OTUs) closely related to PAHs degraders was apparent in both low (1 % v/v scrubber concentrations) and high (10 % v/v) scrubber inputs. This was coupled with the presence of pathways connected to the functional groups of environmental information processing and aromatic compound metabolism.

4.12.T-05 Assessing Cumulative Risk of Metals and Polycyclic Aromatic Hydrocarbons from Ship Activities in Ports
Anna Lunde Hermansson[1]*, Ida-Maja Hassellöv*[2]*, Jukka-Pekka Jalkanen*[3] *and Erik Ytreberg*[2]*, (1)Mechanics and Maritime Sciences, Chalmers University of Technology, Sweden, (2)Chalmers University of Technology, Sweden, (3)Finnish Meteorological Institute, Finland*
Studies show that the shipping sector accounts for a variety of different contaminants, e.g. metals and polycyclic aromatic hydrocarbons (PAHs), are released to the marine environment. Metals and PAHs are found in several contaminant sources from ships, e.g., atmospheric deposition from exhaust; release of biocides from antifouling paints and discharge from onboard operations such as bilge water from the engine room and discharge of scrubber water, i.e. water from exhaust gas cleaning systems. Today, the discharge of scrubber water is only regulated by guidelines of recommendatory nature, despite ecotoxicological experiments showing adverse effects on marine organisms. Earlier this year, the Marine Environment Protection Committee (MEPC) of the International Maritime Organization (IMO) proposed new guidelines on how to assess risk and impact from scrubber water discharge, to aid member states when formulating local regulations. The aim of this work was to examine the applicability of the new guidelines.
Also, the need to adopt a more complete approach was identified, where the contribution from several contaminants and contaminant sources are included when assessing the environmental risks associated to scrubbers and shipping in general. Therefore, an additional aim was to compare the metal and PAH load from different contaminant sources and to assess their contribution to cumulative risk in the marine environment. Discharge data from the ship-activity model STEAM, together with previously derived emission factors, were used as input to the hydrodynamic and chemical fate model MAMPEC, to calculate predicted environmental concentrations (PECs) of PAHs and metals in four different ports. The calculated PECs were used to assess the environmental risk by comparing the PECs with predicted no effect concentrations (PNECs), yielding risk characterization ratios (RCRs) for each contaminant. The loads and the associated risks from different sources were assessed both separately and combined by summarizing the RCRs from metals and PAHs. The results show that the proposed guidelines will not provide adequate protection of the marine environment and that scrubbers and antifouling paint contribute most to the contaminant load and risk in ports, where three out of four ports exceeded the limit for unacceptable risk. This study highlights the importance of accounting for multiple stressors and their cumulative effects when evaluating the environmental risks of shipping.

4.12.P Reducing Marine Pollution and the Role of Ocean Governance on the Road to Sustainability

4.12.P-Tu375 Ecotoxicological Effects of Three Different Scrubber-Waters on The Larval Development of The Polychaeta *Sabellaria alveolata*
Ana Ré[1]*, Alexandra Monteiro*[1] *and* ***Nelson Abrantes***[2]*, (1)Department of Environment and Planning, University of Aveiro & Centre for Environmental and Marine Studies, Portugal, (2)CESAM and Department of Biology, University of Aveiro, Portugal*
In response to the sulphur regulation rules approved and adopted by the International Maritime Organization, many shipping companies have invested in scrubber-water systems instead of using fuels with a lower sulphur percentage, transferring atmospheric pollutants (SOx , NOx and COx, PAHs, metals and particles) to the seawater. This decision was made without any risk assessment on scrubber-water effects in marine and coastal ecosystems. So, the present work was focused on the ecotoxicological effects of scrubber-waters on the larval development of seawater organisms.
The larval development bioassays were carried out with the marine polychaete, *Sabellaria alveolata*. Since this polychaete releases the gametes into the water, the embryonic development was affected by the seawater quality. In this bioassay, three types of scrubber-water produced with Atlantic seawater were used: scrubber-water A (SWA) artificially produced and Scrubber-water B and C (SWB, SWC) produced on board two different ships. The scrubber-waters were tested at distinct concentrations: control; 0,001; 0,01; 0,1; 1,0; 10,0; 25,0; 50,0 and 100,0%, either with or without pH correction.
The scrubber-waters were analysed, showing very low pH values and an enrichment of PAHs and alkylated-PAHs, as well as trace metals. By comparing the concentration of PAHs and alkylated-PAHs, the magnitude order found for scrubber-waters was: SWC > SWB > SWA. Concerning the trace metal levels, they varied according to the elements. V, Zn, As, Cd and U were found higher at SWB while Cr, Mn, Fe, Co, Ni, Cu, Hg and Pb at SWA. SWC was not analysed for metals because the sample was lost.
The exposure of *S. alveolata* embryos to scrubber-waters evidenced concentration-dependent effects on the larval development abnormality. Effects on larval stages were similar to the three scrubber-waters without pH correction and occurred at

concentrations sensibly lower, with NOEC ≤0,001% and LOEC = 0,01%. The scrubber-water more toxic was the SWA presenting an EC_{50} of about 4%. While the SWB and SWC were less toxic, presenting an EC_{50} of 9 and 10% respectively. All the assays performed with pH correction, showed lower toxicity, which can be explained by the decrease in metal's bioavailability. The current results showed that scrubber-water are highly toxic to the tested species. Furthermore, the original polychaeta larval development bioassay showed to be a suitable to assess the risk of scrubber-waters on marine aquatic species.

4.12.P-Tu376 Chronic Toxicity Evaluation Using Sea Urchins of Chemical Additives Present in Oilfield-Produced Water
Fernanda Outes Amigo, Emanuelly Ramos Farias, Leticia Sobral Mais dos Santos Lima, Sarah Dario Alves Daflon and ***Juacyara Carbonelli Campos****, School of Chemistry, Federal University of Rio de Janeiro, Brazil*
The largest volume of effluent from oil and gas exploration and production is oilfield-produced water. In evaluating how produced water behaves in the ocean, it is necessary to know the fate of the components once in the environment and their biological effects, including acute and chronic toxicity, at the concentrations and time of exposure in the environment.
Chemicals are added to the oil or gas field to manage operational problems, such as assisting in the recovery and pumping of hydrocarbons, preventing corrosion in the system, facilitating the separation process of oil, gas and water, and preventing methane hydrate formation in gas production systems. Among the chemical additives are biocides, surfactants, antifouling agents, demulsifiers, defoamers, and others. Part of the chemical additives is disposed of into the sea along with the produced water because they are water-soluble.
This work evaluated the short-term chronic toxicity with sea urchin embryos (*Echinometra lucunter*) with chemical additives present in oilfield-produced water: antifouling, defoamer, surfactant, biocide, reducing agent and demulsifier in the commonly used dosages. The tests were performed according to the procedures described in Brazilian Standard.
The results indicated that most of the chemical additives at the concentrations evaluated represent a high risk to aquatic organisms, with the biocide and demulsifier showing the highest chronic toxicity, even at low concentrations. The NOEC (no observed effect concentration) values obtained were defoamer, 10 mg/L; antifouling agent, 2.5 mg/L; biocide, 0.78 mg/L; demulsifier, 0.35 mg/L and surfactant, 75 mg/L. The reducing agent did not present toxicity at the concentration evaluated (20 mg/L).
This work highlights the importance of evaluating the harmful effects of chemical additives commonly used in the oil platform and the need for treatment processes to reduce/remove these toxic compounds before they cause damage to aquatic biota.

4.12.P-Tu377 Oil in the Sea: Inputs, Fates, and Effects
Carys Louise Mitchelmore*, Chesapeake Biological Laboratory, University of Maryland Center for Environmental Science*
Oil and natural gas represent more than 50 percent of the worldwide energy supply, with high energy demand driven by population growth and improving standards of living. As the consumption, exploration, transportation, and production of oil has increased to meet demand, so have studies of the fate and impacts of oil in the sea. Those studies have helped regulators implement new safety requirements, spill responders to develop innovative techniques, and industry to employ updated operational practices and safety measures to limit the impact of oil on the marine environment. This presentation summarizes the 2022 U.S. National Academies of Sciences, Engineering and Medicine's consensus study, Oil in the Sea IV: Inputs, Fates, and Effects. The report includes major findings on the current state of knowledge on, and the committee's recommendations for, reducing inputs of oil into the seas, as well as for improving understanding of the fates and effects of oil in the marine environment and for reducing the more harmful environmental effects. The study is the forth in a series of Oil in the Sea reports. Since the last study was released, almost 20 years ago, there have been tremendous advances in knowledge concerning how oil in marine waters behaves and effects organisms. These advances are based on improved, and in some cases, new technologies and voluminous numbers of new studies performed by government agencies, industry, and academia. One of the main drivers for this enormous growth in knowledge was the research funds provided after the Deepwater Horizon incident. The National Academies was empaneled to review the current state of knowledge on oil in the sea with specific tasks that included: compiling an inventory of the sources, composition, and quantity of hydrocarbon inputs to the marine environment, as well as mitigation measures, with an emphasis on North American waters; including an assessment of the state of the science on the fate and effects of fossil fuel hydrocarbons in the marine environment.

4.12.P-Tu378 Assessing the Acute Toxicity of Herders to Skeletonema sp and *Tisbe battagliai* in Accordance with the UK Procedures for the Testing and Approval of Oil Spill Treatment Products
Tyler-Rose Woolley[1]*, Fern Lyne*[1]*, Daniel Hill*[1] *and Rob Holland*[2]*, (1)Scymaris, United Kingdom, (2)Oil Spill Response, United Kingdom*
A herding agent (or herder) is a chemical product containing a surface-active ingredient which reduces the surface tension of water to change how an insoluble liquid like crude oil spreads, causing oil slicks to rapidly thicken, making them easier to burn. Herders are commercially ready for use; however, they require appropriate regulatory approvals before they can be considered for use in event of an oil spill. As such, the acute toxicity of a herding agent to the marine alga *Skeletonema sp* and marine copepod *Tisbe battagliai* was determined in accordance with the UK procedures for the testing and approval of Oil Spill Treatment Products (CEFAS, 2020) to allow submission of the product to the MMO (Marine Management Organisation).
The determination of acute toxicity to *Skeletonema sp* generated a fluorescence intensity (measured as a surrogate for algal biomass) EC_{50} of 25.2 mg/L and a growth rate EC_{50} of >100 mg/L. The determination of acute toxicity to *Tisbe battagliai* generated an LC_{50} of 447 mg/L.

Based on assessments of products currently on the UK approved products list, the pass/fail criteria for the testing and approval of Oil Spill Treatment Products sets a threshold EC_{50} limit of >10 mg/L. As the product exceeded this limit in both tests discussed, the criteria were passed, and the product would be suitable for addition to the UK approved products list.

4.12.P-Tu379 Relationships Between Tissue Polycyclic Aromatic Hydrocarbon (PAH) Profiles and Biomarker Responses in Baltic Sea Mussels: A Study Using Compiled Laboratory and Field Exposure Data

Kari K. Lehtonen[1]*, Raisa Turja*[1] *and Roque Gastón Alurralde*[2]*, (1)Finnish Environmental Institute, Finland, (2)Environmental Science, Stockholm University, Sweden*

Polycyclic aromatic hydrocarbons (PAH) remain a ubiquitous component of marine pollution. Apart from exposures related to oil spills and other extraordinary releases of these substances, their presence in the marine ecosystem is relatively constant due to atmospheric deposition. Their role in total toxicity of anthropogenically impacted marine waters remains often uncertain although different PAH exert a wide range of effects from acute toxicity to carcinogenesis and endocrine disruption. For this study, extensive chemical-biological data sets collected from previous laboratory oil exposure experiments and field caging studies at sites characterised by different degrees of pollution using Baltic mussels (*Mytilus trossulus*) in the northern Baltic Sea were compiled. Multivariate statistical analyses were carried out examining the relationships between selected biomarkers measured in individual mussels and tissue concentrations of different PAH measured in pooled samples from the same experimental treatment or field site. The biomarkers included consisted of biochemical parameters associated with the antioxidant defence system (glutathione *S*-transferase, glutathione reductase, catalase and superoxide dismutase activities, and lipid peroxidation), neurotoxicity, (acetylcholinesterase activity), genotoxicity (micronuclei and other chromosomal aberrations), and general health at the cellular level (lysosomal membrane stability). In addition, data on other contaminants measured in the tissues of mussels (organochlorines, organotins and trace metals) as well as relevant abiotic environmental factors were included in the analyses as explaining parameters. The results indicate that certain patterns of biomarker responses are associated with the PAH profiles observed in the tissues (e.g., abundance of low or high molecule weight PAH, methylated PAHs, benzo compounds). Thus, the expected sublethal impacts are dependent on the type of PAH contamination and the profile of bioavailable compounds in the environment. The results of the analysis can be used for an improved risk assessment of marine sites characterised by different types of PAH contamination.

4.12.P-Tu380 Dumped Chemical Warfare Agents - Acute Toxicity and Sublethal Effects in Aquatic Organisms

Raisa Turja[1]*, Sarah Johann*[2]*, Johanna Järvistö*[1]*, Matti T Leppänen*[1]*, Noora-Kaisa Rantanen Rantanen*[3]*, Matti Kjellberg*[3]*, Harri Kiljunen*[3]*, Henner Hollert*[4]*, Paula Vanninen*[3] *and Kari K. Lehtonen*[1]*, (1)Finnish Environmental Institute, Finland, (2)Department Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (3)Finnish Institute for Verification of the Chemical Weapons Convention, Finland, (4)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany*

After the World War II, massive quantities of chemical warfare agents (CWAs) were dumped into the seas worldwide. Only in the Baltic Sea approximately 50,000 tons of chemical weapons were disposed of while in the adjacent Skagerrak Strait the estimated amount reaches 170,000 tons. By now, many of the shells and casings of munitions have corroded to the extent that the CWAs are leaking to the water and sediments. The possible impact of dumped CWAs on aquatic ecosystems is scarcely studied, and especially the degradation products of different CWAs and their toxicity to aquatic organisms are largely unknown.

In the present study, the phenylarsenic agents Clark I (DA), Adamsite (DM) and triphenylarsine (TPA) and their degradation products, such as DA related diphenylthioarsinic acid (DPTAA), were identified in the sediments collected from the Bornholm Basin dumping site. Acute toxicity of these compounds was tested using water flea *Daphnia magna* (48 h immobility test) and zebrafish *Danio rerio* (fish embryo acute toxicity test until 120 hours of post fertilization, hpf). After establishing their acute toxicity, very low effect concentrations (≤ EC10) of some of these compounds were further tested to detect possible sublethal effects applying biomarkers of oxidative stress, biotransformation activity, neurotoxicity and behavioral responses.

In *D. rerio* the $EC50_{120hpf}$ was 80-250 µg/L for DA, DPTAA and DM, no effects were observed for TPA and TPA-related compounds. *D. magna* were even more sensitive and showed acute effects for DPTAA, DA, DM and TPA; the $EC50_{48h}$ values were 32, 50, 250 and 417 µg/l, respectively. TPA-O did not induce immobility and TPA-S had partial immobility at 400 – 9000 µg/l. Significant biomarker effects were also observed in both test species exposed to sublethal concentrations compared to the control treatments. Similar or even higher toxicity effects are expected for methylated degradation products of DA for which the analyses are currently ongoing.

These results show that CWA compounds and their degradation products present in the sediments possess a high toxicity potential for aquatic species. Since environmental conditions and human activities may change in the dumping areas, it would be important to monitor the concentrations of the CWA related chemicals including their toxic degradation products as well as possible biological effects related to the CWA contaminated sediments.

4.13.P Scientific Advances in Understanding Environmental Fate and Effects of Polymers

4.13.P-Th330 A Proposal For a Three-tiered Approach for Standard Information Requirements for Polymers Requiring Registration Under REACH

Jens C. Otte[1]*, Heli Hollnagel*[2]*, Christiane Nagel*[1]*, Renata Gerhardt*[1]*, Wendel Wohlleben*[1]*, Nathalie Vallotton*[2]*, Diederik Schowanek*[3]*, Gordon Sanders*[4]*, Joe Frasca*[5]*, Tushar Mahale*[6]*, Mark Pemberton*[7]*, Bjoern Hidding*[1] *and Robert Landsiedel*[1]*, (1)BASF SE, Germany, (2)Dow Europe, Switzerland, (3)Procter & Gamble, Belgium, (4)Givaudan International SA, Switzerland, (5)ExxonMobil, United States, (6)Lubrizol, India, (7)Systox, United Kingdom*

Polymers are a diverse set of chemistries, part of our daily life and provide a multitude of technical functionalities. As part of the EU Commission's Chemical Strategy for Sustainability (CSS), there are efforts to develop environmental and human health standard information requirements (SIRs) for man-made polymers requiring registration (PRR) under a revised Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH) Regulation.
By their nature, polymers are different to small and discrete molecules and conventional risk assessment approaches cannot be applied to most polymers. Therefore, the European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC) Polymers Task Force has developed a conceptual three-tiered proposal to generate data to assess individual and groups of polymers requiring registration (PRR). A prerequisite is the grouping of polymers according to three criteria: chemistry, physico-chemical properties and hazard similarity. The proposed approach considers the limited bioavailability of polymers as a prominent difference to many small molecules and takes this into account as a central element, in particular for human health. Among others, methods for assessing a potential for systemic bioavailability are integral to Tier 1. Within Tier 1, basic data will be generated on a single polymer or polymer group making use of non-vertebrate testing methodologies. Decisions for further studies at higher tiers are based on considerations of properties and effects, combined with systemic bioavailability, and use and exposure considerations. For many PRRs, Tier 1 data on hazard, use and exposure will likely be sufficient for achieving the protection goals of REACH. Vertebrate animal studies and higher-tier fate testing in Tiers 2 and 3 can be focussed on testing needs according to the combined factors above.
The ECETOC Polymers Task Force is of the opinion that the principle of a tiered approach with no vertebrate animal testing at Tier 1, followed by justified, limited and targeted vertebrate testing in higher tiers considering systemic bioavailability estimates, use and exposure considerations and material properties first, provides a basis for modern and intelligent data generation for the next decade as well as an adequate level of protection of humans and the environment.

4.13.P-Th331 An Integrated Approach to Assess the Chronic Effects Induced By Water-soluble Polymers
Lara Nigro[1]*, Stefano Magni*[2] *and Andrea Binelli*[3]*, (1)Biosciences, University of Milan, Italy, (2)Bioscienze, Università degli Studi di Milano, Italy, (3)Dipartimento di Bioscienze, Università degli Studi di Milano, Italy*
Water-soluble polymers (WSPs) represent a new class of emerging contaminants whose widespread use in several applications such as detergents, paints, pharmaceuticals, personal care products or pesticides determined their release into the environment. Despite this large use, their environmental presence and concentration are unknown and their behaviour and impact in the ecosystem is unclear. This could be attributed to the fact that this WSPs do not fit into the polymer size-based classification, escaping the current legislations towards physical contaminants as plastic.
For this reason, the aim of the present study was the evaluation of toxicity induced by three of the most common used WSPs: the polyvinylpyrrolidone (PVP), polyacrylamide (PAA) and polyethylene glycol (PEG). We assessed the chronic toxicity of different WSP concentrations (1 µg/L, 0.5 mg/L and 1 mg/L) in the fish *D. rerio* (exposure from 0 to 120 hours post fertilization - hpf). For the assessment of the chronic toxicity and to understand the mode of action of these WSPs, we evaluated the effects at a high level of biological organization through the monitoring of the alteration on the swimming performance of the exposed specimens. Besides, the high-throughput technology of proteomics has been assessed on the organisms exposed to the highest concentration (1mg/L) of all the three WSPs to investigate the effects at deeper level of the biological complexity and to investigate the possible mechanism of action of these WSPs.
The results regarding *D. rerio* locomotor response to different cycles of light/darkness, underlined PVP as the most effective WSP, since it affected behavioral parameters (total distance moved, mean velocity, mean mobility) at all the concentrations. The same parameter has been affected after the exposure to the highest concentrations of PEG, while PAA seemed the less effective. Concerning proteomics results, PEG and PVP showed a similar way of action impacting on proteins mainly involved in genetic processes, while PAA showed a different pathway of action, impacting most on proteins involved in protein binding and transport.

4.13.P-Th332 Bridging the Gap – An Analytical View on Data Requirements for Polymer Risk Assessment
David Schaffert*, BASF SE, Germany*
Synthetic polymers are integral enablers of modern life, due to their versatility and ease of production. Their usefulness renders them ubiquitous in the modern world leading to an increasing build-up in different terrestrial and aquatic ecosystems. This ongoing development is generating considerable concern from the public, leading to requests to close the perceived data gaps on identities, properties, use patterns and fate of polymers in the environment.
To close these knowledge gaps the European Chemicals Strategy for Sustainability extents the substance registration under REACh to all polymers on the European Market. The registration process will be based on a stepwise approach, comparable to the registration of small molecules. In the initial phase all polymers sold on the European market need to be notified and the polymers requiring registration (PRRs) have to be identified using a set of to be defined criteria. These criteria should be science-based and together with a clear guidance on data generation facilitate the registration of this heterogenous substance class. As PRR decision, grouping, downstream (eco)toxicological studies and subsequent risk assessments rely on the availability of high-quality data, robust methods and clear guidelines for the characterization of polymers are needed.
The sheer number of polymers on the European market results in an urgent need for standardized analytical methods to facilitate polymer data generation and risk assessment. In contrast to small, defined substances polymers are by definition mixtures, thus complicating sample preparation, measurements and data interpretation. Defining robust data requirements is no trivial task as existing test methods (e.g. OECD or ISO methods) are not necessarily transferable to polymers and can result in unreproducible or misinterpreted data and biased risk assessments if not modified for use on polymers. In case of other endpoints adapted from small molecule REACh, suitable and validated test methods do not exist and need to be developed.

This presentation will focus on exemplary requirements (e.g. molecular weight, solubility, log Pow) relevant for PRR classification and risk assessment to illustrate the analytical challenges imposed by this complex substance class and the potential influence on subsequent assays and risk assessments. Practical examples based on the currently available methods underline the need for new methods and clear guidance on the testing of polymers.

4.13.P-Th333 Influence of the PH Value to the Degradation of Ester-Based Thermoplastic Polyurethanes
***Simone Weber**, Bundesanstalt für Materialforschung und –prüfung (BAM), Germany*
Microplastics are solid polymeric particles with a size of 1-1000 µm (ISO/TR 21960:2020), which can be emitted from mismanaged waste into the environment, where microplastic is now ubiquitous. What happens to the microplastics after ending up in the environment, which risks entail and what effects it has are not sufficiently clarified up to now. The most certain issue is that the plastic particles in the environment are exposed to natural ageing, are fragmenting and degrading, such that the potential risk to ecosystems and humans is increasing due to the formation of smaller and smaller particles, potentially even including nanoplastics, if these are ingested before their further degradation. Therefore, and in view of a possible registration of polymers under REACH in the future, it is necessary to investigate the degradation of thermoplastic polyurethanes (TPU) regarding hydrolysis stability to evaluate possible risks and effects to the environment.
In the present studies, one thermoplastic polyurethane – with and without hydrolysis stabilizer – is exposed to different pH buffers at 50°C for 14 days to investigate hydrolysis depending to different pH values (acid, alkali and neutral) based on OECD guideline TG111. The hydrolysis behavior of the TPUs is characterized by surface sensitive techniques and on bulk properties. First degradation effects can be detected by SEC. Hydrolysis, especially under acidic und basic conditions, leads to chain scissions to lower molecular masses. Furthermore, the degradation products which indicate the structure of the bulk material were detected by thermo-analytical methods like TGA-FTIR for the small degradation products and the thermo extraction/desorption-gas chromatography/mass spectrometry (TED-GC/MS) for bigger degradation products. Acidic and basic hydrolysis shows the same degradation behavior which is caused by a preferred scission of the ester and urethane functionalities. Surface-sensitive techniques such as XPS demonstrate less carboxylic acid formation at acidic than at alkaline pH value in the TPU without stabilator, whereas the TPU with stabilator ages to the same extent in both pH ranges. Altogether, the hydrolysis of TPUs – independently of added stabilizer or not – in acid and alkali environment is accelerated compared to the neutral hydrolysis.

4.13.P-Th334 Regulatory Developments in Environmental Hazard Assessment of Polymers Under REACH
***Ewa Skowron**[1] and Arnaud Catherine[2], (1)ECHA, Hazard assessment unit, European Chemicals Agency, Finland, (2)European Chemicals Agency, Finland*
Historically, regulatory frameworks have considered polymers of lower hazard than non-polymers, as a result of their high molecular weight (MW). The assumption is that high MW is associated with poor bioavailability and hence low toxicity. This is supported by the 'rule of five' (Ro5) which correlates certain molecular parameters and descriptors (molecular weight, logarithm of the octanol-water partition coefficient - logKow, number of hydrogen bond donors - HBD, number of hydrogen bond acceptors - HBA) with the likelihood of a substance to cross biological membranes. In particular, the Ro5 posits that substances with a MW > 500 Da have poor absorption and permeation, thus their (systemic) bioavailability will be limited. However, 20 years from the introduction of the Ro5, scientific research demonstrates that the 500 Da cut-off is questionable. This is illustrated by a substantial increase in the amount of oral drugs with MW > 500 Da (and therefore capable to be systemically available) approved by Food and Drug Administration (FDA) since 2000 [1]. Pharmaceutical literature reports that molecules with MW > 800 Da (*e.g.*, paclitaxel) or even > 1200 Da (*e.g.*, cyclosporine) are not hindered in their membrane permeability [2]. With this change in paradigm, high molecular weight substances such as polymers can no longer be regarded as innocuous by default.
The objective of this presentation is to highlight the areas where more research is needed to understand the polymer's bioavailability and in support of the upcoming development in hazard assessment of polymers under REACH. In this context, a tiered approach is being proposed which includes reduced information requirements for certain types of polymers based on assumptions that their large molecular size limits transport across membranes and therefore their bioavailability.

4.13.P-Th335 Anaytical Approaches to Characterize and Quantify Process Related Minor Constituents/Impurities in Polymers
***Sebastian Schmiedt** and Paul Bendig, Eurofins Agroscience Services EAG Laboratories, Germany*
In the context of REACh the view on polymer assessment is in transition and a more thorough characterization will be needed. Besides the molecular weight distribution and content of monomeric substances, there are further constituents/impurities which could originate from the manufacturing process. Oligomeric reaction products, residual solvents and catalysts could be targeted. Our aim is to discuss the capabilities and limitations of conventional chromatographic techniques such as gas chromatography (GC) and high performance liquid chromatography (HPLC) using different detectors and mass spectrometry.
Identification of such process related minor constituents could be straight forward in many cases while quantification is difficult to achieve due to the lack of readily available reference substances. Thus, alternative quantitation approaches will need to be developed and assessed. While GC-FID (Flame Ionization Detector) provides a carbon based response and is a well-established tool for standard-less quantification, responses in HPLC detectors typically vary dependent e.g. on the molecular structure.

4.13.P-Th336 Applicability of Standard Environmental Fate and Effects Methodologies for Non-ionic Water Soluble Polymers
***Kristin A Connors**[1], Jennifer Menzies[1], Jessica Brill[1], Ashley Wilcox[1], Brian Morris[1], Ken Casteel[1], Maura Hall[1], Monica Lam[2] and Kathleen McDonough[1], (1)Procter & Gamble, (2)Procter & Gamble, United States*

There has been an increasing regulatory interest in the environmental hazard and fate profile of polymers. Discussions to include polymers under REACH regulation are on-going. Regulatory submissions require a suite of standard assays to characterize a compound's hazard and risk. It is therefore important to assess and validate these existing methodologies and any modifications needed when evaluating polymers. In this study, we focused on evaluating water soluble polymers commonly used in the down the drain products including polyethylene glycol, polyvinyl alcohol, and carboxymethyl cellulose. Polymers evaluated had varying structural characteristics. We applied standard environmental effects assays including OECD 201 algal growth inhibition assay, OECD 202 acute Daphnia immobilization assay, and OECD 236 fish embryo acute toxicity (FET) assay to evaluate applicability. Further we applied standard environmental fate methods for down the drain chemicals to assess method applicability and modifications needed when evaluating biodegradation of polymers. These methods included the OECD 301B Ready Biodegradability TG and the OECD 302B Zahn Wellens TG. In addition, we assessed the presence of competent degradation in river water using non-standard assessment methods. Results will be discussed and recommendations regarding method modifications will be provided.

4.13.P-Th337 Aromatic Isocyanate-based Polymeric Prepolymers: Investigation of Structure-Property Relationships to Aquatic Exposure and Acute Aquatic Toxicity

Nathalie Schraepen[1], *Christian Boegi*[2], *Georg Pirkl*[3], *Timothy Feeley*[3], *Yunzhou Joe Chai*[4], *Mark Spence*[5], *Lauren Ward*[5] *and Robert J. West*[6], *(1)Nathalie Schraepen, Belgium, (2)BASF SE, Germany, (3)Covestro, Germany, (4)Dow Chemical Company, (5)International Isocyanate Institute, (6)Tessenderlo Kerley, Inc. / NovaSource*

The future registration of polymers in the EU will require the submission of hazard data. A testing program has been performed to explore the potential for exposure and associated health and environmental hazards of aromatic isocyanate-based polymeric prepolymers. The precursor Diisocyanate (DII) substances can be of concern during manufacture or application of polyurethane (PU) raw materials. The hazard potentials can be reduced by the reaction of DII precursors with various polymeric polyether and polyester polyols, which meet the OECD definition of a polymer, to produce isocyanate-terminated prepolymers. This work explored how variation in structures of the DII precursors and polyol building blocks and in the physical–chemical properties of NCO-terminated prepolymers, such as log K_{ow} and molecular weight (MW), contributes to their aquatic exposure and hazard potentials with residual DII precursor content < 0.1%. A group of 10 aromatic prepolymers ranging in MW from 750 – 6,600 g/mol, NCO-functionality from 2 – 4, and calculated log K_{ow} from -5 to +45 were synthesized from among different DII precursors and polyol types. The aquatic exposure potentials were determined using OECD Guideline 120, from which the water-accommodated fractions (WAF) were obtained for testing acute immobilization of *Daphnia magna* according to OECD Guideline 202. For prepolymer loading rates of both 100 and 1000 mg/L in water and prepolymers with a calculated log K_{ow} value of > 10, water-extractable reaction products (measured as dissolved organic carbon, DOC) were not quantifiable. Below log K_{ow} of 10, the quantifiable DOC concentrations showed an expected inverse correlation with calculated log K_{ow}.
All prepolymer substances independent of log K_{ow} exhibited 48-h median effective loading rates (EL_{50}) of > 100 mg/L. Thus, the acute aquatic hazard potential for this NCO-terminated prepolymer substance class is very low, regardless of structure features, physical-chemical properties, or magnitude and composition of their WAF. The revelation of these trends in aquatic exposure and hazard potentials could now provide a basis for regulatory screening of aromatic-NCO-based polymeric prepolymers, while also informing the design of such substances having reduced exposure and/or hazard profiles.

4.13.P-Th338 Assessing the Potential Role of Bioinformatics Tools in Future Polymer Biodegradation Testing

Edward Thomas Logan Mitchell, *Environmental Engineering, Newcastle University, United Kingdom*

In recent years, our knowledge of molecular Biology and Bioinformatics has undergone a massive expansion, and this has paved the way for the development of *in silico* tools that can predict biodegradation of a test compound. However, these tools were developed for low molecular weight chemicals and have not been assessed for their applicability in predicting polymer biodegradation. If effective, such tools could form part of a new framework for assessing the biodegradability of polymers, providing an insight into this that may inform the choice of subsequent lab tests carried out on the polymer. To fill this knowledge gap, we assessed two of the most prominent biodegradation prediction tools currently available: enviPath and PathPred by testing them on a range of monomers and oligomers that form larger molecular weight polymers. We compared their predictions for the biodegradation of these polymers, with and without various modifications. There was significant disagreement between the tools on the biodegradation of many polymers' constituent oligomers, suggesting that one or both still need refinement before they can be considered reliable. Agreement on the presence or absence of biodegradation pathways was found only 47% of the time. Therefore, the tools are likely not yet ready for integration into polymer biodegradation testing frameworks but do show promise, with further refinement tools like these could be a useful addition. It would be beneficial for the tools' predictions to be verified with lab-based biodegradation tests on the chosen polymers and oligomers in the future. The results of these tests could indicate which of these tools, is more accurate and therefore has greater potential for improvement that may make it effective to a future polymer biodegradability assessment framework.

4.13.P-Th339 Challenges and Limitations in the Determination of Molecular Weight and Oligomer Content of Polymers with Regard to Risk Assessment

Timo Florian Beskers, ***Claude Arreyngang Tabe*** *and Denis Botin, BASF SE, Germany*

Polymers are large molecules, that are composed of similar or identical repeating units, the monomers. Due to the nature of polymer synthesis, polymer materials show distributions instead of a single value in many properties, of which molecular weight is probably the most important one. The molecular weight of the polymer molecules has a strong influence on their solubility,

mobility and therefore availability to the environment. Consequently, the molecular weight distribution (MWD) and values derived from it – such as the oligomer content - is an important input for the risk assessment of polymers.
There are several methods to determine an average molecular weight of polymers, but only fractionation techniques can yield the full MWD. The state of the art technique is Size Exclusion Chromatography (SEC or GPC) and two OECD guidelines (118 and 119) are devoted to the application of SEC in polymer characterization. Currently there are no alternatives to SEC for the determination of the oligomer content, also given as amounts < 1000 g/mol and < 500 g/mol.
However, SEC is not universally applicable to all polymer products. Not all polymers are soluble, which is a prerequisite for SEC. Some polymers may be crosslinked or of ultra-high molecular weight, which exceeds the separation limit of SEC. For certain polymers, a large amount of salt or modifier needs to be added to the solvent, which often interferes with the oligomer content determination. Sometimes, no suitable column is commercially available. SEC, as a realtive method, depends on suitable calibration standards. The availability of those can also be challenging.
In summary, despite SEC being a well-established technique, there are many pitfalls and exceptions to consider when one determines the MWD and the oligomer content of polymers. For some of those limitations there are approaches on how to resolve them. However, determination of MWD and oligomer content is not possible for all polymers.
This contribution will provide an overview on the current limitations of the application of SEC to characterize polymers, which is important for their risk assesment, and present strategies to overcome or circumvent some of these challenges.

4.13.P-Th340 Development of a Testing and Evaluation Methodology for Polymeric Substances in Soils
***Marie Winter*[1]*, Karsten Schlich*[1]*, Michael Huben*[2]*, Gabriele Broll*[3]*, Annika Jahnke*[4]*, Andreas Schäffer*[5] *and Julia Marie Peters*[1]*, (1)Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany, (2)Ecological Chemistry, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany, (3)University of Osnabrueck, Germany, (4)Department of Ecological Chemistry, Helmholtz Center for Environmental Research, Germany, (5)Institute for Environmental Research, RWTH Aachen University, Germany*
Agricultural management faces new challenges due to climate change and simultaneous population increase. The optimum crop emergence is therefore a high priority objective. By developing new innovative multifunctional seed coating systems, the Fraunhofer PREPARE project SeedPlus contributes to reaching this aim. The project corresponds to integrative plant protection management standards by ensuring an inherent and sustainable water- and plant protection management for efficient emergence even under suboptimal environmental conditions. Lately, especially (bio-)polymers are increasingly used to improve seed germination. However, (bio-)polymers are not yet considered in regulatory requirements of soil protection (e.g. Federal Soil Protection Act).
To address this at an early stage, an evaluation methodology of (bio-)polymers in soils is being developed that considers the ecotoxicological safety as well as the environmental fate of the substances using a stepwise approach. In the first step miniaturised screening approaches will be used, followed by a validation of the screening tools with standard tests according to OECD guidelines (e.g. OECD 201, 202, 301). Finally, the outcome of the two steps will be proven in lysimeter simulations under environmental conditions.
For ecotoxicity, the impact of the substances on the compartments soil and water is investigated. As terrestrial model organisms, e.g. soil microorganisms (MicroResp™) and earthworms (ISO 17512) were chosen, representing parts of the micro- and macrofauna. Aquatic model organisms of different trophic levels, i.e. the green algae *Raphidocelis subcapitata* (OECD 201), the invertebrate *Daphnia magna* (OECD 202) and zebrafish *Danio rerio* (omics approaches) will be used. To consider effects on degrading bacteria in sewage sludge the inhibitory effect on *Vibrio fischeri* according to ISO 11348 will be observed. In addition, the environmental fate of the substances will be determined in sewage sludge (OECD 301) and soil (OECD 307) test systems. ^{14}C-labelling will be used to trace the degradation of the polymers. Possible degradation products of the polymers will be identified by using substance-specific analytics, e.g. gel permeation chromatography and pyrolysis gas chromatography/mass spectrometry, to develop new analytical end points.
First results of the test miniaturisation for ecotoxicological testing and environmental fate will be presented at the conference.

4.13.P-Th341 Environmental Fate of Water-Soluble Polyethers in Soils: Analytical Method Development, Impact of Polymer Properties, and Implications for Fate Assessment
***Hattie Cerridwen Catherine Brunning*[1]*, J Brett Sallach*[2] *and Alistair B.A. Boxall*[1]*, (1)University of York, United Kingdom, (2)Department of Environment & Geography, University of York, United Kingdom*
Polyethers present in household products, such as polyethylene glycol (PEG), polypropylene glycol (PPG), and their copolymers, may be released to surface waters from wastewater effluent or to soils from agricultural irrigation and sludge application, and have been previously identified as potentially posing environmental risk. However, like many water-soluble polymers (WSPs), environmental fate data are scarce and standard fate test methods developed for smaller molecules may not be directly applicable. In this study we developed an HPLC-MS method to characterise individual homologues of low molecular weight polyethers (PEG-9 and PPG-7) that had previously been prioritised from household products. OECD-type sorption studies were then used to characterise the sorption behaviour of the polymers in a range of soil types. Polyethers of varying functionality and molecular weight were studied in order to assess the impact of polymer properties on sorption, with characterisation of individual homologues allowing analysis of mixture effects and testing of the applicability of established test methods.
Relatively low levels of sorption were observed for PPG, along with increased levels of sorption with increasing polymer chain length as has been observed previously for PEG. In addition, longer chain lengths were shown to sorb preferentially to soils at high concentrations, occupying sorption sites in place of shorter homologues. Bulk analysis of polymer mixtures during testing

may therefore underestimate sorption of high molecular weight components, and overestimate sorption of low molecular weight components, which may be important in polymer fate studies and risk assessment. The PEG studies are ongoing.
The findings of the present study provide insight into the extent that polyether functionality, molecular weight, and molecular weight distribution may influence fate, with implications for risk assessment and grouping. This work also presents a case study for application of established test methods to WSPs.

4.13.P-Th342 It's a Challenge: Determination of Physical Chemical Properties of Polymers
Nora Hartner*, Friederike Luenne and David Schaffert, BASF SE, Germany*
As part of the EU's Green Deal and Chemical Strategy for Sustainability it was recently decided to extend the REACh registration to polymers. For the identification and registration of polymers requiring registration (PRRs) a set of criteria need to be determined. For small molecules, data requirements for registration include several physical chemical properties, such as water solubility, surface tension, and partition coefficient (n-octanol/water), as these often form the basis for ecotoxicological and toxicological studies. To generate analytical data on these parameters in a consistent and comparable way, different OECD guidelines are available. Transitioning from defined molecules to polymers, however, is more complex as polymers are inherently characterized by distribution of chain lengths, chemical compositions, end-groups, or architectures. Therefore, the applicability of the existing guidelines on polymers is limited and involves the risk of generating unreliable data with detrimental impacts on risk assessments.
The development of standardized methods for physical chemical characterization is essential, since already the sample preparation has been shown to have a huge impact, e.g. on the water solubility/extractability. Current results and challenges obtained while applying the existing guidelines (OECD 115, 117, 120) on representative polymers are shown and discussed in this poster. In addition, alternative approaches more suitable for polymers are presented. However, it needs to be taken into account, that there is a wide variety of polymers (liquid, viscous, dispersions) on the market, which requires a broad applicability of the methods. Finally, it must be emphasized that in the analysis of polymers there is always a risk of impurities influencing the obtained results. All in all, there are still numerous aspects to be clarified on how robust physical chemical properties of polymers can be determined, to generate a reliable basis for registration and risk assessment of polymers.

4.13.P-Th343 Modernizing the Assessment, Regulation and Management of Environmental Hazards of Polymers
Ksenia J Groh[1]*, Hans Peter Arp*[2]*, Matthew MacLeod*[3] *and Zhanyun Wang*[4]*, (1)Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)Stockholm University, Sweden, (4)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland*
In the recent years, a considerable amount of research and policy attention has focused on understanding and mitigating environmental impacts caused by (micro)plastics. At the same time, the environmental safety of polymers, a much broader group beyond just the components of plastics, has received much less attention. In fact, the fundamentals of current approaches to assessing, regulating and managing polymers were developed in the early 1990s, and little has changed since then. Currently, the European Union is developing a regulatory proposal to initiate registration of (selected) polymers under REACH. This offers a unique opportunity to modernize polymer assessment schemes and start collecting the missing information to close scientific and policy gaps. To inform the ongoing discussions, we performed a critical appraisal of recent science advances on the environmental fate, exposure and effects of polymers, which allowed us to identify several opportunities for improving current approaches to regulatory assessment and management of polymers. Four major aspects require more attention in the regulation of polymers: (i) increasing transparency about chemical identities, physical characteristics and grouping approaches for in-use polymers; (ii) improving understanding of the environmental fate of polymers and materials composed of polymers across size and density categories and exposure profiles; (iii) enabling a more comprehensive assessment of the environmental hazards of polymers, taking into acount the effects of degradation and weathering as well as the actual uptake, long-term toxicity, and geophysical impacts; and (iv) incorporating the production volume and use/release patterns in determining regulatory data and testing requirements. Transitioning toward a toxic-free and sustainable circular economy will likely require additional policy instruments to reduce the overall complexity and diversity of in-use polymers and polymeric materials. While using the REACH proposal as an example, our analysis has focused on individual assessment criteria that are used in many jurisdictions worldwide, and is therefore broadly relevant for scientists, regulators and other stakeholders working on polymer assessment and management.

4.13.P-Th344 Screening of Polymers for Interface-activity with Lipid Layers
Coralie Sophie Schneider, ***Wendel Wohlleben,*** *and Lan Ma-Hock, BASF SE, Germany*
Studying the interaction of chemicals with assays of the key initiating event enables a screening for potential hazard via adverse outcome pathways (AOP). Here we focused on the screening of both soluble ("functional") polymers and insoluble, solid polymers (micro- and nanoplastics) with regard to the published AOP of Halappanavar et al. (Small 2021, 17, 2007628). The screening is equally relevant to the criteria of the US-EPA concept of "poorly soluble low toxicity PSLT polymer" and to the EU concept of "polymers requiring registration PRR".
We have implemented three methods for the preparation and characterization of lipid layers, functioning as a model of a) living cell membrane (DOPC phospholipid, relevant both for environmental species and for humans) and b) the alveolar lining fluid (DOPC, DPPC, DPPG phospholipid, relevant to pulmonary species, incl. humans). The assays detect the interaction of the lipid layers with different chemicals: Firstly, with the quartz-crystal microbalance with dissipation monitoring (QCM-D), where we have prepared a supported lipid bilayer (SLB) at the solid/water interface. And secondly, with interfacial rheology, where a lipid layer is prepared at the water/air interface of a drop. Both preparation methods were successfully implemented. The presence of a

SLB was confirmed by other surface-sensitive methods and the lipid layer at the drop surface was characterized yielding very good agreement with the literature. And lastly, with analytical ultracentrifugation (AUC), which allows to test the interaction between unilamellar lipid vesicles via the integration of the test item or bridging of vesicles. In a first step, chemicals were tested with all three methods, and we see agreement regarding the severity of interaction of chemicals with the lipid layers. Controls included inorganic natural particles (Kaolin), and small-molecule interface-active molecules (surfactants, Triton X), and finally PLGA polymer, which is approved by the US-FDA as carrier in pulmonary delivery of medical actives.
We categorize the tested polymers by their characteristic interaction, or lack of interaction. At the same time, interface activity is essential for many polymers to achieve the required performance in the intended use, e.g., in cleaning, textile washing, cosmetics, medical formulations, waste water treatment flocculation, etc. Trade-offs must be balanced in a safer-by-design approach.

4.14 Tire Wear and Microrubber Particles – Problems to Solution

4.14.T-01 Mapping Our Way Towards an Integrative, Tire Microplastic Mitigation Strategy in a Multi-stakeholder Context

Sya Hoeke[1]*, Ad M. J. Ragas*[2]*, Harold Krikke*[1]*, Jikke van Wijnen*[1] *and Ansje Löhr*[3]*, (1)Open University, Netherlands, (2)Environmental Science, Radboud University, Netherlands, (3)Department of Environmental Sciences, Open University, Netherlands*

Tire microplastics, such as tire wear particles, are an important source of microplastics in the environment. This raises the question how to effectively and efficiently mitigate the environmental release of tire microplastics. Assessing whether a mitigation intervention is appropriate requires insight into the environmental sources, pathways and consequences of tire microplastics, but also into the tire's lifecycle, the supply chain, the stakeholders involved and potential socio-economic consequences of interventions. This study provides a first step towards the development of an effective mitigation strategy based on an integrative multi-stakeholder approach.
The aim of this study was to map the tire microplastic emissions along the tire's lifecycle. Thus, providing a systematic overview of the processes associated to the tire's lifecycle and how they relate to microplastic emissions, including the identification of and collaboration with relevant stakeholders. Stakeholder involvement was integrated to utilize their knowledge and expertise and to build trust for further collaboration necessary to ensure that the mitigation strategy is rooted in reality with sufficient support. To this end, the supply chain was mapped and translated into a material system analysis with the Netherlands as geographical location and 2021 as the year of interest. This resulted in the quantification of tire and tire microplastic streams along the supply chain. The total initial release of tire microplastic emissions estimated in this study was 22,593 t/y (74% by tire wear and 26% by infill). Part of the initial emissions are never release to the environment, e.g. due to entrapment in asphalt. The emissions that are emitted to the environment were estimated at 11,163 tonnes, of which 83% to soils and 17% to surface waters.
The presented mapping method can be applied to other regions to acquire insight into the link between the tire's lifecycle and tire microplastic emissions. Actors, such as regulators and the tire industry, can apply these results to initiate changes by better understanding their own role and how emission sources relate to processes in the supply chain.
As this study only provides the first stage, additional steps are needed in order to reach an effective mitigation strategy. Future research steps include the coupling of the presented mapping results to a fate transport model and further integration of stakeholder collaboration and environmental modelling.

4.14.T-02 Online Thermogravimetric-gas Chromatography Mass Spectrometry Coupling for a Fast Detection and Quantification of Tyre Wear Particles in Road Dusts

Kieran Evans[1,2]*, Danial Baqer*[2]*, Krystelle Mafina*[3]*, Patrick Sears*[4] *and Maya Al-Sid-Cheikh*[4]*, (1)Applications, PerkinElmer, United Kingdom, (2)Chemistry, University of Surrey, United Kingdom, (3)PerkinElmer, United Kingdom, (4)University of Surrey, United Kingdom*

This work describes the use of thermogravimetric analysis coupled to gas chromatography-mass spectrometry (TGA-GC/MS) to carry out both qualitative and quantitative analysis of tyre rubbers in road dust samples. Currently, no methodology allows for identification of rubber particles in environmental samples without sample preparation, as is demonstrated in this work. The work described here provides several advantages such as the ability to collect direct quantitative data on samples though thermogravimetric analysis and the uses a less polar GC column phase, allowing for better separation of degradation products and much faster run times. This work revolves around using the TGA-GC/MS system in two modes of operation to understand the thermal degradation of both sidewall and tread of passenger car tyres as they are subjected to controlled temperature ramping: (1) conventional TGA-GC/MS; and (2) PyroTGA-GC/MS, which involves pyrolyzing the sample at an elevated temperature and again measuring the evolved gases with GC/MS.
The presentation will show TGA-GC/MS analysis of tyre rubber from home-made standards and PyroTGA-GC/MS analysis of road dust from environmental samples collected next to the M25 and M34 in United Kingdom and centre London. This research provides understanding in the thermal degradation of tyre tread and sidewall rubber, allowing for a differentiation between the two, based on markers of styrene-butadiene rubber (SBR) and natural rubber (NR) also seen in other work. Furthermore, going beyond conventional pyrolysis-GC/MS, PyroTGA-GC/MS is used to identify the presence of tyre rubber in road dust samples. The presence of degradation products of vulcanising agents and other additives, such as SO_2 and aniline, is also seen in the chromatogram. The thermogravimetric analyzer provids direct quantitative information on the polymer content in the road dust samples. In the road samples anlaysed, the polymer content was ca. 3.1%. This work proposes a new method whereby tyre rubber and road dust samples can be analyzed with minimal sample preparation, providing information on the presence of rubber

particles, degradation products and additives, in environmental samples as well as information regarding thermal degradation patterns of tyre rubbers.

4.14.T-03 Tire Wear Particles and Chemicals: Emissions, Runoff, and Presence in San Francisco Bay, USA

Kelly Moran[1]*, Alicia Gilbreath*[1]*, Miguel Alexander Mendez*[1]*, Ezra Miller*[1]*, Edward P. Kolodziej*[2]*, Diana Lin*[1] *and Rebecca Sutton*[1]*, (1)San Francisco Estuary Institute, (2)University of Washington*

Every vehicle on the road sheds tiny particles from its rubber tires into the environment. As they disperse into the environment, tire particles convey tire tread ingredients into the air, into runoff, and eventually into surface waters. In most of the USA, including California's San Francisco Bay area, urban stormwater runoff usually carries tire particles from roads directly to surface waters, through separate storm drain systems designed to prevent flooding and avoid sanitary sewer overflows. San Francisco Bay area monitoring found that tire particles are the single most common microplastic flowing into the Bay and that after storm events, tire and roadway contaminants reach detectable concentrations in Bay water near stormwater discharge locations as well as in the center of the Bay, even with dilution from mixing. Furthermore, 6PPD-quinone reaches concentrations that may be of concern for endemic salmonids both in the creeks during storms and within near-shore Bay water post-storms. To inform future monitoring design and mitigation strategies, we estimated tire wear emissions in the San Francisco Bay area. Using tire sales and measured tire wear particle emissions data from reliable sources and local vehicle miles traveled data, we have estimated annual total and per-capita vehicle tire particle emissions. We used two approaches: (1) the emission factor/mileage method and (2) the sales/tread-loss method. We compared the estimated annual tire wear particle emissions to monitoring-based estimates of total annual tire-wear particle flows into San Francisco Bay to obtain insights into the transport of particles between on-road emissions and aquatic habitat.

4.14.T-04 Deep Dive Into the Chronic Toxicity of Tyre Particle Mixture and their Leachates to the Planktonic Crustacean *Daphnia magna*

Paul Benjamin Boisseaux[1]*, Cassandra Rauert*[2]*, Pradeep Dewapriya*[2]*, Marie-Laure Delignette-Muller*[3]*, Robyn Barrett*[4]*, Lee Durndell*[4]*, Florian Pohl*[5]*, Richard Thompson*[6]*, Kevin Thomas*[2] *and Tamara Galloway*[7]*, (1)Biosciences, Exeter University, United Kingdom, (2)University of Queensland, Australia, (3)Université de Lyon 1, France, (4)School of Geography, Earth and Environmental Sciences, University of Plymouth, United Kingdom, (5)University of Plymouth, United Kingdom, (6)Plymouth University, United Kingdom, (7)University of Exeter, United Kingdom*

This study compares the chronic toxicity of tyre-tread particles and their leachates toward *Daphnia magna*. Sigmoidal survival curves allowed the calculation of LCx(21d) for both, particles and their leachates. Particle mixture induced hormesis response on the reproduction, while leachates severely decreased it (as described by the 21d-benchmark doses). At environmentally relevant concentrations, tyre particles triggered an hypertrophia of daphnids tail, while their leachates increased body length and width. A clear dose-dependent tyre particle ingestion in daphnids' gut was observed. A slight alteration of haemoglobin content and thiol proteins was suggested (trends only). Tyre-tread microparticles were characterised by stereomicroscopy (size distribution and concentrations) as well as scanning electron microscopy. The leachates characterization revealed a metal predominance of Zinc, Titanium and Strontium. Plenty of organic chemicals were found, with a total of 50 molecules shared across the 5 tyres used in the mixture. Many of these chemicals are known to be very toxic and will put ecosystems under strong chemical pressure. Overall, this study demonstrates that tyre-tread particles are chronically lethal to *D. magna* at worst-case environmental concentrations, while tyre concentrations closer to environmental reality alter strongly the reproduction and morphology development of daphnids. In conclusion, this study provides an overview of why tyre particles are hazardous pollutants of particular concern.

4.14.T-05 The need For Environmental Regulation of Tires: Challenges and Recommendations

Steffen Foss Hansen[1]*, Louise Halle*[2]*, Maria Bille Nielsen*[1]*, Kristian Syberg*[3]*, Kristoffer Kampmann*[4]*, Farhan R. Khan*[5] *and Annemette Palmqvist*[6]*, (1)Technical University of Denmark, Denmark, (2)Department of Science and Environment, Roskilde University, Denmark, (3)Roskilde University, Denmark, (4)Danish Environmental Analysis, Denmark, (5)Norwegian Research Centre (NORCE), Norway, (6)Dept. of Science and Environment, Roskilde University, Denmark*

The interest in tire wear particles (TWPs), generated from abrasion of tires, have gained traction over the past few years, both in regards to quantifying particulate emissions, leaching of different compounds, toxicity, and analytical methods. The life of a tire, from cradle to end-of-life, crosses over different scenarios during its lifetime and transcends environmental compartments and legislative areas, underlining the need for a collective approach. Sustainability for a tire encompasses the use of raw materials, recycling of raw materials, circular economy and material sourcing. The tire industry is currently making significant efforts towards a greener and more sustainable production considering reduction of CO2-emissions, recycling, material sources and imple-menting the use of biomass from plants rather than oil-derived alternatives. In this paper, we aim to analyze and discuss the need for environmental regulation of tires in order to provide a series of targeted recommendations for future legislation. Our study shows that the numerous regulations related to tires focus on chemicals, manufacturing, raw materials, use of tires on roads, waste handling, safety and polycyclic aromatic hydrocarbons (PAHs) in different life cycle stages of a tire. However, none directly addresses the contribution of TWPs to the environment. Despite the overall good intentions of the existing regulations, there is a lack of focus on the compounds that partition from the tire and disperse in the environment, their mixture effects, and the trans-formative products from the parent compounds in the environment. Therefore, a renewed focus is needed on risk assessment of complex mixtures like TWPs. Thus, transparency in regard to use of chemicals in TWP, mixtures, minimization of emissions, and capture of particulate pollution should be a priority

4.14.P Tire Wear and Microrubber Particles – Problems to Solution

4.14.P-Th345 Fast Detection and Quantification of Tyre Wear Particles in Road Dusts via Online Coupled TG-GC-MS

Daniel Baqer[1], *Kieran Evans*[2], *Patrick Sears*[3] *and Maya Al-Sid-Cheikh*[3], *(1)Department of Chemistry, University of Surrey, United Kingdom, (2)Applications, PerkinElmer, United Kingdom, (3)University of Surrey, United Kingdom*

The generation of tyre wear particles (TWP) by abrasion of vehicle tyres against road surfaces has gained global attention due to potentially being the largest source of microplastic contamination in the environment. Currently reported experimental data disagrees with these estimations of TWP emissions in the environment. This discrepancy maybe due to a low environmental availability or, an inadequacy of detection due to lack of standardisation in the methodologies and the fact that TWP do not respond well to common microplastic separation and detection techniques. Here we present a method for detecting and quantifying TWP in road dusts by online coupling of thermogravimetric analyser (TGA) and gas chromatography mass spectrometry (GCMS) for a fast, high-throughput, automated analysis. Various thermal degradation products of rubber elastomers were identified in different car tyre brands as common markers for TWP. Evaluation of the treads and sidewalls showed different rubber compositions that could potentially indicate the origin of the rubber fragments – a tyre wear or tyre blowout. Subsequent analyses of road dust samples collected from two major highways in the United Kingdom confirmed the presence of TWP and were quantified as percentage mass of the environmental sample. Historical road dust samples collected in 2009 from various points through London congestion zone were also investigated. This approach requires minimal to no sample preparation eliminating the risk of sample loss or contamination and reducing variability in data amongst researchers when different sample preparation methods are used.

4.14.P-Th346 Infrared Measurement of Tyre Wear Microplastics

Cristina Román-Zas[1], *Javier Terán Baamonde*[2], *Jose Andrade*[3], *Purificación López-Mahía*[2], ***Soledad Muniategui-Lorenzo***[2], *M. Estela del Castillo Busto*[1] *and Borja Ferreiro*[1], *(1)Chemistry, Group of Applied Analytical Chemistry. University of A Coruña, Spain, (2)Universidade da Coruña, Spain, (3)Chemistry, University of A Coruña, Spain*

The scientific attention on tyre and road wear particles (TRWPs) has increased notably in recent years as road traffic has proved to be an important contributor to the release of microplastics (MPs) to the environment. More than 1 million tons of tyre degradation particles per year are estimated for European roads. There are also significant differences between tyres used in cars, composed mainly of synthetic rubber (SBR or BR), and those used in planes, trucks and busses, which use more natural rubber. Further, the original composition of TWPs evolve with the temperature when driving, chemical/physical reactions with the asphalt compounds, friction, etc. All this make the characterization of microplastics from tyre wearing difficult. In this work several forms of reflectance measurements are studied in order to select the most suitable one for current monitoring purposes; namely: macro attenuated total reflectance (ATR), micro reflectance spectrometry and micro imaging with a quantum cascade laser-based IR system. The spectra from the different instruments will be compared to ascertain the chemical information they offer and how viable they are for the analysis of actual field samples.

4.14.P-Th347 Aging of Tire and Road Wear Particles – Results of a Lab Study

Steffen Weyrauch[1], *Bettina Seiwert*[1], *Stephan Wagner*[2] *and Thorsten Reemtsma*[3], *(1)Helmholtz Center for Environmental Research, Germany, (2)Institute for Analytical Research, University of Applied Science Fresenius, Germany, (3)Department of Analytical Chemistry, Helmholtz Center for Environmental Research, Germany*

Tire and road wear particles (TRWPs) are emitted into the environment where cars are driven on road surfaces. Global emission was estimated to amount to approx. 6×10^6 t/a and to 1.3×10^6 t/a in Europe. It is largely unclear how long TRWPs remain in the different environmental compartments after creation and distribution, how long it takes for them to be degraded and how their properties change during aging in the environment. This study investigated changes in physical and chemical properties of TRWPs by different environmental stressors, namely elevated temperature, sunlight and mechanical stress, using a combination of analytical techniques. Contrary to tire particles (TP) which are often used in lab experiments, TRWPs are heteroaggregates of tire particles with road material. Aging experiments under controlled conditions in the laboratory were performed with TRWPs to simulate real world aging. Physical and chemical properties are observed using a range of analytical techniques. Particle size distribution (laser obscuration), morphology (dynamic image analysis), particle density (sequential density separation), as well as around 20 organic constituents (extractables) and the release of organics into water (leachables) by LC-MS.
No marked changes were observed for size and density distributions of TRWPs by the aging experiment. However, mechanical stress appeared to induce a loss of mineral incrustations from the particles surface.
Changes in the organic chemical composition by exposure to elevated temperature and sunlight were much more pronounced. Sunlight exposure had stronger effects on the chemical composition than elevated temperature. These changes in the chemical composition of the particulate phase were largely reflected in the respective leachate, though modulated by ongoing transformation for some of the compounds.
The results of this lab aging study suggest that TRWPs, although being heteroaggregates, are comparatively stable particles against mechanical stress. First signs of physical breakdown may be the loss of mineral incrustations from the surface. However, exposure to elevated temperature and sunlight has strong effects on organic chemicals, the extractables and leachables of TRWPs and should be considered further also in studies on effects of TRWPs.

4.14.P-Th348 Leaching of Organic Compounds from Microrubber Under Conditions Simulating the Sea Surface and the Deep Sea

Natascha Schmidt[1,2], *Aurelio Giovanni Foscari W. R.*[3], *Dorte Herzke*[1], *Bettina Seiwert*[3], *Marc Garel*[2], *Thorsten Reemtsma*[4],

Christian Tamburini[2] and Richard Sempere[2], (1)Norwegian Institute for Air Research (NILU), Norway, (2)Aix-Marseille University, MIO - Mediterranean Institute of Oceanography, France, (3)Helmholtz Center for Environmental Research, Germany, (4)Department of Analytical Chemistry, Helmholtz Center for Environmental Research, Germany
Microrubber (MR) can contain high amounts of additives, such as vulcanization agents (e.g. 1,3-diphenylguanidine (DPG) and benzothiazoles), antioxidants and antiozonant (e.g. N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine (6-PPD)) and heavy metals like zinc, which can leach out. Here, we present results from two experiments aiming to investigate the leaching of organic compounds from MR under conditions simulating (1) the sea surface and (2) the deep sea. Different MR materials were tested: (i) cryo-milled tire thread (CMTT), (ii) 'virgin' crumb rubber (VCR) and (iii) weathered crumb rubber (WCR) which consisted of VCR that had been immersed in the sea for 12-18 months prior to the experiments. The MR (1 g L^{-1}) was added to filtered seawater and exposed to the following conditions: (1) UV irradiation (300 W m^{-2} at 300-800 nm, 22±2°C) vs dark controls, for max. 336 h simulating 31 days in the environment or (2) high hydrostatic pressure (200 bar) vs atmospheric pressure conditions, for max. 14 days. Leachates were then analyzed for organic compounds using RPLC-HRMS and for dissolved organic carbon (DOC).
We observed (1) a considerable increase in DOC concentrations in samples exposed to UV irradiation compared to dark controls for all materials. This trend is generally reflected by the leaching of vulcanization accelerators, such as DPG and benzothiazole. In contrast, 6-PPD quinone (6-PPDQ), one oxidation product of 6-PPD, showed a 2-5 fold increase in dark conditions compared to light conditions in CMTT (max. 0.5 µg L^{-1}) and VCR (max. 0.2 µg L^{-1}) samples. In WCR samples, however, 6-PPDQ concentrations increased steadily in light and dark conditions, but with significantly lower values overall (max. 0.03 µg L^{-1}). (2) Preliminary results indicate higher DPG concentrations for CMTT under high hydrostatic pressure conditions compared to atmospheric pressure conditions (max. 71 µg L^{-1} vs 47 µg L^{-1}, respectively), whereas benzothiazole (max. ~160 µg L^{-1}) and 6-PPDQ (max. ~1.5 µg L^{-1}) exhibited similar concentrations in the leachates of both pressure conditions.
Our study showed that MR particles release organic compounds under all tested conditions, with patterns dependent on compound classes and exposure conditions. After ≥12 months in the environment, WCR still released a variety of organic compounds, often in concentrations similar to those of VCR. This suggests a long-term potential of MR to release additive compounds into the marine environment.

4.14.P-Th349 Chemical Evolution of Metals During Tire Weathering in a Marine Environment
*Carmen Moscoso-Pérez, Verónica Fernández-González, Estefanía Concha-Graña, Purificación López-Mahía and **Soledad Muniategui-Lorenzo**, Universidade da Coruña, Spain*
Tires are a chemically complex and heterogeneous mixture, consisting of approximately 5–10% additives needed for tire production, stability and durability. Thus, a tire can be composed of as many as 200 different additives that may be released into the aquatic environment through leaching.
Tires contain several potential toxins, including the heavy metals zinc, cadmium and lead. Zinc oxide is added as an activator during the vulcanization process used to reinforce rubber, and cadmium is mineralogically associated with zinc. Lead is present in the steel fibers used to reinforce the rubber. Other heavy metal elements in tire tread are Mn, Fe, Co, Ni and Cu.
As part of the MicroplastiX project's research activities, in-situ experiments were carried out simultaneously in 5 port sites in Europe and in an extra location in Brazil. The experiment aims to assess degradation, fragmentation and weathering of different polymers under environmental conditions.
In this work, the tire weathering study to monitoring changes in its metal additives composition is presented. The weathering experiment has been carried out during the summer, autumn, winter and spring of 2021-2022 in a sport port in Ares, A Coruña, Spain. Subsamples were analyzed at each season at 0, 30, 60 and 90 days of exposure. 15 metals were simultaneously measured by ICP-MS after microwave acid digestion.
Seasonal variations were found, being the summer season the one with the highest concentration values for some of the metals analyzed. Ca, Fe, Mg and Zn are the metals analyzed that have been found in the highest concentrations; on the other hand, Hg was not found at any time in any of the stations. In addition, the time trend of the metals was analysed individually, both in terms of leaching in some of them and adsorption from the marine environment to the tire for others.

4.14.P-Th350 Biodegradation Studies on Tire Tread Particles: A Comprehensive Investigation on Leachates Composition
***Aurelio Giovanni Foscari W. R.**[1], Bettina Seiwert[1], Matthias Schmidt[1] and Thorsten Reemtsma[2], (1)Helmholtz Center for Environmental Research, Germany, (2)Department of Analytical Chemistry, Helmholtz Center for Environmental Research, Germany*
Tire wear particles (TWPs) in aquatic environment act as a source of various organic pollutants released by leaching. These contaminants consist of a complex mixture of tire additives needed for tire production and for stabiliziling them during use, such as vulcanization accelerators and antioxidants. Biodegradation studies on TWPs and their related compunds are very scarse, with a major focus on single compounds than the whole pool of substances in the leachates, that may interact with each other. Here, we report the first biodegradation study on both TWPs and their leachates performed with a cryo-milled tire tread (CMTT) particles mixture dispersed in a mineral medium with active sludge. Both leachates, first in presence and then in absence of the CMTT particles acting as a source, were investigated. Furthermore, a surface particle characterization was performed on the CMTT particles after the biodegradation.
The CMTT was prepared by mixing together 20 types of new, used and aged tires. The mineral medium and the active sludge collected from a waste water treatment plan (WWTP) were prepared accoding to the OECD 301 guidelines. The CMTT particles and sludge concentration used was 4 g L-1 and 0.3 g L-1, respectively. The Eyetech Combi particle analyzer and the Zeiss Merlin

VP scanning electron microscope (SEM) were used for the size and shape characterization of the particles, while the leachates were analyzed by ultra-performance liquid chromatography time-of-flight mass-spectrometry (UPLC-TOF-MS).
As a result, the sludge inoculum had a key role in both CMTT particles and leachates. On the surface of the CMTT particles a biofilm formation was visible. The lower DOC concentrations found in the aqueous phase confirmed that biodegradation of many leachables took place, in particular for our compounds of interest. Most of the vulcanization accelerators and antioxidants were biodegraded by the sludge, promoting the formation of new transformation products. Furthermore, the combination of both experimental parts performed with and without CMTT particles showed a different biodegradability behaviour of the leachates when the source is present, suggesting that the biofilm played a relevant role in the particles leachability.

4.14.P-Th351 Laboratory Studies on the Degradation Behaviour of Tire Wear Particles in Aquatic Ecosystems
Robin-Macmahon Bähre[1]*, Mirko Wiebking*[2]*, Hannah Behnsen*[2]*, Jacek Lecinski*[2] *and Hans-Josef Endres*[2]*, (1)Mechanical Engineering, Leibniz University of Hannover, Institute for Plastics and Circular Economy, Germany, (2)Leibniz University of Hannover, Institute for Plastics and Circular Economy, Germany*
Tire wear particles (TWPs) are among the biggest sources of microplastic pollution. A considerable portion of the contaminant ends up in surface waters, which leads to unpredictable consequences for sensitive aquatic ecosystems. In this work TWPs were generated in a tire tread buffing process and subsequently examined in two experiments to investigate the role of different parameters on the degradation behaviour of TWP. Three main influence categories are considered: (i) the material composition of TWPs (e.g. rubber type, anti-aging agents), (ii) the relevant environmental conditions in aquatic ecosystems (e.g. temperature, light availability (UV), salinity, mechanical stress) and (iii) the morphology of TWPs (e.g. particle size, specific surface area).
During this study two different experimental setups were used to investigate the degradation behaviour of TWPs. The first is an open microcosm experiment, in which different physical influencing factors (temperature, UV, mechanical stress) are used to simulate a surfzone within a beach environment. For the second approach, manometric respirometry is used to investigate the biodegradation of TWPs for different scenarios via oxygen consumption. To measure degradation processes the study uses accompanying analytical methods like imaging techniques (SEM, particle measurement) as alongside thermo-analytical approaches (TGA, Py-GC/MS).
The potential findings of this work help to determine the fate and impact of aquatic ecosystems that are exposed to TWPs. In order to develop effective mitigation strategies and retention measures, the understanding of the persistence and underlying degradation mechanisms of TWPs must be further investigated.

4.14.P-Th352 Investigation into the Oxidation and Ozonolysis of 6PPD and 6PPD-quinone
Rory Mumford[1] *and Pete Yeomans*[2]*, (1)Environmental Fate and Metabolism, Smithers, United Kingdom, (2)Environental Fate and Metabolism, Smithers, United Kingdom*
Research into Urban Runoff Mortality Syndrome (URMS) has sought to identify some of the pollutants that are potentially toxic to species present in urban watercourses. Certain species were identified as being particularly sensitive to 6PPD-quinone, a degradation product of a 6PPD, which is one of the most widely used antiozonants present in tires and other rubber products produced and used globally. Literature has suggested that tire and road wear particles (TRWP) are a potential source of 6PPD-quinone in watercourses.
The current study was undertaken to further understand the behaviour of 6PPD and 6PPD-quinone in the solid state when exposed to various concentrations of oxygen and ozone. ^{14}Cradiolabelled 6PPD and 6PPD-quinone were synthesised to aid the tracking of degradation products throughout the study. The oxidation of 6PPD and 6PPD-quinone were studied at reduced and atmospheric levels of oxygen. The ozonolysis of 6PPD and 6PPD-quinone was studied at environmentally-relevant levels of ozone. In both cases, the effects of the presence or absence of sunlight was studied. The results of the study are discussed in this presentation.

4.14.P-Th353 Investigation into the Hydrolysis of 6PPD and 6PPD-Quinone.
Rory Mumford[1] *and Graham Crabtree*[2]*, (1)Environmental Fate and Metabolism, Smithers, United Kingdom, (2)Environental Fate and Metabolism, Smithers, United Kingdom*
Research into Urban Runoff Mortality Syndrome (URMS) has sought to identify some of the pollutants that are potentially toxic to species present in urban watercourses. Certain species were identified as being particularly sensitive to 6PPD-quinone, a degradation product of a 6PPD, which is one of the most widely used antiozonants present in tires and other rubber products produced and used globally. Literature has suggested that tire and road wear particles (TRWP) are a potential source of 6PPD-quinone in watercourses.
The current study was undertaken to further understand the behaviour of 6PPD and 6PPD-quinone once they have entered the aquatic environment. ^{14}C-radiolabelled 6PPD and 6PPD-quinone were synthesised to aid the tracking of degradation products throughout the study. The hydrolytic behaviour of 6PPD and 6PPD-quinone were studied through the environmentally-relevant pH range using the standard OECD TG111 buffers. Because trace elements are known to impact the rates and the routes of degradation in the environment, sterile natural waters were used to assess the influence of alkalinity, hardness, salinity, and trace element content.
Comparison with active natural water was made to assess the biotic effect on hydrolysis and degradation. The results of the study are discussed in this presentation.

4.14.P-Th354 Procedures to Assess Traffic-related Micro- and Nanoplastic Exposure
Esther Lenssen[1]*, Lorenzo Scibetta*[2]*, Marja Lamoree*[2]*, Adriaan Duijndam*[3]*, Laurens Dirk Bernardus Mandemaker*[4]*, Florian Meirer*[4]*, Dirk Brossell*[5]*, Asmus Meyer-Plath*[6]*, Nico Dziurowitz*[6]*, Carmen Thim*[6]*, Paul-Tiberiu Miclea*[7]*, Salvatore Chiavarini*[8]*,*

Korinna Altmann[9], Raymond Pieters[10] and Gerard Hoek[10], (1)Institute for Risk Assessment Sciences, Utrecht University, Netherlands, (2)A-Life, Vrije University Amsterdam, Netherlands, (3)Utrecht University, Inorganic Chemistry and Catalysis, Department of Chemistry, Netherlands, (4)Chemistry, Utrecht University, Netherlands, (5)BAuA, Germany, (6)Federal Institute for Occupational Safety and Health, Germany, (7)Fraunhofer IMWS - Institute for Microstructure of Materials and Systems, Germany, (8)ENEA Environmental Chemistry Division, Italy, (9)Federal Institute for Materials Research and Testing, Germany, (10)Utrecht University, Institute for Risk Assessment Sciences, Netherlands
There is increasing concern about micro- and nanoplastics (MNP) in the environment. One of the predominant sources releasing MNPs into the atmosphere is motorized traffic tyre wear. The aim of this study was to develop procedures to characterize and quantify potential traffic-related MNP exposure in various urban settings.
4-hr air sampling was performed within Utrecht, the Netherlands, with a potential high contrast in MNPs and other major air pollutants. Measurement sites were a stop-and-go location, highway and city park as urban background location. Using a high volume sampler quartz filters were collected for MNP analysis using pyrolysis- and Thermo-Extraction/Desorption (TED)–Gas Chromatography/Mass spectrometry (GC/MS), other major traffic contaminants were measured using Inductively Coupled Plasma (ICP)-MS. Gold-coated Nucleopore filters were collected and assessed for spectroscopic MNP analysis using Scanning Electron Microscopy coupled with an Energy Dispersive X-Ray analyser and Raman microspectroscopy analysis. We determined PM10 mass concentrations and particle number concentrations (PNC).
Air sampling and analytical procedures were adapted to assess MNPs while avoiding contamination. Analysis of the collected filters is still ongoing. 9 µg of styrene-butadiene rubber (SBR) and 186 µg (poly-ethylene) per half of the stop-and-go quartz filter were found using TED-GC/MS analysis after pre-treatment with density separation, which is a factor 100 above the LOD of pristine polymer measurements. The average zinc and ΣPAH concentrations at the stop-and-go location were respectively 8.95 (7.7) ng/m^3 and 2359 (1972) pg/m^3, which was 4.7x and 2.7x higher compared to the urban background location. The average PM10 mass and PNC concentrations, together with the major air pollutants, were highest at the highway, with respectively 35.0 (17.1) µg/m^3 and 35,600 (20,900) pg/cm^3.
Zinc is often used as a marker for tyre wear. Together with the preliminary TED-GC/MS results, this might indicate that the traffic-related MNP contribution was higher at the stop-and-go location compared to the urban background location. Results will be presented on differences in MNP concentrations at these three locations, also supported by data on chemical characterization of the collected samples. The exposure estimates will be used in a human volunteer study, assessing immuno-toxicological effects of exposure to traffic-related MNPs.

4.14.P-Th355 Tire Wear Particles in Soils Along Low Traffic Density Roads
***Elisabeth Støhle Rødland**[1], Lene Heier[2], Ole Christian Lind[3], Malcolm Reid[1] and Sondre Meland[1], (1)Norwegian Institute for Water Research (NIVA), Norway, (2)Norwegian Public Roads Administration, Norway, (3)Norwegian University of Life Sciences (NMBU), Norway*
Recent studies have suggested high concentrations of tire wear particles in road dust and soil along roads with high traffic density. There is, however, less knowledge about the levels of tire wear particles along roads with low traffic density. In this study we have explored the levels of tire wear particles in road-side soils along country roads in Trøndelag, Norway, where the traffic density was between 650 and 12500 vehicles /day and traffic speed between 60 and 80km/hour. Samples were collected from 0m, 1m, 3m and above 6m distance from the road. Samples were collected from the topsoil (0-0.1m) and lower soil layer (0.1-0.2m). Soil samples were analyzed using pyrolysis gas chromatography mass spectrometry for tire wear particles and ICP-MS for metal concentrations (Zn, Ni, Cd, As, Cr, Pb). Levels of tire wear particles varied between different sites, from 2040 to 26 400 mg/kg. These levels are comparable to one previous study of road-side soils with medium traffic density (AADT 36 000), and far exceeds the levels reported in another study with high traffic density (AADT 71 250). This suggests that levels of tire wear particles in soils are less impacted by traffic density. No significant difference was found for samples grouped by soil layer, distance from the road or traffic speed either. The variation of tire wear particles in the soil were further explored by redundancy analysis, where metals measured in the soil samples were also included. Using all the explanatory variables for traffic (speed, traffic density) and soil properities (loss of ignition, soil type, soil layer, drainage profile) had no significant relationship with the tire wear particle levels, however, they explained 42% of the variation found for metals. This study is an important contribution to the knowledge base on tire wear particles in different environments, especially liked to lower traffic densities. It is also valuable to compare results between tire wear particles and other road pollutants that have been studies for decades already, such as metals.

4.14.P-Th356 Vertical Distribution of Microplastics Including Tire Wear Particles in the Air, Sea Surface Microlayer and Underlying Water in Swedish Fjord Systems
***Isabel Goßmann**[1], Oliver Wurl[2], Tiera-Brandy Robinson[2], Karin Mattsson[3], Martin Hassellöv[4], Andreas Held[5], Claudio Crazzolara[5] and Barbara Scholz-Boettcher[6], (1)University of Oldenburg, Institute For Chemistry And Biology Of The Marine Environment, Germany, (2)Carl von Ossietzky University of Oldenburg, Center for Marine Sensors, Institute for Chemistry and Biology of the Marine Environment (ICBM), Germany, (3)Department of Marine Sciences, University of Gothenburg, Sweden, (4)University of Gothenburg, Sweden, (5)Technical University Berlin, Chair of Environmental Chemistry and Air Research, Germany, (6)University of Oldenburg, Institute For Chemistry And Biology Of The Marine Environment (ICBM), Germany*
Microplastics (MP) and tire wear particles (TWP), recently included in the MP definition, are omnipresent in the (marine) environment. Still, little is known about these pollutants concerning mass-based concentrations, transport and effects in the marine environment and boundary layer, which covers air, sea surface microlayer (SML) and underlying water (ULW). The SML is a ubiquitously occurring, predominantly organic film with a thickness below 1 mm.

Air, SML and ULW (1 m depth) samples were collected simultaneously with a remote-controlled research catamaran. Three Swedish fjord systems with different anthropogenic influences (urban, industrial and rural areas) were chosen for sample collection with the aim to learn more about vertical MP transport and potential enrichment in the SML.
Identification and quantification were conducted with pyrolysis-gas chromatography-mass spectrometry based on polymer specific backbone-related clusters. These polymer clusters were indicated by the prefix "C" and included amongst others polyethylene (C-PE), polypropylene (C-PP), polyethylene-terephthalate (C-PET), car, and truck TWP (CTT&TTT).
All air and water samples contained MP. Most occurring polymer clusters in the air were CPET and CPC. Concentrations in the air reached up to 49 ng/m^3 air in the fjord in the urban area. Least polluted was the fjord in the rural area. This also applied for the water samples. The fjords in urban (8.5 µg/L SML and 6.0 µg/L ULW) and industrial environments (6.6 µg/L SML and 7.3 µg/L ULW) were more polluted than the rural fjord system (1.8 µg/L SML and 2.0 µg/L ULW). Water samples were predominantly polluted by C-PMMA, CTT and C-PET. C-PE, C-PP, C-PET and CTT were accumulated in the SML while C-PMMA and C-PC were more present in the ULW.

4.14.P-Th357 Determination and Mitigation of Microplastic and Pollutant Emissions from Synthetic Turf Sports Fields
*Laura Pruin[1], Mike Wenzel[2], **Carmen Wolf**[2] and Jochen Tuerk[3], (1)IInstitut für Energie- und Umwelttechnik e. V. (IUTA), Germany, (2)Institut für Energie- und Umwelttechnik e. V. (IUTA), Germany, (3)Institute of Energy and Envionmental Technology e.V. (IUTA), Germany*
Synthetic turf is becoming increasingly popular. However, the use of plastics as a surface covering is also potentially associated with the risk of a possible release of microplastics and other chemicals into the environment.
To assess and determine the infill losses released into the environment, approximately ten different artificial turf pitches are under investigation. The emissions of microplastics and chemicals of concern will be evaluated in water, soil in the surroundings of the sport fields as well as air using TED-GC-MS analysis. To ensure correct identification and quantification of the polymers, an optimisation of the analytical parameters will be carried out before the sampling campaign.
The effectiveness of particle removal of infill losses from new and old sports facilities, taking into account factors such as ageing, weather conditions and frequency of use, will be analysed as part of the project. Furthermore, a new filtration technology for particle separation that is installed directly on the playing field will be evaluated at Sittensen, Germany.
After completion of the investigations, the loads of microplastics and other water-relevant pollutants will be calculated.

4.14.P-Th358 Can Tire Wear Markers Be Used to Estimate the Load of Microplastics Derived From Tires in River Bed Sediments?
***Heather Carter**, Richard Cross, David J Spurgeon and M. Gloria Pereira, UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*
Tire wear particles (TWP) have been proposed as a significant contributor to microplastic contamination of freshwater environments through road run-off and are predicted to concentrate in sediments given their relatively high density. Estimates have been made as to the emissions of this material to freshwaters, but given the complex nature of this composite material, these must be grounded on robust, reproducible and quantitative methods.
In this pilot study we attempted to establish a reproducible method for the analysis of TWP in sediment matrices using Gas Chromatography-Mass Spectrometry (GC-MS). TWPs offer a unique challenge compared to other microplastic materials due to their optical properties, which prevents their detection in complex matrices using the more traditional method of Fourier Infrared Transformation, FTIR. Importantly, GCMS offers the potential to quantify mass of TWP, a key requirement for parameterising and ground truthing material flow assessments and models of microplastic fate in the environment. Quantification of TWP will be compared to other microplastic loads in select sediments (FTIR) to provide insight into the relative contribution of this source of pollution in sediments.
We used 6-PPD (N-phenyl-N'-(1,3-dimethylbutyl)-p-phenylenediamine) as a marker to assess the presence of TWP. We established a method where TWP were extracted from sediments using microwave digestion followed by clean-up steps before analysis on GCMS. For quality purposes, a surrogate compound was used to spike the samples prior to extraction to demonstrate consistent recovery of 6-PPD standards from sediment matrix. Quality assurance and control in new methods is essential, so the approach and results from this effort will be reported and general lessons summarised.
Given the high heterogeneity of sediments, any method employed must be sufficiently sensitive to measure relevant differences between sampling sites. With this in mind, the design of river sediment sampling was such that the spatial heterogeneity of sediments could be interrogated using two exemplary sites, one on the Thames River, and the other in the Greater Manchester catchment, UK. In doing so, not only is a method of a relevant marker for TWP from complex sediment samples presented, but also insights into the degree of heterogeneity inherent to river sediments. This knowledge is essential to underpin the design of sampling and monitoring campaigns for this pollutant in the future.

4.14.P-Th359 First Screening of Volatile Methylsiloxanes in Crumb Rubber
***Nuno Ratola**[1], Tiago Ferreira[2], Arminda Alves[2] and Vera Homem[2], (1)Universidade do Porto, Faculdade de Engenharia, Portugal, (2)University of Porto, LEPABE, ALiCE, Portugal*
One of the possible "destinations" of recycled tyre rubber are synthetic turf sports' facilities, where this material is commonly applied as infill, in the form of small granules – crumb rubber – now included in the family of microplastics (<5 mm). In spite of the benefits that this approach carries from a circular economy perspective, several public health concerns have been raised regarding a recurrent contact with crumb rubber during physical exercise, with several studies having detected the presence of potentially hazardous chemicals in this matrix, including PAHs, plasticizers and heavy metals, among others. The main goal of

this work was to evaluate for the first time the presence of volatile methylsiloxanes (VMSs), a class of ubiquitous anthropogenic contaminants, in crumb rubber. A total of 126 samples were analysed – 120 field samples (108 of crumb rubber and 12 of other infill materials) and 6 commercial unused samples. Seven VMSs were analysed – three linear (L3, L4, L5) and four cyclic (D3, D4, D5, D6). The extraction protocol employed consisted of an ultrasound-assisted extraction, using a 1:1 (v/v) mixture of n-hexane and dichloromethane, with a QuEChERS clean-up methodology. The quantification of the extracts was carried out by gas chromatography coupled with a mass spectrometry detector (GC-MS). The method detection limits ranged from 0.006 to 4.46 $ng.g^{-1}$ (for D5 and D3, respectively). VMSs were detected in all samples, in total concentrations ranging from 10.29 to 5,089 $ng.g^{-1}$. D3 and the linear compounds were not detected in any of the field samples – only in commercial crumb rubber. The mean concentration of commercial samples (976.1 ± 2,016 $ng.g^{-1}$) was 17.6 times higher than field crumb rubber (34.50 ± 16.09 $ng.g^{-1}$), and cork was the only infill material with a lower mean concentration than crumb rubber (27.14 ± 31.22 ng.g-1). From these results, oral and dermal exposure doses were estimated for assiduous users of synthetic turf football fields: young players (6-11 years old), adult players and turf maintenance workers. "Worst-case scenario" oral doses ranged from 8.23 to 21.3 $ng.kg^{-1}.year^{-1}$ and dermal doses from 0.598 to 0.898 $ng.kg^{-1}.year^{-1}$.

4.14.P-Th360 Environmental Dispersion and Fate of TWP in the Environment: The LEON-T Approach: Towards Reliable and Comparable Data

*Peter Tromp Sr[1] and **Joris T.K. Quik**[2], (1)TNO, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands*

In the past decade, microplastics have drawn much attention. Tyre wear particles (TWPs) are estimated to be a large source of microplastics (MPs) emission. To understand their impact on the environment better, reliable and comparable data on their distribution, physicochemical properties and fate is necessary. This data is key to allow balanced legislative measures to limit the spread of these particulate emissions to be adopted. Several models exist that estimate the dispersion of particulate matter from the road into the wider environment (air, soil, water). However, these models lack calibration data for the actual particle size distribution of the emitted particles and for the quantification and possible transformation of particles in the different environmental compartments. In the European project LEON-T (Low particle Emissions and lOw Noise Tyres) thermo-analytical and microscopic techniques and methods have been assessed and improved, and a methodological framework was set up for measuring TWP to allow reliable quantification and size selective characterization of TWP in environmental matrices. For the evaluation of thermo-analytical techniques, a selection of environmental samples was analyzed using different methodologies described by Tromp (TNO), Eisentraut (BAM) and Unice (ISO/TS 21396 & 20593). Furthermore, to gain more insight in the contribution of TWP to microplastic distribution in the environment selective field measurements were performed based on identified data gaps from existing field data. These monitoring campaigns involved measurements of TWPs in air, atmospheric deposition, surface water, sediment and soil at varying distances from highways, urban and rural roads. To gain inside into the physicochemical properties, photochemical transformation and degradation processes, road simulator tests were performed to collect tyre wear material for additional accelerated UV aging experiments. The collected samples were analyzed using a complimentary toolbox of techniques, i.e., cascade-filtration, pyrolysis gas-chromatography with tandem mass spectrometry (TGA-TDU-GCMSMS) and high-resolution scanning electron microscopy in combination with energy dispersive X-ray analysis and cathodoluminescence (FEG-SEM-EDX/CL)). The obtained data will be used to validate the new LEON-T emission model to be developed to further estimate the fate of TWP in the environment (air, water and soil) and inform policy on effective measures to reduce TWP emission.

4.14.P-Th361 Microplastics Pollution from Communication Routes: Detection of Tire Particles in Environmental Samples

***Katarzyna Styszko**[1], Jagoda Worek[1], Xymena Badura[2], Anna Białas[1], Joanna Chwiej[1] and Kamil Kawoń[1], (1)AGH University of Science and Technology, Poland, (2)Oil and Gas Institute, National Research Institute, Poland*

Microplastics are one of the largest pollutants in the world. Since the 1970s, it has already existed, but there has been no better alternative than plastic. It is related to easy and cheap production, high availability, and specific properties of plastics, such as plasticity, chemical resistance, and lightness. An important issue related to dust emission is the microplastic of tyres and brake blocks. Typically, two estimation methods are used to quantify tire wear. The first concerns the application of the emission factor to the vehicle per kilometer. The second method is based on estimating the degree of loss of tire mass. The emission masses per capita are estimated to be in the range of 0.2 to 5.5 kg / year (Jan Kole et al., 2017). So far, there has been only a few studies that have detected tire microplastics in environmental samples. Research onthis topic, especially on environmental samples, is insufficient.

This study attempted to identify microplastics from transport, mainly targeting microplastics from tyres (J. Worek et al. 2022). Fourier transform infrared (FTIR) spectroscopy was used for the identification of synthetic rubber, most likely derived from car tyres. To confirm the results from FTIR, the complementary method of molecular spectroscopy, namely Raman microspectroscopy, was applied. Soil samples and road dust from the areas with heavy traffic. An average of 372±50 fragments per kilogram of dry weight were detected in the soil samples. In the case of road samples, this number was 515±20 fragments per kilogram of dry matter. More than 90% of the black fragments later identified as synthetic rubber were found in the samples. The microplastics from the road dust was less degraded than the microplastics from the soil. The influence of the environment in which microplastics reside on the leaching of various substances, especially organic compounds, is still a big gap in knowledge. The great advantage of the research conducted is the combination of infrared and Raman methods. These are complementary methods.

4.14.P-Th362 Deposition of Airborne Microplastic and Tire Wear Particles in Salt Marsh Habitats: Proximity to Bridges
John E. Weinstein[1], *Mary C. Ballentine*[1] *and Bonnie M. Ertel*[2], *(1)Biology, The Citadel, (2)University of South Carolina*
The pathways by which microplastic and tire wear particles (TWP) enter coastal ecosystems remain poorly understood, especially those pathways transporting airborne particles. As such, the objective of this study was to assess the deposition of airborne microplastics, including TWP, into three salt marsh and salt marsh-adjacent locations around Charleston Harbor, SC (USA). To accomplish this, we collected samples using stainless steel buckets (324 cm^2) through passive deposition during both wet and dry periods. Retained particles were filtered onto glass fiber filters and visually analyzed under a dissecting microscope. Suspected microplastic particles were confirmed as synthetic with the hot needle test, and a subset were examined using FTIR spectroscopy. Microplastic deposition was dependent upon location ($p<0.0001$) with the highest abundances associated with the site adjacent to a bridge crossing Charleston Harbor (4,825.8 ± 816.5 MP/m^2/day). Most particles (95.3%) at this site were TWP. Deposition at the other two sites ranged from 137-802 particles/m^2/day and were not significantly different from one another. At these two sites, fibers and TWP were the most common particles. Deposition of airborne microplastics at all three sites was not dependent upon precipitation ($p=0.60$). Future research will investigate the morphological features of the particles (size and shape), and the correlation between particle deposition at these sites and meteorological factors (wind speed and direction). These results suggest that proximity to sources, such as roadways and bridges, significantly influence the abundance and types of microplastic particles deposited in salt marsh habitats through airborne pathways. This is the first evidence of airborne TWP in the size fraction 63 - 5000 µm being deposited in salt marshes and underscores the need to include airborne pathways when holistically assessing microplastic exposures in these sensitive coastal habitats.

4.14.P-Th363 Quantification of TWP/TRWP in PM10 Airborne Dust of Contrasting Sites
Juanita Rausch, *Particle Vision, Switzerland*
The link between particle pollution and health issues has been widely demonstrated during the last decades. Consequently, the WHO recommended new limit values for particulate matter PM10 and PM2.5 in September 2021. Following these recommendations it can be expected that many inhabited areas are affected by PM10 and PM2.5 exceedances. Therefore, authorities have more than ever the need of seeking lowering PM values. To achieve this by implementing targeted dust mitigation measures it is necessary to first obtain a better understanding on the fine dust constituents. Unfortunately, there is no one single method that can characterize the totality of PM10 owing to the intrinsic different characteristics of particles, and hence, stability and detectability with the various available methods. In particular, the differentiation and quantification of tyre/road wear particle mixtures (TWP/TRWP) has not been yet routinely included in the PM characterization and monitoring due to the analytical difficulties encountered, so far. Here, we present a newly developed approach based on morpho-chemical single-particle analysis by Scanning Electron Microscopy (SEM) coupled to Energy Dispersive X-ray Spectroscopy (EDX) complemented with a machine-learning (ML) based algorithm that classifies and quantifies TWP/TRWP in passively collected (Sigma-2, VDI 2119:2013) airborne dust samples.
Measurements at multiple sites with contrasting characteristics were performed in Switzerland (Bern, Zurich and Bussigny) and Great Britain (London). Clear differences in the concentration of TWP/TRWP were observed between the various site typologies with the highest TWP/TRWP concentrations in Switzerland at the traffic/urban canyon site in Bern (2.2 µg/m^3 annual mean) and the lowest in the urban background site in Zurich (0.3 µg/m^3 annual mean). Furthermore, seasonal variations most likely related to (a) meteorological conditions likely to induce particle accumulation and subsequent enhanced resuspension, and to (b) higher biogenic activity during autumn and summer were detected.
Similarly, among the London sites, the urban background site presented the lowest TWP/TRWP and metal wear concentrations (in average, 0.5 µg/m^3 and 0.7 µg/m^3, respectively) resembling values determined in the urban background site in Zurich (CH). The traffic site with a speed limit of 50 mph showed the highest concentrations with 2.0 µg/m^3 of TWP/TRWP and 9.5 µg/m^3 of metal wear particles in average.

4.14.P-Th364 Roadway to Linking Exposure and Effects of Highway Stormwater Runoff and Particulate Matter – First Case Study Results from a Highly Frequented Highway in Germany
Markus Thomas Schmitz[1], *Selina Seibold*[1], *Alexander Maria Pape*[1], *Kun Qiao*[1], *Martin Krauss*[2], *Miklós Bálint*[3], *Alper James Alcaraz*[4], *Milena Doreen Esser*[4], *Markus Brinkmann*[4], *Markus Hecker*[4], *Regina Dolny*[5], *Simone Lechthaler*[5], *Volker Linnemann*[5], *Sabrina Schiwy*[1] *and Henner Hollert*[1], *(1)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (2)Department of Effect-Directed Analysis, Helmholtz Center for Environmental Research, Germany, (3)Functional Environmental Genomics, Senckenberg Biodiversity and Climate Research Centre, Germany, (4)Toxicology Centre, University of Saskatchewan, Canada, (5)Institute of Environmental Engineering, RWTH Aachen University, Germany*
Awareness and knowledge about road runoff toxicity and tire and road wear particles (TRWPs) are rapidly increasing. Yet, the fate and ecotoxicological effects outside of communal wastewater treatment systems are insufficiently understood paired with a lack of data about how TRWPs interact with other road runoff pollutants.
Consequently, aquatic environmental risk assessment of TRWP polluted runoff faces the following challenges: **(1)** Due to structural and chemical variability of TRWP, no standardized sample preparation protocols for (bio-)chemical assessment are available; **(2)** The lack of environmentally relevant effect data complicates *a priori* decisions on endpoints of interest to investigate. Therefore, comprehensively investigating the ecotoxicity of TRWP demands a bottom-up scientific approach generating a broad knowledge base covering both chemical and biological effect information for different environmental model scenarios.
The project *RoadTox* aims for a quantitative ecotoxicological risk assessment of stormwater runoff sampled from highly frequented urban, country, and highway roads. Here we present the current project state with a special focus on results obtained

from an extended fish embryo toxicity assay battery on *Danio rerio* embryos combining several sublethal endpoints. Presented data includes standard sublethal effects complemented with spontaneous tail coiling, heartbeat-tracking, light-dark-transition responses and *in-vivo* EROD-activity. Additionally, supporting *in-vitro* data (e.g., EROD, estro- and androgenicity), chemical data, and road site biofilm community information from metabarcoding will add to the discussion.
Current results strongly indicate that road runoff toxicity is largely driven by particulate-bound contamination. Applied sublethal non-standard endpoints in zebrafish (e.g., light-dark transition response and *in-vivo* EROD) were able to detect effects in low concentration ranges ($\leq EC_{10}$). Chemical profiles strongly depend on preceding weather conditions but display a mutual composition pattern between different samples obtained from the same site. Both PAHs and metals concentrations in parts reached concentrations which may impact fish health. However, at this stage, no general conclusion is possible yet.

4.14.P-Th365 Effects of Nano Tire Wear Particle Exposure and Increasing Temperature on an Estuarine Indicator Species

***Lauren Miki Kashiwabara**[1], Jillian Ragno[1], Stacey L Harper[2], Bryan J. Harper[2] and Susanne M Brander[1], (1)Department of Fisheries, Wildlife, and Conservation Sciences, Oregon State University, (2)Environmental & Molecular Toxicology, Oregon State University*

Tire wear particles (TP) are synthetic rubber particles commonly released into the environment from automobiles. Our lab has previously found that the model organism, mysid shrimp (*Americamysis bahia*), exposed to nano-size TP showed changes in behavior and growth. Further, preliminary results from our lab indicate that temperature in combined exposures to nanofibers may also drive physiological changes in mysid shrimp. To provide insight into how organisms may fare with increasing TP pollution and changing ocean conditions, we will run a factorial experiment testing the effects of varying TP concentrations (5, 50, 500 particles/mL) and temperatures (12, 14, 16 C) on mysid shrimp. After a 7-day exposure, we will examine behavior, hypoxia tolerance, reactive oxygen species, and caloric value. The results of our experiments with model organism *A. bahia* will show multi-stressor effects of pollution and climate change and may indicate how populations of a mysid shrimp species off of the Oregon Coast, *Holmesimysis sculpta*, a significant component of gray whale diets in the same order, may be impacted by increasing marine debris and ocean temperatures.

4.14.P-Th366 Chronic Effects Induced by End-of-Life Tire (ELT) Derived Rubbers: An Integrated Approach by Biomarkers and Proteomics

***Stefano Magni**[1], Beatrice Plebe[1], Lara Nigro[1], Riccardo Sbarberi[1] and Andrea Binelli[2], (1)Biosciences, University of Milan, Italy, (2)Dipartimento di Bioscienze, Università degli Studi di Milano, Italy*

Every year a large amount of tires reaches their end-of-life and becomes wastes. Most of the so-called End-of-life-Tires (ELTs) are recycled to produce other objects or used for energy recovery. The aim of this study was the evaluation of the chronic toxicity induced by leachates of ELT-derived rubber granules (GR; from 0.8 to 2.5 mm, rough size) and powder (PW; < 0.8 mm, rough size) in the freshwater model *Danio rerio* (zebrafish). We firstly investigated the leachate composition (100 mg/L) characterizing the released chemicals, as well as the eventual presence of micro- and nanoparticles. Subsequently, we exposed the zebrafish embryos from 0 to 120 hours post fertilization (hpf) to the ELT leachates. Considering the Lowest Observed Effects Concentration (LOEC) of 10 mg/L ELTs, obtained in our previous study on zebrafish, we decided to perform the exposure to 0.1, 1 and 10 mg/L of both GR and PW. As endpoints of sub-lethal effects, we performed some biomarkers of cellular stress, as the activity of the antioxidant/detoxifying enzymes superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), glutathione-S-transferase (GST) and ethoxyresorufin-O-deethylase (EROD), as well as the measurement of Reactive Oxygen Species (ROS). As biomarkers of neurotoxicity, we evaluated the activity of acetylcholinesterase (AChE) and monoamine oxidase (MAO). Subsequently, also the high-throughput analysis by proteomics was performed to highlight the eventual modulation of zebrafish proteins. We observed only a significant modulation ($p < 0.01$) of EROD activity in specimens exposed to 1 and 10 mg/L of GR, while proteomics revealed the modulation of many proteins, from 37 in the organisms exposed to 0.1 mg/L of GR to even 108 in both 0.1 and 1 mg/L of PW experimental groups. The network analysis highlighted that many modulated proteins are involved in nitrogen and aromatic compound metabolism. This evidence suggests the possible adverse effects induction by the chemicals in the ELTs, as polycyclic aromatic hydrocarbons (PAHs; presents in ELTs as carbon black contaminants) and nitrogen compounds (e.g. adsorbed during the road activity). Currently, based on the high release of Zn by ELTs, we are measuring the metallothionein induction. Lastly, as apical endpoints, we are performing the analysis of behavioural alteration, to also provide the mode of action of ELTs on freshwater biological model.

4.14.P-Th367 Daphnia Reproductive Impacts Following Chronic Exposure to Micro and Nano-Scale Particles from Three Types of Rubber

*Brittany Cunningham[1], **Bryan J. Harper**[2], Susanne M Brander[3] and Stacey L Harper[4], (1)Toxicology, Oregon State University, (2)Environmental & Molecular Toxicology, Oregon State University, (3)Department of Fisheries, Wildlife, and Conservation Sciences, Oregon State University, (4)Oregon State University*

Environmental sampling has documented high levels of black rubber microplastics in aquatic environments. These are often attributed to particles shed from driven tires; however, the use of recycled, or crumbed, rubber particles in artificial turf and flooring is another source of these particles. Studies have shown that acute exposure to micro, and nano-sized tire particles, as well as tire leachate can be toxic to aquatic organisms. Chronic toxicity assessments with tires are limited, and there is a need to evaluate impacts of rubber particles in smaller size-classes and from different sources to better understand the role that these features play in conferring toxicity. We investigated the impact of chronic exposure of *Daphnia magna* to micro (1-20 µm, $3.13 \times 10^4 - 1.25 \times 10^5$ particles/ml) and nano (<1 µm, $1.25 \times 10^5 - 1.0 \times 10^7$ particles/ml) sized rubber particles. The rubbers included tire particles (TP) and two types of rubber from recycled tires (called recycled rubber (RR) and crumb rubber (CR) based on their product labels). Triplicate exposures began at 7 days old and lasted for a total of 28 days. Mortality, reproduction, and molting were assessed daily, and growth was measured at the end of the exposure. Additionally, the F_1 generation was reared for 28 days in particle-free water to assess multigenerational impacts. Exposures were conducted at sublethal levels where mortality was not observed. Chronic exposure to the micro rubber particles had severe impacts, delaying, decreasing and even eliminating reproduction starting at 6.25×10^5 particles/ml. Chronic exposure to the nano rubber particles had less severe impacts, but delayed and decreased reproduction at the highest exposure level, 5.0×10^7 particles/ml. Exposure to nano rubber in the parental generation had impacts on reproduction in the F_1 generation. Compared to acute exposures, much lower concentrations of rubber particles in both micro and nano sizes caused impacts for chronically exposed *D. magna*. Furthermore, the immense reproductive effects that chronic exposure to rubber particles have shown could have devastating impacts on populations of aquatic invertebrates.

4.14.P-Th368 Toxicity of Tire Particles From Personal Mobilities on Soil and Aquatic Organisms

***Lia Kim**, Haemi Kim, Tae-Yang Lee and Youn-Joo An, Konkuk University, Korea*

Tire particles (TPs) generated from the roads are one of the microplastic source in the ecosystem. These particles directly release to soil and contact with water-media and leaching some additive-chemicals. TPs are continuously exposed to both soil and aquatic environments and threaten the living organisms. Using the TPs and TPs-leachate, the overall toxicity of TPs was evaluated. Three types of TPs (from bicycle, car, and electric scooter) were prepared and then exposed to *Vigna radiata* and *Folsomia candida* at 10 g/kg soil concentration. TPs-leachates were also prepared and then 50% concentration of leachate was exposed to aquatic organisms (*Daphnia magna* and *Danio rerio*). TPs directly induced the inhibition on the growth of *V. radiata* and *F. candida*. TPs-leachate also disturbed the movement of *D. magna* and normal development on *D. rerio*. This result suggests that TPs from road directly induce the growth inhibition on soil organism and release some chemicals, eventually affecting aquatic organisms.

4.14.P-Th369 Developmental Toxicity of Recycled Tire Wear Microplastic Leachates to Larval Lamprey (*Lampetra planeri*)

***Flora Rendell-Bhatti**[1], Arne Jacobs[2], Elma Lahive[3], Eva Jimenez-Guri[4] and Colin Bull[5], (1)Biological and Environmental Sciences, University of Stirling, United Kingdom, (2)University of Glasgow, United Kingdom, (3)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (4)University of Exeter, United Kingdom, (5)University of Stirling, United Kingdom*

Whilst research on the occurrence of microplastic in freshwater environments has been increasing in recent years, the consequences of the presence of microplastics for these ecosystems are not elucidated. Particularly, whether the early developmental stages of protected vulnerable species are impacted is a pertinent question when trying to understand the consequences of plastics in our natural environment. Untreated road run-off is a significant source of tyre wear particles and associated contaminates to the freshwater environment, often exceeding the lethal concentration of some chemicals to aquatic biota. The impacts of tire wear particle contamination on early developmental life stages are understudied, and yet the outcomes of this sensitive period being disrupted could have important ecological consequences. Tire wear particles are a substantial proportion of microplastics reported in the aquatic environment and they can leach a range of chemical compounds, which have been shown to elicit toxic effects. Lamprey species in Europe are undergoing important population declines due to a multitude of stressors, which are essential to understand if we are to conserve and manage threatened populations. To the best of our knowledge, this is the first study to observe developmental defects that leachates from tyre wear particles elicit in lamprey embryos. We use recycled tire wear particles to generate a microplastic leachate in which embryos were cultured. Preliminary data suggest that exposure to leachates, following 10-day incubation of <65µm tire wear particles at 0.5%, elicits consistent defects in the brook lamprey (*Lampetra planeri*) embryos. The phenotype we observe in the microplastic treatment suggests that compounds in the leachate weaken the vitelline membrane, causing the yolk to leak out. This study documents developmental defects in larval lamprey which were exposed to leachates of tire wear particles, demonstrating the potential contribution of this stressor to the population status of this vulnerable species. Further research on the ecotoxicological impacts of tire wear particles is needed to aid our understanding of whether this complex contaminate has a role in lamprey population declines.

4.14.P-Th370 Gene Expression Analysis of *Chironomus riparius* in Response to Acuate Exposure to Tire Rubber Particles and Leachates

***Patricia Caballero Carretero**[1], Victor Carrasco Navarro[2], Jussi Kukkonen[2] and Jose-Luis Martinez-Guitarte[3], (1)National Distance Education University (UNED), Spain, (2)University of Eastern Finland, Finland, (3)UNED, Spain*

Aquatic pollution caused by tire rubber microparticles (TRP) entering aquatic ecosystems through stormwater is an important challenge. Tire rubber includes many microplastic particles and chemical additives which are a cause for concern. Currently, the information on the molecular effects of TRP, or specially its additives, in freshwater organisms is scarce.

To address this problem, an array covering different cellular processes has been designed for the freshwater midge *Chironomus riparius*. Fourth-instar larvae were exposed to two concentrations of TRP (1 $mg \cdot L^{-1}$, 10 $mg \cdot L^{-1}$) and two concentrations of tire rubber leachates (TRL) (0,0125 %, 5 %) to evaluate the transcriptional activity by Real-Time PCR. To assess acute toxicity, larvae were exposed for 24h and genes related to endocrine system, stress response, DNA repairing mechanisms, oxidative stress, and detoxification mechanisms were evaluated. The activity of the enzymes: glutathione S-transferase (GST) and catalase was also examined.

The main pathway affected was the stress response, showing overexpression of *HSPs*. Moreover, there is a reduction of the *GSTd3* and *catalase* disrupting the antioxidant system. Most of these alterations are caused by TRL, showing higher toxicity than TRP. The results obtained in this work provide the first approach at the molecular and cellular levels to elucidate the impact of

TRL in freshwater organisms. To perform a realistic evaluation of the TR effects, additional research is required to assess the TR long-term effects at the molecular level.

4.14.P-Th371 Mitigation of Tire Rubber Microplastic Ecotoxicity by Combined Vacuum UV and UV-C treatment

*Emil Bock Nielsen[1], Niels Iversen[1] and **Peter Roslev**[2], (1)Department of Chemistry and Bioscience, Aalborg University, Denmark, (2)Aalborg University, Denmark*

Synthetic rubber is one of the most widely used plastic polymers in products such as footwear, rubber bands and vehicle tires. A significant source of microplastics in the environment is tire rubber microplastics (TRMP) and the average global emission of TRMP has been estimated to 0.8 kg/year per capita. Some TRMP settle close to the emission source, but a significant fraction can be transported in air and water between environmental compartments, and may eventually end up in surface waters. Degradation of TRMP in surface waters is very slow and can take hundreds of years. Most TRMP are therefore persistent pollutants in aquatic ecosystems. The effects of TRMP on most aquatic life is poorly understood but significant ecotoxicity to some species has been observed. A potential degradation pathway for TRMP is photodegradation and in particular exposure to short-wave ultraviolet light (UV). This study investigates the effects of short-wave UV irradiation of TRMPs and TRMP leachates on degradation and ecotoxicity. TRMP particles and leachates in water were exposed to different UV regimes including UVC (254 nm) and combined UVC and vacumm UV irradiation (185 nm). Combined VUV/UVC irradiation has a potential to degrade TRMPs due to generation of different reactive species that can interact with rubber constituents. UV irradiation was conducted using a collimated beam setup with different UV exposure doses. Ecotoxicity of non-treated and UV-treated TRMPs was examined using a battery of test organisms that included the luminescent bacterium *A. fischeri*, the freshwater microalga *R. subcapitata*, and the crustacean *D. magna.* Changes in genotoxicity was measured using the SOS Chromotest. The study confirmed the presence of several toxic constituents in TRMP leachates including zinc and PAHs such as fluoranthene, pyrene and benzo(a)pyrene. Interestingly, VUV/UVC treatment removed toxic compounds from TRMP leachates and decreased the overall ecotoxicity. PAHs were degraded by up to 90% by VUV/UVC treatment and the apparent ecotoxicity decreased 5-fold as indicated by changes in median effective concentrations (EC50). These findings indicate a potential of VUV/UVC treatment as a method to mitigate toxic compounds in TRMP leachates.

4.14.P-Th372 Investigation of in-vivo Biomarker Responses in *Danio rerio* Embryos Exposed to Highway Stormwater Runoff following different Precipitation Scenarios

***Alexander Maria Pape**[1], Selina Seibold[1], Markus Thomas Schmitz[1], Kun Qiao[1], Martin Krauss[2], Regina Dolny[3], Simone Lechthaler[3], Volker Linnemann[3], Henner Hollert[1] and Sabrina Schiwy[1], (1)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (2)Department of Effect-Directed Analysis, Helmholtz Center for Environmental Research, Germany, (3)Institute of Environmental Engineering, RWTH Aachen University, Germany*

In recent years, the adverse effects of road wastewater and tire and road wear particles (TRWP) have attracted increased focus in environmental sciences. However, distribution and ecotoxicological implications in the environment are poorly understood, and only few data on the interaction of TRWP and other road-related pollutants are available.

This study is part of the project “RoadTox: Ecotoxicological Assessment of Tire and Road Wear Particles in Stormwater Runoff of Heavily Frequented Roads”, investigating the acute toxicity of highway runoff samples to aquatic organisms via exposure to sublethal concentrations of road runoff, including selected biomarkers.

Runoff samples were taken at the federal highway 4 in Aachen, North-Rhine Westphalia, Germany, during rain events. Samples were filtered and fractioned into three groups (unfiltered runoff, filtered < 63 µm, or 0.3 - 0,6 µm). This poster presents experiments with *Danio rerio* embryos assessing acute toxicity until 120 hpf according to FET DIN EN ISO 15088, as well as several *in-vivo* biomarker responses. Biomarker endpoints comprise dioxin-like activity (EROD), synaptic signalling (AChE) effects, as well as possible oxidative stress (e.g., glutathione peroxidase or catalase). In addition, this study compares several environmentally relevant scenarios throughout the year, e.g., snow melting events in spring or heavy rains after long dry periods, possibly leading to an increase in particles and pollutants in runoff and subsequent leaching of contaminant loads. Preliminary results show a strong difference in acute toxicity over the year and an increase in EROD activity, indicating metabolism and potential bioactivation of xenobiotics.

Native samples were chemically analysed for carbohydrates (PAH and mineral oils), (heavy) metals, and microplastics shared by the Institute for Environmental Engineering at the RWTH Aachen (ISA). For completion of data, organic extracts were analysed by the Helmholtz Centre for Environmental Research for a wide variety of common TRWP contaminants.

4.14.P-Th373 Sub-cellular Effects of Tire Particles and Bioaccumulation of Their Associated Chemicals in the Aquatic Insect *Chironomus riparius*

***Rébecca Beauvais**[1], Thibault Masset[2], William Dudefoi[3], Kristin Schirmer[3], Alan J Bergmann[1], Etienne Vermeirssen[1], Florian Breider[2] and Benoit J.D. Ferrari[4], (1)Ecotox Centre, Switzerland, (2)Ecole Polytechnique Fédérale de Lausanne – EPFL, Switzerland, (3)Environmental Toxicology, Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (4)Centre Ecotox, Switzerland*

Through road runoff, tire and road wear particles (TRWP) can reach freshwater ecosystems and settle down in river or lake sediment. Benthic organisms, for instance insect larvae, will potentially be exposed to TRWP and associated chemicals (e.g. PAHs, metals, antioxidants/antiozonants) through direct contact and/or ingestion. While many ecotoxicological studies have been published on pelagic organisms, research concerning organisms living in or on sediment are scarce. Among them, chironomid larvae are a source of food for fish and therefore relevant to the trophic transfer of chemicals in aquatic ecosystems. To assess the potential effects of tire particles, we evaluated biological endpoints and bioaccumulation of TRWP-associated chemicals in

Chironomus riparius. For our experiment, we used cryogenically milled tire tread (CMTT) particles as a proxy for TRWP. We exposed 4th stage larvae for up to 4 days to clean sand or sand spiked with 0.5% CMTT (dw). The expression of 16 genes involved in detoxification, immunity, response to oxidative stress and endocrine response were assessed after the 4-day exposure. Bioaccumulation of CMTT-related chemicals were measured after 2, 3 and 4 days on depurated larvae. We observed no mortality nor effect on growth in larvae exposed to CMTT. We however observed a differential gene expression for 4 biomarkers, namely for a gene involved in immunity (*defensin*) and for the detoxification (*CYP450*). The dysregulation of this expression helped larvae to cope with the stress caused by the exposure to the spiked sand. Bioaccumulation kinetics showed chemical-dependant rates as some compounds reached steady state after 4 days of exposure while others did not. Overall, for most tire-associated chemicals, Biota-Sediment Accumulation factors were low and ranged from 1.3 to 6.3. Although the chironomids have accumulated CMTT-related chemicals, there was no ecotoxicological effects on 4th stage larvae at the individual scale. As such, contaminated larvae could represent an important source of TRWP-related chemicals for fish. Our study additionally helped to gain mechanistic knowledge of this particular mixture on model invertebrates. Future experiments will aim at studying the contribution of ingested particles to the accumulation of CMTT-associated chemicals in larval tissues. To support the molecular responses, the level of activity of enzymes, (e.g. phenoloxidase for immune response, catalase for oxidative stress) will be analysed.

Track 5: Life Cycle Assessment and Foot-Printing

5.01 Circularity, Recycling and Multi-Functional Systems

5.01.P-Mo342 Applying System Expansion with Multiple Functions to Address the Overall System Burdens of Recycling in Comparison to other Circular Economic Material Strategies

***Simon Alexander Saxegård**, Fredrik Wikstrøm and Helén Williams, Karlstad University, Norway*

It is common in LCA today to environmentally evaluate material recycling from a product level perspective. A problem with the product level perspective is that the total burden of recycling is divided into several product value chain stages that are inherently connected by the recycled materials without fully disclosing the overall system level burden of recycling. Therefore, it is challenging to compare recycling to otherwise linear not-circular product material strategies and derive at one unambiguous conclusion at the overall system level, and in turn the societal level perspective. Amplifying the multi-result output problem when addressing the different stages of recycling from the product level perspective is that there exist many LCA methods for dividing the burdens across the three product life cycles stages connected by the recycled material of which many give different results for the same material recycling scenario. Our suggestion to solve for both of these problems is to address recycling at the overall system level using the LCA method of System Expansion with Multiple Functions (SEMF) by summing together recycle-cascading product life cycles using methods that maintain physical realism at the overall system level and compare these to the alternative Circular Economic (CE) material strategies Reduce, Replace, Recover or any combination of these for an equal number of products. To ensure physical realism, we employ MFA to trace the flow of recyclable and not-recyclable materials through the individual product value chains and across the recycle-cascading product value chains. Our hypothesis is that once we can find one overall system level environmental impact result for recycling, we can compare recycling to and in combination with other material strategies to determine its environmental performance with basis in regionalized socio-technological conditions. The main results shall demonstrate whether the MFA based SEMF method enables a compatible comparison of recycling to other material strategies at the overall system level, and the underlying differences between the product level and overall system level LCA assessment method scopes. This study provides a suggestive LCA framework for addressing the long-standing conundrum in LCA regarding how the academic society can environmentally evaluate recycling relative to other material strategies and gain one unambiguous finding at the overall system level.

5.01.P-Mo351 Contextualized Phosphorus Recycling: Potential Diminution of Phosphorus Criticality at Territory Scale - Application to Agricultural LCA

***Perlette Totoson**, INRAE, France*

Phosphate rock is classified as critical raw material for the European Union's economy. It provides phosphorus (P), which is an essential element for food production and is used as a mineral fertilizer. Due to a lack of a phosphorus substitute in fertilization, recycling is presently the only solution to reduce criticality, especially for countries such as France, that has no phosphate rock reserve and thus, must depend on foreign countries for its P needs for agricultural purposes. MAFOR or fertilizer mineral/organic matter from waste can contain available phosphorus. However, the recycling of P from these deposits for agriculture involves many actors (farmers, regulators, etc.) and depends on the studied spatial scale and its context (economic, regulatory, social, etc.) which can be either constraints or drivers for P recycling. Nevertheless, these issues are not taken into account in the recycling rate used in the raw material criticality assessment nor in the LCA methods. Therefore, it is necessary to contextualize P recycling for a better understanding of phosphorus recycling, and to allow a relevant phosphorus criticality assessment and an environmental impact assessment of phosphorus recycling at a local scale. In order to achieve this, a contextualized model is developed. The goal is to be able to quantify phosphorus which would potentially be used by farmers, originated from the total available quantities of deposits, by respecting the context of the studied territory. The originality of the model lies in the integration of context-factors that can affect the use of P contained in MAFOR by farmers. The model will be applied in two territories in France, which are different regarding the origin of MAFOR produced. As output of the model, four indicators are expected: the effectiveness and efficiency of phosphorus recycling, the dependence on phosphate mineral fertilizers imported from outside France and the contextualized balance between supply and demand in P recycling-derived fertilizers. The model gives a methodology advancement, which would improve or be a complement of the LCA tool to assess territorialized recycling scenarii. The output indicators would improve the understanding of P circularity and, help determine a suitable P recycling pathway to reduce P criticality at a territorial scale and relevant from an environmental point of view.

5.01.P-Mo353 Life Cycle Assessment of emerging Carbon Capture for Utilisation Technologies: Methodological Archetypes at VIVALDI Project

***Jorge Senan-Salinas**, Sergio Ponsá, Laia Llenas and Joan Colon, University of Vic-Central University of Catalonia, BETA Technological Center, Spain*

Carbon Capture technologies for Utilisation (CCU) aim to mitigate climate change through the sequestration of CO_2 from industrial streams within the structure of valuable products for the Technosphere (such as chemicals). Therefore, understanding the environmental impacts of the technology at early stages is useful to reach the final aim of the research. For this purpose, Life Cycle Assessment (LCA) has been pointed out as the most suitable tool. Nonetheless, this methodology has relevant methodological choices that could affect the final decision. Some authors distinguish these issues between non-CCU-specific and CCU-specific.

Among the non-CCU specific issues, we found common LCA issues such as the definition of the functional unit, the approach, the allocation method and so on. Nonetheless, there is an apparent emerging consensus in the definition of methodological choices through the specific definition of the goal. This goal should define, for instance, if the assessment is oriented to understand the process or the product impact (Process-oriented versus product-oriented), if the main goal is to account for the impact or understand the consequent impacts of a decision (attributional versus consequential approach).

On the other hand, besideS the CCU-specific issues, a few points should be remarked such as the consideration of the CO_2 streams (as a co-product or waste), the source (fossil or biogenic), the legal status, the business model of the CCU or the polity framework. This discussion can have some relevance in the methodological choices and can interfere with the abovementioned frameworks.

VIVALDI project aims to convert biogenic carbon dioxide from bioindustries into CO2-based organic acids. The poster will summarise the main potential archetypes identified (n>10) in the context of the VIVALDI project and how these methodological archetypes can be correlated with specific goals and interact with contexts such as the business models, type of CO_2 sources, and potential policy frameworks of the near future.

5.01.T-01 Environmental Assessment of Producing Rigid Polyurethane Foams Using Unrefined Crude Glycerol - Different Strategies

***Paula Quinteiro**[1], Nuno V. Gama[2], Artur Ferreira[2], Ana Dias[2] and Ana Barros-Timmons[2], (1)CESAM, University of Aveiro, Portugal, (2)University of Aveiro, Portugal*

Rigid polyurethane foams (PUFs) are normally used in thermal insulation for construction mainly because of its thermal insulating and mechanical properties. These foams are synthetized by reacting a polyol with an isocyanate in the presence of a catalyst, a surfactant and a blowing agent. So far, most of the polyols used are derived from crude oil feedstocks. Yet, the increasing concerns over environmental issues have been promoting the use of renewable/recycled feedstocks, such as crude glycerol (CG) derived from bio-based feedstocks, like soybean, rapeseed, palm and waste cooking oil (WCO). In turn, from the perspective of a circular economy, recycling PUF waste to recover its polyol or CG content and use it as a partial substituent of virgin polyol or CG in the production of new rigid PUFs (close-loop recovery), rather than disposing it in landfill, is generally seen as a suitable option.

To evaluate that perception, this study compares the environmental impacts of rigid PUF produced using polyol derived from crude oil and unrefined CG derived from bio-based feedstocks, based on life cycle assessment following a cradle-to-grave approach. Three optimised formulations of PUF derived from polyol/CG were considered. Furthermore, recycling of rigid PUF wastes, to recover its polyol/CG, was compared with its disposal in landfill. The results obtained revealed that the different formulations used in this study had distinct impacts depending on the scenarios considered. Moreover, these results have also clearly demonstrated that, overall, the environmental superiority of bio-based feedstocks compared to their fossil feedstock counterpart to produce rigid PUFs cannot always be claimed. Regardless of the scenario considered, the methylene diphenyldiisocyanate is the main hotspot for all impact categories other than marine eutrophication (ME), ranging from 50 to 98% of the total impacts. As regards the scenarios involving polyol/CG recovery, the environmental impacts from the polyol/CG recovery process exceeded the environmental benefits from the PUF waste recycling and the inherent partial replacement of virgin polyol/CG. Indeed, the polyol/CG recovery resulted in a slight increase of the total impacts compared to those without polyol/CG recovery. The perception that introducing the concept of circularity in the rigid PUF production leads to better environmental performance of this industry will require significant improvements in the chemical recycling of PUF.

5.01.T-02 Key Challenges of Bio-fertilisers Modelling (LCA And Non-lca Indicators): A Roadmap to a Consensual Pef-compliant Methodology in the Circular Economy Transition of Agricultural Systems

***Jorge Senan-Salinas**[1], Nancy Peña[1], Karetta Timonen[2], Pasi Korkalo[2], Daniel Egas[1], Laia Llenas[1], Juha-Matti Katajajuuri[2], Joan Colon[1], Ilkka Leinonen[2], Marzena Smol[3] and Paulina Marcinek[3], (1)University of Vic-Central University of Catalonia, BETA Technological Center, Spain, (2)Natural Resources Institute Finland (Luke), Finland, (3)Mineral and Energy Economy Research Institute of the Polish Academy of Sciences*

Nutrient-recovering technologies and alternative fertilisers are key elements in the Circular Economy transition of societies andbthe agro-food industry ,in particular. They are embedded within European policies such as *Farm-to-fork* and new Fertilising Product regulations. These products and technologies allow the obtention of valuable nutrients such as nitrogen (N), phosphorous

(P) or potassium (K) from different waste sources such as organic wastes from agricultural and livestock sectors or urban and industrial wastewater.
Life Cycle Assessment (LCA) has been pointed out as a useful tool for holistic environmental assessment. Generic ISO standards (eg. ISO 14040/4, ISO 14067) and different guidelines, including the Product Environmental Footprint (PEF) guide. Nontheless, they leave numerous open questions and choices of LCA practitioners which might easily direct to the situation where different LCA studies with different choices are not at all comparable. This lack of consensus is an important barrier to benchmarking fertiliser products and delays the decision-making of policymakers, industrial stakeholders and consumers. Moreover, several sustainability issues are only partially covered by LCA impact categories; for example, alternative fertilisers can impact biodiversity, soil propierties and soil carbon sink capacity as well as have an effect on ecosystem services. The scientific consensus on what are the main environmental issues and how to assess them is not well covered and is needed.
NOVAFERT project (EU-funded Horizon Europe grant agreement No 101060835) aims to propose a starting point to fulfil this normative gap by proposing a PEF-compliant methodology of alternative fertilising products covering every life cycle stage: production, storage, distribution and application.
The general methodology follows these three steps: i) the mapping of the current state-of-the-art and identification of key challenges (e.g. emissions modelling, non-LCA indicators) and main methodological choices (e.g., functional unit, system boundaries) of the alternative fertilisers modelling within the existing guidelines, databases (Ecoinvent, Agribalyse…), ii) the assessment of the adaptability of these challenges to PEF normative constraints and its potential to generate a broader consensus; and iii) the establishment of a public debate to route towards a consensual method (e.g., fertiliser scientist, soil scientists, LCA community, industry).

5.01.T-03 Comparative Environmental Life Cycle Assessment of Agrivoltaic Systems in Austria Using a System Expansion Approach

***Theresa Krexner**, Alexander Bauer, Francisco Medel, Andreas Gronauer and Iris Kral, Institute of Agricultural Engineering, University of Natural Resources and Life Sciences, Austria*

Agrivoltaic (APV), the double use of agricultural land for food/feed and electricity production via photovoltaic (PV)-modules, has recently been a popular topic in research. So far, no holistic assessment of environmental impacts on an agricultural site in Austria has been conducted. Therefore, this study compares a stilted (S-) with a vertical bifacial (VB-)APV system and further the simple management scenarios of an unmodified agricultural production (Agri-only) and an open-space PV system (PV-only) by using life cycle assessment. To conduct a fair comparison of mono-use of land (Agri-only and PV-only) with a dual-use (APV scenarios) on a comparable basis, every scenario needs to provide the same outputs. Based on ISO 14044 recommendations to deal with multi-outputs, the methodical approach of system expansion is applied with a common functional unit (FU) above all scenarios. Hence, in Agri-only an additional electricity production (Austrian production mix or green electricity) is added, while agricultural production is added in PV-only. As FU a sum of outputs is used: 1 kWh electricity+60 g of agricultural goods. The impact categories global warming potential (GWP), human toxicity (HCT), terrestrial ecotoxicity and acidification (TAP), freshwater and marine eutrophication (MEP), fine particulate matter formation, mineral and fossil resource scarcity are assessed. Results show that Agri-only with Austrian produced electricity leads to the highest environmental impacts in four assessed impact categories, S-APV in three categories. Overall, VB-APV can reduce environmental impacts by 15-81% compared to the Agri-only scenario with Austrian produced electricity, S-APV by 3-70% except for HCT and TAP, where the scenario has the highest contributions due to high steel demand for the mounting structure and the PV-module production. A hotspot in both APV-scenarios is the PV-module production in China, due to the high demand and impact of electricity, in the S-APV scenario further the steel mounting structure. Results show a GWP of 49 g CO_2 eq. per FU for VB-APV and 73 for S-APV, respectively, while being slightly higher for PV-only (80 g CO_2 eq. per FU); for the Agri-only scenario it depends which electricity mix is used for system expansion (26 and 176 g CO_2 eq. per FU for the green and Austrian mix, respectively). Overall, it is shown that APV-systems can reduce environmental impacts compared to the Agri-only scenario with Austrian produced electricity.

5.01.T-04 Exploring Life Cycle Assessment Methodologies for Multi-Functionality in the Steel Sector with a CCU Example

***Marta Cruz Fernandez**[1], Peter Hodgson[1] and Jon McKechnie[2], (1)Tata Steel UK, United Kingdom, (2)Faculty of Engineering, University of Nottingham, United Kingdom*

An ever-growing body of scientific evidence proves climate change and its dangerous effects. To tackle this, the focus has been on stopping the increase of greenhouse gas (GHG) emissions as soon as possible, with the long-term goal of achieving a near zero emissions by mid-century. The iron and steel industry is a major emitter of greenhouse gases (GHG), responsible for 7-9 % of global anthropogenic CO_2 emissions. Some of the alternatives to reduce emissions include the use of Carbon Capture Utilisation and Storage (CCUS) and new iron and steelmaking processes.
The use of CO_2 as a carbon source allows the synthesis of valuable products with a lower carbon footprint than those produced from fossil fuels. The latest projections by Volker et al. demonstrate a large potential for CO_2 capture and utilization by 2050. At 10% market share, CCU could permanently remove over a gigaton of atmospheric CO_2 annually, and, as a carbon feedstock for the circular economy, could replace even more new fossil carbon.
Overall, CCU has key advantages relative to CCS: it provides a means to create valuable carbon-based products, and it can be instrumental in promoting a circular carbon economy. To ensure its effectiveness, CCU must be rapidly scaled to a global industrial level while being thoughtfully planned and consistently evaluated to minimize unintended consequences. This emphasizes the need for robust methods to assess the environmental impacts of the CO_2-based products. Life Cycle Assessment

(LCA) is a standardised method to evaluate the environmental impacts of processes and products by including all life cycle steps from the cradle to the grave.
The application of LCA to CCU can help support decision making and prioritizing different CCU technologies and products. However, there are different issues in dealing with CCUS within LCA. Goal and scope definition. It is possible to set up the LCA study from two different perspectives, the CO_2 producer or the CO_2 user. This will impact the system boundaries and functional unit. Allocation methods for CO_2-based co-products. An important methodological choice in Life Cycle Assessment (LCA) lies in the question of how to deal with multifunctional systems (for example, the production steel and a CO_2-based fuel).
This presentation will discuss the issues of attributing emissions and environmental impacts to steel industry products and co-products in LCA studies, through the example of CO_2-based fuels.

5.01.P Circularity, Recycling and Multi-Functional Systems

5.01.P-Mo342 Applying System Expansion with Multiple Functions to address the overall system burdens of recycling in comparison to other Circular Economic material strategies
Simon Alexander Saxegård*, Fredrik Wikstrøm and Helén Williams, Karlstad University, Norway*
It is common in LCA today to environmentally evaluate material recycling from a product level perspective. A problem with the product level perspective is that the total burden of recycling is divided into several product value chain stages that are inherently connected by the recycled materials without fully disclosing the overall system level burden of recycling. Therefore, it is challenging to compare recycling to otherwise linear not-circular product material strategies and derive at one unambiguous conclusion at the overall system level, and in turn the societal level perspective. Amplifying the multi-result output problem when addressing the different stages of recycling from the product level perspective is that there exist many LCA methods for dividing the burdens across the three product life cycles stages connected by the recycled material of which many give different results for the same material recycling scenario. Our suggestion to solve for both of these problems is to address recycling at the overall system level using the LCA method of System Expansion with Multiple Functions (SEMF) by summing together recycle-cascading product life cycles using methods that maintain physical realism at the overall system level and compare these to the alternative Circular Economic (CE) material strategies Reduce, Replace, Recover or any combination of these for an equal number of products. To ensure physical realism, we employ MFA to trace the flow of recyclable and not-recyclable materials through the individual product value chains and across the recycle-cascading product value chains. Our hypothesis is that once we can find one overall system level environmental impact result for recycling, we can compare recycling to and in combination with other material strategies to determine its environmental performance with basis in regionalized socio-technological conditions. The main results shall demonstrate whether the MFA based SEMF method enables a compatible comparison of recycling to other material strategies at the overall system level, and the underlying differences between the product level and overall system level LCA assessment method scopes. This study provides a suggestive LCA framework for addressing the long-standing conundrum in LCA regarding how the academic society can environmentally evaluate recycling relative to other material strategies and gain one unambiguous finding at the overall system level.

5.01.P-Mo343 LCA of Hybrid Smelting Process for Copper
Akito Tani *and Norihiro Itsubo Tokyo City University, Japan*
Renewable energy and electrification of industry will be critical in the journey to carbon neutrality. Copper is an essential resource in electric infrastructure and, thus will be critical on the journey to Net Zero. On the other hand, demand for copper is expected to increase, while supply is projected to fall short of forecast demand. For this reason, it will be necessary to sustainably expand the use of both copper ore and recycled raw materials to meet increasing demand.
This study analyzed data from JX Nippon Mining & Metals, which is actually engaged in copper mining development, copper smelting, and copper recycling, and conducted a LAC analysis based on various assumptions.
The Company aims to move in the following directions: (1) Reduce carbon footprint. (2) Increase recycling ratio (From 12% now to 50% in 2050). (3) Promote responsible procurement and ESG initiatives. (4) Form Green Enabling Partnerships.
CFT and other environmental impact assessments in JX Metals' trials suggested that the integration of ore-derived and recycled copper is a sustainable and stable supply system for copper from a holistic perspective.
The combination of primary resources and recycling will be the only possible solution for the sustainable copper supply. GHG emissions will increase by combustion of plastics adhering to end-of-life copper products. Development of the technology to remove plastics clearly from the scraps. Product design to facilitate separation of copper from other materials after disposal Further GHG emissions reductions will be required for ore mining, beneficiation and transportation process. Introduction of renewable energy and electrification in mines and transport. Improvements in transport efficiency of raw materials.
To meet increasing demand for copper in future, it is required to ensure the sustainable copper supply by increasing the proportion of recycled raw materials to the primary smelting process.
Compared to steel, LCA analysis of copper lacks examples of initiatives, such as the absence of rules in ISO. It is necessary to reach a common understanding of LCA analysis methods for stable copper supply through many studies, including this study.

5.01.P-Mo344 Life Cycle Assessment of Steel Ladle Refractories Management According to Circular Economy Criteria
Ivan Muñoz[1] *and Aintzane Soto*[2]*, (1)2.-0 LCA consultants, Spain, (2)Sidenor I+D, Spain*
We present the outcome of applying LCA to the management of ladle refractories by a steel factory in Spain, melting 1 million tonnes of steel scrap per year. Ladles are the vessels used to refine, transport and pour out molten metal, and constitute one of the pieces of equipment that consumes the largest amounts of refractories in a steel shop. The study addresses two situations, namely

before and after implementing circular economy strategies developed within the RFCS-funded project E-CO-LadleBrick. Such strategies include reduction of refractory waste generated in the ladles by optimising the ladle life, increasing amounts of worn bricks that can be reused in the production process or for other purposes, and increasing the amounts of waste refractories that can be recovered as secondary raw materials through recycling. The LCA applies consequential inventory modelling principles (multifunctionality dealt with by substitution, constrained suppliers excluded) and includes the entire life cycle of refractory products: mining of minerals, processing to obtain refractory raw materials, manufacturing of finished products, use phase and management as waste). Inventories were built for production of 12 different raw materials and 13 finished shaped and unshaped products. Data were also collected from the steel manufacturer in terms of refractories consumption, waste collection and treatment. As background database, the EXIOBASE v3 was used. The advantage of using an input-output based database as EXIOBASE is its high level of completeness, as well as the ability to cover processes in different countries with country-specific data. The main limitation of such a database, namely the level of aggregation of activities, is managed by disaggregating them whenever necessary, using process-specific data from other sources. The LCA addressed a set of 14 environmental indicators by means of the Stepwise method. The results show that adopting the developed strategies by this factory leads to annual savings of, among others, 2,000 tonnes CO_2-eq/year. This is achieved mainly by improvements in waste management (reuse, remanufacture and recycling), leading to the substitution of primary products, and second by the reduction in refractories use as a result of optimising their useful lives in the ladles. A life cycle costing (LCC) study carried out in parallel to the LCA also showed substantial benefits, namely a reduction in life cycle costs by approximately 1 million €/year.

5.01.P-Mo346 LCA as a Tool for Eco-design on Early Stages of Photovoltaic Technology Development: A Case Study on Silicon Heterojunction Tunnel – Interdigitated Back Contact (SHJ-IBC) Technology

Sabela Teixeira Taboada[1], *Angelique Leonard*[2], *Ana Molinari*[3], *Piter Miedema*[3], *Andreas Waltinger*[4], *Jochen Fritsche*[4], *Christian Hagendorf*[5], *Paul Gebhardt*[6], *David Moser*[7], *Atse Louwen*[7], *Gerry Knoch*[8], *Bonna Newman*[9], *Øyvind Østrem*[10], *Antonello Casale*[11], *Klaus Veit*[12], *Gizem Nogay*[13], *Bertrand Paviet-Salomon*[13], *Rainer Grischke*[14], *Damien Lachenal*[15], *Gilles Arnoux*[16], *Nicolas Bassi*[17], *Christian Fischer*[18], *Antonin Faes*[19], *Chris Rider*[20] *and Lucie Spevakova*[21], *(1)Chemical Engineering, University of Liege, Belgium, (2)University of Liege, Belgium, (3)UNIRESEARCH BV, (4)MEYER BURGER, (5)Fraunhofer CSP - Center for Silicon Photovoltaics, Germany, (6)Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany, (7)EURAC, (8)EXATEQ, (9)TNO, Netherlands, (10)Norwegian Crystal, (11)Padanaplast, (12)ISRA, (13)CSEM, (14)MBCH, (15)MBR, (16)PASSAN, (17)PASAN, (18)Wacker, (19)EPFL, Switzerland, (20)Cambridge Photon Technology, (21)FZU*

The development of photovoltaic technology (PV) has allowed to convert sunlight into electrical energy and has made solar PV a fast evolving industry in the last decades. To reach climate targets, the decarbonization of the energy system is essential and for this, photovoltaic solar energy is expected to play a key role.

There exist several PV technologies under development. Silicon heterojunction tunnel – interdigitated back contact (SHJ-IBC) technology is promising in terms of efficiency and it is proven on lab-scale. Its scalability will be developed, with the goal of adding 30% to the total capacity of PV cell production in Europe (compared to 2020). Full control over the PV supply chain will not only smoothen the path for energy transition in Europe but it will also facilitate the knowledge about the environmental hotspots of this technology, so actions can be taken to lessen its impacts.

At this point, supporting the technological development from an environmental point of view is crucial to ensure low carbon footprint as well as enhance circularity. Eco-design at early stage of research development processes allows more sustainability improvements. Hence, Life Cycle Assessment (LCA) is used to support the eco-design of tunnel IBC PV modules and manufacturing lines towards zero-waste as well as comparing different end-of-life alternatives. This will also contribute to develop optimization roadmaps for potential recyclability.

Methodology Guidelines on LCA of PV elaborated by the International Energy Agency (IEA) and Environmental Footprint 3.1 impact assessment method will be used. The model will be done in SimaPro 9.4.0.2. Primary data will be collected from pilot plants while Ecoinvent 3.6 database will be used as secondary data source.

Eco-design practices will result in reducing the environmental footprint of SHJ-IBC technology compared to current technologies. Most appropriate materials and processes to close the loop on PV panel recycling will be suggested.

All this will contribute to rebuilding the "made in Europe" brand: using state-of-the-art technology which complies with the last environmental standards. Therefore, security of supply, affordability and a more sustainable future EU low-carbon energy system will be guaranteed.

5.01.P-Mo347 Life Cycle Assessment of Four-terminal (4T) Perovskite-on-silicon Tandem PV Modules Using Different Recycling Routes

George Wong[1,2], *Karsten Wambach*[3], *Caterin Salas Redondo*[4], *Jean Rousset*[2,5] *and Lars Oberbeck*[2,6], *(1)TOTALENERGIES ONE TECH, France, (2)Institut Photovoltaïque d'Ile-de-France, France, (3)Bifa Umweltinstitut, Germany, (4)Sweep, (5)Électricité de France, (6)TotalEnergies OneTech, Belgium*

We have previously presented a comprehensive life cycle assessment (LCA) for large area (~ 2 m^2) perovskite-on-silicon tandem PV modules with 30% power conversion efficiency (PCE), 30-year lifetime, and 0.5% annual degradation, manufactured in a gigawatt-scale production facility. In a subsequent step, the LCA results are updated to include a full inventory (LCI) that considers different end-of-life (EoL) management strategies and forward-looking energy matrices.

In this study, we focus on the end-of-life stage and perform a full Life Cycle Inventory (LCI) compilation through literature review and direct contact with industrial recyclers.To date and to our knowledge, this is the first study of its kind for four-terminal (4T) perovskite-on-silicon tandem recycling.

During the study, prototype four-terminal (4T) perovskite-on-silicon tandem solar modules are processed according to the proposed recycling routes and physicochemical analyses are performed throughout the process. The main results of this study are the separation efficiency of recycling technologies, the physicochemical properties of recycled materials, the environmental impacts of recycling processes, and the potential environmental credits of recycled materials. These credits are calculated using the cut-off approach.
We observed that for all impacts categories, advanced recycling processes show significant lower environmental impact, compared to the 1st generation recycling processes (reference case). Techno-economic assessment and experimental data will complement our study and further demonstrate the scalability and viability of advanced recycling technologies in terms of material sustainability, processing time and cost.

5.01.P-Mo348 Life Cycle Assessment of Fibre Reinforced Composites from Retired Aircrafts
Su Natasha Mohamad[1], *Rachael Rothman*[2] *and Antony Ryan*[2], *(1)Chemical and Biological Engineering, University of Sheffield, United Kingdom, (2)University of Sheffield, United Kingdom*
Many modern aircraft are built with a high percentage of plastic composites such as fiber-reinforced plastics (FRP) to achieve optimum light weighting whilst retaining robust performance. The use of FRP in aircraft frames and interiors helps to reduce fuel consumption and lower manufacturing cost compared to using metal. The excellent flame retardant properties of FRP make it a more favourable candidate compared to wood and bamboo. However, the use of FRPs make recycling at end-of-life very difficult and the circularity and carbon footprint should be measured to have a more informed understanding of the impact of materials choice on the environment. Aircraft are retired when they are no longer safe and economical to maintain; which usually equates to 20-30 years of service. Other external factors, such as the Covid-19 pandemic, have witnessed a decline in demand for some aircraft e.g., the Airbus A380 goes into early retirement after only 10 years in service. The increase in retired aircraft means boneyards are filling up with complex plastic-composites. This paper assesses the materials used in aircraft interiors to evaluate the potential of moving to a more circular economy through either recycling or reuse. In this study, various plastic parts from the cabin interior of an aircraft's fuselage (e.g., hinges, parts of the passenger safety unit, tubing, window pane, rim holder, panels and lid cover) were collected and analysed by size, colour, weight and polymer type through Attenuated Total Reflectance Fourier-Transform Infrared Spectroscopy (ATR-FTIR). Among the predominant plastic materials identified are polyetherimide, polycarbonate, nylon, polyvinylchloride, silicon rubber, polymethyl-methacrylate, polysulfone and polyvinyl alcohol. Identification by ATR-FTIR is followed by life cycle assessment to understand the environmental hotspots and cost trade-offs of material choices and in this respect, the implications of waste management strategy to either recycling or reusing these parts.

5.01.P-Mo349 Mineral Waste Recycling For Construction in Wallonia Using Life Cycle Assessment as an Eco-design Tool
Nadine Riiashi[1], *Angélique Léonard*[2], *Thomas Pardoen*[3], *Pierre Bollen*[3] *and Stéphane Neirynck*[4], *(1)University of Liege - Chemical Engineering, Belgium, (2)PEPs, Laboratory of Chemical Engineering, Department of Applied Chemistry, University of Liège, Belgium, (3)Université Catholique de Louvain, Belgium, (4)Centre Terre et Pierre, Belgium*
Today's global needs for mineral resources are on a continuous increase, resulting in an intensification of their extraction and environmental pollution. In Wallonia (region of southern Belgium), those threats are shifting the industrial interests in the construction sector towards sustainability development plans based on reverse mineral industries.
The main challenge of this study is the selection of local mineral wastes from deconstruction to obtain materials with equal or superior properties and minimal environmental impacts.
Supported by research institutes, industries will conduct studies to spur the development of new sectors and value chains, under the umbrella of 'REMIND' program (Reverse Mineral Industry in Wallonia).
Thus, a case-by-case characterization of waste will be carried along with Life Cycle Assessment (LCA) as a decision-making tool to support the eco-design and the strategic alternative choices associated with targeted construction materials (insulating foams, concrete aggregates, self-compacting concrete materials, high-performance cement, and alternative binder materials for cement). An upscale approach will also be adapted to the potential market.
The strategy, including LCA, is expected to lead to new resource-saving and energy-saving technologies as well as alternative business opportunities that will turn into economic trends in Wallonia. LCA will be coupled to a rational material science approach in order to guide the optimization of materials with respect to the constraints of specific applications, involving the environmental impact as an objective to minimize.
The idea of processing mineral wastes will make a circular economy in the region possible to implement, which will not only improve the efficiency of industries but also have a strong ecological, social, and economic effect in the future.

5.01.P-Mo350 Development of Environment Friendly Binders for Soil Treatment, Waterproofing and Roads Applications in the Walloon Region, Belgium (ECOLISER)
Pablo Francisco de la Reta[1], *Angélique Léonard*[2], *Séverine Marquis*[3], *Luc Courard*[4], *Hugues Legrain*[5], *Sébastien Moro*[6], *Frédéric Collin*[4], *Jevgenij Lazko*[7], *Maria Traianidis*[5], *Véronique Vandeneede*[5], *Pascal Pilate*[5] *and François Collignon*[6], *(1)Chemical Engineering, University of Liege - Chemical Engineering, Belgium, (2)PEPs, Laboratory of Chemical Engineering, Department of Applied Chemistry, University of Liège, Belgium, (3)Centre de Terre et Pierre, Belgium, (4)University of Liege, Belgium, (5)Belgian Ceramic Research Centre, Belgium, (6)Certech, Belgium, (7)Materia Nova, Belgium*
The building and construction sector plays a crucial role in our wellbeing. However, construction consumes more than 30% of the global resources and is responsible for the generation of more than 40% of the total solid waste volume. By consequence, there is a growing concern over making this sector more sustainable by the application of eco-design together with the improvement of resource efficiency and management.

The ECOLISER project aims to develop environment friendly binder formulations based on secondary materials and industrial byproducts (slag, blast furnace ash, fly ash, etc.).
This project's main objective is to minimize the impact of human activity on the environment in the Walloon region (Belgium), focusing on the industrial sector. The rehabilitation of brownfield sites into areas for new industries plays a significant role as well as limiting the landfill of industrial byproducts.
There are 3 types of alternative environment friendly binders targeted: for the stabilization of soils, for soil sealing and tightness, and the installation of reactive waterproofing barriers to fix heavy metals and micropollutants from percolating water and the production of cohesive materials for road infrastructure.
The first phase of this project is the global validation stage (experimental pilot site). Afterwards, a phase of constant evaluation of the performance of the technological solutions is applied in terms of sustainable development. This is achieved by using the life cycle assessment (LCA).
This LCA aims to study the potential environmental impacts produced by 1 km of road in Belgium. A road with hydrocarbon coating and a concrete road type are studied. These cases are compared to a road using the best proportion of the ECOLISER binders. In addition, to analyze the stabilization of soils upstream of road construction, LCAs are carried out for the conventional treatment of 3 types of soil: sandy, clayey and loamy.
The methods recommended by ILCD were chosen to evaluate the environmental impact of the road (European Commission JRC-IES, 2011). The modeling is performed in Simapro software, using Ecoinvent 3.9 databases.
Eco-design practices will result in reducing the environmental footprint of the ECOLISER binders compared to current products used in road construction.
Globally, and in a circular economy perspective, this project promotes one of the promising solutions to preserve natural resources as well as limiting the landfill of this byproducts.

5.01.P-Mo351 Contextualized Phosphorus Recycling: Potential Diminution of Phosphorus Criticality at Territory Scale - Application to Agricultural LCA

***Perlette Totoson**, INRAE, France*

Phosphate rock is classified as critical raw material for the European Union's economy. It provides phosphorus (P), which is an essential element for food production and is used as a mineral fertilizer. Due to a lack of a phosphorus substitute in fertilization, recycling is presently the only solution to reduce criticality, especially for countries such as France, that has no phosphate rock reserve and thus, must depend on foreign countries for its P needs for agricultural purposes. MAFOR or fertilizer mineral/organic matter from waste can contain available phosphorus. However, the recycling of P from these deposits for agriculture involves many actors (farmers, regulators, etc.) and depends on the studied spatial scale and its context (economic, regulatory, social, etc.) which can be either constraints or drivers for P recycling. Nevertheless, these issues are not taken into account in the recycling rate used in the raw material criticality assessment nor in the LCA methods. Therefore, it is necessary to contextualize P recycling for a better understanding of phosphorus recycling, and to allow a relevant phosphorus criticality assessment and an environmental impact assessment of phosphorus recycling at a local scale. In order to achieve this, a contextualized model is developed. The goal is to be able to quantify phosphorus which would potentially be used by farmers, originated from the total available quantities of deposits, by respecting the context of the studied territory. The originality of the model lies in the integration of context-factors that can affect the use of P contained in MAFOR by farmers. The model will be applied in two territories in France, which are different regarding the origin of MAFOR produced. As output of the model, four indicators are expected: the effectiveness and efficiency of phosphorus recycling, the dependence on phosphate mineral fertilizers imported from outside France and the contextualized balance between supply and demand in P recycling-derived fertilizers. The model gives a methodology advancement, which would improve or be a complement of the LCA tool to assess territorialized recycling scenarii. The output indicators would improve the understanding of P circularity and, help determine a suitable P recycling pathway to reduce P criticality at a territorial scale and relevant from an environmental point of view.

5.01.P-Mo352 Effect of Hazardous Waste Landfill Leachate on Bentonite Barrier Stability

***Kristyna Markova**[1], Katerina Bobcikova[1], Jakub Riha[1], Jan Rohovec[2], Karel Sosna[3] and Alena Sevcu[1], (1)Technical University Liberec, Czech Republic, (2)Institute of Geology of the Czech Academy of Sciences, Czech Republic, (3)SG Geotechnika, Czech Republic*

Although the number of landfills for solid waste disposal is going to decrease, some waste will still be landfilled, especially toxic waste including incinerator fly ash. The structural elements of landfills often include sealing geosynthetic clay (bentonite) liners to separate solid waste from the subsurface environment. During the period of productive activity, the waste material creates suitable conditions for different microbial communities and generates heat. This often creates highly aggressive substances, accompanied by increased temperature affecting the functionality of sealing geosynthetic clay liners. Our study aims to determine bacterial populations that increase in the bentonite saturated with hazardous waste landfill leachate and whether this impacts the bentonite's isolation properties.
Freshly collected landfill leachate from the hazardous waste landfill was transported to the laboratory and mixed with bentonite. Mixtures were airtight and incubated at 50 °C for three months in a self-developed anaerobic atmosphere. As the controls, vessels containing bentonite mixed with tap water and sterilized (Gamma irradiated) landfill leachate were added to the same heated box. At the end of the incubation, samples were collected for DNA extraction and tests of bentonite's chemical, geo-mechanical and hydro-dynamical properties. Extracted DNA samples were used for qPCR and NGS analyses to compare the abundance and composition of bacterial communities in bentonite mixtures.

Most bentonite samples had higher bacterial abundance after incubation compared to the beginning of the experiment. Bentonite mixed with the landfill leachate contained high amounts of acetogenic, iron-reducing, and sulphate-reducing bacteria. The physical properties of bentonite saturated with the leachate deteriorated dramatically compared to the control with tap water. A decrease in the bentonite sorption and swelling capacity could be caused by the high salinity of the landfill leachate.
The extreme chemical properties of hazardous landfill leachate with the high activity of microorganisms can influence the bentonite sorption capacity and its isolation properties. This can lead to the leakage of toxic substances into subsoil and groundwater. This phenomenon could probably be avoided or reduced by proper pre-hydration of bentonite with fresh water during landfill construction.

5.01.P-Mo354 Effectiveness of Layered Wearing for Mitigating GHG Emissions
Toshiro Semba[1]*, Norihiro Itsubo*[1] *and Atsushi Inaba*[2]*, (1)Tokyo City University, Japan, (2)Japan Life Cycle Assessment Facilitation Centre LCAF, Japan*
The Ministry of the Environment of Japan has adopted "Warm Biz" as a measure to combat global warming. By wearing layered clothing in winter, room temperature can be set lower. However, few studies have examined the relationship between how clothing is worn and its effectiveness in reducing greenhouse gas (GHG) emissions. Therefore, this study aims to quantitatively calculate the GHG emission reductions from layering clothing by using life cycle assessment (LCA). PMV, an index of thermal comfort, was used to determine the set temperature of heating equipment in the house. The clo values used in the PMV equation were measured using thermal manikins and values cited in the literature. For the rest, the metabolic rate was 58.2 W/m^2, air velocity was 0.1 m/s, radiant temperature was 20.0°C, external work was 0.0 W/m^2, and relative humidity was 50.0% to obtain room temperature at which PMV = 0. Internet Questionnaire Survey was conducted to clarify the use of heating equipment and clothing in the home. A total of 2,000 people living in Hokkaido, Miyagi, Tokyo, Osaka, and Fukuoka prefectures were targeted. The survey included the type, temperature setting, duration, and time of use of heating equipment, the number and useful life of winter clothing and heat-retaining underwear, and the time spent in the house before and after COVID-19. The system boundary is assumed to be from the manufacture of the garment to its wearing (air conditioning use), washing, and disposal. GHG emissions over the entire life cycle were calculated for one year. Based on the results of Internet Questionnaire Survey, clothing in Tokyo residences is assumed to be worn: a cloak, sweatshirt top, sweatshirt bottom, underwear, and socks. The calculation results will be discussed on the day of the presentation. It was found that GHG emissions from heating equipment use account for the majority of GHG emissions over the entire life cycle.

5.01.P-Mo355 An Integrated Strategy to Address the Biodegradability of Cosmetic Formulations as Part of a Corporative Sustainability Initiative
Cyro Zacarias[1]*, Andreia Ávila Soares Oliveira*[2]*, Leonardo Bruno Federico*[2]*, Mayara Fregonezi Paludetti*[2] *and Caroline Bianchi*[2]*, (1)Product Safety, Natura Cosmetics, Brazil, (2)Natura Cosmetics, Brazil*
Biodegradability of organic chemicals usually disposed-off down-the-drain in their normal life cycle is a key parameter to be considered by industries pursuing sustainability in their new product developments. It is a property that, once improved in any formulated product portfolio, will enable a significant decrease in the presence of its ingredients in the natural environments, with a potential reduction in the pollution related post-consumption environmental impact as a consequence. Considering the importance of biodegradability as an indicator of product environmental performance and the lack of internationally recognized standards for complex mixtures, the present article aimed to propose an intelligent strategy to address this parameter in the cosmetic sector, with possibility to support both product claims and corporate sustainability initiatives. A case study is presented and discussed in detail, as a proof of applicability of the whole framework to support new developments towards improved environmental performance in terms of chemical persistence. Important insights in terms of ingredients assessment criteria are also presented.

5.01.V Circularity, Recycling and Multi-Functional Systems

5.01.V-01 Human Toxicity Assessment of Waste Electric and Electronic Equipments (WEEE) Recycling Process
Neeraj Tripathi[1]*,* ***Ana Nioac de Salles***[2]*, Sebastian Reinhardt*[1] *and Peter Fantke*[3]*, (1)Fraunhofer ICT - Institute for Chemical Technology, Germany, (2)Environmental Engineering, Fraunhofer ICT - Institute for Chemical Technology, Germany, (3)Technical University of Denmark (DTU), Quantitative Sustainability Assessment (QSA), Denmark*
The generation of Waste Electric and Electronic Equipment (WEEE) is growing quickly, producing vast amounts that are not sustainably disposed. WEEE consists of a considerable portion of plastic containing harmful chemicals, like legacy brominated frame retardants (BFRs), which are not easily recycled. With the aim to deal with WEEEs, the European research project Plast2BCleaned developed an innovative dissolution-based recycling process. The process requires the use of chemicals and demands that all workers who have contact with such chemicals follow applicable health & safety measures. However, there is currently a lack of data for most chemicals regarding human toxicity during their use phase, which creates an information gap in Life Cycle Assessment studies that consider the human toxicity of these chemicals. Thus, the goal of this study was to assess human toxicity impacts on plant workers during the Plast2BCleaned recycling process, as a complementary aspect to assessing life cycle impacts of WEEE recycling. Exposure and potential toxicity effects were identified for relevant steps of the process, such as during the filling of a solvent (to be mixed with plastics during the dissolution process) and during storage of the final products (where the chemicals are emitted in the air in a closed environment for a limited time). The USEtox scientific consensus model was used to determine the impacts of this exposure for humans working in the process, by adapting underlying aspects for direct emissions and for chemicals released from materials for the three selected solvents. The concentration in air,

characterisation factors and impact scores for each chemical in different steps of the process were determined. Endpoint impact results (expressed in Disability Adjusted Life Years - DALYs) for different solvents and BFRs were obtained. The results show that all three chemicals have their concentration levels below the regulated Threshold Limit Values (TLVs). The estimated emissions of solvents to the air during the filling process and in a spillover scenario, exceeds the TLVs by a factor of 5 to 10. However, in the study conservative time for the filling was assumed and in the real scenario safe short term exposure limit is not exceeded. The endpoint impact results for human toxicity in terms of DALYs are very low for the given worker's exposure time to the chemicals. Our study is a starting point for combining direct worker effects with life cycle impacts.

5.01.V-02 Combination of Life Cycle Assessment and Process Simulation to Improve Recycling Processes and Scale-up
Yvonne Kaye Perocillo[1] *and Angelique Leonard*[2]*, (1)University of Liege - Chemical Engineering, Belgium, (2)University of Liege, Belgium*
In this time of increasing demand for raw materials, and environmental awareness, designing an efficient metal recycling process is increasingly becoming critical in achieving a more circular-oriented economy. Despite numerous literatures of successful processes developed for specific waste materials, there are only a few that have been applied in the industry. The challenge lies not just in the technical viability of the process upon scale-up, but also on the possible burden shifting of environmental impacts due to said process. Using life cycle assessment (LCA) to assess these impacts is necessary. But since LCA was initially developed to assess a system's primary function, dealing with multifunctional systems like a recycling process is only based on the practitioner's discretion thus needing improvement. Scaling up the process is also technically challenging because of the great variation in the process' efficiency and performance in the laboratory and when scaled up. Though process simulators give perspective on how the process performs in terms of products and material or energy flows, effects of equipment size and design are not necessarily considered on most simulators. This research aims to address these challenges in both LCA and process simulation through case studies of several types of recycling metal loops for both experimental and industrial metal recycling processes especially those dealing with end-of-life for electromobilities.

5.02 Guidance for LCA of Recycling Abiotic and Biobased Materials and for the Transition to a Resilient Low Carbon, Resource-Efficient and Circular Economy

5.02.T-01 A Guideline for Life Cycle Assessment of Carbon Capture and Utilization as Negative Emissions Technologies
Sibylle Duval--Dachary[1,2]*, Amandine Pastor*[2]*, Sandra Beauchet*[1]*, Daphné Lorne*[1]*, Thibault Salou*[2] *and Arnaud Helias*[2]*, (1)IFP Energies Nouvelles, France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France*
Moving towards a circular carbon economy would reduce the extraction of additional fossil raw materials. Carbon capture and utilization (CCU) technologies could thus reduce greenhouse gases emissions by replacing fossil-based products by CO_2-based products (avoided emissions). In this study, we focus on CCUNET: CCU systems combining these avoided emissions with negative emissions technologies (NET). Quantifying the whole environmental impacts (both avoided and negative emissions) is complex. Guidelines to harmonize LCAs of CCU systems and improve results comparability between several studies exist. However, the coupling with NET generates issues on, for instance, system boundaries or biogenic carbon accounting. To address these concerns, existing recommendations to perform LCA on CCU or NET systems are identified and discussed. This allows proposing tailored recommendations for LCA of CCUNET systems. The guideline addresses, among others, the choice of i) the functional unit, ii) the system boundaries, iii) the method to deal with multifunctionality, and iv) the integration of biogenic carbon flows, including soil carbon sequestration. For instance, the functional unit should consider carbon sequestration to allow comparison with other NET. A case study is modelled to exemplify this guideline. To be able to evaluate negative emissions, the system boundaries must be cradle-to-grave, i.e. from CO_2 removals from the atmosphere to the end-of-life of the CO_2-based product. Thus, the case study includes i) biomass production (CO_2 removal from the atmosphere by photosynthesis during biomass growth), ii) conversion of the biomass into energy and capture of the produced CO_2, iii) transformation of the captured CO_2 into a value-added product, iv) use of the CO_2-based product, v) end of life of the CO_2-based product. For instance, it could be CO_2 captured in a fuel ethanol plant supplied by corn, miscanthus or even wood residues. This CO_2 will then be transformed into a reusable plastic bag. At its end-of-life, the plastic bag can be recycled, landfilled, or incinerated with carbon capture and storage. This LCA study innovates by proposing to model a complete CCUNET system and provide some first insights on the potential of CCUNET system to reach negative emissions. This framework is interesting in view of the growing interest in both CCU and NET systems, that will hopefully result in more and more LCA on CCUNET systems.

5.02.T-02 Future Greenhouse Gas Emissions from Metal Production and their Relationship with Climate Goals
Ryosuke Yokoi[1]*, Takuma Watari*[2] *and Masaharu Motoshita*[1]*, (1)National Institute of Advanced Industrial Science and Technology (AIST), Japan, (2)National Institute for Environmental Studies (NIES), Japan*
Metals play an essential role in human life, while metal use is associated with not only metal depletion but also environmental concerns. To discuss strategies towards sustainable metal use with lower environmental impacts in line with climate goals, quantifying future environmental impacts from metal production and exploring effective measures for alleviating the environmental impacts are essential. Therefore, we estimated the global greenhouse gas (GHG) emissions from the future production of six typical metals (aluminum, copper, iron, lead, nickel, and zinc) under the five shared socioeconomic pathways (SSPs) for 2010-2100 and compared the results with a GHG emission reduction target (2°C target). In addition, we explored the influential parameters of metal cycles to reduce the environmental impacts by scenario analysis.
We show that trends for GHG emissions from metal production are significantly different among SSPs, while the 2°C target will not be achieved for the metal sector under any SSP, mainly due to the increase in GHG emissions in the early 21st century in

middle-income countries. This suggests that substantial efforts to reduce GHG emissions are required in addition to the transition to the sustainable socioeconomic pathway. From a short-term perspective, lowering the per capita in-use metal stock level and GHG emission intensity of metal production is identified to be effective. From a long-term perspective, improving the recycling rate will also be an effective way. However, our analysis shows improving a single parameter is expected to be insufficient for achieving the 2°C target. Given that GHG emissions from metal production will increase mainly in the early century and improving parameters cannot be achieved promptly, implementing multiple measures immediately with international cooperation, as well as following the sustainable socioeconomic pathway, is essential for sustainable metal use in line with the climate goals.

5.02.T-03 Life Cycle Assessment of Biogenic Carbon Capture and Storage Processes: Review of Life Cycle Inventories and Recommendations

*Sibylle Duval--Dachary[1], Sandra Beauchet[1], Daphné Lorne[1], Thibault Salou[2], **Arnaud Helias**[2] and Amandine Pastor[2], (1)IFP Energies Nouvelles, France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France*

Bioenergy with carbon capture and storage (BECCS) are part of the solution to reduce greenhouse gas emissions into the air. The idea is to capture biogenic carbon before it is emitted into the atmosphere and stored permanently. If biogenic carbon is stored indefinitely, it generates a flow of carbon from the atmosphere to a permanent sequestration. Thus, BECCS systems are considered as negative emission technologies (NET). However, in seeking to reduce the climate change impacts of BECCS systems, the technologies that comprise the BECCS system may impact other environmental phenomena. This may result in pollution displacement. Different technologies are available at each stage of the life cycle of a BECCS system. It is important to provide the decision maker with a clear understanding of the environmental impacts associated with the choice of these technologies. The objective of this study is to review the quality of the life cycle inventory data available in the literature and to provide recommendations to conduct a quality BECCS Life Cycle Inventory. An analysis of 35 LCA studies was conducted. These studies had to propose a BECCS life cycle inventory. The BECCS technologies considered start in the field with the cultivation of the biomass (depending on the type of biomass) and its harvesting. Several technologies can then be used to ensure the pre-treatment of this biomass, its combustion and gasification, and finally the capture of the biogenic CO_2 emitted. Afterwards, the CO_2 can be compressed for transport and then stored. Only 13 of the 35 articles reviewed provide life cycle inventory tables. Inventory data is often marked by a lack of reproducibility, of data. Nevertheless, this study provides LCI data and recommendations for conducting LCIs to facilitate harmonization between future LCAs on the BECCS. It is important that the inventory data be transparent with a clear display of boundaries and system assumptions. It would also be interesting for BECCS LCI to define the temporality of the data and their geographical representation. Each data quality criteria must be discussed as recommended by ISO 14 040/44.

5.02.T-04 Operationalizing the Geopolitical Supply Risk Potential as a Supply Risk Indicator for Use in Life Cycle Assessment

*Anish Koyamparambath[1], Steven Young[2], Jair Santillán-Saldivar[3] and **Guido Sonnemann**[3], (1)CyVi - ISM - University of Bordeaux, France, (2)University of Waterloo, Canada, (3)University of Bordeaux, France*

The geopolitical supply risk (GeoPolRisk) method evaluates raw materials criticality in Life Cycle Assessment, complementing other resource use and environmental impact indicators. However, calculating characterization factors (CFs) for the Geopolitical Supply Risk Potential as a supply risk indicator at midpoint level for use in life cycle assessment, (GeoPolRisk midpoint) is challenging. Therefore, we developed a calculation library to operationalize the GeoPolRisk method to fulfil two functions: 1) to facilitate the calculation of the CFs for the GeoPolRisk midpoint indicator and 2) to showcase its application as a comparative risk assessment. The geopolrisk-py is a python-based library containing functions in multiple modules providing the users a wide array of options. Users can provide unique trade data for a company/organization level assessment with the library for more specific values. The library also hosts functions that allow users to extract and visualize results. The structure of the library and its functioning has been demonstrated in multiple case studies. The application of the tool is presented through integrated LCA study with GeoPolRisk of an electric car and a comparative risk assessment case of cobalt imports to three companies in the United States of America, Sweden, and South Korea. Finally, a web tool has been developed with the library as its framework to conduct an assessment using a graphical user interface. The CFs for the GeoPolRisk midpoint indicators are available to download at request from the web tool.

5.02.T-05 A Host-to-Byproducts Matrix to Help Assessing Abiotic Resources Accessibility

***Titouan Greffe**[1], Manuele Margni[1] and Cecile Sophie Marie Bulle[2], (1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)UQAM, Canada*

There is a growing concern about our current unsustainable management of abiotic resources over their entire life cycle. Operational life cycle impact assessment (LCIA) methods consider that making a resource inaccessible has a potential impact, regardless of its functionality and the future demand of services provided by the resource. However, the extent of damages of a resource made inaccessible i.e. dissipated, with (or without) substitutes and with low/high demand for the services it provides may be very different. A LCIA framework has been developed by Greffe et al. (2022) to link resource dissipation to the deficit of services. To operationalize the fate model of the LCIA framework, a dynamic material flow analysis under constraints has been developed. It traces the fate of resources and materials from the extraction from the accessible to stock to the in-use stock (with recycling flows). It proposes to assess the mismatch between demand and supply of resources in the in-use stock. The flows of resources from one stock to another are constrained by a maximum yearly production. Most metals used in a wide range of products are extracted as byproducts of hosts, meaning their accessibility depends on the demand of host elements, such as zinc, iron, aluminum or nickel. Although plenty of estimates of metals content in different sources such as mineral ores, slags or

tailings are available, there is currently no harmonized dataset that enable to answer to the question: what is the average quantity of byproduct b potentially recoverable with regards to the extraction of host h? Our current work aims at answering to such question.
We present a consistent methodology to calculate host-to-byproducts ratio for all abiotic resources used in the economy. We harmonize the data from the literature and we will present our preliminary results for dozens of metals, with a confidence interval (5th and 95th percentile). This matrix can then be used in material flow analysis of multiple resources to model their fate in the economy. The host-to-byproducts matrix will enable to determine the flows of byproducts that will be accessible to fulfill services to humans. It will then be possible to characterize the impact of dissipation of resources, applying the LCIA framework of Greffe et al. (2022).

5.02.P Guidance for LCA of Recycling Abiotic and Biobased Materials and for the Transition to a Resilient Low Carbon, Resource-Efficient and Circular Economy

5.02.P-Mo356 The Importance of Land in a Low Carbon and Bio-based Economy: Quantifying Supply Risk in a Life Cycle Perspective

Lazare Deteix[1]*, Thibault Salou*[2]*, Sophie Drogué*[3] *and Eleonore Loiseau*[2]*, (1)National Research Institute for Agriculture, Food and Environment (INRAE), France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (3)MoISA, Univ Montpellier, Institut Agro, IRD, France*
The transition toward a low-carbon economy relies on the use of renewable energy and bio-based material. These systems require large amount of land, such as photovoltaic system or industrial crops, adding pressure on the resource. Although acknowledged as a key resource, land has not been included in criticality assessments, in particular in the recent criticality methods developed for inclusion in life cycle assessment (LCA), which use the supply risk (SR) index, reflecting the possibility of supply disruption for a given material based on its geological, economic or geopolitical availability, to develop new characterisation factors. This study therefore aims at developing country level land supply risk (SR) indexes in line with two existing criticality methods for other resources. These developments should allow for the quantification of risks related to potential inaccessibility of land resources and for disparities between countries to be revealed.
To extend the SR framework to land resources, every SR component for mineral resources is adapted to land in both methods, when appropriate. This approach ensures comparability across resources. The developed land SR are computed at the country level to consider local drivers influencing land accessibility. The main adaptations include the definition of a land stress index, representing the physical availability of land, and an internal land concentration index, relating to the concentration of landowners within a country.
Finally, land supply risk indexes are computed for 76 countries, including 24 European countries for which the results of the two criticality methods are compared. Comparison points to divergences in the country ranking for land accessibility, thus underlining the importance of methodological choices in the construction of the indexes.
The results of this study showed that the criticality framework could successfully be applied to the land resource, highlighting the various factors that can prevent access to land in different countries. Yet, the model could be further improved by focusing on finer distinctions between types of land use and taking into account land quality. The current integration of the criticality concept in LCA could benefit from these land supply risk indexes, which could be used to derive characterisation factors for future LCA criticality assessments.

5.02.P-Mo357 Greenhouse Gas Removals Via Biochar Production From Food Waste Digestate in the UK

Sarah Rodgers[1]*,* ***Disni Gamaralalage***[1]*, William Meredith*[1]*, Helen West*[1]*, Jessica Alce*[2]*, Andrew Gill*[3]*, Jon McKechnie*[1] *and Colin Snape*[1]*, (1)University of Nottingham, United Kingdom, (2)Severn Trent Green Power, United Kingdom, (3)Coal Products, United Kingdom*
Biochar can potentially contribute as a Greenhouse Gas Removal (GGR) technology to achieve UK's net zero emission target by 2050, but risks being constrained by the availability of conventional feedstocks such as wood. Biomass wastes which are less attractive in energy applications, particularly anaerobic digestate, can extend the scale of biochar deployment. Application of stable biochar in the soil is capable of achieving a long-term carbon storage with potential co-benefits for improving the soil quality. Hydrothermal carbonisation, with subsequent high temperature torrefaction, is capable of directly producing stable biochar from wet wastes such as digestates. In this work we evaluate the potential scale of biochar production from anaerobic digestates in the UK for 2030 and assess the techno-economic and life cycle environmental viability of this approach.
Anaerobic digestion (AD) plants treat numerous feedstocks including the current input of around 30% is from the food waste; in 2019, over 4 million tonnes of food waste were treated in the AD plants. Future growth in the sector will be driven by food waste management, where AD is viewed as an environmentally favourable treatment method for unavoidable food waste. Our analyses indicate the biochar production from food waste digestate achieving a substantial net greenhouse gas (GHG) removals of approximately 1.6 t-CO_2eq.t-biochar^{-1}. Transport distance and soil effects are uncertain but are estimated to have a small impact on GHG emissions, highlighting that the majority of emissions reductions are from the physical storage of carbon in biochar (1.9 t-CO_2eq.t-biochar^{-1}). The use of 50% of UK's projected available food waste digestate by 2030 can sequester around 85 kt-CO_2eq p.a., requiring 28 individual 20 kt p.a. biochar production facilities. Commercial biochar production from food waste digestate is able to provide cost-effective GHG removals of less than £100 t-CO_2^{-1} avoided. Other wet wastes such as green waste will command a lower gate fee resulting in higher costs of avoiding CO_2. Sensitivity analysis demonstrates the heavy influence of the gate fee and its importance for biochar process establishment. This work considers a highly promising opportunity in solving a

waste disposal burden and simultaneously removing atmospheric GHGs. Multiple sources of biochar will be needed to make significant contributions to the UK's GGR target.

5.02.P-Mo358 Life-Cycle Approach in the Valorisation of Maize Bran for the Biotechnological Production of Ferulic Acid

*Ricardo Rebolledo Leiva[1], **Sara Lago Olveira**[2], Maria Teresa Moreira[1] and Sara González-García[3], (1)Universidade de Santiago de Compostela, Spain, (2)University of Santiago de Compostela, Spain, (3)Chemical Engineering, University of Santiago de Compostela, Spain*

Agro-industrial residues provide a great source of sugars, pigments, proteins, antioxidants, etc. Among the group of polyphenols, ferulic acid offers potent antioxidant activity, and excellent antimicrobial and antifungal activity. In this work, two bio-based strategies to produce ferulic acid (FA) from maize bran were evaluated from an environmental approach. The aim is to determine those aspects that can hinder the viability of these valorisation routes, and thus, to establish improvement strategies during the early stage of the process. The Life Cycle Assessment (LCA) methodology is used to determine the environmental performance of bio-based FA production, through a life cycle perspective and following ISO 14040 and 14044 guidelines. The functional unit corresponds to 1 kg of PA, based on a "cradle to gate" approach. FA production was modelled in Superpro designer® v11 software, considering a small-scale biorefinery located in Egypt. The plant provides a maize bran capacity of 16,350 $t \cdot y^{-1}$. The production stages were pre-treatment (to obtain de-starched maize bran), heat treatment (steam explosion or autoclaving), enzymatic hydrolysis and downstream processes. The first scenario (SET) corresponds to a steam explosion followed by enzymatic hydrolysis followed by enzymatic hydrolysis by adding 3% w/w protein/bran of enzyme (Novozyme 342) for 24 h at 40°C. In contrast, the second scenario (AUT) considers an autoclave treatment followed by enzymatic hydrolysis with 1% enzyme (feruloyl esterase, FAEA) for 16 h at 40°C. The pre-treatment and subsequent processes were the same for both routes. To obtain the environmental profiles, the characterization factors of the ReCiPe Midpoint v1.07 (H) method and SimaPro 9.1 software were used. In addition, background process inventory data were obtained from the Ecoinvent® v3.8 database. Global Warming (GWP), Freshwater Eutrophication (FE) and Freshwater Ecotoxicity (FEC) were some of the impact categories evaluated. Results indicate that the AUT strategy obtains the best environmental performance in all categories. Highlighted results for the AUT scenario (related to the SET strategy) were observed in FEC and FE categories with a reduction of about 57% and 50%, respectively. Moreover, the GW profile of both strategies was 660 and 432 kg CO_2eq per kg of FA for SET and AUT, respectively. The results can be explained due to the FA content present in the maize bran (3.1% w/w) and the intense heat demand of the process.

5.02.P-Mo359 Reviewing the Life Cycle Assessment of Engineered Wood Products in the Built Environment: Gaps, Challenges and Opportunities for Improvement

***Elizabeth Migoni Alejandre**[1], Alexander Wandl[2] and Arjan van Timmeren[2], (1)Urbanism-ETD, Leiden University, Leiden, Netherlands, (2)Technical University Delft, Netherlands*

The built environment accounts for approximately 37% of the global carbon emissions. As buildings become more energy efficient, embodied carbon is becoming the target of multiple efforts to transition the built environment towards more sustainable practices. The use of engineered wood products (EWPs) presents opportunities in the construction sector by meeting strict quality and structural properties while presenting a low embodied carbon profile and the capacity to store carbon for a long period of time. Environmental implications of product or services systems is usually assessed with Life Cycle Assessment (LCA) studies. LCA is an internationally standardized method that allows to translate the resource consumption and emissions associated with a product system, into potential environmental impacts. In order to compare the environmental implications of building with conventional materials vs. engineered wood products, LCA studies rely on inventory databases, EPDs, and available impact assessment methods to compare between the alternatives assessed. However, recent studies have pointed out the limitations observed when conducting LCA studies in compliance with European Norms in regards to the environmental benefits of long-term carbon storage provided by wood products. Besides these limitations, several differences, both in inventory and impact assessment, regarding bio- and conventional materials, might be hampering an accurate representation of the impacts and benefits associated with the use of EWPs. To determine if methodological and/or operational characteristics should be improved for a robust assessment of EWP in the built environment, this study targets the assessment of EWPs in LCA by providing an overview of identified gaps and recommendations to further develop and improve their assessment. The findings are expected to contribute to the body of knowledge covering circularity and biomaterials in the built environment, as well as efforts to improve the impact characterisation and impact assessment methods used in LCA.

5.02.P-Mo360 ALIGNED: A framework for the LCA of Bio-based Products

*Massimo Pizzol[1], Søren Løkke[1], **Agneta Ghose**[2], Karen Nørgaard Bollesen[1], Jurjen Spekreijse[3], Patrick Reumerman[3], Steven Van Passel[4], Maxim Tschulkow[4], Lorie Hamelin[5], Marcos D. B. Watanabe[6], Narie R.D. Souza[6] and Francesco Cherubini[6], (1)Aalborg University, Denmark, (2)Department of Planning, Aalborg University, Denmark, (3)BTG - Biomass Technology Group, (4)University of Antwerp, Belgium, (5)Toulouse Biotechnology Institute, Université de Toulouse, France, (6)Norwegian University of Science & Technology (NTNU), Norway*

The assessment of bio based products presents several challenges: from the definition of system boundaries and choice of system models, modeling competition for biomass and for land, to performing dynamic and time specific accounting, making scenarios and considering uncertainty.

We present the background, methodology, and expected results of the Horizon-Europe-funded project "Aligning Life Cycle Assessment methods and bio-based sectors for improved environmental performance" (ALIGNED, grant number 101059430). Targeting five sectors namely woodworking, pulp and paper, biochemicals, construction and textiles, ALIGNED fulfils three

research needs: 1) to improve, harmonize, and align LCA methodology for the assessment of bio-based products covering environmental and socio-economic aspects, 2) to demonstrate the harmonized methodology to improve the environmental performance of specific technology development cases in industries within the bio-based sectors 3) to inform and involve stakeholders, enabling an efficient methodological uptake.
ALIGNED modelling framework does not intend to provide a new standard or guideline but instead to make available an ecosystem of science-based and open approaches and tools to ease the assessment of bio-based products. Key elements in such framework include: 1) A science and evidence-based approach: scientifically sound modelling as close as possible to reality, avoiding normative rules, and favoring models that can be validated and revised when new data become available as well as an ecosystem of interacting models and tools. 2) A life cycle perspective: the assessment takes the full life cycle of bio-based products into account. 3) Relevance for decision-makers and usefulness for decision support: we focus on modelling what are the consequences of specific decisions. We explicitly consider uncertainty in the decision support. 4) Balancing model complexity and model applicability: we select and use in this framework models that are scientifically robust but also usable by practitioners to the largest extent, keeping in mind the trade-off between model complexity and applicability. 5) Adherence to open-science practices: models, tools, and their documentation are open, while data should be as open as possible. 6) Ensuring relevance for bio-based products: the modelling framework considers the specific challenges and issues that exist in the assessment of bio-based products.

5.02.P-Mo361 Application and Analysis of Different Methodologies for Modelling Temporal Carbon Sequestration of Biobased Materials

Felix Wanielik[1], *Felipe Cerdas*[2] *and Christoph Herrmann*[2], *(1)Technical University Braunschweig, Germany, (2)Institute of Machine Tools and Production Technology, Chair of Sustainable Manufacturing and Life Cycle Engineering, Technische Universität Braunschweig, Germany*

Biobased materials can reduce the Global Warming Potential (GWP) of products when substituting other materials and have the chance to sequester carbon for their useful life, thus reducing the total amount of atmospheric Green House Gases (GHG) temporary. State of the art Life Cycle Assessment (LCA) does not take into account the effects of temporal biogenic carbon sequestration and the time of release of GHGs, thus not representing differences due to the expected useful life and cascade use of the material. Multiple approaches exist to model these differences connected to temporal carbon sequestration such as the static approach proposed in the ILCD handbook or dynamic approaches such as dynamic LCA, GWP bio or a Climate Tipping Point Metric. Even though there is a consensus in scientific literature that it is important to model such temporal effects, these modelling approaches are only seldom applied and there is no consensus on which modelling approach is the most feasible to be used in LCA studies. Within this work, different approaches for the inclusion of temporal carbon sequestration will be applied for two different use cases for biobased materials with scenarios for multiple life cycles: a) the application of a wood-based door impact beam in a car with different scenarios for the useful life and b) the application of a wood-based foam made from primary and secondary material for a surf board. The methodologies will then be analyzed regarding ease of use, availability and reliability of data and implications for the decision making processes, thus showcasing problems and chances with the application of the different methodologies and advancing the discussion of temporal carbon sequestration within the field of LCA.

5.02.V Guidance for LCA of Recycling Abiotic and Biobased Materials and for the Transition to a Resilient Low Carbon, Resource-Efficient and Circular Economy

5.02.V-01 Is Circular Economy Truly Sustainable? Robust Comparative LCA of Circular Pavement Designs Using a Probabilistic Approach

Zhi Cao, *University of Antwerp, Belgium*

As global climate change becomes evident, reducing CO2 emissions is regarded as one of the most pressing issues for our industry and society. The asphalt pavement industry is also identified as one of the important CO2 emission sources. Life cycle assessment (LCA) has been widely used to quantify the environmental benefits of designs or practices that can improve the sustainability of asphalt pavements, such as reusing end-of-life pavement materials in new asphalt mixtures. However, due to the paucity of representative and good quality data, LCA results of pavements are associated with considerable uncertainty, thus unable to ascertain the benefits of sustainable designs or practices.
Against this backdrop, this study develops parametric models to characterize energy uses and CO2 emissions occurring in key life cycle stages (including bitumen production, asphalt mixing, and pavement construction). A probabilistic approach is employed to quantify the uncertainty of input parameters and LCA outputs under three scenarios: (1) Baseline, (2) 0% RAP, and (3) +4cm durability.
The results indicate that reusing end-of-life pavement materials does not necessarily reduce the CO2 emissions of a pavement over its life cycle. The CO2 benefits of reclaimed asphalt pavement (RAP) depend on the durability of asphalt pavements. More interestingly, the certainty of conclusions varies across comparisons. When comparing the Baseline scenario (in which RAP accounts for 27% of asphalt mixture compatible with Belgium's construction requirements) with the +4cm durability scenario (in which more RAP is used to compensate for durability loss), we are highly confident that the former leads to less CO2 emissions. However, when comparing the Baseline scenario with the 0% RAP scenario (in which no RAP is used), we are less confident that the former leads to less CO2 emissions. In addition, the results reveal that transport contributes the most to the uncertainty of LCA outputs, suggesting that more high-quality data on transport is needed to improve the accuracy of LCA results and the confidence in the conclusions drawn from comparative LCA.

5.03.A LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Comprehensive Analysis

5.03.A.T-01 Assessment of Sustainability Labels in the Context of a Life Cycle Assessment

Andreas Roesch*, Thomas Nemecek and Gerard Gaillard, Agroscope, Switzerland*

During the last few years, scientific publications on environmental labeling have substantially increased in number, which is an indication of greater international interest in mitigating environmental degradation, as well as with the increase in political and technical-scientific conferences on the subject. Labels should provide consumers with simple and catchy information on sustainability, nutritional and health aspects.

The objective of this study is to assess critically some selected labeling systems in terms of completeness, double counting and reliability. Special emphasis is placed on how method developers incorporate life-cycle thinking into their design. This study is based on a literature review of studies focusing on sustainability scores, including—beyond peer-reviewed articles—specific reports on sustainability scores that are publicly available.

An evaluation of various sustainability labels revealed several deficiencies regarding its scientific basis. The analysis showed that most labeling systems profit from a clear and catchy visual declaration. However, a closer examination of sustainability labels has shown that their scientific basis and completeness are questionable in some cases. Awarding additional points to food products that have already been awarded by another label from a third-party organisation was also judged critically, as this procedure increases the probability of double-counting.

We conclude that the enhancement of labeling beyond the LCA is critical, as this may lead to double-counting, green-washing and a lack of transparency. The elaboration of new labels should always follow strict scientific rules to avoid subjective weighting and redundancy. Modifications and expansions of labels based on the preferences of stakeholders and organisations should be avoided. Further, it is recommended to develop the LCA if necessary to enable the calculation of labels using a single method, thereby avoiding the implementation of workarounds.

In summary, it is crucial to inform consumers in a transparent and easily understandable way about gaps and weaknesses in the labelling scheme. Currently, however, European sustainability labels for products (such as the Eco-Score or Planet-Score) tend to overweigh certain aspects, without a sound scientific basis. It is strongly recommended to provide additional information, such as production standards and origin as separate information.

5.03.A.T-02 Enabling a Holistic Assessment for Foodware and Food Packaging to Protect Environmental and Human Health

Justin Michael Boucher[1], Florian Suter[1], Lisa Zimmermann[2], Kyle Meisterling[3] and ***Jane Muncke****[1], (1)Food Packaging Forum Foundation, Switzerland, (2)Food Packaging Forum (FPF), Switzerland, (3)Scope 3 Consulting*

In an ideal world, foodware and food packaging enable circular and fair business models, do not have adverse impacts that destabilize the planet's ecosystems, and internalize the costs they have on humans and the natural environment we coexist with and depend on. However, in reality, the foodware and food packaging used to enable today's highly globalized, increasingly convenience-focused food system is being ever more identified as a source of damage to both human and environmental health. Currently, what stakeholders assess and how they assess it is neither consistent nor comprehensive. Different sustainability criteria are being applied across assessments and often with a narrow focus on single-impact areas, such as greenhouse gas emissions.

To enable a more holistic assessment and procurement of truly sustainable foodware and food packaging products, decision-makers need science-based guidance and tools. To support this, we have developed the Understanding Packaging (UP) Scorecard as an open access, transparent, and LCA-based calculation methodology and tool to help decision-makers compare over 100 generic foodware and food packaging products across six metrics: climate change, water use, plastic pollution, sustainable sourcing, recoverability, and chemicals of concern. Raw emissions as well as normalized scores are calculated for each metric, and all metrics are further weighted equally to define a single, normalized summary score.

The results of the UP Scorecard's assessment across a wide range of generic products reveal some clear trends that can help procurement professionals better consider a wider array of environmental and human health impacts when selecting products. This includes achieving the lowest impacts through implementing reuse systems, while single-use plastic products are often associated with the overall highest impacts.

This methodology aims to expand the impact areas considered within the current life cycle and sustainability assessments for foodware and food packaging. Given the complexity of materials used as well as the global diversity of (un)available infrastructure to manage end-of-life treatments for these products, the novel qualitative metrics included here can become more robust and accurate pending better availability of the underlying data. Additional impact areas could also be implemented within this methodology to even more holistically assess products, such as contributions to biodiversity loss.

5.03.A.T-03 Consequential Life Cycle Assessment of a Diet Change Following Planetary Boundaries Recommendations

Aurore Guillaume*[1] and Vladimír Kočí[2], (1)Department of Chemical Engineering, KU Leuven, Belgium, (2)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague, Czech Republic*

Environmentally friendlier diets are needed and at the same time health issues linked to a non adequate nutrition are rising. The aim of the planetary health diet developed by the EAT Lancet commission is to sustainably feed 10 billion people in 2050 while not execeeding planetary limits. According to these guidelines, a switch between legumes and red meat consumption is desired for European citizens. To evaluate environmental and economic consequences of this diet change, a partial economic model was combined with Life Cycle Assessment. A scenario of 80% decrease in red meat consumption in Europe in 2030 was simulated in order to assess crop and animal production changes associated with the diet change. The major output from the partial economic model was the significant gap between consumption and production of red meat and legumes. Indeed, European production was only slighty changed and overstock of red meat or missing stock of legumes were respectively exported or imported. Additionnaly, the partial economic model allows to capture indirect changes in agricultural production. These direct and indirect changes in production and trades were used as inputs of Life Cycle Assessment. Using Environmental Footprint 3.0 methodology, the environmental assessment showed benefits for all impact categories. The desalignement between production and consumption in Europe would potentially have several negative consequences such as Europe dependancy and vulnerability towards big economic players or social consequences for farmers where exports take place. Changes in consumers behavior is not enough and strong policies targeting production such as incentives for decreasing meat production or subsidies to encourage transition to legumes production are needed. Overall, our results contribute to a better understanding of economic and environmental consequences of diet changes and to implied recommendations for policies.

5.03.A.T-04 Revisiting the Territorial Life Cycle Assessment Framework to Account for Ecosystem Services
*Jérôme Lavoie[1], Eleonore Loiseau[2] and **Cecile Sophie Marie Bulle**[3], (1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (3)UQAM, Canada*
At the core of the territorial life cycle assessment T-LCA framework lies the idea that indicators of provided services be quantified to account for the multifunctionality of territories. This poses an innovative basis for the inclusion of the ecosystem services (ES) concept in life cycle assessment (LCA). By revisiting the T-LCA framework, a new methodological framework for environmental land planning is proposed. The academic literature was explored and revealed three general approaches for the inclusion of ES in LCA. These approaches were consistently analyzed and combined in a comprehensive novel framework. The analysis shows that incorporating ES at the different phases of a LCA can be done coherently as long as spatial and temporal concerns are taken into consideration. In the goal and scope phase, ES are considered as services offered by the techno-ecological system that is the territory. Here the focus is on the foreground system and all types of ES can be considered. For regulation and maintenance type of ES, the incorporation into the framework can occur at the life cycle inventory step, as they mediate the emission of certain substances in the environment. At last, all types of ES can also be considered within an area of protection at the life cycle impact assessment step, by developing models that quantify the impact of emissions or resource use on the potential future delivery of those ES for both the foreground and background systems. Impacts on ES generated the territory can be considered along with the ES of the functional unit without generating any double counting issue since the environmental impact would be measured on the potential future delivery of ES while ES considered in the G&S phase represent the actual delivery at the time the assessment is carried. In conclusion, combining the inclusion of ES at different steps of an LCA allows for a more comprehensive sustainability assessment of territories by putting into perspective the benefits offered with the impacts generated by the multifunctional nature of territories via the eco-efficiency ratio of T-LCA.

5.03.P-We315 A Participatory Life Cycle Sustainability Assessment Framework for the Appraisal of Estate Regeneration Schemes in London
***Sahar Nava**[1], Esfandiar Burman[2] and Zaid Chalabi[2], (1)Bartlett School of Environment, Energy and Resources, UCL, London, United Kingdom, (2)Bartlett School of Environment, Energy and Resources, University College London, United Kingdom*
To enable sustainable growth, the assessment and analysis of the regeneration schemes should consider their socio-economic as well as their environmental impacts. The methodology which includes the three sustainable development pillars is called Life Cycle Sustainability Assessment (LCSA). To reflect the priorities of an array of stakeholders in options appraisal, key stakeholders should be engaged in different stages of decision analysis. This study aims to develop a participatory approach to LCSA for the appraisal of estates' regeneration schemes. The complex mixed methods research design consists of a pilot study, surveys, knowledge mobility, co-design workshops, ethnographic observations, semi-structured interview, and simple mathematical calculations. Review of the literature and findings of the pilot research have assisted in identifying a preliminary list of sustainability indicators for the framework. Key stakeholders including the community members and built environment specialists have participated in a survey which have resulted in eliciting the weights (preferences) of meta criteria for the framework. The proposed framework consists of 5 stages: Goal and Scope Definition; Scenario Development; Assessment; Aggregation; Interpretation. These stages can be repeated until consensus is achieved at different phases of the project. The collaborative methods of this research are expected to assist in developing a framework for the assessment and analysis of the lifecycle sustainability of regeneration schemes to be used for consensus and holistic decision-making on the appraisal of housing estates in London. The proposed framework benefits from taking into account the priorities of the key stakeholders of the schemes, and using simple and transparent mathematical calculations for interpretation of the assessment results to make it suitable for non-expert stakeholder groups. The study aims to apply its findings to be implemented to support better decision-making on the regeneration of housing estates and other types of regeneration projects in different locations.

5.03.P-We320 Simulating Sustainable Farming Strategies in Luxembourg with a Hybrid Agent-Based and Life-Cycle Assessment Model
*Alper Bayram[1], Antonino Marvuglia[1], **Tomas Navarrete Gutierrez**[1], Hélène Soyeurt[2], Anthony Tedde[2] and Stéphanie Zimmer[3], (1)Luxembourg Institute of Science and Technology (LIST), Luxembourg, (2)TERRA Research and Teaching Centre, Gembloux Agro-Bio Tech, University of Liège, Belgium, (3)Institut fir Biologësch Landwirtschaft an Agrarkultur Luxemburg (IBLA), Luxembourg*
Agent-based modelling (ABM) has been gaining interest in socio-economic systems modelling since it allows to consider heterogenous agents and their interactions. This is particularly relevant in agricultural systems since the farms are run by actors (often family businesses) which interact with each other and whose strategies can be affected by personal preferences and

traditions and not only by profit maximization. To understand to what extent environmentally sounder agricultural and farming practices can be enforced and how these can spread among farmers, we implemented a hybrid ABM-LCA model and used it to simulate and compare different sustainabilitydriven scenarios.
We simulated five different scenarios. Scenario A is the baseline scenario, which represents the current situation. Scenario B considers reducing the stocking rate from 1.6 to 1.3 livestock unit per ha (LSU/ha). Scenario C brings the stocking rate further down (to 1 LSU/ha). Scenario D aims at reducing the soybean ratio in animals' feed rations to the minimum possible level that is feasible for each farm. Scenario E simulates an increase in soybean autonomy, i.e. the farmers with the highest green consciousness choose to use local soybean (instead of imported one), increasing its cultivation. The LCIA scores are calculated automatically in Python using the ReCiPe LCIA method in the Brightway2 LCA framework and relying on the *ecoinvent 3.7.1* database for the background processes.
As expected, when we reduce the stocking rates all impact categories show improvement. In fact, as there are fewer and fewer animals in the system, freshwater ecotoxicity and eutrophication categories show significant improvements since less manure is produced and thus there is less nitrogen leakage to the soil. Globally, Scenario C scores the best in almost every category. However, enforcing this scenario involves a reduction in farmers' revenue, that would have to be compensated by subsidies to make it accepted by farmers.
We also quantified the *systemic uncertainty* of the model, i.e. the uncertainty due to the inherent variance of the underlying system. The results show that the highest variability is obtained for the Resources endpoint categories.
In conclusion, the simulation tool we built can help policymakers to simulate possible emission mitigation strategies and quantify the subsidies that should be put in place to convince farmers to follow more environmentally sustainable practices.

5.03.P-We325 Weighted Eco-efficiency for Energy Systems: What Can We Learn From Different Stakeholder Groups?
Dominik Huber[1]*, Maeva Lavigne Philippot*[2] *and Maarten Messagie*[2]*, (1)EVERGi Group, Vrije University Brussels, Belgium, (2)Vrije University Brussels, Belgium*
Nowadays energy systems are expected to comply with a great range of technical, economical, environmental, and social criteria. Due to the pressuring climate targets launched by the European Union, more attention and effort is paid to decarbonize the current energy systems, e.g. by integrating more renewable energy carriers into the electricity grid.
Next to economic evaluations of energy systems, more environmental assessments were established over the last decade. However, decision-makers and stakeholders are left with a wide range of indicators to find consensus amongst the evaluated energy systems. Additionally, stakeholders might express different preferences for the single indicators.
Therefore, a new method is proposed to reflect the stakeholder preference for economic and environmental evaluation of energy systems. To exemplify this new method and the results of different stakeholders, a case study of a residential energy system is presented.
First, the energy system is designed and optimized using mixed-integer linear programming. Second, the carbon footprint (CF) and the levelized cost of electricity (LCOE) are calculated and integrated into the model. Third, the CF and LCOE are then weighted according to the preferences of different stakeholders. Consumption and generation data of the residential energy system originate from primary sources. Weighting data are thereby obtained from stakeholder workshops. Forth, the weighted CF and LCOE are used to calculate the eco-efficiency of the energy system for various stakeholders. Fifth, in the same manner, the eco-efficiency of the national grid is determined and used as a benchmark.
Overall, a higher eco-efficiency will represent higher emissions and costs. Therefore, the eco-efficiency of energy systems integrating more renewable energy sources will be expected to be lower, compared to the benchmark.
In general, this study exemplifies the linkage of CF and LCOE methodology with energy system programs, which can be adapted to other sites. Besides, the variance of the eco-efficiency of different stakeholders is presented.
In the context of the European energy crisis, the proposed method provides a valuable assessment for further accommodating renewable energy carriers.

5.03.B LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Comprehensive Analysis

5.03.B.T-01 On the Complexity of Sustainable Production-consumption Systems: Using Agent-based Modelling to Understand the Role of Sustainable Behaviours
Gustavo Larrea Sr, Enrico Benetto, ***Antonino Marvuglia*** *and Tomas Navarrete Gutierrez, Luxembourg Institute of Science and Technology (LIST), Luxembourg*
The effect of sustainable behaviours across supply chains is important to understand key factors and potential intervention opportunities both at supply and demand level. However, for the suppliers that adopt a "sustainable" behaviour there is no guarantee that this will result also in an economically profitable strategy. Thus, the need to investigate beforehand, in a simulation environment, the consequences of this behavioural shift, both from the perspective of the single supplier and of the entire network of companies in the supply chain. For this, our objective was to answer two questions: 1) are companies always disadvantaged when adopting a sustainability-driven behaviours in a system dominated by profit-driven agents? and, 2) how much the system improves (added value, environmental impact reduction) from this behavioral change? For this, a supply network composed by producers, traders and consumers was simulated using an agent-based model where agents were programmed relying on an Algebraic FRamework for Instantiating Computational Agents (AFRICA), developed for this purpose. The simulation environment was implemented using the package *pacha*, a python toolkit designed for simulating interactions of socio-technical systems. We set a pool of 202 agents composed by 100 fish-meal producers, 100 fish-meal consumers, and two wholesalers. The production and consumption networks were initialized using the Barabasi-Albert and the Watts-Strogatz models, respectively. We

demonstrated that there exist strategies and network configurations where the adoption of an environmental business norm can reduce considerably the impact of the system whilst not representing a risky decision for the agent. Moreover, when a sustainability-driven company appears randomly in the network, the probability of going bankrupt does not vary significantly even when the system is dominated by profit-driven agents. In contrast, when the green companies appear in locations closer to the consumption side, the risk for the agent is even lower and the increase in environmental performance is much higher. The utility of our study is twofold. First, a clear notion of the risk of adopting a particular business norm can facilitate companies' decision with respect to becoming an AOC. And secondly, understanding the effects that individual changes produce over the system and over the agents can aid the design of more adequate policies.

5.03.B.T-02 Life Cycle Sustainability Assessment using the Social Footprint Methodology 2021: Comparing Sustainability Performance of Bio Fiber with Conventional Glass Fiber

Hanie Zarafshani[1]*, Ponnapat Watjanatepin*[1]*, Bertram F. de Boer*[2]*, Bo P. Weidema*[3] *and Karel Van Acker*[1]*, (1)KU Leuven, Belgium, (2)2.-0 LCA consultants, Denmark, (3)Aalborg University, Denmark*

Life cycle assessments are frequently used by organizations to evaluate and compare the environmental performance of their processes, even though it is well known that sustainability goes beyond environmental performance and that the social and economic performance of products is also particularly important.

One cause for this is the lack of a standardized method or indicator for evaluating the sustainability performance of a good or service that includes all the effects linked to its social, environmental, and economic performance.

Weidema provides an open-access methodology called "Life Cycle Sustainability Assessment using the Social Footprint methodology 2021" to overcome this challenge. It provides a summary measure of income redistribution and all productivity-decreasing externalities associated with a particular product or activity. This model applies sustainable well-being (utility) measured in Quality-Adjusted person-Life-Years (QALY) as a summary indicator for all social, ecosystem, and economic impacts. By having a cardinal-scale quantitative indicator, QALY, this method helps to quantify trade-offs and synergies between impact categories and compare business decisions, performance, and improvement options across the industry sector.

This study demonstrates the model's potential by calculating the total QALY value for hemp and glass preform from cradle-to-grave to compare their sustainability while taking into account all the impacts associated with the social, ecosystem, and economic aspects.

Additionally, all impacts were included in the pricing, and the real value of the preforms was determined in euros. The results show that when the impacts were internalized, the price of hemp and glass fiber increased. In addition, strengthening the non-production-specific impact (impacts of missing governance), specifically addressing the labor costs of the farmers, is essential to improve the sustainability impact of hemp fibre production.

In the end, the contributions of particular impact pathways and their indicators scores were defined. The total impact category impact for the hemp and glass preform for each UN Sustainable Development Goal (SDG) and area of protection draw a clear direction to act upon.

5.03.B.T-03 Implementing and Extending Different Types Of LCA, Focusing on Sustainability Assessment of Investment Products

Thomas Schaubroeck, *Ioana Popescu, Thomas Gibon, Claudio Petucco, Claudia Hitaj, Ankit Arora and Enrico Benetto, Luxembourg Institute of Science and Technology, Luxembourg*

There are various types of Life Cycle Assessment (LCA) methods to assess the environmental impact of product systems, especially when considering an open framework. In this study, we review LCA types and in a second step investigate these specifically in the context of investment products. We focus on two prominent types of attributional LCA (ALCA) and consequential LCA (CLCA), as (1) they answer different relevant ethical research questions and (2) are prominently present in literature with many databases considerably aligning to either one of them. Within the context of investment products, EU regulations and investor demand pushing the investment industry towards life cycle or supply chain assessment of investment products, applying LCA to investment products is the obvious solution, but the choice of method and dataset are not straightforward for identifying the investment product with the lowest environmental impact per euro. We will tackle specific challenges for this context: (1) investments directly or indirectly lead to effects on production and consumption through financial, economic and corporate processes, (2) investments may lead to different sets of products, which should be considered, and (3) there are also different types of investment products (e.g. debt versus equity). For the first challenge, we consider these mechanisms as a black box and look at the finality of effects. For example, in case of a product amount increase, the ratio of product amount per euro needs to be derived. Concerning the second challenge, product utility needs to be regarded to have an adequate comparison in ALCA. For CLCA, this is not always needed. Most importantly, when considering a demand-constrained market, producing more will just shift the market composition. In other words, a substituted market mix that provides the same functionality as that of the product, will go down in tandem. For the different investment types, we propose specific types of LCA, e.g. organizational ALCA (e.g. using IO-based databases) in case of stocks based on the company share, this for an attributional perspective. The study is timely, as it serves as a guide for applying LCA to investment products, in line with upcoming regulations and investor demand. A more thorough analysis and case study are being finalized.

5.03.B.T-04 Methodological Approach to Account for Natural Hazards in the Life Cycle Assessment of the Energy Production Sector

Alejandra Cue Gonzalez[1]*, Eric Rigaud*[2]*, Paula Pérez-Lopez*[3] *and Philippe Blanc*[3]*, (1)O.I.E., MINES Paris, France, (2)CRC, Mines Paris PSL University, France, (3)O.I.E., Mines Paris PSL University, France*

Several factors must be considered when addressing planning and decision-making for the present and future of the electricity production sector, such as logistics related to the geographic location, and technical, social, political, economic, and potential environmental aspects. The latter can be estimated through environmental impact assessments. Life Cycle Assessment (LCA) is one of the widely accepted tools to obtain relevant results for planning and decision-making.
Despite the global scope of the LCA method, its typical application focuses on evaluating scenarios describing average or steady states, thus not accounting for the potential environmental consequences of abnormal events, such as natural hazards that can result in important damages. However, it is imperative to consider the latter in the environmental assessment since their possible consequences may irreversibly change the planned projects negatively for all stakeholders.
A way to approach this is to take a scenario-based and parametrized approach to LCA. It aids the practitioner in considering multiple situations in the product system, but this has limitations in a sector-wide evaluation that considers the negative influences of natural hazards on the system and the environmental impacts of said disturbances.
The purpose of this work is to address these limitations by analysing each phase of the LCA methodology and adapt it for a comprehensive treatment of natural hazards in LCA. The objective is to provide a decision-making framework that supports decision-makers in making decisions based on the knowledge and needs of the present that will still be considered fair decisions in the future, especially when considering impacts related to the occurrence of a significant natural event.
As a first attempt, the analysis and the methodological approach to design are based on a case study on the France's photovoltaic (PV) pathway. Only a few natural hazards, known to be able to cause important disturbances and damages to PV systems are considered. The results from the case study will not be significant to represent a real situation and draw relevant conclusions within the PV sector. However, they will illustrate the strengths, limitations, and feasibility of the proposed methodological framework, thus permitting its continuous improvement and open potential scientific discussions and developments for the PV and the electricity sector.

5.03.B.T-05 Towards Prospective Territorial LCAs: Considering the Effects of Global and Local Environmental Changes on the Performance of Irrigated Areas
Nicolas Rogy[1]*, Amandine Pastor*[2]*, Agata Sferratore*[3]*, Nicolas Géhéniau*[4]*, Arnaud Helias*[2] *and Eleonore Loiseau*[2]*, (1)National Research Institute for Agriculture, Food and Environment, France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (3)Société du Canal de Provence et d'aménagement de la région provençale, France, (4)BRL Ingénierie, France*
Territorial Life Cycle Assessment (T-LCA) is a meso-scale adaptation of the conventional LCA framework, allowing to assess the environmental performance of a territory and an associated land planning scenario while considering its multifunctionality (e.g. economic, social or environmental land use functions). For that purpose, eco-efficiency ratios, i.e. services provided by the territory to its environmental impacts, are computed. To date, the approach has been static, assessing the eco-efficiency of a scenario for a given year. However, the environmental performance of a system can be affected by feedback from the ecosphere, which are stimulus on the ecosphere that are returned to the technosphere through a series of interactions. This issue is particularly important to determine 'no-regret' land planning scenarios over the long term.
This study aims at developing a methodology to assess both global and local environmental feedback on the environmental performance of scenarios. The proposed methodological developments will be used to compare the evolutions of eco-efficiencies of agricultural land planning scenarios with and without irrigation considering the effects and interactions of climate change and water scarcity over time.
The core of the methodology is based on a coupling between a crop model, the Aquacrop model of the Food and Agriculture Organization of the United Nations (FAO), and the T-LCA approach. The first step consists in defining the land planning scenarios to assess, i.e. in this study, agricultural planning scenarios using different crops with the implementation or not of a hydraulic infrastructure to secure local water supply (i.e. a hill reservoir). The next step is data collection, i.e. input data for Aquacrop and data for the Life Cycle Inventory (LCI). Third, climate change and water scarcity feedback are taken into account through modelling with Aquacrop. Fourth, LCI are built with primary data from Aquacrop simulations, i.e. yields and water balance, and secondary data from existing LCA database, literature and expertise. Finally, the environmental performance of the scenarios are compared with their eco-efficiency ratios, calculated with the mass of agricultural products (one of the services provided by the territory).
These works highlight the importance of considering global and local environmental changes when assessing the environmental performance of long term land planning scenarios to make "no regret" decisions.

5.03.P LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Comprehensive Analysis

5.03.P-We315 A Participatory Life Cycle Sustainability Assessment Framework for the Appraisal of Estate Regeneration Schemes in London
Sahar Nava[1]*, Esfandiar Burman*[2] *and Zaid Chalabi*[2]*, (1)Bartlett School of Environment, Energy and Resources, UCL, London, United Kingdom, (2)Bartlett School of Environment, Energy and Resources, University College London, United Kingdom*
To enable sustainable growth, the assessment and analysis of the regeneration schemes should consider their socio-economic as well as their environmental impacts. The methodology which includes the three sustainable development pillars is called Life Cycle Sustainability Assessment (LCSA). To reflect the priorities of an array of stakeholders in options appraisal, key stakeholders should be engaged in different stages of decision analysis. This study aims to develop a participatory approach to LCSA for the appraisal of estates' regeneration schemes. The complex mixed methods research design consists of a pilot study, surveys, knowledge mobility, co-design workshops, ethnographic observations, semi-structured interview, and simple mathematical calculations. Review of the literature and findings of the pilot research have assisted in identifying a preliminary list

of sustainability indicators for the framework. Key stakeholders including the community members and built environment specialists have participated in a survey which have resulted in eliciting the weights (preferences) of meta criteria for the framework. The proposed framework consists of 5 stages: Goal and Scope Definition; Scenario Development; Assessment; Aggregation; Interpretation. These stages can be repeated until consensus is achieved at different phases of the project. The collaborative methods of this research are expected to assist in developing a framework for the assessment and analysis of the lifecycle sustainability of regeneration schemes to be used for consensus and holistic decision-making on the appraisal of housing estates in London. The proposed framework benefits from taking into account the priorities of the key stakeholders of the schemes, and using simple and transparent mathematical calculations for interpretation of the assessment results to make it suitable for non-expert stakeholder groups. The study aims to apply its findings to be implemented to support better decision-making on the regeneration of housing estates and other types of regeneration projects in different locations.

5.03.P-We316 (How) Can Ontologies Help to Integrate Sustainability Dimensions? Learnings From the ORIENTING Project

Thomas Sonderegger[1], *Chris Mutel*[1], *Till Bachmann*[2], *Luca Zampori*[3] *and Janire Clavell*[4], *(1)Ecoinvent Association, Switzerland, (2)EIFER, Germany, (3)PRé Sustainability, Netherlands, (4)Tecnalia, Spain*

ORIENTING is a H2020 funded project, which aims at integrating different sustainability topics –the environmental, economic, and social domains as well as material circularity and criticality assessments – into a single operational methodology for Life Cycle Sustainability Assessment (LCSA). This needs alignment of concepts and data structures across the different topics for which ontologies were considered helpful. An ontology is a formal description of concepts and their relationships in a domain. For example, activities (or processes) and flows (or exchanges) are concepts in the LC(S)A domain, related by flows being inputs and outputs of activities.

ORIONT builds on the BONSAI ontology which itself builds on previous ontologies suggested for sustainability assessments. To capture all ORIENTING topics, the BONSAI ontology needed extensions. This meant adding new classes, sub-classes, and ranges of instances to a) capture missing concepts such as stakeholders in social LCA; b) further distinguish existing elements (such as flows) into different types; and c) introduce LCIA.

ORIONT was used in ORIENTING as guidance to, for example, assign differently named data points used in the different sustainability topics to the same or equivalent classes. This was achieved by an ontology visualisation, which was discussed with topic experts. In a similar way, ORIONT could guide discussions in the LC(S)A community about, for example, data formats and conceptual and terminological alignment. A technical implementation would allow a connection to data and help in data integration as exemplary shown by the BONSAI ontology authors. This was beyond the scope of ORIENTING and would come with a considerable amount of technical expertise needed. This leaves us with several trade-offs and related questions about further use of ontologies in the LCSA field: Visualization only versus full technical implementation: To what degree can and should ontologies be used in the LC(S)A field? A working ontology offers a connection to the semantic web and data in it: Which and how much semantically classified data is available? Are there other (and maybe easier) ways to achieve our goals such as data collection and integration? An ontology could be at the core of data format converters: Is this feasible or does every conversion have its own rules?

With this contribution, we would like to stimulate a discussion based on the experiences made in ORIENTING.

5.03.P-We317 LCSA and Sustainability

Tomas Ekvall, *TERRA, Sweden; Technology Management and Economics, Chalmers University of Technology, Sweden*

Life cycle sustainability assessment (LCSA) is often defined as the sum of life cycle assessment (LCA), social LCA, and life cycle costing (LCC). Both LCA and LCC calculate impacts per functional unit – typically a basic unit chosen to quantify the function generated by the product or service investigated (e.g., supplying a litre of oil, a cubic meter of gas, or a MJ of heat). The results can be used to measure environmental and economic efficiency, i.e., what volume of functional output we can get for a given environmental or economic cost. However, efficiency is just one perspective on sustainability. Environmental sustainability depends less on the environmental efficiency and more on the total environmental impacts. A gas pipeline might deliver gas with less climate impact per cubic meter, compared to the shipping of liquid natural gas; if the pipeline makes the gas more accessible and cheaper, however, it can still increase the climate impact by stimulating an increased use of the fossil gas. By changing the calculation basis from the basic unit of the functional output (e.g., a cubic meter of gas) to a time span (e.g., 1 year) or to a specific project (e.g., a pipeline), the LCSA can account for changes in the functional output and generate a more relevant measure of environmental sustainability. The equivalent approach in LCC means presenting the total cost for the time span or project rather than the cost per litre or MJ. However, economic sustainability depends not only on projected costs, but also on economic risks and business opportunities, and on the existence of applicable market and business models. The Nordstream gas pipelines reduced economic risk by adding new routes for transferring gas from Russia to the EU, but increased economic risk by reinforcing the dependency of EU on Russian gas. Such important aspects of economic sustainability can typically not be quantified. Hence, a sustainability assessment should include also qualitative aspects. The imp ta aspects of social sustainability are highly case-specific. For the Keystone XL pipeline, the crucial social aspect was the ground over which the pipeline would have run. The Nordstream and Keystone cases illustrate that key sustainability aspects need not have a cradle-to-grave perspective. Hence, to assess the sustainability of different options an LCSA should have a broad systems perspective but need not have a cradle-to-grave perspective in all parts.

5.03.P-We318 Investigating Switching Shipping's Fossil Fuel Use with Alternative Options for a Low Carbon Future - A Comparative LCA Study

Branwen Ap Dafydd Tomos[1], *Laurence Stamford*[2] *and Andrew Welfle*[3], *(1)Tyndall Centre for Climate Change research, Tyndall Centre for Climate Change Research, University of Manchester, United Kingdom, (2)University of Manchester, United Kingdom, (3)Tyndall Centre for Climate Change Research, University of Manchester, United Kingdom*
The international shipping sector is responsible for 3% of total global GHG emissions, and is in urgent need of decarbonisation. Alternative fuels are a potential solution, therefore, this research compares the environmental burden of a broad range of fuel options including: Hydrogen (green and blue), Ammonia (green and blue), E-methanol, bio-methanol, bio-methane, and FAME biodiesel. Each potential option has varied life cycle GHG contributions due to different production methods and on-board use. Life cycle assessment (LCA) techniques are applied to compare each fuels' potential to lead the sector towards a sustainable, low carbon transition. GaBi software and ReCiPe2016 are utilised alongside EcoInvent 3.7 and further data from literature.
The research presented establishes novel inventories for the production and use of alternative fuels on board shipping vessels. A top down analysis of the sector's global propulsion energy is performed and combined with LCA results to investigate each alternative fuels' capacity for global shipping GHG emission reduction. Consideration is given to alternative fuel production capacities, both now and in the future, as well as to the shipping industry's relationship with the wider energy system.
The results reflect the complexity of the challenge at hand. For example, GHG emission reduction from non-biogenic Methanol is found to be limited, due to its carbon content. On the other hand, restricted capacity for sustainable production of bioenergy feedstocks limits the extent by which the biogenic carbon cycle can be utilised for GHG emission reduction. This research also found that nitrous oxide from ammonia combustion could result in Ammonia fuel having significantly higher GHG emission potential than previously expected by literature.
Overall, GHG reduction is shown to be possible with a switch to alternative fuels, provided that the sector has a commitment to a life cycle perspective on decarbonisation. There is also a requirement for the timely development of global production capacity of alternative fuels, and the introduction of energy efficiency measures within the industry if decarbonisation is to be achieved. This research offers contributions to LCA inventories for alternative fuel production and use, and advances understanding of methods to account for shipping's global scale within LCA studies.

5.03.P-We319 Pioneering Historical LCA - A Perspective of the Development of Personal Carbon Metabolism 1860 to 2020

Simon Bruhn[1], *Trine Røgild*[2], *Matilde Andreasen*[3], *Julie Larsen*[4], *Nana Sønderholm*[5], *Ciprian Cimpan*[5] *and Morten Birkved*[5], *(1)Center for Life Cycle Engineering, University of Southern Denmark, Denmark, (2)Teknologisk Institut, (3)Ramboll, (4)Bureau Veritas Group, (5)University of Southern Denmark, Denmark*
The world at large has agreed that anthropogenic climate change is an urgent matter, that should be mitigated. Different schools of though exist on how reduce the emission of greenhouse gasses, a debate sometimes referred to as "boomsters vs doomsters", arguing whether or not technological change inevitably will solve the issues, or if we humans have to put more effort in changing our consumption patterns, as to achieve a sufficient green transition. The IPAT equation conceptually defines the environmental impact (I) to be a product of the population (P), its' affluence (A), and the technological efficiency (T), and can hence give a perspective to the debate.
A Danish research project investigates the personal carbon metabolism of Danish urban citizens, and how it developed since "the black transition" with occurred at the industrial revolution almost 200 years ago. The overarching objective is to develop scientifically backed museum exhibitions, which can provide a public debate and perspective on the current green transition. The project is an interdisciplinary collaboration between museums and researchers within both humanities and engineering.
The personal carbon metabolism is quantified via historical LCA – an until now unexplored field. This LCA can be considered partially dynamic, and has similarities to the field of prospective LCA. The LCA considers changes in consumption as well as technology,and includes a range of significant consumption segments; namely transport, food, housing, and energy use. By estimating the LCA at five timesteps, a perspective is provided on the personal carbon metabolism and how it has changed in the period 1860-2020.
Due to the historic nature, data availability is a significant challenge, hence different means to provide qualified scenarios are explored. The project is ongoing till spring 2023, but current results reveal that the massively increased technological efficiency is not sufficient to keep up with our even more drastically increased affluence. On the more bright side however, the results indicate that the focus on the green transition has led to a decrease in the accelerating growth since the 1970's. The findings of the research is of relevance as it provides a historical perspective on how changes in technology and consumption has affected the impact on climate change, empowering citizens and scientists to see the current green transition in this context.

5.03.P-We320 Simulating sUstainable Farming Strategies in Luxembourg with a Hybrid Agent-Based and Life-Cycle Assessment Model

Alper Bayram[1], *Antonino Marvuglia*[1], ***Tomas Navarrete Gutierrez***[1], *Hélène Soyeurt*[2], *Anthony Tedde*[2] *and Stéphanie Zimmer*[3], *(1)Luxembourg Institute of Science and Technology, Luxembourg, (2)TERRA Research and Teaching Centre, Gembloux Agro-Bio Tech, University of Liège, Belgium, (3)Institut fir Biologësch Landwirtschaft an Agrarkultur Luxemburg, Luxembourg*
Agent-based modelling (ABM) has been gaining interest in socio-economic systems modelling since it allows to consider heterogenous agents and their interactions. This is particularly relevant in agricultural systems since the farms are run by actors (often family businesses) which interact with each other and whose strategies can be affected by personal preferences and traditions and not only by profit maximization. To understand to what extent environmentally sounder agricultural and farming practices can be enforced and how these can spread among farmers, we implemented a hybrid ABM-LCA model and used it to simulate and compare different sustainability driven scenarios.

We simulated five different scenarios. Scenario A is the baseline scenario, which represents the current situation. Scenario B considers reducing the stocking rate from 1.6 to 1.3 livestock unit per ha (LSU/ha). Scenario C brings the stocking rate further down (to 1 LSU/ha). Scenario D aims at reducing the soybean ratio in animals' feed rations to the minimum possible level that is feasible for each farm. Scenario E simulates an increase in soybean autonomy, i.e. the farmers with the highest green consciousness choose to use local soybean (instead of imported one), increasing its cultivation. The LCIA scores are calculated automatically in Python using the ReCiPe LCIA method in the Brightway2 LCA framework and relying on the *ecoinvent 3.7.1* database for the background processes.
As expected, when we reduce the stocking rates all impact categories show improvement. In fact, as there are fewer and fewer animals in the system, freshwater ecotoxicity and eutrophication categories show significant improvements since less manure is produced and thus there is less nitrogen leakage to the soil. Globally, Scenario C scores the best in almost every category. However, enforcing this scenario involves a reduction in farmers' revenue, that would have to be compensated by subsidies to make it accepted by farmers.
We also quantified the *systemic uncertainty* of the model, i.e., the uncertainty due to the inherent variance of the underlying system. The results show that the highest variability is obtained for the Resources endpoint categories.
In conclusion, the simulation tool we built can help policymakers to simulate possible emission mitigation strategies and quantify the subsidies that should be put in place to convince farmers to follow more environmentally sustainable practices.

5.03.P-We321 Sustainable Freshwater Consumption of the Agricultural Crop Production in a Highly Dense Population Setting
Kamrul Islam[1]*, Ryosuke Yokoi*[2] *and Masaharu Motoshita*[2]*, (1)Research Institute of Science for Safety and Sustainability, National Institute of Advanced Industrial Science and Technology, Japan, (2)National Institute of Advanced Industrial Science and Technology, Japan*
Global crop production consumes a huge amount of freshwater due to which regional freshwater overconsumption is evident from major watersheds of the world. We as a global community are facing the dilemma of identifying ways to feed the billions of people and ensuring that our food production follows a sustainable practice. Bangladesh is a densely population country with one of the lowest per capita agricultural lands of the world. In recent days, the country is gradually becoming self-reliant on food production. There are few issues regarding the limited freshwater resources of the country: seasonal freshwater overconsumption during the dry period, and water pollution due to agricultural intensification. In this study, we aim to assess the sustainability of the crop water use for supporting Bangladesh's diet and gain the implications for future sustainable national diet focusing on the aspect of water resources. The updated WaterGAP 2.2d model is used to calculate the freshwater overconsumption of Bangladesh's watershed, and the overconsumption associated with the crop production in the country is estimated corresponding to the total agricultural production for 1960–2019 period using updated crop evapotranspiration value. According to the results, the average overconsumption of freshwater from agricultural crop production during 2000–2016 period in Bangladesh was ~20,433 million cubic meter which was mainly due to own consumption of several crops e.g., rice, areca nuts, wheat, jute etc. Furthermore, we also seek to identify the relationship between the nutrient density of the food crops and induced freshwater overconsumption, which gives the implications towards the achievement of the sustainable national diet. The outcome from this study will provide strategies for sustainable crop production in the country with the identification of the key crops and the watersheds that need improvement in the context of sustainability of water use.

5.03.P-We322 Environmental Impacts and Sustainability Implications of Aquaponics-exploring Aquafeed
Andrea Hicks[1]*, Ramin Ghamkhar*[1] *and Marissa Breitenstein*[2]*, (1)University of Wisconsin, Madison, (2)Civil and Environmental Engineering, University of Wisconsin, Madison*
Closed loop agricultural systems, such as aquaponics, have the potential to reduce the environmental impact of food production through the efficient usage of nutrients and water. Aquafeed, however, with critical components such as fish meal and fish oil often harvested from wild forage fish population are a growing area of concern which has led to a number of potential replacements being considered. Not all replacements have a lower environmental impact, as it is dependent as to what materials they are sourced from. Life cycle assessment and multicriteria decision analysis informed by farmer survey data will be used to explore this issue. A midpoint life cycle assessment using the TRACI environmental impact categories will be conducted along with survey data gathered from aquafarmers in Wisconsin, USA. This work found that although some fish meal and oil replacements in aquafeed have a lesser environmental impact than conventional feeds, that is not true across the board. Further, aquafarmers are heterogenous in their beliefs which influence the potential for them to adopt fish meal and oil free feeds. This study is particularly relevant as aquaponics and aquaculture are fast growing methods of food production, and current forage fishing practices have the potential decimate food webs.

5.03.P-We323 Economic and Environmental Assessment of Two Industrial Symbiosis Opportunities in the Copper Sector
Belen Estefania Rosas Rodriguez[1]*, Daniele Dalla Vecchia*[2]*, Alain Vassart*[2]*, Symeon Christofyllidis*[3] *and Nele Deleebeeck*[1]*, (1)Arcadis Belgium, Belgium, (2)Resilience, Arcadis Belgium, Belgium, (3)Regulatory Affairs, European Copper Institute, Belgium*
Sustainability is a multi-faced topic, and industry has acknowledged the need to pursue it for increasing its resilience. One way to do this is via Industrial Symbiosis (IS). IS is the exchange of by-products among different stakeholders, as well as the sharing of infrastructure and the joint provision of services to increase material and energy efficiency and achieve cost savings. One of the sectors with big amounts of by-products and high impact is the copper sector. Looking at opportunities for IS and measuring its benefits is a way to improve the sector's footprint. In this project, we first analysed which Cu by-products and Cu-bearing

products would be eligible for IS. The streams viable for IS were identified by means of a literature search. The potential economic and environmental benefits were quantitatively assessed using a market study/cost-benefit analysis and an LCA, respectively, and were combined to build a business case. Two relevant material streams were identified: iron silicate (Fe-Si) from Cu slags from smelting and refining, and End-of-Life Electric Vehicle Batteries (EOL EVB). The IS scenarios built were the use of Fe-Si to replace natural aggregates in cement and concrete manufacturing or in road construction, and the use of EOL EVB in large scale energy storage applications, replacing new batteries using virgin materials. The results of the LCA showed that, in the case of Fe-Si, the impacts of IS are significantly lower (> factor 2) compared to using gravel in roads. When natural aggregates are replaced by Fe-Si in cement and concrete production, the impact is also lower. For EOL EVB, the IS scenario scored better in most of the impact categories, with a 28% improvement in climate change, 23% in resource use of minerals and metals, and 48% in resource use of fossils. Most of the environmental benefits were found to come from avoiding the production of new batteries from virgin materials. The market analysis showed a good opportunity for stakeholders in the sector in both cases, as demand for raw materials is increasing. The cost analysis was promising for Fe-Si, with a case-by-case study needed, considering local context. For EOL EVB, re-purposing was found to be cheaper than recycling and reuse cheaper than new battery use. The study has shown that IS can be economically feasible and environmentally beneficial to the copper sector and can create an opportunity to decrease the sector's footprint and increase its circularity.

5.03.P-We324 Understanding What Is Required To Make Reusable Packaging Sustainable: Combining Life Cycle Assessment and People's Willingness

Maryam Hoseini[1]*, Saima Eman*[2]*, Paul Mattinson*[3]*, Rachael Rothman*[1]*, Antony Ryan*[1]*, Patrick Fairclough*[3]*, Sarah Greenwood*[4] *and Thomas L Webb*[5]*, (1)University of Sheffield, United Kingdom, (2)Department of Psychology, University of Sheffield, United Kingdom, (3)Department of Mechanical Engineering, University of Sheffield, United Kingdom, (4)Department of Chemistry, University of Sheffield, UK and Grantham Centre for Sustainable Futures, University of Sheffield, United Kingdom, (5)Department of Psychology, University of Sheffield, United Kingdom*

Today plastic pollution has become one of the most pressing environmental issues. Plastic packaging can be particularly problematic as it accounts for 50% in weight of the total plastic waste in the world and it is a linear system; raw materials are taken from the Earth to make packaging products and then, after being used by consumers, thrown away as waste. Therefore, to develop a more sustainable plastic packaging system, the focus should be on new design and technology to move to a more circular economy and keep materials in use to prevent waste and protect and restore the environment. One of the solutions to change from a linear system to circular is the reuse system model. However, there is currently limited understanding about required factors to implement such a circular economy. While the reuse system should be environmentally beneficial, it needs to be accepted by people to be implemented in practice not only be technically possible or possible in theory.

This presentation will discuss work from the "Many Happy Returns" project that examines the sustainable reuse of plastic packaging by identifying the best reuse model for different contexts, exploring the optimum materials, process and technologies for smart reusable plastic packaging systems and developing practices to encourage reuse. People's willingness was measured and integrated into LCA results to show how technology and packaging design can make a balance between these to enable a reuse system as a sustainable solution for plastic waste. In particular, analysis of returnable cups and bowls for use in cafes as take-out packaging, were analyzed. The analyzed midpoint impact categories have been aggregated into the three main life cycle phases: production, use and End of Life (EoL). Then, they have been used to assess the environmental break-even point (BEP), i.e. the minimum number of uses necessary for a returnable cup and bowls to be preferable than some single-use ones. Results showed that the weight of bowls, moving to renewable energy and End of Life (EoL) of the reusable products are key factors to identify possible strategies to improve the implementation and success of reusable products.

5.03.P-We326 Life Cycle Assessment of Room Air Conditioners Using Big Data of 70,000 Units in Japan

Genta Sugiyama[1]*, Tomonori Honda*[2] *and Norihiro Itsubo*[1]*, (1)Tokyo City University, Japan, (2)National Institute of Advanced Industrial Science and Technology, Japan*

It is estimated that two-thirds of the households in the world will have air conditioners installed, and the current energy demand for air conditioning, which accounts for 10 percent of global electricity consumption, will be tripled by 2050. Economic growth in developing countries has allowed their residents who could not have air conditioners installed in their homes to do so. Global warming also increases the demand for air conditioners. The increased demand for air conditioners burdens the electricity systems in many countries as well as boosting the amount of greenhouse gas (GHG) emissions.

In Japan, about 25 percent of the entire residential GHG emissions comes from the use of air conditioners. The country has set a goal to reduce GHG emissions by 66 percent from the 2013 level to achieve carbon neutrality by 2050. One of the problems arises, however, regarding the calculation of assessments, because the data that shows the use of air conditioners in the Tokyo area is taken as a standard value to indicate the data of the entire Japan. Since the Japanese islands stretch from north to south, there is a concern that the assessments may be inaccurate disregarding a variety of diverse in Japan.

In this study, I have looked into big data, i.e., the data that describes actual usage of about 70,000 air conditioners in Japan from 2017 to 2021 to illustrate the discrepancy between actual data and the standard values. I also conducted a life cycle assessment reflecting the actual usage. I have found that the actual averages are about 18% lower in annual operating hours and 23% lower in annual energy consumption than the standard values, thus the assumption of the standard values may be overestimated. This divergence resulted in a variation of approximately 28% (22%~37%) in the LCA results for air conditioners. In my future study, I will estimate future heating and cooling demand associated with future temperature changes based on actual usage by region, and make proposals for air conditioner usage methods to achieve carbon neutrality.

5.03.P-We327 Sustainability Assessment of Plasma Gasification as Waste-to-energy Strategy: Review on Environmental, Economic, and Social Aspects

Ana Isabel Ramos, *INEGI, Portugal*

Following the actual pace of industrial development, due to the ever-growing tech- and resource-savvy society, unprecedented waste amounts are generated on a daily basis. Therefore, waste-to-energy (WtE) techniques appear as a possible approach to convert solid residues into energy, within more energy-efficient processes to emit less or no CO_2. Plasma gasification constitutes a proficient and clean alternative with multiple environmental gains, simultaneously reducing or eliminating toxicity and pollution issues while avoiding the landfilling of huge amounts of residues. To evaluate the performance of this WtE treatment, the life cycle thinking (LCT) methodology gathers useful impact assessment tools, providing quantifiable indicators on multiple domains. The lack of works reporting the combined assessment of the environmental, technical, economic and social spheres of WtE has been previously noticed and, to the best of the authors' knowledge, there is no such review so far for plasma gasification. This work proposes a deep review of literature on the life cycle assessment, life cycle costing and social impact assessment of plasma gasification, to evaluate how LCT tools are applied to the energetic valorization of solid residues by this technique, as a measure of sustainability. This provides insights on the contribution of energy recovery as a circular strategy, diverting waste from open dumps or landfills, while producing renewable energy and/or by-products that will replace the use of virgin materials. Herein, an attempt to complement the knowledge in the sectors of renewable energies and waste management is conducted, to support the fulfillment of circular economy goals and contribute to a more sustainable society and way of living.

Keywords: plasma, gasification, LCA, LCC, social assessment, circular economy

5.03.P-We328 Sustainability Risk Screening: The Definition and Undertaking of a Counterfactual Sustainability Screening Assessment

Edward George Platt[1] *and Peter Styring*[2]*, (1)The Department of Chemical and Biological Engineering, University of Sheffield, United Kingdom, (2)Chemical and Biological Engineering, University of Sheffield, United Kingdom*

The need for screening sustainability assessments, especially for low Technology-Readiness Level (TRL) technologies, is at its highest point given the extreme rate of innovation as the chemical synthesis industry looks to source sustainable supply chains. A screening assessment allows for the early understanding of the sustainability of low-TRL technologies based on scaled or simulated data, allowing for the detection of "hotspots" but rarely as a tool for informed decision-making. This research looks to define and prove, as a concept, a counterfactual sustainability screening assessment which looks to assess the sustainability performance of low-TRL technologies compared to the current, fossil-based industry standard. The method employs a frequency-based, semi-quantitative assessment methodology similar to that of a standard risk assessment. For a list of environmental, economic and social metrics, the likelihood of a process' performance outperforming the current industry standard allows for the generation of a single score, without the need for exact quantitative impacts for each metric. The decision to pursue a sustainability risk assessment is down to the accepted idea that predicting the probability of a process' sustainability impact exceeding a defined benchmark avoids many of the subjectivity pitfalls associated with predicting the exact impact of a process' adoption, a concept outlined by Glenn Suter in the Journal of Environmental Management. This will therefore likely reduce variance between assessment undertakers and therefore dampen the effects of subjectivity on the final result.

This presentation looks to build on previous presentations, outlining the final list of sustainability assessment metrics, followed by the definition of the counterfactual baseline and a proof of concept in the form of a sample assessment, looking at the formation of defossilised α-olefins for utilisation within liquid surfactants.

5.03.P-We329 Assessment of Reference Values in a Social Life Cycle Assessment: Concepts, Usefulness, and Examples

Andreas Roesch*, Melf-Hinrich Ehlers and Melanie Douziech, Agroscope, Switzerland*

The main purpose of reference values (RVs) is to facilitate interpretation of (social) indicators. RVs allow policymakers, farmers, consumers and various other stakeholders to assess better the results from indicator-based studies. Definitions of RVs are however numerous and no consensus exist either on how they should be defined. The objective of this study is therefore twofold namely first to evaluate the purpose and use of RVs, with a particular focus on social life cycle assessment in agriculture and second to provide guidance on how to derive RVs. To reach this objective, a comprehensive literature review and an internal workshop with experts from different disciplines were carried out. Three approaches were identified to derive RVs: (i) science-based values, (ii) political targets, and (iii) stakeholder/ experts opinions, whereas a clear distinction between the three is not always possible. RVs can also be derived from combining scientific findings, expert judgement, references to international conventions and statistical knowledge. From these three approaches, deriving RVs from scientifically agreed knowledge should be preferred. In fact, changing legislation, laws and rules do not allow for robust RVs definition. Another difficulty when defining RVs lies in potential conflicts when substantial economic and social impacts are anticipated, no matter whether science-based or politically determined RVs are used. This is particularly important as many agricultural issues have moved into the political limelight. In those cases, determination of references values based on compromises can be a solution. Setting objective, transparent and robust RVs to avoid the method being questioned can be an additional way of handling this challenge. The literature review further revealed that RVs are mainly used to (i) interpret indicators while allowing comparisons across space, locations, actors, companies (farms), sectors, and over time, (ii) give advice on how to improve sustainability, (iii) normalize indicators allowing subsequent aggregation and (iv) provide a reference for determining reference scales. These diverse uses suggest that how to best deal with RV would be use- and goal-specific. Future research will focus on the use of RVs in agriculture systems and on fit-for-purpose methods for deriving robust and widely accepted RVs.

5.03.V LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Comprehensive Analysis

5.03.V-01 Dynamic Carbon Footprint Using Factory Iot and Sensoring Systems

Takahiro Hashimoto[1]*, Norihiro Itsubo*[1]*, Teruo Ohashi*[2] *and Hiroki Ookubo*[1]*, (1)Tokyo City University, Japan, (2)LEXER RESEARCH*

According to data released by the Ministry of the Environment on greenhouse gas emissions in FY 2019, the industrial sector has the highest CO2 emissions, accounting for about 35% of total domestic emissions. Since about 94% of the industrial sector consists of manufacturing, a policy shift toward decarbonization of the manufacturing sector is strongly required in order to achieve Japan's greenhouse gas reduction targets. According to the Energy Saving Factory, "A large portion of electricity consumption in factories is attributed to the production process, and in order to achieve carbon neutrality, a complete switch to renewable energy and a review of the entire production process to reduce losses and electricity consumption from existing production processes are the manufacturing industry's efforts to become carbon neutral. This is an effort for manufacturers to become carbon neutral.

In addition, while there are many existing literatures that strive to improve productivity in factories, there are few papers that evaluate "environmental impact" as one parameter, and this study, which focuses on the theme of environmental impact and productivity, is highly novel.

Based on the above, the purpose of this study is to improve productivity and reduce environmental load in a factory using IoT, simulation, and LCA, and to identify the optimal layout.

The research method is to first understand the layout of the target factory and data on energy consumption, workers, and production using data collection and sensors. In particular, for data on electricity, ammeters will be installed and accurate data at regular intervals will be obtained through Raspberry Pi. By modeling these production process information and inputting it into simulation software, the "environmental impact" and "productivity" of each production process can be visualized. By identifying production processes that have a large environmental load and low productivity from such visualized information, and repeating verification and improvement on the simulation, the maturity of factory design can be improved, and both productivity improvement and environmental load reduction can be achieved. Therefore, the optimal layout is identified and a proposal for improvement of the factory layout is proposed.

5.03.V-02 Exploring the Use of ProScale as a Complementary Tool in SLCA

Ida Aguilar Johansson[1]*, Malin Björkner*[2]*, Nilay Elginoz Kanat*[1]*, Klara Midander*[1] *and* **Tomas Rydberg**[1]*, (1)Swedish Environmental Research Institute, Sweden, (2)Chalmers University of Technology, Sweden*

The research presented aimed to further assess the operationalization of the subcategory *Health and Safety* within Social Life Cycle Assessment. ProScale is a tool in development by IVL Swedish Environmental Research Institute. The tool aims to assess the toxicological potentials of product systems. Since it follows a life cycle-oriented approach, it was tried out in our Social Life Cycle assessment in an aim to explore the usefulness of ProScale to operationalize the health and safety subcategory.

Occupational health should aim at: the promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations the prevention amongst workers of departures from health caused by their working conditions.

The results of ProScale shows that the main risk from toxiocological exposure is at the spinning stage of fabric production. The main contributor is Cotton dust from the spinning process, here followed by starch and polyvinylalcohol exposure in the sizing process.

The application on ProScale as a complementary tool to the Health and Safety subcategory gave additional information on the substances included in the same lifecycle, as well as their risk of direct toxological effect on workers in the production. The compatibility with the methodology of SLCA suggested by the UNEP Guidelines, only additional data collection of substances their massflow and H phrases was needed. ProScale is useful in the sense that the substances can be presented as a hotspot analysis comparing substances against each other. The ProScale factor has less function in indicating the general risk of the substance. A factor indicating a reference level for each substance would be a possible development for ProScale in this context. The potential of applying ProScale in similar SLCA studies is judged to be feasible and give deeper information of the product systems social risks regarding health and safety.

5.03.V-03 Carbon Footprint of Tourism in OECD Countries Using Satellite Accounts

Akihiko Tsutsumi *and Norihiro Itsubo, Tokyo City University, Japan*

The 26th Conference of the Parties to the United Nations Framework Convention on Climate Change (COP26) was held in Glasgow, Scotland, from October 31 to November 12, 2021, and the Glasgow Declaration was adopted to address climate change in the tourism industry. The Declaration calls for halving CO2 emissions from the tourism industry by 2030, and virtually eliminating CO2 emissions by 2050. The Declaration also includes five initiatives, one of which is to "measure and disclose all CO2 emissions related to travel and tourism," and to promote LCA.

A 2017 study of Japan's tourism industry evaluated greenhouse gas (GHG) emissions and reported annual emissions of 1.36 billion t-CO2eq, with emission factors for inbound, domestic, and international travel, showing that each travel mode has its own characteristics. Although it is reported that GHG emissions from tourism account for approximately 8% of the world's total emissions, there are few examples of GHG emissions from tourism in the world.

Based on the above, the objectives of this study are (1) to compare GHG emissions in different countries, (2) to understand the characteristics of the global tourism industry, and to discuss the relationship between tourism and the environment.

This study targets inbound and domestic travel in about 50 OECD-related countries and uses the OECD Tourism Trends and Policies 2020 (OECD Data), a tourism satellite account data (hereinafter referred to as TSA) that aggregates consumption in the tourism industry, and the OECD Data, which is an economic and environmental transaction table for 190 countries around the

world. GHG emissions are calculated by combining the OECD Tourism Satellite Accounts data (hereinafter referred to as "TSA"), which aggregates tourism consumption, and the Multiregional Input-Output (MRIO) table, which is an economic and environmental transaction table for 190 countries.
GHG emissions from Japan's tourism industry in 2017 were found to be equivalent to about 5% of annual emissions. The results also show that domestic emissions are about five times higher than inbound emissions. The majority of the emissions from Japan's tourism industry are attributable to domestic travelers.
In the future, we would like to create a correlation chart based on the GDP of each country and the calculation results and discuss the relationship between the economy and the environment in the tourism industry.

5.03.V-04 Complementarities of Responsible Research and Innovation and Life Cycle Sustainability Assessment
Melanie Douziech *and Melf-Hinrich Ehlers, Agroscope, Switzerland*
Responsible Research and Innovation (RRI) becomes increasingly relevant, for example in European research and innovation programs. RRI aims to guide research and innovation towards socially desirable outcomes by means of collective stewardship. Four keys facilitate this collective stewardship: anticipation, reflexivity, inclusion and responsiveness. Anticipation explores futures of relevance to identify risks and opportunities. Reflexivity implies to put assumptions to a test. Inclusion means participation of stakeholders and the wider public in discussions and actions on research and innovation. Finally, responsiveness is the ability to change direction and shape of research and innovation based on new findings. Each key can be implemented using opening-up and closing-down methods to either gather diverse perspectives on a subject or to make decisions on how to progress with a project. We explore how RRI and sustainability assessment can complement each other in attempts to achieve desirable social and environmental impacts of research and innovation projects. First, we summarized key-specific methods that support RRI. Second, we reviewed relevant sustainability assessment methods. Third, we identified key advantages and drawbacks of each approach. Finally, we explored how life cycle sustainability assessment (LCSA) – the combination of life cycle assessment (LCA), social LCA and life cycle costing – can complement RRI in terms of aims, methods and results. Besides opening-up or closing-down discussions on RRI, the methods to implement RRI keys can be useful in various steps of LCSA. They can help identifying which indicators are most relevant for project stakeholders. Knowledge of these methods can be particularly useful in generating data needed for social LCA. Quantitative results of LCSA can trigger reflexivity or be a valuable input for anticipation activities. Stakeholder participation in selecting relevant indicators for a LCSA supports the inclusion key, while outcomes of participatory deliberations on RRI consultations could trigger demand for LCSA. Building on these preliminary findings, future work will investigate possibilities to combine RRI and LCSA, or sustainability assessment more generally.

5.03.V-05 Life Cycle Cost-Benefit Analysis of Reinforced Concrete River Wall
***Mony Rith So*[1]** *and Norihiro Itsubo[2], (1)Environmental Management, Tokyo City University, Japan, (2)Tokyo City University, Japan*
Global warming and continued development in flood-prone areas progressively increase river flood risk in the future. At the same time, projected social and economic growth further increases exposure to flood events. Adequate flood risk reduction strategies can substantially reduce the projected increase in flood risk with global warming. The construction of river dike systems or river retaining walls is one of the adaptation strategies. Moreover, International Standard Organizations (ISO 14007) determines and communicates, the environmental costs and benefits associated with their environmental aspects, impacts, and dependencies on natural resources and ecosystem services. The standard is designed to be used in a range of applications that inform environmental management. It can be noticed that it is needed to develop a method of CBA and share a case study to facilitate understanding of the procedure because actual case studies are limited so far.
This research aims to assess the sustainability of reinforced concrete (RC) river walls in terms of environmental impacts, economic issues, and cost-benefit analysis.
To achieve the aim of this study, life cycle assessments (LCA), life cycle costs (LCC), and a GIS-based Hydrological Modeling will be implemented. This study will assess environmental impact using SimaPro software and involve a full life cycle material assessment from Cradle-to-Grave, covering raw material extraction up to end-of-life stages. The functional unit will be described as a linear running meter of the wall. Using openLCA software, LCC will be estimated as the expenditures related to material and activities along wall life spans based on their present value (PV) given as Internal cost in Japanese Yen (JPY). Furthermore, the environmental impact obtained from the LCA calculation will also be converted into the external cost of the wall. Both costs would sum up to the total cost of the wall. The benefit will be considered as Damages Avoided by evaluating physical damages under scenarios with and without the project, assisted by the GIS-based Hydrological Modeling as a flood map model. Balancing the cost and benefit of the RC floodwall will be performed conclusively.
This study will fill the research gap by concurrently conducting a sustainability assessment of the RC river wall considering environmental impact, cost, and benefit.

5.04.A LCA as an Effective Tool in Decision-making

5.04.A.T-01 A Comparative AB-LCA Evaluation of a Policy Instrument to Source Agricultural Biomass For Biofuels
***Raül López i Losada*[1]** *and Ralph K. Rosenbaum[2], (1)Lund University, Centre for Environmental and Climate Science, Sweden, (2)Institute of Agrochemistry and Food Technology, Spain*
Introducing grass leys in crop rotations in arable land with depleted Soil Organic Carbon (SOC) levels offers the potential to increase SOC stocks and crop yields as a step towards sustainable farming systems while also providing biomass for biofuels. In consequence, Sweden introduced a payment for grass leys, which is now under scrutiny: SOC gains in the region have been

uncertain in practice, as the payment largely compensates farmers for leys that would have been there regardless, while it has failed to penetrate intensive arable land where SOC is depleted. Had the incentive achieved its goal, its overall environmental performance would still be an open question, as land use pressure from displaced foodcrops risks translating into environmental impacts elsewhere.
This example illustrates the need to study the system wide impacts of agricultural policy prospectively, in a framework that can capture the dynamics of environmental changes and structural production shifts to which they give rise. To this end, we propose an integrated economic-environmental approach coupling modularly an Agent-Based Model of farmer behavior, AgriPoliS, and Life Cycle Assessment (LCA). Recently, AgriPoliS has incorporated SOC dynamics validated with long-term field experiments and subsequent effects on yields and optimal N fertilisation levels. This allows for our approach to consider both the local multifunctionality of grasses in crop rotations and crop-displacement effects elsewhere in the environmental evaluation of policy instruments.
Our results show that the current payment of 500 SEK is too low to achieve any changes in intensively-managed farms, and it only compensates livestock enterprises for existing grass leys in fields that do not show depleted SOC levels. A 5000 SEK/ha payment specific to highly productive land capped at 25% of the area would achieve homogenous adoption of grass leys in intensive crop rotations, while compensating farmers for their loss of income from food crops and preventing simplification of the landscape mosaic. The policy intervention would yield a positive environmental outcome overall, but only if grasses are actively used for bioenergy purposes.
Our work contributes to expanding the environmental assessment of land-based biofuels at a time when their overall sustainability is highly debated. Doing so, we aim at improving scientific input for policymaking in the task of shaping sound strategies to source agricultural biomass for biofuels.

5.04.A.T-02 Development of an Easy-to-implement Pesticide-related Food Product Label: Potential and Limitations
Cédric Furrer*, Thomas Nemecek, Laura Iten and Gerard Gaillard, Agroscope, Switzerland*
There is a rising interest of customers to be informed about what they eat and how it is produced. Retailers and supermarkets have realized such needs and start to introduce labelling systems to facilitate customer information. According to customer surveys, a label, which assesses the ecotoxicological consequences of pesticide use from food production, is of great interest and has not yet been introduced. We therefore aimed to develop an easy-to-implement method, which outlines possible impacts of pesticide use from agricultural production of plant-based food products.
The ecotoxicity potential of food products was estimated using the pesticide consensus approach as defined by the OLCApest project. Characterization factors from USEtox, OLCApest and EF were adapted to consider the emissions to the different compartments (air, agricultural soil, natural soil, surface water) and linked to the active ingredients present in the lists of legally approved plant protection products (LPPP) of different countries. Ecotoxicity potentials were calculated using different types of information from LPPP. Several options were tested to aggregate ecotoxicity potentials in order to avoid overestimation. Aggregated ecotoxicity potentials were transferred into a scoring system classified by five groups with fixed percentiles and a plausibility check was performed.
The developed "Method M-Check PPP" evaluated exclusively the freshwater ecotoxicity potential for aquatic organisms and provided plausible results for the investigated food products within the range of production- and label systems. Although a clear pattern was not observed, the different means of aggregation (i.e. median or arithmetic mean) seemed to affect scores less than different data availability. Aspects such as e.g. the use of robust crop varieties, specific breeding programs, yields, site parameters (e.g. soil properties, rainfall, etc.) could not be included due to missing data or limitations in the method.
An under- or overestimation of the ecotoxicity potential compared to reality is possible because currently only theoretical data from LPPP's is used. Aspects such as the availability of information from LPPP's of different countries, the integration of new LPPP data into the ecotoxicity calculation, and the rating of compound foods are some of the points that have not been conclusively clarified and need to be further elaborated in the future.

5.04.A.T-03 From a Farm Specific Diagnosis Tool to Farm Specific Improvement Paths and a Prioritisation of Subsidies
***Veerle Van linden**[1], Anne-Sophie Sacré[2] and Reindert Heuts[1], (1)Flanders Research Institute for Agriculture, Fisheries and Food, Merelbeke, Belgium, (2)ILVO, Belgium*
Climate change is a major global challenge for agriculture today. Although it is the prime sector to be affected by climate change, it is also under rising pressure of both, policy makers and consumers, who demand a sharp decrease of the climate impact of our food, even so in Flanders. The need for more climate-friendly and climate-robust farm management is strong, especially for dairy farmers who are bound by a Covenant commiting to reduce greenhouse gas (GHG) emissions and more specifically the methane emissions with 27% (compared to 2018) by 2030. Given these challenges, the sector insisted on a tool to support dairy farmers in reducing their impact on climate. But insight is not enough to result in action. Farmers run a business and they need to assess the impact of a business change -whether an investment or managerial- in terms of technical feasibility and economic viability prior to implementation. Additional support beyond diagnosis is essential. For policy makers, it is key to know what significant mitigation strategies are not cost efficient in order to better target their subsidies. An evidence based decision tool will help both parties and enable GHG reduction. To answer to these challenges, an LCA-based climate scan for dairy farms (Klimrek) was developed. The scan includes scenario analysis with cost-benefit information on proposed mitigation measures, and has proven to be an effective instrument to offer dairy farmers insight regarding the environmental impact of milk production at farm level, and support them in the selection and implementation of cost-effective climate measures. Important success factors of the approach are (1) the co-creation process -from initial scope and definition drafting a system analysis - up to interpretation of the results, (2)

a web based LCI with validation and automatic detection of possible mitigation measures, (3) cost-benefit information and additional farm specific indicators listed alongside the results, and (4) guidance from a consultant from start to finish.

5.04.A.T-04 LCA Tool to Explore Emission Mitigation Options of Pig and Cattle Production at Farm Gate
***Annika Erjavec**, Jannick Schmidt and Iris Weidema, 2.-0 LCA consultants, Denmark*
Livestock production is a major driver of climate change, representing approximately 14.5% of all anthropogenic greenhouse gas (GHG) emissions with the demand for meat products predicted to rise in the future. Consequential life cycle assessment (LCA) is used in this study to develop a tool that enables the user to explore the environmental impacts of various production methods for pigs and cattle. This is a useful decision-making tool for farmers to improve production, for companies to build industry standards or governments to create policies in this arena.
Consequential LCA methodology is used in this study to calculate the environmental impacts from demanding an additional kilogram of live weight pig or cattle at farm gate. By-products such as animals to rendering and manure are modelled using substitution. The background database used is the input-output database EXIOBASE v.3.3.16b2 and the environmental impacts are calculated using Stepwise 2006 v. 1.07. The tool is Excel-based and the user can insert any combination of input data and the results will be presented immediately. The tool calculates a) country-specific national baseline emissions, b) farm-specific emissions, or c) a combination, where if the farmer does not or cannot provide every single data point, the model will populate the remaining data with national average data.
The tool contains several modules, including: a crop module that calculates field emissions at farm level related to fertiliser and crop residue inputs, with a basis in emission models from IPCC 2019; and an animal module that models emissions from housing and storage, again taking a basis in IPCC 2019 and using additional emission models where supplementation is necessary.
This tool is unique as it enables the user to alter the input data to explore different scenarios. By providing quick, visual and easily digestible results, people outside the scientific community can understand the effects of changing farming practices. On a governmental or EU level, policy-makers can explore the effects of different practices, and by gaining the knowledge of these effects, solutions such as financial incentives can be implemented. This demonstrates that consequential LCA plays a key role in creating science-based models that can quantify the effects of various farming practices and provide decision-making support on multiple levels, especially in modern times where it is vital to decrease our environmental emissions.

5.04.A.T-05 Life Cycle Analysis to Determine the Trade-offs Between Food Waste Reduction and the Implementation of Monitoring Technologies
***Tamiris Pacheco da Costa**[1], Xavier Cama-Moncunill[1], Shane Ward[1] and Fionnuala Murphy[2], (1)School of Biosystems and Food Engineering, University College Dublin, Ireland, (2)University College Dublin, Ireland*
The importance of reducing food waste has been recognised worldwide not only because food waste causes economic severe impacts but also due to environmental and social consequences Significant carbon emissions result from the production of food that is wasted, and the wasted food will emit more GHG in landfill, causing significant environmental impacts. Recent research supports the importance of using smart technology such as the Internet of Things (IoT) to help reduce food waste by monitoring food quality, managing food close to its shelf life, and improving the management of inventory and store layout. However, although integrating IoT technologies to monitor food quality conditions can have many advantages, the environmental implications of using these technologies have been scarcely debated. Therefore, the goal of this assessment is to understand the trade-offs between optimising the refrigeration monitoring of an abattoir in Ireland using IoT technologies to reduce food waste and its potential environmental impacts through the Life Cycle Assessment (LCA) methodology. The meat manufacturing company is located in Ireland and produces meat from three different animals' livestock, cattle, sheep and swine. The activities related to the meat manufacturing company serves as the baseline and the second scenario includes the IoT technologies used to monitor the food quality conditions in the dry ageing chambers during the cold storage process. The characterisation factors and the impact categories used in this study are those of the ReCiPe method. According to the results, the strategy to integrate IoT technologies to monitor temperature/humidity conditions did not adversely affect the organisation in a significant way. In addition, if the reduction in meat waste reaches 1%, then, the avoided environmental impacts resulting from this strategy could avoid a significant amount of carbon dioxide emissions per year, i.e. 35071 kg of CO_2-eq. Therefore, this methodology proved to be suitable for determining environmental impacts and savings of food companies and can equip decision-makers to understand the environmental performance of their companies through a comprehensive and science-based methodology.

5.04.B LCA as an Effective Tool in Decision-making

5.04.B.T-01 Relevance for Society and Decision-support of Attributional and Consequential Life Cycle Assessment
***Thomas Schaubroeck**, Luxembourg Institute of Science and Technology, Luxembourg*
A main goal for any sustainability assessment method is to be relevant for society and support decision-making. We aim to evaluate this specifically for two methods that assess product system sustainability and possibly support the choice of product selection in different ways: attributional and consequential life cycle approaches. We build further on evaluations from literature, but also deviate from them and expand the analysis. One of the differing aspects in our work, is that attributional and consequential life cycle assessment (LCA) are consistently considered as exactly defined by the UNEP-SETAC. Concisely, attributional LCA (ALCA) assesses the global impact share of a product life cycle and consequential LCA (CLCA) covers the consequential impact of a decision. In this conducted analysis, we first select criteria for evaluation and then, second, specify to which extent they are fulfilled by both approaches. It is quintessential to make a distinction between ideological and practical criteria. From an ideological perspective, CLCA aims to address realistic effects of the studied decision, implying complete

alignment with a first criterion on realistic modelling, desired in a sustainability assessment. Similarly, it covers a pure scientific thinking and follows fully consequential ethics on a conceptual level. Attributional LCA, does not completely align with these matters. The main reason is the rules that are behind ALCA. For example, a complete product life cycle needs to be covered, considering the past before product provision. However, following rules aligns with so called rule-based ethics, which are prevalent in society. The ALCA rules can be regarded in the same way, but society-wide acceptance is lacking. Given this potential complementarity, different ways of decision support are ideally possible. In practice, ALCA may be more readily applied because of its bigger uptake in standards and broader set of databases, but at least one database version exists purely for CLCA. Yet, it seems a misconception that the uncertainty and complexity of CLCA modelling would be way higher, since also in ALCA complex processess need to be considered as also the world harbors these and changes over time (e.g. the market mix does not stay constant). Overall, it is quite clear that both ALCA and CLCA can be of relevance. Yet, ALCA mainly needs to address acceptance of its rules from an ethical viewpoint, and CLCA needs to be more implemented in practice.

5.04.B.T-02 Is data sharing in LCA FAIR?

Agneta Ghose*, Department of Planning, Aalborg University, Denmark*

In the light of rising awareness, and growing need of better data management across disciplines, it is pertinent to investigate how the FAIR principles are utilized in the LCA domain. The purpose of this research is to investigate the status quo of data sharing by LCA practitioners. This study will look into data shared in relation to research outputs (e.g. peer reviewed articles). The life cycle inventory (LCI) is the most common data that is re-used, hence this study investigates how the LCI is shared in peer reviewed articles. A review of the findability, accessibility, interoperability and re-usability of the LCI data of 25 peer reviewed articles was performed. This study highlights although there is growing awareness on the importance of data sharing , the lack of a clear guidelines within the LCA domain as well as limited infrastructure is a major barrier in implementing FAIR principles. Research data sharing is beyond the sole responsibility of individual researchers. The overall research and funding infrastructure must consider the diversity of practices, differences in fields, facilitate the sharing of a broad range of research outputs. Current gaps in academic data sharing can be seen as opportunities to build a common framework.

5.04.B.T-03 Life Cycle Assessment, Quo Vadis? Is There One Right Way of Performing LCA? Preliminary Results from a Survey

Miguel Brandão*, Royal Institute of Technology, Sweden*

Life cycle assessment (LCA) has been recognised as an important environmental systems analysis tool due to its potential for providing holistic results about the environmental impacts of alternative production and consumption systems that can lead to decisions towards greater sustainability in both private and public-policy contexts. However, LCA has been under increased scrutiny due to the wide range of published results on similar systems, such as biofuels, which can be contrasting. This variability is, in part, due to the proliferation of guidelines that have emerged over the last 20 years, and it has been suggested to undermine the robustness of LCA as a decision-support tool. Following some interesting discussions on this topic in different fora, we took the pulse of the LCA community on this topic via a survey. We received around 100 responses from respondents who varied in their background and experience in LCA (most were academics and/or had more than 10 years' experience), as well as in their opinions on whether they saw the inconsistency of published results problematic or not for decision making. Preliminary results suggest that respondents are of the opinion that i) there is no one right way of performing LCA; ii) the ISO 14040-44 standards were insufficient for guiding LCA practice; iii) the large flexibility with which practitioners perform LCA undermines its validity as a robust tool for decision making, and that iv) further efforts in harmonizing LCA practice would be beneficial, despite the mixed opinions shown by respondents, which indicates the divisive nature of this topic in the LCA community. Further harmonization would help to ensure consistency in the application of the tool by practitioners which, in turn, would ensure results would be less variable and arguably more meaningful. It is likely that the associated methodological issues remain unresolved in the near future.

5.04.B.T-04 Using LCA as a Tool for Investigating and Enhancing the Net Negative Emission Potential of Climate Positive Technologies

Shraddha Pankaj Mehta[1]*, Cristina-Maria Iordan*[1]*, Simon Roussanaly*[2] *and Rahul Anantharaman*[2]*, (1)Climate and Environment, SINTEF, Norway, (2)SINTEF, Norway*

Climate-positive technologies (or Negative emission technologies) are technologies that remove carbon dioxide (CO_2) or methane (CH_4) from the atmosphere thus generating so-called negative emissions. These have been highlighted as a key component of nearly all pathways to limit warming to 1.5°C above pre-industrial levels. However, a challenge in this area is the evaluations of both techno-economic and environmental performances which are key to understand opportunity and unravel challenges. Amongst these aspects, there is a need to evaluate their environmental performances to determine the net negative emission potential considering impacts from their whole specific value chains using a consistent system boundary. The need for a consistent system boundary to include all upstream and downstream emissions is essential to evaluate the actual negative emission potential and to avoid underestimation.

The present work aims at developing a framework for a fair and transparent benchmarking of climate-positive concepts to identify the most promising technologies based on a standard set of guidelines. Many of these climate-positive technologies are currently in a conceptual phase and we propose LCA as a tool for optimizing the value chain in order to minimize negative environmental impacts, as well as avoid problem shifting.

By developing conceptual LCA models of selected climate-positive pathways, the environmental hotspots of these emerging technologies will be identified. This in turn will facilitate decision making regarding choice of processes, source of energy,

location, scale, materials and end of life treatment. The wider impacts of some these pathways on other systems like food value chains and energy production will also be investigated to give a complete picture of the indirect impacts. This work will further look into which type of LCAs (attributional, consequential, comparative) are suitable for the decision-making process based on the user group i.e. technology developers, project owners, policy makers, regulatory bodies etc.
Benchmarking the CCS technologies while understanding the associated positive and negative consequences will provide a solid knowledge base for developing future national GHG reduction strategies. Furthermore, a detailed environmental LCA will help foresee if the technologies have any negative consequences on other impact categories than global warming potential and help recognize the problem of burden shifting early on.

5.04.P-Tu381 Modelling of Electricity in Product Environmental Footprints
Tomas Ekvall[1,2]*, Katarina Lorentzon*[3]*, Elin Einarson Lindvall*[3]*, Eva-Lotta Lindholm*[4]*, Björn Spak*[5] *and Sara Palander*[6]*,*
(1)TERRA, V Frölunda, Sweden, (2)Technology Management and Economics, Chalmers University of Technology, Sweden, (3)Energy and Environmental Systems Analysis, RISE Research Institute of Sweden, Sweden, (4)Swedish Energy Agency, Sweden, (5)Swedish Environmental Protection Agency, Sweden, (6)Swedish Life Cycle Center / Chalmers University of Technology, Gothenburg, Sweden
The EU framework for Product Environmental Footprint (PEF) is now being referred to in EU legislation. Requirements on the maximum carbon footprint are included both in the draft Ecodesign Regulation for photovoltaic (PV) modules and inverters, and in the Commission proposal for a new Battery Regulation. The climate impact of these products will be calculated using the PEF methodology. Since this will be the first time a piece of legislation using the PEF methodology comes into to force, it may become a precedent for future use of PEF in a policy context. However, the rules for modelling the electricity supply in the draft PV Regulation do not reflect the calculation rules in the most recent PEF guidelines. These rules, in turn, have been criticized for lack of clarity and for allowing for greenwashing. We investigate the need for revised texts regarding the modelling of electricity production in the EU Ecodesign Regulation for photovoltaics and in the general PEF rules. We also produce suggestions for such revisions. These revisions will also have an impact on the battery regulation since this also refers to the PEF method. Through interviews with various actors, we gather information on what is unclear and controversial in these texts and suggestions on how to improve them. In a literature study, we compare the draft PV Regulation to various versions of the general PEF guidelines and to the Product Category Rules (PEFCR) for PV. This serves the purpose to better understand the origin of the text in the draft PV Regulation and to investigate how this text should be revised to reflect the current PEF methodology. To identify alternative rules and explanations of these rules, we compile information on how the electricity supply is modelled in various other frameworks: Environmental Product Declarations, the EU Renewable Energy Directive, etc. Early results indicate that deviations in the draft PV Regulation from the general PEF rules are in part deliberate abbreviations of the text. However, an up-to-date Regulation should allow for the use of data representing the residual mix in the EU or the region where the electricity is used. It should perhaps also not require the use of national data from the Sphera database. The general PEF rules should be supplemented with additional guidance for LCA practitioners on how to interpret and apply concepts such as contractual instruments, tracking, and tracking systems.

5.04.P-Tu382 Determining Missing Life Cycle Inventory Data Using the Research – Reaction – Energy – Modeling (RREM) Approach: An Example of Surfactants in Cosmetics
Daria Blizniukova*, Elena Huber, Vanessa Bach and Matthias Finkbeiner, Chair of Sustainable Engineering, Technical University Berlin, Germany*
In life cycle assessment (LCA) the granularity level of the underlying inventory data can greatly affect the results. Specifically, this refers to the modeling of products made from complex chemical compounds, such as personal care products and cosmetics. While existing LCA databases contain life cycle inventory (LCI) data for most common organic chemicals, more complex substances are often represented only at the level of chemical classes or in accordance with their function (e.g., non-ionic surfactants).
Existing approaches for modeling missing inventory data are either based on molecular structure and thus do not comply with a life cycle perspective, or are only applicable to compounds with relatively small shares of a product, given their high uncertainty level. The previously published Research – Reaction – Energy – Modeling (RREM) approach provides a novel framework for establishing process-based LCI for chemicals in the absence of primary data.
In this work, an updated version of RREM will be tested on an example of common surfactants in cosmetics derived from fatty acids divided into sulfonates, glucosides, and glycols. Thereby, the global warming potential (GWP) of the modeled substances will be compared with that of corresponding generic datasets available in LCI databases as well as RREM-based “special proxies” (s-proxies). Additionally, a sensitivity analysis will be carried out to evaluate the impact of assumptions.
Preliminary results indicate an underestimation of GWP results by 2 to 4 times when applying generic datasets to model fatty acid sulfonates. In contrast, the results for glucosides modeled by RREM are nearly twice as low compared to those of generic datasets. For glucoside-based surfactants, no clear trend has been observed. In light of the previously published results, it is likely that RREM-based proxies overestimate the impact assessment results.
RREM approach may be a promising way of modeling the environmental impacts of complex chemicals from a life cycle perspective with relatively little effort. RREM as such is not directly linked to the FAIR-principles, but could be adapted to them. The next step should involve obtaining statistically significant results for evaluation of the robustness of the approach. Further, a more sophisticated set of assumptions for building s-proxies should be provided, such as those pertaining to reaction types.

5.04.C LCA as an Effective Tool in Decision-making

5.04.C.T-01 Review of Life Cycle Assessments for Maritime Fuels
Megan Roux[1], *Concetta Lodato*[2] *and Thomas Fruergaard Astrup*[1], *(1)Environmental and Resource Engineering, Technical University of Denmark, Denmark, (2)Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark*
As part of an increasing awareness of the detrimental environmental effects of the use of fossil fuels for maritime transport, the sector's emissions have been met by targets on regulatory and company levels, with the International Maritime Organisation (IMO) setting reduction targets of 50% of these emissions by 2050 when compared to 2008.
Alternative non-fossil based fuels have been identified as a key lever through which to reduce the maritime transportation sector's carbon footprint. These fuels include biofuels and electrofuels, like hydrogen and methanol. The environmental performance of these fuels – in areas other than just climate change – should be a deciding factor in their adoption in the sector's green transition. Life cycle assessment (LCA) is an effective methodology tool for assessing this environmental performance and have been used in decision-making in various sectors. Several LCAs of maritime fuels have been conducted. However, assumptions made when conducting these LCAs can have substantial effects on the results, and therefore need to be well documented and transparent. With the aim of providing insight into the state of the existing research on the environmental impacts of maritime fuels, a systematic review of existing maritime fuel LCAs published in peer-reviewed journals was conducted.
The review conducted revealed key gaps to be addressed in future LCAs of maritime fuels, including a lack of transparency when reporting key elements of the LCAs, such as an underreporting of the functional unit. Most of the LCAs assessed in the review only considered climate change, resulting in little information about other potential environmental impacts. For example, uncertainty analyses were not conducted in most of the reviewed LCAs, which is important to ensure the robustness of an LCA study.
Following the gaps identified in the review, an LCA modelling framework will be created to ensure inclusion of all important factors and limit the potential of burden shifting of environmental impacts. The framework aims to be comprehensive and systematic, and provide a guideline for decision-making with regard to fuel for maritime transport.

5.04.C.T-02 LCA-based EU Policies For Low-carbon Hydrogen Deployment: Risks And Opportunities
Alessandro Arrigoni[1], *Marco Buffi*[2], *Oliver Hurtig*[2], *Antonio Valente*[3], *Vincenzo Santucci*[2] *and Umberto Eynard*[2], *(1)European Commission Joint Research Centre, Netherlands, (2)European Commission Joint Research Centre, (3)European Commission Joint Research Centre, Italy*
Future EU policies aimed at reducing greenhouse gas emissions will likely rely on life cycle assessments to determine the carbon footprint of products and activities. This can lead to significant benefits in terms of carbon accounting, which is crucial for reaching planned climate targets, avoiding carbon leakage, and greenwashing. On the other hand, the different approaches currently available for LCA-specific methodological choices (e.g., how to handle multi-functional activities in the ISO standards) can have unwanted consequences; specifically a broad range of carbon intensity for hydrogen and its co-products. In this paper, we showed how hydrogen co-produced with methanol could have a carbon intensity varying from 1 to 11 kg CO_2e/kg H_2. This could create distortion in the market and hinder optimal solutions in terms of climate policies. With this contribution we aim to raise awareness on the necessity of strict and harmonized life-cycle based guidelines for each activity covered by the EU climate policies. At the same time, we want to engage the LCA community in supporting the European Commission in the choice of a LCA approach leading to a minimization of the climate impacts.

5.04.C.T-03 Ecodesign Approach Based on Prospective Life-cycle Assessment, To Support R&D Decision Making For New Generations of Batteries
Betsabé Elizabeth Rodríguez Buitrón[1], *Emmanuelle Cor*[2], *Elise Monnier*[2], *Fabien Perdu*[1], *Yvan Reynier*[1] *and Sébastien Martinet*[1], *(1)CEA-Liten, France, (2)CEA- Commissariat à l'Energie Atomique et aux energies Alternatives, France*
The highest levels of environmental performance are achieved when environmental criterion is introduced in the early stages of the design and development process of new technologies. Thus, the availability of environmental information throughout their lifecycle is fundamental for ecodesign and the LCA methodology can provide this information. However, during design decision making in a R&D context, LCA is mainly applied at a low level of technology maturity and for researchers this remains a difficult requirement to consider. This work aims at responding to the challenge of environmental performance criteria integration into technological developments of future generations of batteries and will be applied to three case studies: the advanced Li-ion, Lithium-Sulphur and all-solid-state battery technologies. The objective is to propose a methodology to support researchers through ecodesign decision-making by helping them to understand the environmental issues and to identify the levers for improving the environmental performance of new generations of batteries.
The Design Research Methodology (DRM) framework proposed by Blessing and Chakrabarti (2009) was adopted. The DRM application leads on, among others, the definition of resources and needs in terms of environmental assessment as well as action levers and limits in ecodesign for this R&D context. This results in the identification of three moments of support where environmental evaluation is needed: project set-up, daily R&D tasks and final evaluation of the technology. To meet this needs, the proposal is based on a ecodesign toolbox built on adapted R&D prospective LCA principles which consists of four operational tools for the research teams: A Li-ion batteries environmental impacts database for the 3 new battery technologies and commercial reference technologies. A simplified and parameterised assessment tool where modelling can be performed depending on the researcher context and with a specific assessment of material criticality. An ecodesign suggestion bank which presents a collection of ecodesign tools. And a series of short videos for researcher awareness and training about the issues and challenges arising from the battery sector.

The set of tools that support the new method are being developed and their usability will be validated during the last phase of the DRM. It is expected that this proposal will guide researchers in their decision making all along the design process.

5.04.P-Tu383 LCA-based decision support on the inclusion of mechanical vapor compression in early phases of process design

Hannes Schneider[1]*, Mandy Paschetag*[2] *and Stephan Scholl*[2]*, (1)Chem. u. Therm. Verfahrenstechnik, Technical University Braunschweig, Germany, (2)Technical University Braunschweig, Germany*

Worldwide, chemical industry has set a pathway to the conversion to a CO_2 neutral production. The electrification of processes to substitute fossil-based energy supply may contribute significantly to achieve this goal. This needs the development and implementation of new technologies and the transformation of traditional fossil heated processes. One of those technologies is the Mechanical Vapor Recompression (MVR), which can be used to upgrade waste heat for heat integration in thermal separation processes and thus reduce the externally heat demand substantially.

The complexity of existing installations and the missing experience with those new technologies regarding process design and implementation in thermal separation processes hamper a fast and comprehensive integration of these new technology. Other obstacles, like the lack of good working examples or high investment, hinder a wide application of this technology yet. To assess the sustainability of an MVR implementation into the development of a new or the revamp of an existing process, expertise from different fields needs to be combined.

This contribution presents the development of a comprehensive method, which shall support process engineers to decide at an early design stage, whether and how the implementation of MVR in existing or new rectification columns proves beneficial from a technological, environmental and economic perspective. By combining the expertise of process engineers, compressor experts, and LCA practitioners different process concepts and equipment installations are compared in terms of costs and environmental impact. The approach comprises of an exergy analysis of the given separation problem, the design of optimal compressors and heat exchangers, economic and environmental assessment of different equipment options and a visualization of the results. In further work a tool with a graphical user interface is planed with several default values and assumption of state-of-the-art process parameters, intending a direct and low-threshold usage of the method.

The method offers a decision support for engineers and managers working on optimization and transformation of fossil-based processes to electrification by an early-stage quantitative assessment of the potential of MVR in distillation columns.

5.04.P-Tu384 LCA as a Guide and Decision Support in Technology Research and Development Projects – The Case of the ELSAH Project

David Wilde[1]*, Gertri Ferrer*[2] *and Marta Escamilla*[2]*, (1)Acondicionamiento Tarrasense, Spain, (2)Leitat Technological Center*

A multitude of European research projects aim at the collaborative development of novel and innovative technologies and products. LCA is being applied as one of the primary tools to demonstrate and better understand the potential environmental performance of outcomes, but also to guide the development process itself, from an evidence-based environmental perspective, as it progresses towards higher technological readiness levels. A flexible approach concerning the assessment methods and scope allows support that may range from initial material screening to full LCA implementation including all life cycle stages.

This presentation illustrates the ELSAH EU project as a case study, where LCA is being used to guide the development of a wearable sensor system (for monitoring of molecular biomarker concentrations) towards more environmentally friendly solutions. Cradle-to-gate assessments were applied to subsequent generations of individual components, and integrated or semi-integrated demonstrators, to identify impact hotspots and evolution. A full LCA will be performed of the final prototype towards the end of the ongoing project. However, as is often the case, small-scale and non-industrial production methods associated with research projects, and the lack of real data concerning product use and end-of-life stages, severely limit a more holistic and conclusive impact overview in a broader context and relative to potential competing solutions. Consequently, it is argued that more traditional LCA approaches may be useful to inform project-internal decision making towards more sustainable outcomes, but to facilitate effective broader perspective decision making there is need for more advanced methods, such as theoretical foreground process upscaling and background future scenario modelling, as promoted in prospective LCA approaches.

5.04.P-Tu394 The Agrifood Data Sharing Platform as Pivot for LCI and LCIA Results

Anne-Sophie Sacré[1]*,* ***Veerle Van linden***[2]*, Reindert Heuts*[2] *and Eva Maes*[2]*, (1)ILVO, Belgium, (2)Flanders Research Institute for Agriculture, Fisheries and Food, Belgium*

An LCA-based climate scan for dairy farms (Klimrek) has proven to be an effective instrument to offer Flemish farmers insight regarding the environmental impact of milk production at farm level, and support them in the selection and implementation of cost-effective climate measures. The large need for data associated with the LCA approach, however, makes completing the scan time-consuming, which hampers its roll out on a larger scale. Initial experiences with the scan, which is completed by consultants during a farm visit, show that manually entered data is subject to errors and interpretation. This can affect the correctness and fairness of the scan's results. Automatic input of existing data from other digital data sources, using the Flemish data sharing platform DjustConnect, offers a solution for these problems. DjustConnect is an API-based data sharing infrastructure, that allows exchange of data between data users and providers, only with consent of the farmer. With the climate scan as a catalyser, different data providers made their data available via APIs on DjustConnect. With consent of the farmer, their data can be used to complete part of the life cycle inventory (LCI). The farmer can also use the data sharing platform to share the scan's results and (in the future) export part of the collected LCI data to other digital tools. The LCI is designed to make maximum use of standardised terminology, in order to make data available for other applications.To take full advantage of the benefits of data sharing platforms, consistent use of data standards and farmer acceptance remain important challenges that need to be addressed. At the moment, few data sources use standardised terminology, hampering the easy exchange of data between tools. Besides this, many Flemish farmers are still hesitant to trust and use data sharing platforms. Information campaigns and success cases like the climate scan can boost this lack of confidence and raise awareness for the benefits of safe data sharing.

5.04.P LCA as an Effective Tool in Decision-making

5.04.P-Tu385 A Life Cycle Assessment of a Remanufactured Bicycle at An Mheithal Rothar, a Community Cooperative Bike Shop

Cathy Coote[1], Cherrelle Johnson[2] and ***Sinead Mitchell**[3]*, *(1)An Mheithal Rothar, Ireland, (2)Mechanical Engineering, National University of Ireland, Galway, Ireland, (3)Management, University of Galway, Ireland*

In Ireland, cycling is growing steadily in popularity and the Program for Government plans a €360 million spend on the development of active travel infrastructure, which will lead to increased demand for bicycles. However, recent supply chain disruptions are making it harder to import bikes, and to export waste. A remanufactured bike can save metals and mixed materials from entering the recycling or landfill waste streams.

Remanufacturing can prevent impacts related to the extraction, processing and transportation of virgin material. Remanufacturing is not simply repairing or refurbishing, but through a factory process, as good as new (or better), with a warranty, and you cannot tell the difference. The production stage of a bike has the highest negative impact. A remanufactured bicycle has the potential to generate better environmental benefits than recycling and greater economic output than the materials alone. The markets to export waste materials are closing and may become unavailable to Ireland.

A simplified comparative Life cycle assessment (LCA) was performed using the Environmental Footprint Methodology (EF 3.0) and EcoInvent database v3.9. This LCA was based on a remanufacturing process that restored the highest value parts of a recovered bike from municipal waste, namely the frame, fork and handlebars. The remaining parts were replaced with new ones (e.g. brakes, wires, bike chain) to guarantee the remanufactured, like new or better product output. The bicycle production process data set represents a bike of 17kg including common additions.

The LCA compared a newly manufactured bike to a remanufactured bike, which demonstrates approx. 50% reduction in emissions for the “as new” bike by An Mheithal Rothar, estimated total Equivalent CO2 emission savings of 201.04 Kg CO_2-eq. This result will support the decision to scale up production of remanufactured bikes, and guide future development of circular economy solutions and inform circular economy enterprises, policymakers and government of the benefits of remanufacturing to achieve decarbonisation, emissions reductions and increased circularity rates in Ireland.

5.04.P-Tu386 Applying Circular Economy Principles to the Problem of International Catering Waste – A Life Cycle Assessment Case Study of the Aviation Waste Sector

***Lois Pennington**[1]*, *Andrew Welfle[1], Ben Parkes[2] and Nigel Scrutton[3], (1)Tyndall Centre for Climate Change Research, University of Manchester, United Kingdom, (2)Department of Mechanical, Aerospace, Civil and Environmental Engineering, University of Manchester,United Kingdom, (3)University of Manchester, Manchester Institute of Biotechnology, United Kingdom*

The advent of commercialised flights has brought an increasing demand for international travel. Alongside the effect of increased fuel burn on the climate, the growth of air travel has brought an additional problem; the management of cabin waste. Many countries have strict legislation controlling the disposal of this waste, due to the possible presence of animal by-products such as meat or dairy derivatives. The risk of cross-contamination onboard means all cabin waste from international flights is classified as high-risk (CAT1) International Catering Waste (ICW). Previous studies estimate that up to 80% of cabin waste is either recyclable or compostable. As a result, in areas such as the EU and the UK, it is currently only permitted to either send this waste to landfill or incineration. The volume of waste generated and the resultant environmental impact of its disposal is currently not required to be reported. There is also no evidence of a risk or impact assessment being undertaken before the implementation of this legislation.

This research, developed in collaboration with Manchester Airport, aims to quantify the volume of cabin waste entering the UK and the impact of existing legislation on its disposal footprint. Initial estimates show that around 116,000 tonnes of waste are generated yearly on incoming flights to the UK; a similar volume as would be generated by a city such as Belfast. Life Cycle Assessment methodologies are applied to existing disposal methods to estimate the environmental impact of this cabin waste. These results are compared to speculative disposal pathways if the policy were to changed to allow the application of circular economy principles to this waste; prioritising reuse and recycling, and the generation of bioenergy through anaerobic digestion. In total, eight scenarios are modelled for comparison. The LCA is completed using SimaPro software and a combination of data from literature, the EcoInvent 3.7 database and pilot plant results.

The results emphasise the highly negative environmental impact of landfill & incineration as disposal methods. It quantifies the reduction in Greenhouse Gas emissions that could be achieved by the implementation of more risk-based measures and Circular Economy Principles. The use of LCA in this project aims to provide a data-based evidence source to inform policymakers, responding to recent calls by airlines and the International Air Transport Association for smarter regulation of cabin waste.

5.04.P-Tu387 A Novel ‘Hub and Spoke’ Framework for the Holistic Sustainability Assessment of Chemical Value Chains

***Alex James Kenneth Newman**[1]* *and Peter Styring[2], (1)University of Sheffield, United Kingdom, (2)Chemical and Biological Engineering, University of Sheffield, United Kingdom*

Sustainability assessment has emerged as a critical sub-field within ongoing industrial ecosystem development. This has led to the question; ‘How can explorative and holistic value chain-oriented sustainability assessments support strategic decision making?’. Guidelines targeting isolated life cycle analyses (LCAs) and techno-economic analyses (TEA)s currently dominate, neglecting

both their integration and the addition of social impact analysis (SIA). This shortcoming is manifested through inter-strand burden shifting, negating any improvements in the assessed strand. An ISO 14K aligned framework is needed for holistic, modular assessments of complex value chains.
The developed methodology builds upon GCI's "Techno-Economic Assessment & Life Cycle Assessment Guidelines for CO_2 Utilisation" and the McCord et al. "Triple Helix Framework". Assessments comprise of interchangeable modules; core processes, or 'hubs', and input/output flows, termed 'spokes'. In this, a 'plug and play' approach to industrial value chain modelling is developed. Thus, competing value chains are fairly and robustly compared with congruent system boundaries and assumptions. Inventory sheets are completed for each of the spokes considered, and models of the hub processes constructed. Multiple production or disposal routes may be assessed for each flow crossing the hub's boundary; these are grouped into 'spoke sets'. Life cycle impact analysis (LCIA) is completed for each spoke in isolation, generating indicator results relative to a local functional unit. These indicator results are then scaled to the relevant hub's reference flow. When aggregated, these modules generate assessments of the full value chains.
To facilitate tailored value chain recommendations, spokes' indicator scores are normalised within the set in which they are a constituent. Multi-criteria decision analysis (MCDA) in the form of tiered analytical hierarchy process (AHP) is employed to identify the best performing spokes in the context of decision maker value choices. Assessment results are generated in two parts; traditional objective results (impact indicators), calculated via characterisation models, and a subjective MCDA derived overall score, aggregating normalised indicator scores using AHP weightings. To conclude, the methodology will provide industry with a decision-making tool aimed at the strategic development of incoming sustainable value chains while maintaining granularity and robust objective results.

5.04.P-Tu388 Sustainable Comfort on Board – Using LCA Data for a New Cruise Ship Cabin Design

Mareike Tippe[1]*, Urte Brand*[2] *and Thomas Vogt*[2]*, (1)DLR-Institute of Networked Energy Systems, Germany, (2)Energy Systems Analysis, German Aerospace Center, Institute of Networked Energy Systems, Germany*
According to an agreement of the International Maritime Organization (IMO) the shipping industry is supposed to cut its CO_2 emissions by not less than 50% by 2050. With shipping contributing to a great degree to climate change, diverse measures have to be taken in order to decrease these emissions. Following a different approach than solely focusing on the propulsion system of ships, in the project EcoCab (funded by the German Federal Ministry for Economic Affairs and Climate Action) decentralized cabin-air and energy-supply concepts were developed together with the ship-building yard MEYER WERFT GmbH & Co. KG. With up to 3500 cabins per cruise ship, their usage and material composition significantly contribute to the environmental footprint of the ship.
Since the cabins serve a strong representative purpose for the shipping company while also being the passengers' private space on board, major changes of those utilities go along with a diverse set of challenges that relate to all dimensions of sustainability. Not only focusing on the decentralized energy supply and air conditioning, but also on the use of cradle-to-cradle materials for the cabin structure and interior, a multidimensional assessment framework was set up to compile data on environmental, economic, social, technical and legal matters. LCA data were combined with assessment results from the other dimensions in form of a multi-criteria decision analysis (MCDA).
Results showed, that design and construction options with the – according to the LCA – least environmental impact often interfere with either legal requirements (e.g. IMO guidelines and norms) or matters of acceptance when it comes to the installation of e.g. photovoltaic modules on the cabin balcony. Also, standardisation of construction and building processes impose a great challenge, that has to be considered when making decisions on the implementation of environmentally friendly options.
Our contribution to the conference will focus on the methodological approach of conducting an LCA and processing the according data within a multidimensional assessment framework and MCDA. Next to the presentation of LCA results of a complex, multi-component system that the ship cabin constitutes, insights and experiences from the result integration in the decision-making and communication process will be shared.

5.04.P-Tu389 NEPTUNUS-WEF1.0: A Friendly Tool in the Decision-making Process Related to the Seafood Production and Consumption

Sandra Ceballos-Santos*, Jara Laso, Laura Ulloa, Maria Margallo and Rubén Aldaco, Department of Chemical and Biomolecular Engineering, University of Cantabria, Spain*
In the current and future context of global competition for limited resources to meet the demand for freshwater, energy and food, the habits and actions of individuals, companies and governments must be rethought and adapted. Consequently, most industries, such as the European seafood sector, will require a modernisation of the current trajectory to gain resilience and cope with global competition, undervalued prices, fishing quotas, but also adapting fisheries to climate change. Against this backdrop, stakeholders in production sectors are increasingly turning to environmental certification standards, also called eco-labels, to stand out and to reach consumers, in the belief that these labels bring more added value to their products. In this regard, life cycle assessment (LCA) has become a flourishing methodology to measure the environmental impact of products and services. However, the long-standing strength of LCA studies can also be interpreted as a major limitation in communicating the environmental profile of a product beyond the scientific community.
To overcome this situation, the NEPTUNUS project has developed a methodology to perform environmental footprints studies of seafood products in a harmonized and consistent manner, under a life cycle perspective. The project aims to pursue a new transnational clustering concept approach to review, examine and harness key eco-labelling and key enabling eco-innovations. NEPTUNUS includes the introduction of the Water-Energy-Food (WEF) NEXUS variable in the decision-making process related to the circular economy of seafood, in addition to the typical economic, environmental, and social variables. The term NEXUS

implies that an action in one of the systems has also consequences in the others and it is therefore important to understand synergies and trade-offs to develop response options that ensure a more sustainable environment. Such methodology has been implemented in a friendly tool for producers and consumers. This simplified widget will provide the WEF NEXUS score of a wide variety of fisheries, aquaculture and processing activities through an ecolabel. The design contains an easy-to-read image composed of four footprint symbols, plus the nexus score as a percentage with a colour scale.
Using this tool both producers and consumers will be able to improve their decisions based on a science-based ecolabel that creates trust and security by enabling green and conscious choices when buying sea products.

5.04.P-Tu390 Life Cycle Assessment of Fisheries: The Need for Adopting a "Fishnet Approach"
Gregoire Gaillet[1]*, Aurore Wermeille*[1]*, Arnaud Helias*[2] *and Anne Asselin*[1]*, (1)Sayari, France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France*
While Life Cycle Assessment methods are increasingly tackling impact of human activities on biodiversity, the main threat on marine ecosystems identified by the IPBES: direct exploitation of biotic resources, is still hardly included. A new method of assessing these impacts in the Area of Protection – Ecosystem Quality has recently been developed by Hélias, Stanford-Clarke and Bach. This work proposes characterization factors (CFs) linked to the exploitation of a given species in each FAO Major Fishing Area.
We propose to expand the assessment to all species caught in the fishing activity (the use of a given gear to target a given species in a given area). The goal of this paper is to i) describe how to apply a "fishnet approach" of fishing activities in the context of LCA, ii) apply it to a LCIA case study of resource depletion potential with data from a Marine Stewardship Council report on a German saithe fishery (*Pollachius virens*) and iii) discuss results, advantages, and limitations of such an approach.
Results show that the fishnet approach gives an impact per mass unit of up to 2.95×10^{-9} PDF.year/kg of saithe (live weight) whereas a single-species approach gives an impact per mass unit of 2.52×10^{-9} PDF.year/kg of saithe (live weight) for this case study. It thus better reflects the impact the activity can have on the ecosystem by combining the depletion of both the targeted stock and bycatch. Vulnerable stocks (in this case: pollack, *Pollachius pollachius,* and Atlantic cod, *Gadus morhua*) contribute greatly to the total impact under the fishnet approach despite representing a small fraction of the total catches.
The method is greatly data-demanding but estimations of potential bycatch in a given fishing métier may be found in a variety of sources (Regional Fisheries Management Organisations, FAO, National Fisheries Science Organisation). By combining the impacts on all potentially caught stocks, vulnerable and not commercialized species are assessed even if they represent a small fraction of the total catches. The use of this approach would provide decision-makers with more accurate assessments for an ecosystem-based management of fisheries.

5.04.P-Tu391 Assessing the Environmental Impact of the Application of a Smart Farming System via Life Cycle Analysis – Recommending Best Management Practices
Thanasis Karagkounis[1]*, Evangelia Fragkou*[2]*, George Tsegas*[2]*, Fotios Barmpas*[2] *and Nicolas Moussiopoulos*[2]*, (1)Department of Mechanical Engineering, Sustainability Engineering Laboratory, Aristotle University of Thessaloniki, Greece, (2)Sustainability Engineering Laboratory, Mechanical Engineering, Aristotle University of Thessaloniki, Greece*
The Life Cycle Analysis (LCA) presented in this study is undertaken in the LIFE GAIA SENSE project and aims to assess the potential environmental benefits of Smart Farming (SF) by producing quantified results, as well as to recommend SF-based best agricultural management practices, in the context of supporting decision making. SF is a state-of-the-art digital-based technology for agricultural management, which practically focuses on minimizing field-inputs (fertilizers, pesticides and irrigation) and subsequently, reducing the related environmental impacts. In the LCA study, comparison of the environmental performance of conventional field management practices (reference fields) with those using SF technology (treatment fields), under similar soil and climatic characteristics, for the same cultivation years, was conducted. A cradle-to-field gate approach was followed, while the inventory was based on the data monitored in crop logbooks and questionnaires handed out to smallholder farmers in Greece, participating in the project. The data included details about all field cultivation and management operations that took place in the 2020 and 2021 cultivation years. The findings indicate that, except from the cases that showed no differences by applying the SF technology, there were mainly reductions in most of the impacts studied, potentially resulting from the implementation of the agricultural advices that the SF system suggested. In terms of recommending management practices, single scores were calculated by normalizing and weighting the results with the provided set from ReCiPe 2016 (H) method. The results highlight resources (fossil and mineral) depletion as the most important impact, which is mainly decreased for the treatment fields in comparison with the reference ones, implying that SF can also lead to significant resource efficiency benefits. Recommending agricultural management practices focused mainly on fertilizers application and irrigation practices. As for fertilizers application, recommendations pointed at different fertilizer types, resulting to variations in NH3 air emissions, their effect on air quality and its associated impacts, while for irrigation, at the environmental performance of different irrigation methods. Finally, the main contributors of each impact were also analyzed, in the context of examining the space, time and crop-specific representativity of the results to facilitate decision making.

5.04.P-Tu392 Environmental Evaluation of a Rotation System Developed in the Two Core Farming Regions of Egypt
Sara Lago Olveira[1]*, Maria Teresa Moreira*[2] *and Sara González-García*[3]*, (1)University of Santiago de Compostela, Spain, (2)Universidade de Santiago de Compostela, Spain, (3)Chemical Engineering, University of Santiago de Compostela, Spain*
Food security is at risk worldwide. While agricultural activities are essential to ensure food availability, they can also pose a risk when practised in an unsustainable manner. Additionally, Egypt is marked by its limited availability of arable land and water stress problems. To confront food shortages in the long term, the Egyptian Government has developed the Sustainable

Agricultural Development Strategy intending to improve agricultural productivity by 2030 in a sustainable manner. In this context, this study evaluates the environmental performance of a rotational system cultivated in two different key farming areas of Egypt (along the Nile River and within the desert). This evaluation aims to understand the environmental burdens of Egyptian agriculture and specificities among regions, and based on the acquired insights, to offer improvements that could guide government decisions and policies towards more sustainable agriculture. The rotation system analysed consisted of white clover, maize, and wheat arranged in a 2-year cycle. The life cycle assessment (LCA) methodology was used from a cradle to farm-gate approach. Global warming (GW), marine eutrophication (ME), terrestrial ecotoxicity (TET), water scarcity (WS) and global Potential Species Loss (PSLglo) were the assessed impact categories, based on one hectare (functional unit). To calculate the environmental impacts, ReCiPe Midpoint v1.07 (H) method, as well as AWARE (in the case of WS) and the countryside species-area relationship (SAR) model (in the case of PSLglo) were used with the assistance of the software SimaPro 9.1. The results reveal that the rotation grown in old lands presents the best environmental profile for all categories except PSLglo, with a reduction ranging from 11% to 68%. The overall better performance of old lands is a consequence of the lower fertilisation rates applied, along with the lower water consumption. Regarding PSLglo, the significant impact in old lands (97% against 3% in new lands) is related to the substantial land use pressures on this area due to anthropogenic activities, in addition to the longer regeneration time required. Moreover, irrigation stands out as the main factor contributing to environmental burdens in new lands (e.g., 62% of GW and 100% of WS), whereas in old lands, on-field emissions from nitrogen-based fertilisers are the main responsible of overall environmental profile (e.g., 90% of ME and 53% of GW).

5.04.P-Tu393 Peat Bog Recultivation and Rehabilitation Strategies in Latvian Conditions: A Carbon Footprint Analysis Implementing LCA

Maksims Feofilovs[1]*, Dita Skujevska*[2]*, Riccardo Paoli*[2] *and Francesco Romagnoli*[1]*, (1)Institute of Energy Systems and Environment, Riga Technical University, Latvia, (2)Riga Technical University, Latvia*

Peat bogs in Latvia account for approximately 10% of the total land area. In 2021, Latvia was the main exporting country in Europe for peat products with 2235.5 thousand tons of peat exported with a profit of 239 million euros. Although the peat industry contributes significantly to the national economy, draining bogs releases a large amount of greenhouse gass (GHG) emissions into the atmosphere, promoting land degradation, which can lead to land erosion. At the same time, peat bogs have a crucial role in carbon sequestration; globally, peat bogs store up to one-third of the world's terrestrial carbon pool. In fact, the European Union is moving towards banning peat extraction in its member states, though there is still no common methodology for estimating the CO_2 emissions and carbon losses created during peat extraction. National GHG emissions reports published on the United Nations website have differences in calculating GHG emissions and determination of emission factors. This can affect the fair implementation of recultivation and rehabilitation of peat fields after closing peat extraction sites. Therefore, this study aims at assessing the reduction of GHG emissions facilitated by different recultivation and rehabilitation strategies for existing peat sites in Latvia according to IPCC methodology within the frame of the life cycle analysis perspective. The study results will help promote optimal management of peatlands during peat development, develop strategies to help understand how to manage peatlands after their closure, and give suggestions towards a common framework for estimating the GHG emissions of peat bogs according to a life cycle thinking-based approach.

5.04.P-Tu394 The Agrifood Data Sharing Platform as Pivot for LCI and LCIA Results

Anne-Sophie Sacré[1]*, **Veerle Van linden***[2]*, Reindert Heuts*[2] *and Eva Maes*[2]*, (1)ILVO, Belgium, (2)Flanders Research Institute for Agriculture, Fisheries and Food, Belgium*

An LCA-based climate scan for dairy farms (Klimrek) has proven to be an effective instrument to offer Flemish farmers insight regarding the environmental impact of milk production at farm level, and support them in the selection and implementation of cost-effective climate measures. The large need for data associated with the LCA approach, however, makes completing the scan time-consuming, which hampers its roll out on a larger scale. Initial experiences with the scan, which is completed by consultants during a farm visit, show that manually entered data is subject to errors and interpretation. This can affect the correctness and fairness of the scan's results. Automatic input of existing data from other digital data sources, using the Flemish data sharing platform DjustConnect, offers a solution for these problems. DjustConnect is an API-based data sharing infrastructure, that allows exchange of data between data users and providers, only with consent of the farmer. With the climate scan as a catalyser, different data providers made their data available via APIs on DjustConnect. With consent of the farmer, their data can be used to complete part of the life cycle inventory (LCI). The farmer can also use the data sharing platform to share the scan's results and (in the future) export part of the collected LCI data to other digital tools. The LCI is designed to make maximum use of standardised terminology, to make data available for other applications.To take full advantage of the benefits of data sharing platforms, consistent use of data standards and farmer acceptance remain important challenges that need to be addressed. At the moment, few data sources use standardised terminology, hampering the easy exchange of data between tools. Besides this, many Flemish farmers are still hesitant to trust and use data sharing platforms. Information campaigns and success cases like the climate scan can boost this lack of confidence and raise awareness for the benefits of safe data sharing.

5.04.P-Tu395 Industry LCA for Hand Dish Washing at Colder Temperatures and Using Shorter Dishwasher Cycles

Jasmin Martinez*, Procter & Gamble, Belgium*

Procter & Gamble's 2030 Sustainability Goals include 100% recyclable packaging, cutting sites greenhouse gas (GHG) emissions in half vs. 2010 and enabling responsible consumption for leadership brands. Encouraging consumers to use products under low-energy conditions can result in significant environmental savings, considering that 5 billion people use P&G products every day and for specific categories such as dishwashing detergent, the consumer use-phase dominates the overall life cycle impact.

This study presents the results of an ISO compliant and externally reviewed life cycle assessment for washing dishes manually at colder temperatures (23˚C vs. 40˚C) and for selecting a short cycle when using a dishwasher instead of the normal cycle.
The main current P&G manual and machine dishwashing detergents were selected for this cradle to grave LCA. For the consumer in-use phase, 12 European countries are included and recent consumer tests used for realistic habits & practice data.
The LCA results confirm the importance of the use-phase with respect to the entire dishwashing life cycle. Both for manual and machine dishwashing, more than 70% of the GHG emissions come from the consumer use life cycle step.
The main conclusion of this LCA is that washing dishes by hand at colder temperatures or selecting a short instead of normal dishwasher cycle have a significant environmental benefit in all relevant impact areas, with no trade-offs. Moving from current hand dishwashing temperatures (around 40˚C) to a 23˚C target has the potential to reduce GHG emissions and energy consumption by more than 45% in all the European countries studied. Selecting a short vs. normal dishwasher cycle has the potential to reduce GHG emissions and energy by more than 20% and 35% respectively.
Both for hand and automatic dishwashing, when the consumer use-phase is excluded, the life cycle stages that contribute mostly to climate change are the formulation (>65% for ingredients production & wastewater treatment), the packaging production & end of life (>2%) and the transportation (>2%). Manufacturing accounts for less than 2%.
Overall, this ISO compliant LCA can be used to guide sustainable R&D product and packaging innovations, make business decisions, create an opportunity for environmental claims and encourage consumers to adopt more sustainable habits by using dishwashing products under low-energy use conditions without compromising on cleaning performance.

5.04.P-Tu396 Development of an Automated System for Conducting Life Cycle Assessments--A Chemical Industry Example

***Ravinder Menon**, EHS, Afton Chemical*

Afton Chemical Corporation is a manufacturer of lubricant and fuel additives. About eleven years or so ago, we started getting requests from our customers for life cycle assessment (LCA) of our products and in particular, for the product carbon footprint (PCF). ese requests started surging since 2019, as a consequence of industry in general and our customers in particular, being more aware of global requirements and initiatives on emissions reduction, carbon neutrality and net zero. Many were also publishing their corporate goals in this area. Afton initially responded to these requests by a combination of consultants and training. As the requests started increasing and, in some cases, providing PCF data became a requirement to bid on new business, we realized we had to change our approach from a "one off" LCA contracted to an external consultant, to the development of a more integrated and automated tool that we could deploy internally in an efficient manner.
We brainstormed the idea internally and then with our consultant. We knew this was not going to be an easy task given the complexity of our product portfolio, the large number of manufacturing sites spread globally, the large number of raw materials that go into making those products and associated complexity of various transportation modes and distances. Further complicating this issue was the fact that our internal data systems were not all on the same platform and in some cases, were manually maintained. Even the consultant, who had a lot of expertise with LCA, had not attempted anything of this complexity and magnitude before.
After several meetings between the two teams, we decided to run a pilot project, with a limited number of products covering multiple sites. The results of the pilot in 2020 showed that it was feasible to develop an integrated and automated tool for conducting LCA of our products. However, there was considerable work involved to gather data on product formulations, raw materials, inbound transportation. As far as production-related activities and emissions go, most of our sites don't have sub-metering, so an allocation methodology had to be developed. After months of work, the LCAT (**L**ife **C**ycle assessment **A**utomation **T**ool) system was developed. This presentation will detail the various steps in the process and how we deploy LCAT currently to meet our customer requirements and to set corporate decarbonization goals.

5.04.P-Tu397 The Choice of Refractories for Steel Ladle Lining: A Life Cycle Perspective

***Md Jubayed**[1], Rinus Siebring[2] and Angélique Léonard[3], (1)Chemical Engineering, University of Liege, Belgium, (2)Ceramics Research Centre, Tata Steel, Netherlands, (3)PEPs, Laboratory of Chemical Engineering, Department of Applied Chemistry, University of Liège, Belgium*

The Steel Industry is the biggest consumer of refractories, with more than 70% of total refractory consumption worldwide. Efficient and innovative use of refractory in steel ladle lining is absolutely relevant to decarbonize the steel industry. Life cycle assessment (LCA) methodology is widely used to evaluate the environmental footprint (EF) of a product or process. However, in literature, very few LCA studies are found regarding refractories used in steel ladle, mostly focusing on manufacturing followed by end of life recycling while ignoring the operational feature (use phase) of the refractory. It is not all about embodied impacts of refractories that should be taken into account but also its properties (i.e. density, thermal conductivity and strength) and design of refractory lining which have significant effect on steel production volume and energy efficiency of steel ladle processes. Therefore, this study aims to evaluate how the choice of refractories considering its operational feature in steel ladle lining influence the overall EF of steel. Cradle-to-gate (including recycling of refractories) attributional LCA will be conducted to quantify environmental impacts of steel maintaining a consistent system boundary. Various scenarios will be analyzed using alternative refractories at each segment of the steel ladle as well as changing the thickness of refractory lining. Data will be collected from industrial partner: Tata Steel, Netherlands. The study will provide a comprehensive LCA framework to support the choice of refractories for steel ladle lining, and the case study itself will be an excellent contribution to fulfilling the current knowledge gap in the literature.

5.04.P-Tu398 Use of Life Cycle Impact Assessment to Advance Holistic Optimization of Radiological Protection and Safety

***Bryanna D Wattier**, Lindsay C Shuller-Nickles, Michael Carbajales-Dale and Nicole E Martinez, Environmental Engineering and Earth Sciences, Clemson University*

Radiological protection seeks to protect patients, the environment, and members of the public from detrimental effects of unnecessary exposure to ionizing radiation. Within the system of radiological protection is the process of optimization, which is a cyclical process aimed at keeping the likelihood of incurring exposure, magnitude of individual doses, and the number of people exposed as low as reasonably achievable (ALARA). In order to do this, the situation is evaluated, the protective options are identified, the best option for protection is selected, and the option is implemented. Life cycle assessment (LCA) is a modeling technique that can be used to determine the cradle-to-grave impacts to humans and the environment for the production of a good or service. LCA can be incorporated into the optimization of radiation protection as a decision-aiding technique (DAT). DATs such as cost-benefit analysis and value of statistical life are already in use for radiation protection because the dose rate should not be the only factor considered for protection. Tools like LCA may be implemented into radiological protection to yield a more holistic perspective and enable comparison with analyses of non-radiological systems. Despite structural similarities to a decision-aiding technique, life cycle impact assessment (LCIA) is not commonly used in the context of optimization of radiation protection.

A proof of principle using concrete as a shielding material for a cesium-137 (Cs-137) point source was conducted for the production of concrete with different cement compositions. The concrete containing the cement composition of 21-35% limestone had the largest global warming potential and water consumption in addition to the second highest ionizing radiation emitted in the production, surpassed only by 36-55% pozzolana and fly ash cement. The concrete containing 21-35% alternative constituents cement had the lowest ionizing radiation emitted and water consumed in addition to the second lowest global warming potential, followed only by the concrete containing 36-55% pozzolana and fly ash cement. LCIA as a DAT would recommend using concrete with 21-35% alternative constituent cement. Additional DATs or impact categories could aid in the decision for the best concrete option to use for shielding the Cs-137 source.

5.04.P-Tu399 Teaching Life Cycle Assessment Using Counterintuitive Examples

***Andrea Hicks**, University of Wisconsin, Madison*

Life cycle assessment is a fundamental tool in industrial ecology. Teaching students at a university level the skill of life cycle assessment is often accomplished through project based learning. The inherent uncertainties present in project based learning has been shown to enhance student learning. This work reflects on a graduate level course on life cycle assessment which utilizes counter intuitive examples, which are problems and systems which seem like one choice should be the clear and easy winner, but that is often not the case. In particular, using the case study on single use versus reusable drinking straws will be explored. The student's level of comfort with their knowledge was gauged with pre and post course knowledge probes, coupled with a guided reflection. This work is still in progress, but is anticipated to illustrate that the usage of counter intuitive examples causes students to probe more deeply into their preconceptions of sustainability and environmental impact. As the skill of conducting a life cycle assessment becomes a more popular and desired skill, it is critical to improve how we teach these skills.

5.04.V LCA as an Effective Tool in Decision-making

5.04.V-01 Carbon footprint of Osaka Expo in 2025

***Ryusei Murata** and Norihiro Itsubo, Tokyo City University, Japan*

In October 2020, former Prime Minister Suga declared Japan`s goal towards carbon neutrality in 2050, and in June 2021, the Green Growth Strategy in conjunction with Carbon Neutrality in 2050 was formulated. Based on goal and strategy, carbon neutrality is considered important for the 2025 Osaka Expo. In addition, the Exposition Association organizing the Expo has compiled the results of studies conducted by the Environment and Energy Committee in the Future Society as the , which sets out six directions for decarbonisation and resource recycling-related initiatives for the said event.

A previous study on Expo Milano 2015 quantifying greenhouse gas (GHG) emissions has been conducted. The main contributors in the previous study were the organisers (offices and transfers, construction sites, pavilion construction, preparatory events, exhibition information and decommissioning) and tourist transportation and movement. The overall GHG emissions for Expo Milano is approximately 103 million t-CO_2eq, of which majority of the emissions were related to tourist transportation and movements accounting for approximately 60% of the total. Previous studies of large-scale events have shown a significant environmental impact related to the movement of tourists and visitors.

Based on the above, the objectives of this study are (i) to estimate the GHG emissions of the Osaka Expo in 2025. (ii) Calculate the GHG emissions of a large-scale event and (iii)present specific reduction measures, which leads to a change in people's behaviour and environmental measures.

This study also covers the Hanazono Expo, a sub-event of 2025 Osaka Expo, and the entire 2025 Osaka Expo. The GHG emissions of the sub-events are assessed by multiplying the monetary data obtained through interviews by the intensity of the Environmental Impact Intensity Data Book (3EID) based on the Japanese input-output table. The GHG emissions for the entire 2025 Osaka Expo are estimated by multiplying the GHG emissions by the intensity of the Environmental Impact Intensity Data Book (3EID) based on the inter-industry relations table from the data on the economic spillover effects of the 2025 Osaka Expo in the Kansai Economic White Paper 2022.

For future research and studies, the evaluation of sub-events and the assessment of GHG emissions from Osaka Expo 2025 Osaka should be further evaluated in detail.

5.04.V-02 Life Cycle Assessment of a District Cooling Plant – Effect of Temporally-resolved Electricity and Heat Supplies
Doris Rixrath[1]*, Gerhard Piringer*[2]*, Raphael Schauer*[3] *and Rosa Weber*[3]*, (1)JRZ LiSA, University of Applied Sciences Burgenland, Austria, (2)Energy and Environment, University of Applied Sciences Burgenland, Austria, (3)University of Applied Sciences Burgenland, Austria*
District cooling networks are becoming increasigly popular as a way to meet cooling demand in urban areas. Their environmental impact is a fundamental consideration. Typically, life cycle assessments (LCA) results for cooling devices are based on annual average electricity and heat mixes. However, electricity and heat mixes in Austria exhibit both seasonal and daily fluctuations.
The objective of this study is (a) to investigate the life cycle environmental impacts of operating a district cooling plant in Vienna, and (b) to study the effect on LCA result of an hourly resolution of both the plant's energy supply (electricity and heat mix) and of its cooling load profile, relative to an annual average resolution.
This study is an attributional LCA of a 19.8-MW district cooling plant featuring four electrically-powered compression chiller units, as well as two district-heat supplied absorption chiller units, and one free cooling system. The Hourly load profile data for the cooling demand were provided by the local utility for the year 2019 and used to weigh the hourly electricity and heat mixes that supply the chiller units. Hourly electricity mix data were obtained for the national grid of Austria in 2019 [4], and hourly heat mix data for district heat for the absorption chillers were supplied by the local utility. The functional unit for the LCA was 1 kWh of cooling energy.
LCA results for the cooling plant will be presented for the individual chiller units as well as for entire cooling plant. The findings will analyze and compare the impacts of the individual different chillers, and compare these impacts to those derived from average annual supply mixes. Preliminary results indicate that load-induced differences in the supply mixes between individual units are as large as the differences to the average annual supply mixes.
The plant's impact is expected to be dominated by the operating energy supplies. Based on previous research on a heat pump, we further expect that the hourly-resolved impacts will clearly differ from those calculated with the annual average mix.
A higher temporal resolution should have a moderate but discernible effect on the LCA of operating a district cooling plant, particularly in a country such as Austria that has a high share of renewables in its electricity and heat mixes. Therefore, these results will form an improved basis for decision-making by urban energy managers.

5.04.V-03 The Environmental Cost of Plant-based Meat: A Lifecycle Assessment
Nichole Eunice Yanson Lalas[1] *and Norihiro Itsubo*[2]*, (1)Department of Environmental Management and Information Studies, Tokyo City University, Japan, (2)Tokyo City University, Japan*
The growing global demand for beef brings environmental consequences of deforestation, climate change, and waste disposal issues. Several businesses today have been innovating toward producing alternative meat to lessen the industry's environmental impact without compromising economic profitability. With consumers gaining awareness of responsible consumption, market demand for alternative meat is booming. Businesses are developing different technologies to meet this demand. Shifting from conventional meat to plant-based meat also aligns with the UN's Sustainable Development Goals on Zero Hunger, Responsible Consumption and Production, Climate Change, and Life on Land.
This study aims to determine the environmental impact of plant-based and conventional meat. Other objectives include the determination of which alternative meat and which specific product lifecycle process contribute the lowest and highest impact.
The study will aid in providing insights and recommendations to assist businesses in strategizing their environmental and economic sustainability initiatives, to aid the government in establishing feasible and practical solutions for future policymaking, to promote individuals' responsible consumption, to help farmers better take care of their farm fields, and to maintain a clean, healthy, and green environment.
The main research subject is DAIZ, Inc, a company producing and selling germinated soybeans and peas in Japan which will then be compared to conventional red meat based on existing literature. The system boundary will cover from cradle (accounts land use change)-to-consumer approach.
Environmental impact is measured through Lifecycle Assessment.
The study will utilize SimaPro 9 software and EcoInvent, IDEA, and openLCA databases. Primary data for plant-based meat and secondary data for conventional meat will be sourced from DAIZ and existing literature.
Expected results of the study include the Environmental Impact of Conventional and Plant-based Meat as measured through GHG emissions and comparative analysis to determine the key differences between output results.
Future research includes the comparative study on DAIZ's germinated soybean and pea plant-based meat versus Impossible Meat, Beyond Burger, and Cultured Meat and the application of the Lifecycle Costing and Social Lifecycle Assessment.

5.05 Life Cycle Impact Assessment Modeling and Application

5.05.P-We330 Ecotoxicity Impact Evaluation for Data Poor Chemicals Under the Global Life Cycle Impact Assessment Method Framework
Melanie Douziech[1]*, Mikolaj Owsianiak*[2]*, Laura Golsteijn*[3]*, Rosalie van Zelm*[4]*,* ***Susan A Oginah***[2]*, Olivier Jolliet*[2]*, Michael Z. Hauschild*[2]*, Leo Posthuma*[5] *and Peter Fantke*[2]*, (1)Agroscope, Switzerland, (2)Technical University of Denmark, Denmark, (3)PRé Sustainability, Netherlands, (4)Department of Environmental Science, Radboud Institute of Biological and Environmental Science, Radboud University, Netherlands, (5)National Institute for Public Health and the Environment (RIVM), Netherlands*
Recommendations from the Global Life Cycle Impact Assessment (GLAM) initiative for ecotoxicity include deriving characterization factors based on measured effect concentrations where 10% of the tested organisms show an effect (EC10) for at

least five species from three species groups. Chemicals with lacking or few measured effect data can therefore not be characterized. One aim of the third phase of the GLAM initiative is to propose practical guidelines for applying the framework to data poor chemicals. To reach this aim, we systematically compare HC20, hazardous concentration, where 20% of the species are exposed above their chronic EC10 derived from modeling approaches, against those obtained from measured effect data. Investigated modelling approaches include extrapolation methods, such as acute-to-chronic ratios and interspecies correlation estimation equations (ICE), and pure prediction tools estimating effect data from physico-chemical properties of the analyzed chemicals (Quantitative Structure-Activity Relationships, QSARs). Based on different criteria, we chose the consensus models of T.E.S.T. to estimate EC50 for *Fathead minnow* and *Daphnia magna* and the VEGA Combase QSAR for the EC50 of *Raphidocelis subcapitata*. Comparing HC20 based only on measured chronic EC10 to HC20 based on a combination of measured chronic EC10 and extrapolated ones led to an R^2 of 88%. Together with already published studies, this supports the use of extrapolation methods whenever measured chronic EC10 are missing. Comparing HC20 relying only on measured, potentially extrapolated, effect data for at least five species from three species groups with HC20 including all measured algae effect data and combinations of two measured and all ICE-based effect data for the missing species group led to R^2 around 50%. The R^2 increased to 63% if all measured effect data were used. Finally, preliminary results showed that completing a set of four measured effect data, meaning two effect data per species group, with one QSAR estimate of the missing species group lead to R^2 above 65%. Based on these findings and published results from the scientific literature, extrapolation methods might be mature enough to help characterize the ecotoxicity of data poor chemicals. Research is ongoing to formulate clear recommendations and evaluate the usefulness of pure prediction tools also in combination with extrapolation methods, particularly for chemicals with no measured effect data.

5.05.P-We331 Deriving Global Normalization References Based on Unit Process Databases
***Nils Thonemann*[1]** *and Alexis Laurent[2], (1)Danish Technical University, Denmark, (2)Technical University of Denmark, Denmark*
According to ISO 14044, normalization is an optional step when conducting a life cycle assessment (LCA) and relates characterized life cycle impact assessment results with a reference. The used data source for building such inventories may differ substantially. Deriving consistent global inventories for all impact categories remains a challenging task due to (i) data availability (e.g., production amount unknown), (ii) emission coverage (e.g., emission not covered by emission report), (iii) inconsistency in data sources (e.g., different data sources and quality for climate change-related and acidification-related emissions), and (iv) temporal mismatch (e.g., outdated reference year). Until now, published normalization references are derived from different data sources. Due to these uncertainty sources and limitations, current LCA practice often leads to normalized impact profiles that are distorted or biased for some impact categories. This limits the LCA practitioners in the interpretation of their normalized impact results. To overcome the outlined challenges, we propose a new approach to derive global normalization references based on unit process databases that address some of the aforementioned problems. This approach allows for the consistent derivation of global normalization references while considering (i) production volumes from one source, (ii) covering emissions as in the background system of the modeled system under study in an LCA, (iii) using the same data source for all data, and (iv) allowing for annual updates. This work has been conducted in the Working Group on Normalization within the Task Force for cross-cutting issues in life cycle impact assessment (LCIA) under the flagship project "Global Guidance on LCIA Indicators and Methods" (GLAM). The overall approach considered in this work is the exploitation of life cycle inventory databases and production data to calculate normalization references. With the described approach, globally consistent normalization references could be derived. To check the procedure's validity, we compared the newly calculated normalization inventories with former normalization inventories The coefficient of determination (r-square), which was calculated to be 0.72, is considered acceptable and unveils for greenhouse gases that the approach using process databases can produce normalization inventories similar to established normalization inventories.

5.05.P-We333 Is Adoption of Agroforestry in Arable Systems Environmentally Sustainable? Accounting for Ecosystem Services in Life Cycle Assessment
***Lieselot Boone*[1]**, *Paul Pardon[2], Bert Reubens[2], Kris Verheyen[3] and Jo Dewulf[1], (1)Green Chemistry and Technology, Ghent University, Belgium, (2)Flanders Research Institute for Agriculture, Fisheries and Food, Belgium, (3)Environment, Ghent University, Belgium*
Intensive agricultural management, despite higher crop productivity, also led to environmental concerns such as biodiversity loss or eutrophication. This gave rise to calls for alternative systems, such as agroforestry, where the delivery of food and biomass, i.e. provisioning ecosystem services (ES_{prov}), is balanced with the supply of regulating (ES_{reg}) (e.g. erosion prevention) and cultural (e.g. recreation) ES. But agroforestry can lead to lower crop yield due to effects of tree presence. Therefore, analysing the environmental sustainability by e.g. life cycle assessment (LCA), including all ES supplied, is required. Though LCA traditionally only considers the harvested product, whereas the product provided by an agricultural system actually includes a bundle of ES.
To address this issue, LCA is here extended with ES assessment to compare the resource footprint of two conventional systems: a field with only an arable component (pure conventional system) and a field (same size) with the same arable crops but with also a tree component (conventional agroforestry system). To distribute the environmental impact across all agricultural output, i.e. ES_{prov} and other ES, allocation factors are calculated. They are defined based on the capacity of the two ecosystems to deliver specific ES. These ES data comes from measurements in Flanders (Belgium) that resulted in a long-term dataset. A weighting factor α (ratio of ES_{reg} over ES_{prov}) is introduced to account for the importance of the bundle of ES_{reg} relative to ES_{prov}.
If only ES_{prov} are considered (), the pure conventional system has a 4 or 15% lower resource footprint than agroforestry, per kg dry matter or per euro of harvested biomass, respectively. However, at equal weighting of ES_{prov} and ES_{reg} (i.e.), agroforestry is preferred to the conventional system, with the latter having an 11 (mass) or 1% (economy) higher footprint. The tipping point at

which agroforestry is less resource-intensive than the pure conventional is at 0.14 (impact per kg) or 0.87 (impact per euro). This indicates the importance of expressing the impact in both mass and economic values and opens the interest in further research into a functional unit that is independent of economic fluctuations but includes the value of harvested products.
The new approach including ES assessment enables thus for a more comprehensive comparison of the environmental sustainability of agricultural systems.

5.05.T-01 Characterizing Sea Level Rise Potential Impacts on Coastal Ecosystem Services in Life Cycle Impact Assessment

Laura Debarre[1]*, Manuele Margni*[1] *and Martin Dorber*[2]*, (1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)Norwegian University of Science & Technology, Norway*

Oceans and coastal ecosystems provide many "ecosystem services" (ES) to humans including food production, climate regulation or coastal protection. Sea level rise (SLR) due to climate change will have a significant influence on coastal ecosystem functions and services due to changes in habitats and species communities. There is growing support for integrating the potential impact of human activities on the functional value of ecosystems as new Area of Protection into the Life Cycle Assessment (LCA) framework. Nonetheless, current coverage of anthropogenic potential impacts on ES in LCA is limited. This research proposes characterization models and factors assessing the potential cost to society resulting from a change of potential coastal ES supply triggered by climate-change-driven SLR. This work offers an innovative approach to integrate ES within LCIA framework building on an ES matrix approach and the benefit-transfer method for the monetary valuation of ES. This method builds on the assessment of the potential ES value of habitats likely to be inundated due to climate-change-driven SLR under two different GHG emission scenarios. Characterization factors (CFs), expressed in \$/tCO2, represent an average global potential impact for RCP4.5 and RCP8.5. These CFs account for the cumulative loss in value of the ES supply between 2015 and 2100 divided by the cumulative amount of CO_2 emitted over the same period. The mapping and identification of habitats under threat of inundation relies on global maps of present (year 2015) and projected (2050 and 2100) inundated coastal zones due to SLR. These inundation maps are coupled with global mappings of Ecosystem Functional Groups (EFG) defined as the main reporting unit for ES, to identify the ES that are present in the inundated zones. The annual monetary value of those ES (in \$/yr) is estimated building on the Ecosystem Service Valuation Database. Results show that the global value of areas likely to be inundated due to SLR, in terms of potential ecosystem services provision, increases by \$1.91E+14 (\$2.47E+14 respectively) between 2015 and 2100 under the RCP4.5 (RCP8.5). CF were found to reach 72.1 (35.9) \$/tCO_2 for RCP4.5 (RCP8.5). Values are probably overestimated and should be reduced by the residual value of the EFG to which the ecosystem is transitioning. Results suggest that potential SLR impacts on coastal ecosystems are significant, highlighting a need for further research on this topic.

5.05.T-02 Estimation of Potential Economic Value Losses Due To Resource Dissipation in LCA Through The EVDP Method: A Case on LIB Recycling

Jair Santillán-Saldivar[1]*,* ***Antoine Beylot***[2]*, Stéphanie Muller*[3]*, Emmanuelle Cor*[4] *and Elise Monnier*[4]*, (1)University of Bordeaux, France, (2)French Geological Survey, France, (3)Bureau de recherches géologiques et minières BRGM, France, (4)CEA-Commissariat à l'Energie Atomique et aux energies Alternatives, France*

Resource dissipation is a phenomenon that has been identified as a barrier towards circular economy causing losses in the technosphere along the life cycle of products. When addressing mineral resources, an identified safeguard subject is the potential to make use of the value that a resource holds for humans; therefore a damage would be the reduction or loss of this potential due to human activity; currently there is a limited number of proposals to assess the impacts of dissipative losses.
Building upon the JRC-LCI and JRC-LCIA methods, we present the Economic Value Dissipation Potential (EVDP) method, an impact assessment method in LCA that integrates the identification of dissipative flows, and the potential value loss associated to them. The method proposes a function that estimates the fraction of a mass flow that can be considered dissipative based on the comparison between a global average minimum grade in primary sources and resource concentration in dissipation compartments. Next, the method assigns a value to this flows based on the integration of their price and economic importance to model a potential value loss.
The method is applied to a case study on Lithium-ion batteries (LIB) recycling through hydrometallurgy. Partial results of the application of the EVDP method include the development of a resource flow analysis based on the JRC-LCI method to better trace the analyzed materials. Results show that the recycling of a kilogram of battery NMC 111 allows the avoidance of the equivalent to 3.79 USD in dissipative losses. The biggest contributors being cobalt due to its high price and economic importance from the point of view of the EU, and aluminum, due to being the element with greater recovered mass in the analyzed process. The EVDP method provides a way to associate potentially dissipative flows to value losses measured in monetary units. It also provides an indicator to quantify the effectiveness of circular economy strategies in maintaining the value of resources in the technosphere. The application of the method to a case study on LIB recycling through hydrometallurgy shows the benefits of this type of practices from a life cycle perspective; further replication of the method is suggested along with other impact assessment methods to support decision-making processes regarding the implementation of circular economy strategies.

5.05.T-03 Temporal Inconsistencies in LCA: Dynamic Climate Change Characterization Factors

Guillaume Batôt*, François-Xavier Dezert, Sibylle Duval-Dachary and Sandra Beauchet, IFP Energies Nouvelles, France*

Achieving Net Zero by 2050 will notably induce delayed emissions, for instance due to carbon capture and utilisation (CCU), e.g. emissions optimisation through temporary storage in materials. The effects of temporary storage on climate change could be worse than doing nothing. That is why impacts should be carefuly assessed using dynamic life cycle assessment (D-LCA). In such a rapidly evolving context, considering temporality in LCA is becoming more and more crucial.

The purpose of this paper is to review the dynamic GWP indicator based on the "time corrected" approach initially proposed by Levasseur, and recently revised by Ventura with the "fixed horizon of impact" method. Even though the latter are useful and provide a clear improvement compared to the basic use of a static indicator in D-LCA, both solutions may not seem entirely satisfactory and a modified version is suggested to keep what seems relevant in each of these two approaches.
These different dynamic versions of the GWP/GTP indicator are compared with regard to the static indicator. Three temporal parameters are therefore used: the time horizon of the study, indicating the total time over which impacts are effectively assessed; the life cycle duration, which is the period of time between the first and the last inventory flow; and the time horizon of the impact, defined by the practionner (e.g. usually 100 years for the GWP).
Applied to the case of a simplified CCU system (life cycle duration of 45 years), the "time corrected" approach and the "fixed horizon of impact" method give similar values and trends for the GWP and GTP, when the time horizon of impact is greater than 20 years. The modification introduced in this work leads to opposite trends and in particular gives higher importance to a future increase in global temperature – that will actually be felt by the next generations.
The choice of the temporal method for calculating a "dynamic" impact is not neutral and should be considered and discussed depending on the stakes at hand. Moreover, adopting a cost-benefit viewpoint would allow to interpret the trends as the weight given to future generation with regards to the actual one: a more than central issue today.

5.05.P Life Cycle Impact Assessment Modeling and Application

5.05.P-We332 Path dependency in Life Cycle Impact Assessment: Are All the Impact Categories Still Relevant?
Jan Matuštík*, Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague, Czech Republic*
Life Cycle Assessment can boast quite a long and rather successful history, being now established at the highest policy levels. The methodology has been evolving for over 30 years, and arguably reached levels of maturity allowing it to be utilized as an official assessment tool, as manifested in the EU Product Environmental Footprint. The EF methodology provides a subset of recommended impact categories, which is in essence similar to the ensemble first used in the CML methodology from the 1990s. The assessed impact categories should be selected to represent the most pressing environmental issues, i.e., they should reflect what society (researchers) perceives as the most relevant. Nevertheless, the environmental debate keeps on evolving: from the focus on radioactivity, through chemical pollution of substances like DDT, resource depletion, forest die-off caused by acidification, or ozone depletion at the end of 1980s, to the current issues of climate crisis, biodiversity destruction, or plastic pollution. In the 1990s, when the subset of impact categories still in use was developed, some environmental issues were well on the road to being "solved" (e.g., acidification in Europe or stratospheric ozone depletion), while some issues were not even formulated or envisaged (ocean acidification or microplastic pollution). While new impact assessment methodologies targeting "emerging" issues are being developed, most LCAs employ the traditional set of categories. Another potential problem with the traditional set of impact categories is that some issues are overrepresented (in Environmental Footprint there are three categories focusing on eutrophication). It begs to question whether this is an intended manifestation of the perceived import or an "accident". Another long-debated conundrum is the issue of resource depletion, which is a purely socio-economic problem. Clearly, the commonly used subset of impact categories is a residuum of a past worldview. As most complex systems, the evolution of impact assessment methodology is path-dependent, the decisions of past researchers still greatly affect how we do LCA today – while many different paths could have been taken just as well. Nevertheless, from a position of a person getting into LCA later, some of those decisions do not seem to make sense anymore. It might be time to reassess which impact categories are still relevant, and which environmental issues are the most pressing in today's world.

5.05.P-We333 Is Adoption of Agroforestry in Arable Systems Environmentally Sustainable? Accounting for Ecosystem Services in Life Cycle Assessment
Lieselot Boone[1]*, Paul Pardon*[2]*, Bert Reubens*[2]*, Kris Verheyen*[3] *and Jo Dewulf*[1]*, (1)Green Chemistry and Technology, Ghent University, Belgium, (2)Flanders Research Institute for Agriculture, Fisheries and Food, Belgium, (3)Environment, Ghent University, Belgium*
Intensive agricultural management, despite higher crop productivity, also led to environmental concerns such as biodiversity loss or eutrophication. This gave rise to calls for alternative systems, such as agroforestry, where the delivery of food and biomass, i.e. provisioning ecosystem services (ES_{prov}), is balanced with the supply of regulating (ES_{reg}) (e.g. erosion prevention) and cultural (e.g. recreation) ES. But agroforestry can lead to lower crop yield due to effects of tree presence. Therefore, analysing the environmental sustainability by e.g. life cycle assessment (LCA), including all ES supplied, is required. Though LCA traditionally only considers the harvested product, whereas the product provided by an agricultural system actually includes a bundle of ES.
To address this issue, LCA is here extended with ES assessment to compare the resource footprint of two conventional systems: a field with only an arable component (pure conventional system) and a field (same size) with the same arable crops but with also a tree component (conventional agroforestry system). To distribute the environmental impact across all agricultural output, i.e. ES_{prov} and other ES, allocation factors are calculated. They are defined based on the capacity of the two ecosystems to deliver specific ES. These ES data comes from measurements in Flanders (Belgium) that resulted in a long-term dataset. A weighting factor α (ratio of ES_{reg} over ES_{prov}) is introduced to account for the importance of the bundle of ES_{reg} relative to ES_{prov}.
If only ES_{prov} are considered (), the pure conventional system has a 4 or 15% lower resource footprint than agroforestry, per kg dry matter or per euro of harvested biomass, respectively. However, at equal weighting of ES_{prov} and ES_{reg} (i.e.), agroforestry is preferred to the conventional system, with the latter having an 11 (mass) or 1% (economy) higher footprint. The tipping point at which agroforestry is less resource-intensive than the pure conventional is at 0.14 (impact per kg) or 0.87 (impact per euro). This

indicates the importance of expressing the impact in both mass and economic values and opens the interest in further research into a functional unit that is independent of economic fluctuations but includes the value of harvested products.
The new approach including ES assessment enables thus for a more comprehensive comparison of the environmental sustainability of agricultural systems.

5.05.P-We334 Development of Biodiversity Damage Assessment in LCIA with the Expanded Impact Categories
***Runya Liu**[1], Haruka Ohashi[2], Akiko Hirata[2], Tetsuya Matsui[2] and Norihiro Itsubo[3], (1)Graduate School of Environmental and Information Studies, Tokyo City University, Japan, (2)Forestry and Forest Products Research Institute, Japan, (3)Tokyo City University, Japan*
During the past century, our planet has gone through an unprecedented change, which boosts human society's development rapidly. However, the alarm of entering the sixth mass extinction urges us to reconsider the necessity of human-nature balance. As IUCN is now working on developing a quantitative methodology to measure and track contributions toward protecting and restoring nature, which is aiming at contributing to a nature-positive future. Lacking a powerful and comprehensive methodology may prevent biodiversity restoration and protection.
Therefore, we are refining the Life cycle impact assessment (LCIA) methodology to offer a far-reaching way to well-consider biodiversity even the implementation by policymakers and stakeholders.
In this research, we have three main objectives. First, try to refresh the LCIA midpoint category menu which is considered to affect biodiversity. Second, compare the LCIA biodiversity indicators and clarify the scientific performance of each, the Potentially disappeared fraction (PDF), and the Expected Increase in the Number of Extinct Species (EINES). Last, try to include the species in the evaluation as much as possible.
As the methodology, by referring to the Life cycle Impact assessment Method based on the Endpoint model 3(LIME3) developed framework, we lodge the biodiversity loss at the stage of the endpoint. Then we integrate the LIME3 framework with Max Entropy (Maxent) which is an application of the species distribution model (SDM). Finally, the output from the model could be applied with LCIA indicators in procuring the damage factors.
As the result, we modified the PDF and compared it with EINES, and the original PDF. Some significant limitations could be eliminated and improved. Then we applied it try to view the global biodiversity status. We found that the mean PDF (Current ~RCP8.5 scenario) shows the highest in the European region and lowest in Asia. The Amphibia shows the highest risk compare to another taxon; the plant is next to it. Bird is most flexible under this scenario due to the long-migration ability.
In future work, we are pursuing to make win-win collaborative research on LCIA and ecology. Borden the possibility to implement the ecological knowledge by LCA users even the business. On another side, gain more agreement on methodology and indicators from a nature-based evaluation. Hope to further contribute to the nature-positive system.

5.05.P-We335 Developing the Fisheries Impact Pathway - Operationalised in the Context of GLAM Phase 3
***Chloe Stanford-Clark**[1], Laura Scherer[2], Francesca Verones[3] and Arnaud Helias[4], (1)UMR ITAP - Elsa, Montpellier, France, (2)Leiden University, Netherlands, (3)Norwegian University of Science & Technology, Norway, (4)ITAP, Univ Montpellier, INRAE, Institut Agro, France*
Marine biodiversity impact coverage is still scarce in the current Life Cycle Impact Assessment (LCIA) framework. The work presented in this abstract supports the development and operationalisation of the recently proposed impact pathway for fisheries impacts on ecosystem quality. This is also a subject of discussion in GLAM Phase 3.
Updated Characterisation Factors (CFs) have been computed, based on a popular fisheries stock management model based. Objectives include incorporation of discards from by-catch in the impact quantification, and to explore the temporal validity of CFs relative to fisheries' trends.
CFs have been computed from depleted fractions of individual stocks (a species in a habitat) and regionalised at the scale of FAO major fishing area. Points of development include: 1) Input data updated from 2015 to 2018, enabling determination of questions of temporality in static CFs. 2) Inclusion of additional but "invisible" impact of discards in fishing activity within the impact assessment. 3) Regional to global impact conversion using two comparable methods, at the regional scale and a species-level alternative to attribute a measure of vulnerability related to species endemicity.
Results include an updated set of operational CFs for the depletion of individual stocks, within current data constraints and with an endpoint unit converted into PDF·year/kg biomass. The CFs should be consistent with Life Cycle Initiative guidelines and could be included in GLAM Phase 3, available for use in LCA studies. The outputs of two regional to global conversion factors are compared to understand whether it is possible to have a per-stock representation of impact at the global scale to give a measure of the endemicity of the impacted stock rather than an aggregation per region. The inclusion of discards increases the impact of depleting each stock by 52% on average. Due to a lack of explicit data, this first attempt is a regional estimation, with the likelihood of accidental capture and subsequent rejection based on the biomass of each species present in the region only.
The current format of the approach and CFs are highly relevant for compatibility with fisheries management regulations and show potential for inclusion in GLAM Phase 3. The inclusion of discards is an important point of progression for the fisheries impact pathway. A future perspective to further develop this impact pathway is the incorporation of ecosystem dynamics.

5.05.P-We336 Ecotoxicity Impacts by the Pesticide Usage in Berry Open Field Production - A Case Study in Finland
***Kati Räsänen**[1] and Marja Rantanen[2], (1)Bioeconomy and environment / Sustainability science and indicators, Natural Resources Institute Finland, Finland, (2)Production Systems/ Horticultural Technologies, Natural Resources Institute Finland, Finland*
Comprehensive data on the use of plant protection products (PPP) and their impacts on different berries are scarce. In this case study, we mapped the use of PPPs on four open field strawberry and three raspberry farms in Finland in 2017-2021 and calculated

their potential freshwater ecotoxic impacts using a method based on the SETAC consensus LCIA (life cycle impact assessment) model of Usetox 2.0. PestLCI Consensus V.1.0 model was used to estimate the pesticide emissions. In the model, parameters that best described a common Finnish strawberry and raspberry plant protection practices and initial primary emission distribution fractions were used. Twenty eight (28) different active ingredients (in average 1,8 kg/ha/year) on strawberry and six (in average 0,6 kg/ha/year) on raspberry were used during the studied time period, respectively. Strawberries were sprayed about 7 times and raspberries about 2 times per year (=one spray equals to use of one active ingredient). Fungicides were the most commonly used pesticides on both crops. According to the impact results, there were large variations between farms in ecotoxic pressure, depending also on the used amounts of PPPs. The impacts of strawberry production were greater than raspberry. According to the sensitivity analysis, plant growth rate and spraying method had an effect on the ecotoxic pressure. A fungicide azoxystrobin induced the greatest impact (35.2 %) of all used pesticides on strawberry (4633 PAF m^3 d/ha/year) and a fungicide iprodione (59.5 %) on raspberry (2058 PAF m^3 d/ha/year). These were followed by insecticide pyrethroid lambda-cyhalothrin and herbicide diquat on strawberry, and an insecticide pyrethroid deltamethrin and fungicide fludioxonil on raspberry. The total impact was 13148 PAF m^3 d/ha/year and when compared to the yield i.e. 0.40 PAF m^3 d/kg/year on strawberry and 3457 PAF m^3 d/ha/year and 0.02 PAF m^3 d/kg/year on raspberry. Using this LCA-based method the environmental impacts of individual hazardous PPPs can be identified. The results show that environmental impacts of PPPs can be decreased by looking for alternatives for the most harmful substances and develop the use of PPPs in a more sustainable direction. Still, extension of broadening applicability of the method needs further development.

5.05.P-We337 Life Cycle Toxicity Impact on Human and Ecosystem Health Caused by Pesticides and Related Chemicals in Major Crop Production Systems in Thailand

***Phatchari Mankong*[1]**, *Peter Fantke[2], Tanapon Phenrat[3], Jitti Mungkalasiri[4], Shabbir H. Gheewala[5] and Trakarn Prapaspongsa[1], (1)Graduate program in Environmental and Water Resources Engineering, Department of Civil and Environmental Engineering, Mahidol University, Thailand, (2)Technical University of Denmark (DTU), Quantitative Sustainability Assessment, Denmark, (3)Department of Civil Engineering, Faculty of Engineering, Naresuan University, Thailand, (4)Technology and Informatics Institute for Sustainability, National Metal and Materials Technology Center, National Science and Technology Development Agency, Thailand, (5)The Joint Graduate School of Energy and Environment, King Mongkut's University of Technology Thonburi, Thailand*

Thailand is a global producer and exporter of various products from major crops. Since pesticides can harm humans and the environment, the current study aims at characterizing the life cycle toxicity impacts on humans and the ecosystem arising from pesticides and related chemical emissions in major crop production systems in Thailand. Pesticides produced and then used in Thai major crop production systems (rice, cassava, sugarcane, and oil palm) are evaluated for human toxicity and ecotoxicity. The inventories are structured into direct (pesticides applied on farms) and indirect (any toxic substance emissions in the upstream processes of pesticide manufacturing) emissions. Three assessment systems are carried out (direct impact-based PestLCI and PEFCR, and the indirect impact-based ecoinvent). Thai-specific characterization factors (CFs) of pesticides are used to yield the total direct impact scores. The indirect impact is quantified using CFs from USEtox 2.12, in SimaPro. Our results illustrate that, for human toxicity impacts, the total direct and indirect emission-related impact is 0.13 and 4.6×10^{-5} DALY/t. Direct emissions are mainly contributing to total human health impact scores ranging from 87 to 100%. The rice system shows the highest direct impact of 0.12 DALY/t mainly caused by Butachlor (51%). The obtained impacts based on PestLCI emissions are up to 2 orders of magnitude higher than those based on PEFCR for rice and sugarcane systems. PestLCI considers emissions reaching the field crop, which will be consumed and cause additional impacts. PEFCR does not account for crop emissions. For ecotoxicity impacts, the total direct and indirect emission-related impact is 3,806 and 104,179 PDF m^3 day/t. Indirect (i.e., supply chain) emissions are mainly contributing to total ecotoxicity impacts ranging from 93 to 99%. The rice system also shows the highest indirect impact of 70,332 PDF m^3 day/t caused by various herbicides (e.g., Alachlor (20%) and Acetochlor (20%)). The materials used in pesticide production can emit numerous toxic substances. Our study illustrates that direct emissions of pesticides are crucial to be considered in LCA due to the majority of total human health impact scores. Indirect emissions dominate the ecotoxicity impact results. The results can fluctuate depending on the underlying emission modelling approaches. Taking into account all direct and indirect emissions helps increase the accuracy of LCIA results.

5.05.P-We338 Ecosystem impacts of Bio-hybrid Fuels in the LCIA: Investigation of Current Model Integration

***Alexandra Sybertz*[1]**, *Martina Roß-Nickoll[2] and Miaomiao Du[2], (1)Institute for Environmental Research, RWTH Aachen University, Germany, (2)RWTH Aachen University, Germany*

Life Cycle Assessment (LCA) is an important method to estimate and compare the impacts of different substances in terms of their potential effects on humans and the environment. In the context of a complete life cycle assessment, we focus particularly on the LCIA phase. Special attention is paid to the consideration of possible impacts on the ecosystem. Initially, the objective is to obtain an adequate insight into the available LCIA models and to decide which model candidates could be used for further investigation in the next step. In addition to the general analysis, the most relevant models are compared in the context of a practical application. The characterisation factors for a bio-hybrid fuel candidate are calculated and compared in LCIA models, such as USEtox or ReCiPe. Furthermore, the models themselves and the assumptions integrated into them will be examined in more details. The aim is to investigate at a conceptual level about how to consider the impact of new potential fuel sources on the environment. In addition to data availability, the consideration of various environmentally relevant aspects will also be addressed. Overall goal is to find out which aspects of environmental effect assessment are already integrated and to what extent further aspects might need to be added into the calculated characterisation factors to sufficiently consider the potential environmental impacts. An appropriate model should be transparent and well documented. This investigation of the conceptual approach to estimate the potential impact on ecosystems is important to uncover data gaps in the LCA and to better predict the influence of a substance release on the quality of the environment in the future. This work is intended to provide an overview of the assumptions currently used to estimate the potential impacts on ecosystems.

5.06.A Prospective Life Cycle Assessment of Emerging Technologies

5.06.A.T-01 Prospective, Anticipatory and Ex-Ante – What's the Difference? Sorting Out Concepts for Time-Related LCA
Rickard Arvidsson[1]*, Björn Sandén*[2] *and Magdalena Svanström*[2]*, (1)Environmental Systems Analysis, Chalmers University of Technology, Sweden, (2)Chalmers University of Technology, Sweden*
Most life cycle assessment (LCA) studies have considered technologies as they are at the time of the study, often in a mature state. Increasingly, LCA studies attempt to assess emerging technologies in imagined states at future points in time, often referred to as prospective, anticipatory or ex-ante. However, a clear distinction between these LCA types is lacking. We aim to sort these concepts into a typology of time-related LCAs, contributing to more purposeful methodological choices. Existing frameworks for time-realted LCA types were reviewed and typology consisting of three dimensions was found to capture the most important differences. The first dimension is real time, which captures the time difference between the functional unit and the LCA. If the technology is modelled at approximately the same time as when the LCA is conducted, it can be called contemporary LCA. If the technology is modelled at a future point in time relative to the analysis, it can be called prospective LCA, and retrospective LCA if it is modelled at a past point in time relative to the study. Dynamic LCA accounts for that a technology can be "stretched out" along the real time dimension. The second dimension is technology maturity, which can be measured by technology readiness levels (TRLs). Ex-ante LCA considers technologies that are immature at the time of the study but model them in a future when they are assumed to have become mature, and is thus a specific type of prospective LCA. In contrast, ex-post LCA refers to studies of technologies that have reached maturity at the time of the study. Anticipatory LCA is effectively similar to ex-ante LCA but also entails the inclusion of numerous stakeholders in shaping the LCA study. Lab-scale LCA is a contemporary LCA of an immature technology with the aim of suggesting improvements to technology developers. The third dimension is causality. Some LCA studies mainly consider causes of a functional unit, which is often referred to as attributional LCA. Other LCA studies mainly consider effects of a functional unit, which can be called consequential LCA. While the former can be said to look backwards in time, the latter can be said to look forward in time from the perspective of the functional unit. Both types can, however, be retrospective, contemporary, or prospective LCAs as defined above. It is also possible to consider different types of causality, which relate differently to real time and technology maturity.

5.06.A.T-02 Prospective Life Cycle Assessments Of Chemicals: Improving Stoichiometry-based Methods
Tim Langhorst[1]*, Benedikt Winter*[2]*, Dennis Roskosch*[2] *and André Bardow*[2]*, (1)D-MAVT, ETH Zürich, Switzerland, (2)ETH Zürich, Switzerland*
Novel production pathways are key for the chemical industry to reach more circularity and reduce the global warming impact. To focus research and development efforts on those technologies offering the largest potential to reduce environmental impacts, prospective life cycle assessment (LCA) should be deployed already in the early stages of process development. However, the quality of input data determines the significance of the LCA results and limits their applicability to decision-making. Particularly for novel processes, knowledge is limited, forcing LCA practitioners to make assumptions and estimate missing inputs. Often, stoichiometry-based approaches are used to estimate missing chemical life cycle inventory data directly from the reaction equation. However, the accuracy of these approaches has not yet been evaluated for a wide range of chemical processes. Thus, no informed decision can be made on the best use of stoichiometry-based approaches.
In this study, we benchmark five stoichiometry-based estimation approaches with a newly derived set of 474 chemical life cycle inventories and derive suggestions for improvement. For this purpose, we compare the results of the estimation approaches to our benchmark data set. We calculate the prediction accuracy for the overall global warming impact, the global warming impact of the raw materials used, and of the process utilities. As a measure of prediction accuracy, we apply the cost estimate class system proposed by the Association for the Advancement of Cost Engineering (AACE).
Our results show that most estimation approaches underestimate the overall global warming impact for more than 70 % of all processes. As the prediction quality differs for raw materials and utilities, we identify the best-performing approach for estimating the global warming impact of raw materials and for the impact of the process energy utilities, respectively. Combining those two approaches increases the overall prediction accuracy from 73 % to 75 % in a worst-case energy scenario but from 76 % to 89 %, assuming the European grid mix.
Our results can be used to estimate more reliable inventories during research and development, improve background data, and inform decision-making by providing insights about the accuracy of the estimation approaches. As many chemical process inventories are not publicly available or roughly estimated using averaged proxies, the combined estimation approach can be applied to close these data gaps.

5.06.A.T-03 Prospective Life Cycle Assessment to Support Decision-making Issues: A Novel Methodological Framework
Federico Rossi*, Riccardo Basosi, Adalgisa Sinicropi and Maria Laura Parisi, University of Siena, Italy*
Prospective Life Cycle Assessment (P-LCA) is a methodology that can be used to predict the environmental impact of product systems, or as future-oriented decision-making supporting tool. P-LCA models are usually based on scenarios designed by combining the foreground parameters of the model. These scenarios can be cross-compared to take the most sustainable decision among a certain range of options. This paper presents an alternative approach that is not based on a comparative assessment, but on an optimization algorithm that identifies the most sustainable solution on a mathematical basis. This approach simplifies the

scenario definition by limiting the number of foreground parameters only to *externalities*, namely those parameters that are not affected by the choice of decision-makers. On the other hand, *internalities* represent those parameters on which decision-makers can have an influence. The optimal values of *internalities* are calculated with an optimization algorithm that minimizes the environmental impact of a product system. A set of constraints shall also be defined to include correlations between all the parameters of the model. This approach has been already used in a case study whose objective is planning the future sustainable development of the automotive batteries industry in Europe. The *externalities* of the model are i) the type of batteries imported from external producers, ii) the maximum annual growth of the batteries industry, iii) the batteries demand, and iv) the percentage of wastes repurposed in second-life stationary applications. The P-LCA model is developed with Activity-Browser and with a modified version of Ecoinvent 3.7 including background scenarios implemented with PREMISE. The optimization model is a Mixed Integer Linear Programming algorithm developed with Python. The model requires as inputs the environmental burdens of battery manufacturing and recycling per GWh calculated with P-LCA. The minimization constraints are the material flow analysis equations that express the correlations between the parameters as a function of time. The proposed approach determines what batteries shall be manufactured and recycled with temporal resolution and it calculates the optimal management of waste cells and secondary resources. As highlighted by the complexity of the results, these outcomes would have been hardly predicted with an *ex-ante* combination of the parameters of the model as in comparative scenario-based assessments.

5.06.A.T-04 Prospective Optimization of Production Systems in Global Supply Chains
*Fabian Lechtenberg[1], **Ioan-Robert Istrate**[2], Victor Tulus[2] and Gonzalo Guillén-Gosálbez[2], (1)Department of Chemical Engineering, Universitat Politècnica de Catalunya, Spain, (2)Department of Chemistry and Applied Biosciences, ETH Zürich, Switzerland*
Whether and to what degree emerging technologies could reduce environmental impacts depends on many choices along their supply chain. Life cycle inventory (LCI) databases depict a detailed process-based representation of products' supply chain with a relatively high technology and geospatial resolution. However, processes in LCI databases are connected in a pre-determined way, representing the current state of production systems. If the goal and scope extend the assessment task by asking for the best production system according to one or multiple objectives, this fixed LCI structure does not allow system-wide optimization via technology choices. Mathematical programming, on the other hand, can efficiently screen through the possible connections across the supply chain in order to determine the best configuration. While the combined use of life cycle assessment (LCA) and optimization has been proposed elsewhere, prior works focused on small systems where LCA data is typically included as cumulative impacts and/or inventory entries for the foreground system. Here, we present a Python-based framework that allows embedding complete LCI databases in optimization problems with the aim of exploiting the high technology and geospatial resolution of these databases, adding also a temporal resolution through the use of future scenarios generated by Integrated Assessment Models (IAM) via the premise package. In contrast to existing works, using the whole technosphere matrix rather than a truncated version also allows for choices at any point across the supply chain (i.e., electricity supplies, means of transportation, raw materials suppliers, etc.) as well as production regions. We demonstrate the capabilities of this framework through the global methanol production system. We find that currently only a handful of regions provide the necessary boundary conditions (e.g., low-carbon intensity of electricity grid and availability of CO_2 as feedstock) to produce environmentally favourable methanol via electrolytic routes. The production of grid-fuelled methanol becomes attractive in energy system decarbonization scenarios, but a decentralized production spread across most regions of the world is required to keep the stress on local electricity grids low.

5.06.P-Th374 Revisiting the Challenges of Ozone Depletion from a Prospective Life Cycle Assessment Perspective
***Anne E.M. van den Oever**[1], Daniele Costa[2] and Maarten Messagie[3], (1)ETEC, Vrije University Brussels, Belgium, (2)VITO, Belgium, (3)Vrije University Brussels, Belgium*
Several challenges for prospective life cycle assessment (LCA) related to each of the four phases of LCA have been identified by previous reviews. The strategies required to address these challenges are specific to each impact category. Currently, the main focus of prospective LCA research is the assessment of climate change. Still, there is a lack of understanding regarding the specific challenges of other impact categories, for example, the ozone depletion potential (ODP). Therefore, this work presents a review of recent studies regarding current ozone layer trends, future ozone layer modelling and characterization to define strategies for assessing the ODP in prospective LCA studies. In addition, a case study comparing different fertilizing practices is presented to demonstrate how these strategies could affect the results. It was found that the phase-out of ozone-depleting substances (ODS) due to the Montreal Protocol is currently not well represented in the ecoinvent database, resulting in large overestimations of the ODP by banned substances. These overestimations will be more important for prospective studies as the use of banned substances decreases. The review has also shown that, to date, anthropogenic N_2O emissions, instead of halocarbons, are the most important contributor to ozone depletion. However, the current standard characterization models for ozone depletion have not yet covered these emissions. In addition, several interlinkages with climate change were found. Based on these insights, recommendations are given for future work to improve the quality of inventory modelling and ODP impact assessment in prospective LCA. For example, strategies for N_2O characterization in prospective LCA will require geographical, temporal and scenario-based differentiation, as the ODP of N_2O depends on the atmospheric temperature, CO_2, CH_4 and chlorine levels. More generally, this work showcases the importance of analyzing the challenges of prospective LCA for each impact category individually and collectively, due to potential interlinkages.

5.06.P-Th375 Future Impacts of EV Battery Raw Materials
***Bernhard Steubing**, Leiden University, Institute of Environmental Sciences, Netherlands*

Battery electric vehicles are seen as a key technology to decarbonize the transport sector. Electric vehicle (EV) batteries are a key component of EVs and associated with considerable production related environmental impacts. These impacts are likely to considerable evolve in the future due to the energy transition, technological learning and improvements, and other factors. Within the HiQ-LCA project we are developing scenarios for future supply chains of virgin and secondary battery raw materials. The presented research will address, amongst others, the following research questions: How will future environmental impacts related to EV batteries and raw materials evolve? What are the most important drivers for improvements? The research is based on prospective life cycle inventory data generated within the project and uses prospective background LCI data to consider the energy transition and other important developments. We show that EV batteries and raw materials will have substantially reduced environmental impacts in the future, albeit not for all impact categories and not in all scenarios.

5.06.P-Th376 Approaches and Challenges of Assessing Future Environmental Impacts Associated with Metal Supply: A Systematic Review

Carina Harpprecht[1,2]*, Brenda Miranda Xicotencatl*[3]*, Sander van Nielen*[3]*, Marc van der Meide*[3]*, Chen Li*[3]*, Zhijie Li*[3] *and Bernhard Steubing*[3]*, (1)Department of Energy Systems Analysis, Deutsches Zentrum für Luft- und Raumfahrt e.V., Germany, (2)Leiden University, Netherlands, (3)Leiden University, Institute of Environmental Sciences, Netherlands*

Metals have an important role in the global economy. With the energy transition, the demand for many metals is expected to sharply increase in the future. Although many studies apply prospective LCA to assess future environmental impacts of metal supply, the methods have not yet converged to a common approach. This study aims to provide an overview of these studies and their approaches, following 2 research questions: *1. Which metals have been addressed by previous prospective LCA studies and what are their expected future supply impacts according to the identified studies? 2. What are the studied parameters of the metal supply chains, the applied scenario modelling approaches, and data sources used?*

We performed a systematic literature review to identify studies which assess future environmental impacts due to the supply of metals. This includes publications about absolute impacts of global metal demand, but also relative impacts assessed by comparative LCAs of emerging technologies. For these studies, we analysed both the results and the methods to integrate prospective elements in the LCA models focussing on the choice of parameters, background scenarios, data sources and modelling approaches.

The literature review yielded 40 papers. We found that the majority of publications investigate bulk metals like Cu, Fe and Al. Most studies investigate relative impacts (i.e. per kg metal produced). Fewer studies also address absolute impacts of the total future demand; however, these mostly agree that absolute environmental impacts associated with global metal demand are likely to increase. Moreover, the results show that the majority of studies assess CO_2 emissions, while other impacts are less often investigated.

Furthermore, we found that the parameters considered most frequently are future ore grades, recycling shares, and energy efficiency. Background scenarios were primarily energy scenarios, which were most often electricity scenarios from the integrated assessment model IMAGE. Background scenarios modelling other developments are less common. Overall, the review reveals a wide variety of parameter choices, scenario modelling approaches and data sources.

This study stresses the necessity to reduce environmental impacts of metal supply. Moreover, it highlights the need for guidelines for prospective LCA as well as for the documentation of modelling choices, LCI and scenario data to facilitate transparency and sharing of LCA scenarios in the community.

5.06.B Prospective Life Cycle Assessment of Emerging Technologies

5.06.B.T-01 Combining Ex-ante Life Cycle Assessment with Scenario-Discovery and Conditional Probabilities to Assist Decision-making under Distinct Degrees of Incertitude

Pierre Jouannais[1]*, Carlos Felipe Blanco*[2] *and Massimo Pizzol*[3]*, (1)Aalborg University, Denmark, (2)Leiden University, Institute of Environmental Sciences, Netherlands, (3)Planning, Aalborg University, Denmark*

In times of ecological emergency, prioritizing investments and allocation of scarce time and resources to specific technological directions is crucial. Ideally, prioritizing should be done before initiating uncertain exploration of novel directions. For instance, should we invest resources in looking for new microalgal compounds to enhance fish health in European aquaculture? Ex-ante LCA can assist such policy-making. However, providing estimates of environmental impacts at the very beginning of a technological exploration which is inherently chaotic comes with substantial degrees of incertitude.

While the ex-ante LCA community often addresses uncertainty in its models, theoretical advances within Post-Normal Science have highlighted the need to differentiate the different degrees of incertitude applying to models and data. In this context, “uncertainty” is a specific degree of incertitude characterized by the incapacity to propose reasonable probabilities for events. If the knowledge about the probabilities is sufficient, the incertitude belongs instead to the domain of risk. More than a semantic debate, the presentation of uncertainty as risk, as often done in ex-ante LCA, entails caveats and overconfidence in the decision-making process.

A way of dealing with parameters for which no distribution can be proposed is to assign values to them within what-if scenarios. A conditional probability of impact can therefore be expressed within these scenarios, as a projection of knowledge conditional to the realization of specific values for uncertain parameters. However, generating scenarios for early-stage developments is challenging and the risk of overlooking important potential configurations is high. Scenario-discovery is an alternative in which algorithms discover scenarios of interest for the decision makers by exploring the output space of a model. The decision makers can eventually focus on estimating the likelihood of the discovered scenarios only.

In our work, we combine ex-ante LCA with the distinction of degrees of Incertitude, conditional probability, and scenario-discovery in a case with substantial incertitude. We demonstrate the approach on a case in which policy-makers should decide whether resources should be invested in looking for new microalgal compounds to enhance fish health in European aquaculture.   th this work, we build a bridge between LCA and Post-normal Science concepts and methodologies to provide sound decision-making assistance.

5.06.B.T-02 A Procedure for Prospective Life Cycle Assessment in Materials Development – The Case of Carbon Fibre Composites

***Frida Hermansson**, Matty Janssen and Magdalena Svanström, Chalmers University of Technology, Sweden*

Life cycle assessment is a powerful tool for quantifying the environmental impacts of products and services and is an essential part of product development. It can, for example, be used to identify hotspots to find ways to keep environmental impacts as small as possible. Assessing a system under development requires a prospective approach. A problem in prospective life cycle assessment (pLCA) is, however, the lack of data, which can lead to inconclusive results. The prospective context, however, also implies that there is still room for process changes and improvements. This paper will present a work procedure for pLCA that was grown out of a multi-year project aimed at developing lignin-based carbon fibres for composites. The intention with this contribution is to provide practitioners guidance on how LCAs in early stages of material development can be handled.

When starting the project, there were no data available for the production of the fibres, still efforts needed to be made to identify hotspots in the life cycle of carbon fibre composites and to show the possible influence of transitioning to a lignin-based fibre, as well as to identify other important routes for decreasing the environmental impacts. The meta-analysis found that a shift to lignin and recycling could decrease the environmental impact of carbon fibre composites, but that this is heavily dependent on the allocation approach used.

To further explore the influence of the allocation approaches, two studies were performed: One for assessing the influence of allocation approaches to lignin production and one for assessing allocation approaches for recycling of composites. As the intention was to apply the allocation approaches in a pLCA, both studies included an assessment on how sensitive the approaches were to changes in, for example, prices. The outcome was that many allocation approaches are sensitive to the temporal settings of the study, in particular regarding demand and quality of the fibres.

When different technology routes and allocation approaches had been identified, the findings were applied in a case study of carbon fibre composites in road vehicles. The end-result, where carbon fibre composites reduced the vehicles' environmental impact in almost all futures, should be seen as an indication of the possible future environmental impacts of the system under study and can provide guidance to technology development.

5.06.B.T-03 Transforming Residual Biomass into Food and Feed – Conditions For an Environmental Success

***Ugo Javourez**[1], Ligia Tiruta-Barna[2], Massimo Pizzol[3] and Lorie Hamelin[4], (1)Toulouse Biotechnology Institute, INSA Toulouse, France, (2)INRAE / INSA Toulouse, France, (3)Planning, Aalborg University, Denmark, (4)Toulouse Biotechnology Institute, Université de Toulouse, France*

This study aims to assess the environmental relevance of "waste-to-nutrition" strategies, that is, strategies transforming residual biomass streams into edible ingredients. Albeit increasingly promoted, these approaches rely on emerging technologies, as showed by the lack of scaled primary data and the heterogeneity of reported lab/pilot-scale datasets. In turn, their future performances are strongly related to uncertain technological efficiency improvements. Therefore, the implications of deploying waste-to-nutrition pathways are poorly understood, and it remains uncertain to which extent these can generate environmental benefits compared to current residual biomass management practices.

We propose to fill this gap by introducing a comprehensive life cycle assessment (LCA) model paired with an advanced global sensitivity analysis (GSA) procedure enabling not only the cross-comparison of 27 different biomass management strategies (15 emerging waste-to-nutrition pathways and 12 conventional management pathways), but also to unravel the necessary conditions required to ensure their environmental success.

To this end, feedstock- and process-dependent parametric inventories were elaborated for each pathway, allowing to explore wide sets of technological performances and biomass compositions. Assumptions and modeling granularity were harmonized, and 293 independent technological parameters were documented. Paired simulations were performed simultaneously with the Morris method over the 27 biomass management pathways, screening the whole range of forecasted technological performances. Besides yielding common GSA results (e.g. sensitivity ratios), this strategy also provides the means to assess effects of individual (or sets of) key parameters on pathways ranking through statistical analysis. The possibilities offered by this LCA model are illustrated on a case study focusing on the french context, where the management of eleven representative local residual biomass streams is assessed. All simulated results were already obtained, but the analysis is still ongoing (conclusions to be delivered at the conference).

On top of proposing the first integrated environmental assessment of waste-to-nutrition strategies, this study also contributes to expand the prospective LCA toolbox by illustrating how the Morris method and statistical analysis can be combined to support decision-making on resource allocation or bioprocesses ecodesign.

5.06.B.T-04 Prospective LCA of Brown-seaweed-based Bioplastic: From Pilot To Industrial Scale

***Maddalen Ayala**[1], Neill Goosen[2], Leszek Michalak[3], Marianne Thomsen[4] and Massimo Pizzol[5], (1)Aalborg University, Denmark, (2)Department of Process Engineering, Faculty of Engineering, Stellenbosch University, South Africa, (3)SINTEF, Norway, (4)Department of Food Science, University of Copenhagen, Denmark, (5)Planning, Aalborg University, Denmark*

Seaweed is gaining momentum as a bioresource for different applications, such as food and feed processing, medical applications and bioplastics Seaweed-based bioplastic is considered an emerging technology from an LCA perspective. It is important to assess early-stage technological development to identify environmental hotspots. However, the data available for these emerging technologies is generally only available at a lab or pilot scale (TRL 4-7). Upscaling methods are needed to develop a life cycle inventory (LCI) for the prospective LCA at industrial scale. We use the consequential LCA approach to assess the impacts of increasing the demand for this novel bioplastic. In this work we upscale experimental lab- and pilot-scale data to 4000T/year. The model under assessment includes seaweed cultivation, seaweed biorefinery, film fabrication and end-of-life modelled as composting of the biodegradable film. We exemplify how various upscaling techniques are combined and utilized at various life cycle stages. The methods consist of a combination of qualitative and quantitative data to prepare for the upscaling of seaweed farming and the process simulations for biorefineries and film production. Namely, interviews for the seaweed cultivation and process simulations for the biorefinery and film fabrication. Seaweed experts were interviewed to anticipate the upscaling of seaweed cultivation and its limitations. The mass and energy flows resulting from the process technology simulation are used in the LCI. An uncertainty analysis will also be performed given the intrinsic uncertainties in emerging technologies. Regarding qualitative results, seaweed cultivation is expected to grow in the future. However, there are different limitations to consider when upscaling seaweed cultivation, such as the carrying capacity of ecosystems, the seaweed species, and the available technology. The preliminary results show a carbon footprint of 2,6 kg CO2 eq. at pilot scale. Although pilot-scale results might not represent the real impacts, they provide a glance of the potential impacts at the industrial scale.

5.06.B.T-05 The Environmental Sustainability of New Ways to Produce Benzene, Toluene, and Xylene

Emma Zuiderveen[1]*, Carla Caldeira*[2]*, T. Vries*[3]*, N. J. Schenk*[3]*, Mark Huijbregts*[4]*, Serenella Sala*[5]*, Steef Hanssen*[6] *and Rosalie van Zelm*[7]*, (1)Environmental science, Radboud University, Nijmegen & European Commission - Joint Research Centre, Netherlands, (2)EC JRC, Italy, (3)BioBTX, Netherlands, (4)Radboud University, Netherlands, (5)European Commission Joint Research Centre (JRC), Italy, (6)Radboud University Nijmegen, Netherlands, (7)Department of Environmental Science, Radboud Institute of Biological and Environmental Science, Radboud University, Netherlands*

The petrochemical industry is one of the world's largest industries and significantly contributes to greenhouse gas (GHG) emissions globally. Producing petrochemicals from renewable feedstock instead of fossil fuels may reduce these GHG emissions and lessen wider environmental impacts. For the aromatic petrochemicals benzene, toluene and xylene (BTX), several production routes have recently emerged that use alternative feedstocks, including biomass and plastic waste. However, a thorough understanding of the environmental impacts of BTX production via these routes, and how they compare against each other and against conventional, naphtha-based BTX production is missing. Here, we assess the environmental impacts of bio-based and mixed plastic waste-based BTX production at a commercial scale in 2022 and at industrial scale in 2050, as compared to conventional BTX production. We employ both a prospective LCA approach, as well as an absolute sustainability assessment using the planetary boundary concept (PB-LCIA) to provide recommendations towards more sustainable BTX production. This study shows the future potential to reduce GHG emissions deploying BTX production based on waste and renewable feedstock in combination with electrification of the processes and a renewable electricity mix, leading to GHG emission reductions up to almost 60%. However, even though the alternative BTX pathways reduce impacts, it does not necessarily mean they are environmentally friendly alternatives, as our research shows that impacts do not stay within the planetary boundaries. To further reduce the climate change impact of mixed plastic waste-based BTX production the release of its fossil-based carbon content should be limited. For bio-BTX production, lower impacts in biomass cultivation related impact categories are necessary to avoid trade-offs and could be achieved by switching to other biomass such as lignocellulosic waste streams. Nonetheless, this study implies that a future petrochemical industry producing aromatics from recycled and bio-based feedstock can lower environmental impacts to a large extent as compared to conventional, fossil-based feedstock.

5.06.P Prospective Life Cycle Assessment of Emerging Technologies

5.06.P-Th377 Choosing the Functional Unit of an Emerging Technology: The Case of Digital Tools in Agriculture

Clémence Huck[1,2]*, Thibault Salou*[2,3]*, Alexia Gobrecht*[3] *and Eleonore Loiseau*[2,3]*, (1)National Research Institute for Agriculture, Food and Environment, France, (2)Elsa, Research Group for Environmental Lifecycle & Sustainability Assessment, France, (3)ITAP, Univ Montpellier, Institut Agro, France*

There are strong expectations around the mobilisation of digital tools to support the transition to agricultural systems based on agroecology to reduce environmental impacts of food sector. Thus, digital tools are gradually being introduced into agriculture whether for data collection, data analysis or to support field action. As emerging technologies, there is a need in assessing the environmental impact of their use in the agricultural context. To date, little has been done.

Prospective Life Cycle Assessment (PLCA) is a way to assess environmental impacts of emerging technologies, which can have unknown consequences or use at the time they are designed. As a consequence, PLCA raises methodological issues regarding the different steps of LCA framework (goal and scope, inventory, impact assessment and interpretation). This work focusses on the goal and scope and more specifically on the choice of the functional unit (FU). The current practice in agri-food sector is to deal with FU related to mass of food or surface of cultivated areas. We carried a literature review on environmental impacts of digital tools in agriculture. None of the authors discussed the relevance of mass or area based FU for these systems, with no thoughts on the suitability between the function of the tool and the FU. This work aims at objectifying the choice of the FU given an agricultural digital tool.

We identified in the literature several classifications of agricultural digital tools, given their place in the data supply chain or the technology. However, none of these classifications were based on the function of the tools, which can make challenging the choice of the appropriate FU. We built a functional classification of agricultural digital tools and proposed associated relevant FU.

Functions were grouped into four sub-functions (time savings, variable rate application, money savings and ethic), each of them being linked to one or two FUs except for ethical sub-function. Indeed, this last sub-function remains difficult to quantify. There might also be missing functions given the huge amount of digital tools and their emergence.
This work designs a decision tree to frame and standardise the choice of the functional unit when applying PLCA to agricultural digital tools. It helps improving quality and comparability of LCA publications. More generally, this work is a first step towards a guideline for LCA applied to agricultural digital tools.

5.06.P-Th378 Early-Stage Decision-Support Tool for the Environmental Analysis of Chemicals Applied to Ethylene Synthesis

Hannah Minten[1], *Bart Vandegehuchte*[2], *Benjamin Jaumard*[3], *Christiane Reinert*[4] *and André Bardow*[4,5], *(1)Chair of Technical Thermodynamics, RWTH Aachen University, Germany, (2)TotalEnergies OneTech, Belgium, (3)TotalEnergies OneTech, France, (4)RWTH Aachen University, Institute of Technical Thermodynamics, Germany, (5)ETH Zürich, Switzerland*

In CO_2-based chemical process development, Life Cycle Assessment (LCA) studies are desired as early as possible to verify targeted global warming impact reductions and to avoid environmental burden-shifting. LCA studies are effortful and require expertise to ensure meaningful results, especially in early-stage LCA, when available data on processes is limited. With a shortage of LCA practitioners and plenty of chemical processes in development, companies need a way to quickly and effectively perform LCA of chemicals to provide environmental guidance.
We therefore present ESTIMATe (Early STage IMpact Assessment Tool), a publicly accessible Excel tool that enables chemists and chemical engineers to perform methodically robust early-stage LCA of CO_2-based chemicals.
For three of the most common goals in process development, we standardize LCA-methodologic assumptions and, thus, minimize the prior knowledge required from the user. The minimum required user input for data generation is the stoichiometric equation, from which ESTIMATe calculates the Life Cycle Inventory (LCI), scaled to the functional unit. The LCI can be adapted as data availability increases. To support data generation, ESTIMATe provides estimation methods recommended in the literature to close data gaps for the LCA of chemicals. ESTIMATe then calculates environmental impacts in multiple impact assessment methods while considering different decarbonization scenarios for the most relevant process inputs, such as reactants and utilities. Finally, the tool output includes figures showing contribution analyses, scenario analyses, and an overview of results in all impact categories according to the selected impact assessment methods.
We apply ESTIMATe for the example of CO_2-based methanol production with subsequent ethylene production in a methanol-to-olefins (MTO) process. In particular, we focus on how the ESTIMATe tool can contribute to process development at different levels of data availability and, in this way, lower the threshold for applying LCA in early development stages.

5.06.P-Th379 Prospective Life Cycle Assessment of a Smart Battery Cell

Daniele Costa[1], ***Maeva Lavigne Philippot***[2], *Maitane Berecibar*[2] *and Maarten Messagie*[2], *(1)VITO, Belgium, (2)Vrije University Brussels, Belgium*

The spatially resolved acoustic, mechanical, and ultrasonic sensing for smart batteries (SPARTACUS) project developed a prototype of a smart battery cell that uses sensors to detect degradation and failure mechanisms during the traction battery operation. This study presents the impacts on climate change (CC) of the SPARTACUS prototype compared to a state-of-the-art (SoA) battery cell based on a prospective life cycle assessment (LCA).
The system boundaries were cradle-to-gate, and the functional unit was 1 kWh of delivered energy. The prototype assembles 3 polyimide (PI) layers (PI#2, PI#3, and PI#4) on a commercial 12 Ah pouch cell. On PI#2 and PI#3, acoustic sensors are used to localize material changes. PI#2 also contains temperature sensors. On PI#4, rubber compression sensors detect mechanical stress and pressure distribution to monitor deformation. A cell management system (CMS) and a pre-processing (PP) board were also included.
The life cycle inventory considered primary data obtained on a lab scale. Two SoA battery cells were cycled for the use stage under the Worldwide Harmonised Light Vehicles Test Procedure (WLTP) cycles. The prototype is assumed to have a 20% higher cycle life. The life cycle impact assessment was conducted using IPCC GWP100a characterization factors. A superstructure prospective database was used. The prospective LCA assessed climate change impacts in 2030, with 2020 as the reference year. The storylines for the assessment were the SSP2-base and SSP2-RCP 2.6 (2°C climate target).
The CC impact of the prototype is at least 160% bigger than the SoA battery cell in all scenarios. The smart cell impact on CC was reduced from 2020 to 2030 in all scenarios. In all years and scenarios, the greatest contributor to CC originated in PI#4 (23% of the total contribution), followed by PI#2 and PI#3 (both accounting for 14% of the impacts). In 2030, in the more stringent scenario (RCP 2.6), the CC impacts of the prototype were reduced by 21%.
Despite its improved performance, the results showed greater impacts on CC for the prototype than the SoA battery cell. However, its impacts are likely to decrease in future scenarios. The next steps to reduce the impacts in the prototype manufacturing phase are identifying the necessary sensors, identifying the marginal impacts of each sensor layer on the use phase performance and assessing cell recyclability.

5.06.P-Th380 Prospective Life Cycle Assessment of Hemp Fiber Production Versus Conventional Glass Fiber Production

Hanie Zarafshani, *Ponnapat Watjanatepin and Karel Van Acker, KU Leuven, Belgium*

Although bioeconomy-related innovations may play a significant role in contributing to the support of a more circular and decarbonized economy, it is crucial to ensure that these technologies are bringing more benefits than burdens at an early stage of development. In addition, identifying and minimizing the trade-offs is essential to direct investment and technological developments toward a sustainable economy.

Assessing the environmental impacts of technologies and products at an early stage is a challenge and it is also true for biobased products.
Here, prospective life cycle assessment plays a significant role. Prospective LCA has become more prominent in the evaluation of the environmental impacts of developing technologies, although there are still some methodological issues with the integration of scale and time. To overcome the mentioned challenges, the scenario analysis was investigated as one significant method of performing the PLCA to address some of these challenges.
Scenario analysis looks at the future environmental impacts of technologies and their products. It assesses how technologies and their byproducts will affect the environment in the future. In addition, scenario analysis will be utilized to evaluate a variety of variables that affect the evolution of such processes.
In this study, the environmental performance of hemp fibre production was compared to glass fibre production at TRL 6 or 7 through an explorative scenario approach for the various pathways in the future (2030 and 2050) in Europe.
In this project, a combination of a causal loop diagram with an LCA flow chart aims at linking, in a visually explicit way, the technical parameters, comprehensive-picture surrounding parameters, and the LCI model itself.
Because the deployment of bio-based product technologies is affected by a variety of technological and socio-economic aspects, the creation of future scenarios in a transparent, consistent, and trustworthy manner has proven challenging.
To tackle these issues, a scenario analysis using the PESTEL method was carried out, taking into account numerous variables that affect the development of bio-based product processes, such as biomass availability, climate conditions, biomass feedstock availability, increase in technological performance or substitution of virgin wood for biomass feedstock.
Finally, the LCA results were calculated for the developed scenarios based on the future's background database.

5.06.P-Th381 Reinforced Polymers for Rotor Blades, With or Without Carbon Fiber? A Comparison Through Life Cycle Assessment
Alicia Maria Benitez Britos[1]*, Christina Wulf*[2]*, Wilhelm Kuckshinrichs*[2] *and Jutta Geldermann*[3]*, (1)IEK-STE, Forschungszentrum Jülich, Germany, (2)Forschungszentrum Jülich, Germany, (3)University of Duisburg-Essen, Germany*
Germany expects to become climate neutral, and scenarios foresee an expansion of offshore wind energy (OWE). Despite diverse pathways, scenarios describe a significant growth of OWE's cumulative installed capacity. Both Prognos CN 65 and CN 60 depict continuous growth over the years, whereas the Kopernikus basis scenario allocates OWE expansion after 2030. In addition, the nominal capacity of offshore wind turbines (OWTs) has risen considerably since their market launch, with learning rates between 8 and 19 %. Scenarios describe different cumulative capacity trajectories, in turn, different improvement rates over the years, for example, weight reduction paces (because processes become more efficient) or more effort in R&D. Vestas and Gamesa promise to produce OWT up to 15 MW but have opted remarkably different technologies. As for the rotors, Vestas made them of reinforced polymers (RP), and has increased rotor diameter by 5 % without weight gain by combining carbon fibre and glass fibre (CFRP/GFRP). Siemens made its rotors mainly of GFRP. While carbon fiber enables longer and more durable rotor blades, the material has a high environmental impact, e.g., 70 kg $CO_{2\text{-eq}}$/kg in comparsion to GFRP (3 kg $CO_{2\text{-eq}}$/kg). Ultimately, small quantities of carbon fiber could have a detrimental effect on the environment, especially if no measures are taken to improve its performance. This study performs a scenario based lify cylce assessment (LCA), compares 2 equivalent rotors (made of GFRP and GFRP/CFRP) and evaluates their impacts to climate change in 2030 and 2050. The study utilizes futurized version of ecoinvent 3.7.1 derived from Premise, combining improvement in both background and foreground systems. The study considers improvement over the years based on cumulative capacity trajectories given by German scenarios, escalates the weight into a 15 MW OWT (rotor 222 m), assumes both rotors – GFRP and GFRP/CFRP – weigh equally and calculates the amount of carbon fibre based on the strength-to-weight ratio of the materials. The annual electricity generation is 82 ± 8 GWh (GFRP rotors) and 84 ± 8 GWh (GFRP/CFRP rotors). Under the same conditions (i.e., location, hub height, distance, and operation speed), the study estimates that 5 % larger rotor diameter means 2 % more GWh per year. However, GFRP/CFRP rotors represent 60 % more emissions to climate change than GFRP rotors in 2030. Despite significant improvement in 2050, the difference is nearly 30 % more emissions.

5.06.P-Th382 Assessing a Novel Multifunctional Autonomous Vehicle Using Electricity Consumption as Functional Unit
Albert Jan van Zuilichem*, IWAR Stoffstrommanagement und Ressourcenwirtschaft, Technical University Darmstadt, Germany*
Inner-city mobility requires large amounts of land use. This is caused by parking and a large number of vehicles per capita. Another issue with inner-city mobility is a lot of traffic jams causing inefficient fuel use. Autonomous electric vehicles are able to resolve these challenges. By using a car-sharing system the amount of vehicles would drastically decrease which also frees up parking space. Using an autonomous system to connect each vehicle should reduce traffic jams due to smart braking. Furthermore, these vehicles will not only be used for person- and goods-transport but a plethora of functions, such as street cleaning and public park maintenance. The challenge in this case is the functional unit of this multifunctional system. For normal transport a functional unit can be '1 km of driving'. However, some functions do not require any mobility and are not included in this functional unit. Therefore, a functional unit has to be implemented which incorporates an interface between all functionalities. Because this multifunctional system is completely electric all of the functions require a certain amount of electricity. Consequently, to tackle the challenge of functional unit a change of perspective is proposed. Instead of looking at production or delivering of a certain function the functional unit focuses on the consumption, in this case the consumption of 1 kWh of electricity. The hypothetical functional unit will be 'the consumption of 1 kWh of electricity from the local grid to perform one of the possible functions'. This functional unit is expected to encompass all functionalities and normalize their impacts through a common denominator, the total amount of kWh consumed. Changing the perspective of the functional unit

towards a consumption point of view enables the interfacing of different functionalities of a product. This facilitates the assessment of other multifunctional products with Life Cycle Assessment.

5.06.P-Th383 How Will Large-Scale Manufacturing of MXenes Impact the Environment?

Ni Made Nindya Desivyana and ***Rickard Arvidsson****, Environmental Systems Analysis, Chalmers University of Technology, Sweden*

MXenes are two-dimensional advanced materials that have become an important focus of nanomaterials research since they were first created in 2011. MXenes can have a wide range of compositions – their formula is $M_{n+1}X_n$, where M is a transition metal (e.g., titanium or vanadium) and X is either carbon or nitrogen. The most widely studied MXene is Ti_3C_2, which has a high electric conductivity that enables a variety of potential applications, for instance as electrode material in batteries. However, Ti_3C_2 production is still restricted to laboratory syntheses, mainly by etching with hydrofluoric acid (HF). To date, no environmental assessment of its potential future production has been performed, neither at laboratory scale nor large scale. In this study, a prospective life cycle assessment (LCA) of large-scale manufacturing of Ti_3C_2 is performed in order to fill this knowledge gap. The goal of the study is to assess different Ti_3C_2 synthesis routes and pinpoint their environmental impacts with a particular emphasis on climate change, energy use, and mineral resource scarcity. This analysis also identifies the manufacturing process steps that have the largest impacts and provides recommendations on how impacts of large-scale production of Ti_3C_2 can be reduced. The LCA is a cradle-to-gate study with a functional unit of 1 kg of Ti_3C_2. Two routes for producing Ti_3C_2 are considered: the HF etching and the in-situ HF synthesis. The distinction between these two routes is that the first adds HF as an etching chemical, whereas the second does not add HF but instead forms it through reactions involving other chemicals. Data on synthesis procedures, material inputs, and energy requirements are obtained from state-of-the-art synthesis descriptions of Ti_3C_2 MXenes in the scientific literature as verified by technology experts in the field. These procedures are then scaled up using process calculations. The sensitivity to different parameters is tested in terms of future scenarios, including different future electricity mixes. Preliminary findings indicate that impacts are dominated by the production of the titanium powder, which constitutes the titanium input to the Ti_3C_2 production. This implies the need to investigate less impacting production routes for titanium to considerably reduce impacts of Ti_3C_2 MXenes.

5.06.P-Th384 Prospective Comparative Life Cycle Assessment of Ethylene Production Through Photoelectrochemistry Vs. Steam Cracking

Ivan Muñoz*, 2.-0 LCA consultants, Spain*

We present the lessons learned from applying LCA in the project LICROX (https://licrox.eu/), aiming to develop a low-TRL prototype for a photoelectrochemical cell (PEC) for converting sunlight, water and CO_2 into organic molecules, with special focus on ethylene. As part of the project, an LCA study was outsourced. The study was a cradle-to-gate, consequential LCA, where PEC-ethylene is compared to ethylene from steam cracking. As part of the LCA, a consequential model for steam cracking was developed. Execution of the LCA was done in 2 iterations: a 1st iteration to identify hotspots, and a 2nd iteration to refine the model. The study had to be put on hold for 1 year, to give the consortium more time to have a clearer definition of their new technology. Data collection and the life cycle inventory for the PEC technology was extremely challenging, due to a lack of data by the consortium on many aspects that an LCA needs to address. The consortium provided data on some of the PEC components, on the PEC manufacturing process and on the operation of a theoretical plant. A huge effort in gap filling was needed, including using data for a similar technology, using basic stoichiometry for the production process, literature on production of many different types of basic materials, as well as expert judgement. Interpretation of results with was mainly focused on GHG emissions. The results for steam cracking showed a relatively low footprint (0.2 kg CO2e/kg ethylene), as a result of adopting a consequential approach. The footprint of LICROX ethylene is higher (5.4 kg CO2e/kg), due to consumption of chemicals during plant operation, as well as due to the impact of infrastructure. An improvement analysis was performed to show the effects of different choices in the design of a hypothetical LICROX plant, or simply to test more optimistic assumptions. Four independent scenarios were tested, as well as a fifth one combining the previous four. The results of this improvement analysis were used to identify potential design choices as well as process variables that matter the most to improve this technology.The study has shown the importance of incorporating LCA expertise in project consortia, rather than have it outsourced. The LCA proved useful to the LICROX consortium to make them reflect on many aspects that might not be apparent to the technology designer, but which prove to be important to understand the environmental credentials of an emerging technology.

5.06.P-Th385 Prospective LCA of Four Climate Positive Technologies

Cristina-Maria Iordan[1]*, Shraddha Pankaj Mehta*[1]*, Simon Roussanaly*[2]*, Rahul Anantharaman*[2]*, Richard Blom*[2]*, Jorunn Skjermo*[2]*, Luca Riboldi*[2] *and Sara Andrenacci*[2]*, (1)Climate and Environment, SINTEF, Norway, (2)SINTEF, Norway*

Most scenarios targeting to limit an increase in global temperatures to 1.5°C above pre-industrial levels, include in their proposed pathways a mix of solutions among which the removal of greenhouse gases from the atmosphere. This project targets developing and maturing promising technologies that remove and permanently store CO_2 and other greenhouse gases from the atmosphere thus generating negative emissions. The four climate-positive solutions investigated in this project are: direct capture of CO_2 from seawater, direct capture CO_2 from air, conversion of biomass into hydrogen and /or heat, and methane removal from air. For all four pathways the last step will be the permanent storage offshore in the Norwegian continental shelf. For the biomass conversion, there are two pathways investigated: farming of algae and biomass from waste flows.

To determine their true potential for net negative emissions, a framework with system boundary which includes all upstream and downstream emissions is essential. Thus, we will apply the “cradle-to-grave approach” from life-cycle assessment methodology to each of these different technologies to evaluate the potential environmental impacts and assess their individual potential for net negative emissions. In addition, since these are emerging technologies, the LCA shall help to identify the most critical parameters for further technological optimization in addition to highlighting potential alternatives for the choice of processes, energy sources, optimal location of sites, materials as well as end of life treatments. Each of these technologies has a different value chain with distinct processes, but we aim to develop a framework which enable fair assessment and comparison of their performances. Thus, we will investigate the use of a common functional unit for all these climate-positive technologies (1 ton of $CO_{2\text{-eq.}}$ removed and stored). In addition, we will address the issue of upscaling these technologies and thus we will qualitatively investigate the requirements and potential impacts.

5.06.P-Th386 Ready-made Composite LCA Inventory Development For High-volume Production of a Drone Frame
Juliana Steinbach[1] *and Sinead Mitchell*[2]*, (1)Mechanical Engineering, University of Galway, Ireland, (2)Management, University of Galway, Ireland*
The design and manufacture of the next generation of delivery drones is complex and material choice is multifaceted due to the different characteristics of the available alternatives. Carbon fibre composites are the most suited material to fabricate drone frames due to its mechanical properties and low weight. Carbon fibre can be combined with thermoplastic or thermoset resins to create a composite. The key advantage to manufacturing composites using thermosetting resins is the low viscosity required to impregnate the fibre preforms. The disadvantages of thermoset resins include a limited shelf life, longer cure times, among others. On the other hand, the challenges with thermoplastic resins are that they are solid at room temperature and require high temperatures and pressures to consolidate the composite due to their high viscosity in molten state.
The most common methodology to assess the environmental impacts of a drone airframe production is the Life Cycle Assessment (LCA). To create an inventory for the assessment data is collected from the materials and processes involved in the manufacturing of the composite part. A large volume production requires manufactures to rely on ready-made composite sheets from other producers. This circumstance adds a layer of uncertainty into the assessment as little information about composite sheet production is disclosed by the producers besides what can be found in datasheets. The production of pre-impregnated sheets (prepregs) using thermoplastics as matrix and carbon fibre as reinforcement has been modelled using data available in the literature and adaptations from the Ecoinvent database. The same was done to the production of organo sheets (Pre-consolidated reinforced thermoplastic laminates - RTL) and thermoset prepreg.
This work will present the methodology developed to bypass the lack of available information regarding carbon fibre composite sheets for high volume production to enable a comparative LCA study between thermoplastics and thermoset alternatives. The result has shed light into the absence of data to assess large scale composite parts production based on the current available base material (prepreg and RTL). Moreover, information about the data available in the database has also been tricky to work with as some of the process for polymers are described as “plastic” transformation with little information about its operational parameters.

5.06.P-Th387 Comparative LCA Study for Assessing the Potential Environmental Benefit of a Photocatalytic in Relation to a Conventional Paint
Thanasis Karagkounis[1]*, Evangelia Fragkou*[2]*, Fotios Barmpas*[2] *and Nicolas Moussiopoulos*[2]*, (1)Department of Mechanical Engineering, Sustainability Engineering Laboratory, Aristotle University of Thessaloniki, Greece, (2)Sustainability Engineering Laboratory, Mechanical Engineering, Aristotle University of Thessaloniki, Greece*
The Life Cycle Analysis (LCA) presented in this study is undertaken in the LIFE VISIONS project and aims to compare the environmental impacts for selected impact categories related to the paint sector, between a conventional paint and the innovative photocatalytic paint with TiO_2 nanoparticles, which was developed in the frame of the project. The photocatalytic paint promotes indoor air quality improvement by degrading NOx and VOCs air pollution, as well as reducing energy consumption by lowering ventilation needs. As the scope of the study is a comparative evaluation of the total environmental impact of the two paint products, the system includes both the manufacturing and the application phases. Therefore, the boundaries are set from cradle to grave to include the paint application and end-of-life processes, while incorporating the cradle to factory-gate for taking into account the secondary data related to the manufacturing line. For this purpose, paint production data (composition, energy and water consumption) for both conventional and photocatalytic paint were provided by the Greek paint industry involved in the project and used as primary input data to create the inventory. In addition, regarding the photocatalytic paint, two different databases were applied in combination with a process modelling approach in order to fill the data gaps related to the materials required for the synthesis of the photocatalytic TiO_2 nanoparticles. Particularly, for the application phase, data were additionally collected from real scale case studies. The resulting environmental impacts were calculated for a number of different application conditions for the purpose of investigating the hypothesis of the comparative sustainability advantage of the photocatalytic product. Regarding the results, the process contribution analysis highlighted the use of ammonia solution as the main cause for the higher environmental impact of the photocatalytic compared to the conventional paint in the manufacturing phase. However, this is outweighed by the environmental advantage of the photocatalytic product when including the application phase, due to the energy savings in the rooms/buildings painted.

5.06.P-Th388 Prospective LCA on the Design of New Refractories for a Greener Steelmaking Process
Sarah Badioli[1,2]*, Thibault Champion*[3]*, Léna Roumiguier*[3]*, Marielle Dargaud*[3] *and Angélique Léonard*[4]*, (1)University of Liege, Belgium, (2)Chemical Engineering, University of Liege - Chemical Engineering, Belgium, (3)Saint-Gobain Research Provence, France, (4)PEPs, Laboratory of Chemical Engineering, Department of Applied Chemistry, University of Liège, Belgium*
Being one of the most energy-intensive industries, steel manufacturing is among the most challenging sectors to decarbonise. This

project aims to describe and quantify possible innovative green steelmaking processes through a comprehensive approach, with a focus on new refractory materials and their impact on the process.
Steel is essential to our society, and its usage has grown dramatically in recent decades, with an increase of annual global production of crude steel from 850 Mt in 2000, to 1869 Mt in 2019. In 2019, the building and infrastructure sector is the first steel user, followed by the mechanical equipment, transport and metal products sectors. Iron and steel industry has a considerable environmental impact, especially related to energy consumption, greenhouse gas emissions, resource depletion and water pollution. Therefore, sustainable production of iron and steel is a huge hard task, essential to preserve our environment.
To face the challenge, this study analyses the impact of new refractory materials on the global environmental burden generated by the steelmaking process. In the first phase, strategies to reduce the impact of new refractory materials are evaluated, by optimizing production routes and raw material sourcing. In the second phase, the usage of these new refractories in steelmaking is investigated, by the quantification of how the change of their properties can impact on the overall environmental footprint. Moreover, to further improve the sustainability of the process, the EAF (Electric Arc Furnace) has been chosen as the core of the steelmaking, and the recycle of refractories is under discussion. For both the phases, the key interest methodology LCA has been chosen to quantify the global environmental footprint.
The relevance of the study relies in the comprehensive and complex approach to the green steel problem, taking advantage of the well-known tool LCA to promote a joint and prospective vision of the product over its entire lifecycle, to address both to the refractory producers and the steel industry. Moreover, the direct collaboration with the two production sectors will allow to obtain a big quantity of real data for the inventory creation. The result of the study should give a powerful tool to renovate steel-making processes, by providing alternative production routes that are not so far from the reality and that could be easily implemented, helping to reach the “green targets” in the short and medium term.

5.06.P-Th389 Comparability of Emerging Technologies at Different Stages of Development Regarding LCIA Scores Using the Example of a New Recycling Technology for PET-Containing Waste

Hannes Schneider[1]*, Mandy Paschetag*[2] *and Stephan Scholl*[2]*, (1)Chem. u. Therm. Verfahrenstechnik, Technical University Braunschweig, Germany, (2)Technical University Braunschweig, Germany*

The ongoing climate change forces the chemical industry for drastic steps to reduce its CO_2 emissions. Circular Economy, especially the recycling of plastics is an import part for reaching this goal, but not all plastic waste can be recycled today and new recycling technologies needs to be developed. In order to legitimate the substitution of conventional, highly optimized and established technologies with new technologies which are not yet as well known, their ecological benefit needs to be proven. This makes it necessary to accompany the development of new technologies with a consistent and transparent ecological assessment in order to meet the requirements of an alternative and sustainable circular economy for plastics. Those prospective LCAs aims to assess the impact of emerging technologies in industrial scale and addresses the problem of the different technology readiness levels (TRL) of the processes routes which needs to be compared.
A detailed prospective cradle-to-gate assessment is carried out for the newly developed recycling process revolPET. revolPET is a Back-to-Monomer recycling (BMR) process for recovering terephthalic acid (TA) and ethylene glycol (EG) from PET containing waste streams, e.g., polyester textiles or opaque or multi-layer packaging. As this is an emerging technology, the current state of development is not direct comparable to the established fossil-based production routes of the monomers. For this reasons, different methods are used for data acquisition, intending representativeness of the future industrial scale and scenarios are presented for some possible technical solutions of not yet implemented process tasks. The influence of the technology readiness level as well as possible process optimization methods are quantified and discussed.
For a better understanding of the uncertainty caused by the state of development, the foreground flows are classified according to the data sources and the state of implementation of the individual unit operations. This quantitative assessment of the result leads to a more accurate comparability with alternative production or recycling routes, taking into account the stage of development and data availability.

5.06.P-Th390 LCA of Phosphorus Recovery from Dairy Wastewater for Fertilisers

Marta Behjat*, Magdalena Svanström and Gregory Peters, Chalmers University of Technology, Sweden*

Phosphorus (P) is a finite, non-renewable mineral resource that is used primarily in fertiliser production. The scarcity and the increasing demand for this finite material led the European Commission to include this resource in the critical raw material list in 2014. Therefore, considering its importance and its limited availability, an alternative to using mineral phosphate for fertiliser production is required. The interest in the development of technologies with regard to nutrient recovery from organic waste streams has increased in recent years, and a potential input waste stream for these technologies is dairy wastewater (DWW). This contribution reports on the use of life cycle assessment (LCA) to analyse the life cycle environmental impacts of different scenarios for P products recovery from DWW, and the use of the P products as fertilisers in agriculture. The assessment of these emerging technologies was done with prospective LCA, studying the technologies in early stages of development but modelling them as more developed in the future. The assessed scenarios include combinations of different DWW treatments, conventional and innovative, emerging P recovery processes, and agricultural activities. The recovery processes use liquid by-products obtained from the wastewater or sludge treatment processes to produce products rich in P. The preliminary results suggest that the addition of P recovery technologies to the DWW treatment with required modifications will not increase the global warming potential or cumulative energy demand much and that those technologies recovering P from the liquid phase will result in lower impacts than those that recover from sludge.

5.06.P-Th391 The Relevance of Early-stage Carbon Footprinting in Sustainable Product Design: The Case of Paper-based Printed Electronics

Akshat Sudheshwar[1], *Valerio Beni*[2], *Nadia Malinverno*[1], *Roland Hischier*[1] *and Claudia Som*[1], *(1)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)RISE Research Institute of Sweden, Sweden*

Novel printed electronics are projected to grow and be manufactured in the future in large volumes. In many applications, printed electronics are envisaged as sustainable alternatives to conventional (printed circuit board-based) electronics. One such application is in the semi-quantitative drug detection and point-of-care device called 'GREENSENSE' that uses paper-based printed electronics. This assessment analyses the carbon footprint of GREENSENSE to identify and suggest means of mitigating disproportionately high environmental impacts, labelled 'sustainability hotspots', from materials and processes used during the pilot- and lab-scale production which would be relevant in high-volume applications.
Firstly, a life cycle model traces the flow of raw materials (such as paper, cellulose nanocrystals, and nanosilver) through the three 'umbrella' processes (circuit printing, component mounting, and biofunctionalization) manufacturing different electronic components (the substrate, conductive inks, energy sources, display, etc.) that are further assembled into GREENSENSE. Based on the life cycle model, life cycle inventories are modelled that map out the network of material and energy flow throughout the production of GREENSENSE. Finally, from the environmental impact and sustainability hotspot analysis, both crystalline nanocellulose and nanosilver were found to create material hotspots and they should be replaced in favor of lower-impact materials. Process hotspots are created by manual, lab-, and pilot-scale processes with unoptimized material consumption, energy use, and waste generation; automated and industrial-scale manufacturing can mitigate such process hotspots. This assessment illustrates how prospective environmental impact assessment of novel technologies can serve as an early warning tool for material scientists and product developers, thereby informing sustainable product design.

5.06.V Prospective Life Cycle Assessment of Emerging Technologies

5.06.V-01 Comparative Evaluation of DACCS Technologies Considering Location and Energy Sources Using LIME3

Hayato Suzuki *and Norihiro Itsubo, Tokyo City University, Japan*

The AR6WG3 stated that the introduction of Negative Emission Technologies (NETs), which directly remove CO_2 from the atmosphere, is essential to achieve a carbon-neutral society by 2050. Research studies on NETs show that in addition to the benefits of carbon removal, there are also disadvantages to ecosystems and capital goods. This study analyzes the environmental impact of carbon removal, land use change, resource consumption, and water consumption of two technologies, Direct Air Carbon Capture and Storage (DACCS) and Bioenergy Carbon Capture and Storage (BECCS), which are expected to be implemented after 2050 for reasons of CO2 removal and external cost. The results of the analysis of environmental impacts and the calculation of external costs associated with these environmental impacts will be presented in this study. For DACCS, the analysis is based on multiple scenarios for two technologies, solvent-based and adsorbent-based, considering electricity and heat sources for each location. In the calculations, a meta-analysis was performed for DACCS and BECCS to collect background data; for DACCS, the analysis was based on existing literature data collected. Secondary data was utilized due to the difficulty of collecting primary data. Multiple scenarios were then simulated and evaluated. For BECCS, the Palm Kernel Shell in Malaysia derived land modification impacts were assumed for power generation. The value conversion of environmental impacts was performed using the integration factor in LIME3, an LCIA method developed by Itsubo et al. This method quantifies the importance of protecting each damage in monetary units by analyzing the additional tax expenditures required to reduce them when human or ecological damage occurs. The results of the analysis showed that in BECCS, the external cost per ton carbon removed was 15 to 200 times higher than in DACCS, with land alteration from plantations as the major factor. The DACCS was a major factor in the external costs derived from land use change impact by implementation of photovoltaics. For future studies and research, DACCS should be further evaluated in detail and expressed in terms of environmental advantages/disadvantages of the target technologies in the form of value conversion, so that these technologies in the carbon removal price study.

5.06.V-02 Multiple Functional Units' Selection in Prospective LCA for Better Representation of Emerging Technologies in Materials Science: A Case Study of Supercapacitors

Ahmad Kamal Kamali *and Guido Sonnemann, University of Bordeaux, France*

Conducting a life cycle assessment (LCA) on emerging technologies of complex multi-functional nature presents novel challenges in the functional unit selection process. In opposition to incumbent technologies with a determined application that benefit from a straightforward selection of functional units, allowing for seamless comparison between product systems. Therefore, prospective LCAs should adopt multiple functional units whenever possible to improve their comprehensiveness, transparency, and utility. Thus, offering a viable extension of the conventional functional units (e.g., mass, pieces) that may not clearly represent technologies' actual application. In this manner, various application scenarios are explored predicting the technology performance under different conditions, which allows technology developers to take an informative decision. Supercapacitors (SCs) act as an ideal case study, given their intermediary location on the energy density versus power density chart. SCs exhibit competitive performance with mainstream and established devices such as capacitors and batteries in terms of both power and energy density. Moreover, the measurement of these two properties involves another parameter which is discharge current density, changing the discharge current density impacts the value of energy and power density substantially. As the discharge current density value emulates working conditions such as the application's energy requirement, it is also worthy to consider it in the life cycle impact assessment results.
Benchmarking three SCs enabled by either aqueous electrolytes or an ionic liquid based on power and energy density at 1 and 2 A/g discharge current density resulted in interesting conclusions. Aqueous electrolytes powered SCs emitted up to 60 times more

CO_2-eq compared to SCs powered by an ionic liquid, this trend was more prominent when increasing the current density to 2 A/g. On the other hand, ionic liquid enabled SCs had 2-10 times lower environmental impacts across all categories when compared based on power density at 1 A/g. In contrast, increasing the current density to 2 A/g narrows the gap between these supercapacitors to the point where an aqueous electrolyte based SC became environmentally advantageous in two midpoint indicators, namely terrestrial acidification and terrestrial ecotoxicity. This case study proves that functional unit selection can substantially impact LCIA results and prospective LCAs conclusions.

5.06.V-03 Combined Technico-Economic Analysis and Life Cycle Assessment of Microalgae Production as Alternative Feedstuff

***Melanie Douziech**, Mariluz Bagnoud, Alexandra Baumeyer Brahier and Gerard Gaillard, Agroscope, Switzerland*

Agriculture and particularly animal husbandry exert environmental pressures. Feed concentrates are one driver of the environmental impacts of meat production, calling for more environmentally friendly alternatives. In this context, microalgae are gaining attention. While studies on microalgae as alternative biofuel exist in literature, evaluating their economic and environmental sustainability as alternative feedstuff brings along a new set of questions. What is the realistic application of the product? What is the reference system to compare the product to? How should the future state of the technology be represented and can its future economic profitability be evaluated? These questions will be addressed first by implementing a combined technico-economic analysis (TEA) and life cycle assessment (LCA). The system under study includes the microalgae production in the bioreactor and the bioprocessing to the final feed. An LCA model will be programed in Python using Brightway2 and lca_algebraic packages based on literature and from laboratory-specific information. The inventory flows expected to change with time will be parameterized to ease the environmental assessment of a potential technology scale-up. Each parameter will be assigned a laboratory-scale value, ideally taken from measurements, an industrial-scale value, relying on scale-up relationships and expert judgments, and a probability distribution function (pdf) to represent the range of these future states. The TEA model will rely on simple process-based relationships coupled with economic values. Here too, parameters will describe the economic flows and their values correspond to the three levels mentioned. Monte Carlo simulations relying on the pdfs will provide ranges of future environmental and economic impacts. Microalgae is often presented as a substitute for the soya bean part of the animal diet, implying that it has similar nutritional properties. Soya bean is a major supply source of the amino acid lysin, has a high protein content, and shows a good digestibility. Evaluating in a second step whether microalgae fulfill or surpass all these requirements and how they can be embedded in animal diets, will help to define the bioprocessing step and the reference system. This research will discuss methodological questions around the comparability of future and current feedstuff and provide insights into the environmental and economic sustainability of microalgae as alternative feedstuff.

5.07 Reducing Plastics Impacts: Integrating Risk Assessment, Life Cycle Analysis and Material Flow Analysis Towards a Circular Economy

5.07.P-Mo363 Modelling the EU Plastic Flows Towards a Circular Plastic Value Chain: Approaches, Data Sources and Hotspots

***Andrea Martino Amadei**[1], Lucia Rigamonti[2] and Serenella Sala[3], (1)Mexico, (2)Politecnico di Milano, Italy, (3)European Commission Joint Research Centre, Italy*

As understood by the European Union (EU) Plastics Strategy, plastics is currently managed in way that leads to severe environmental impacts limiting a “circular” plastic value chain. Several other EU policies actions have been put forward to address the plastic challenge, striving for a circular plastic value chain and dealing with the benefits of an improved plastic recycling system. Material Flow Analysis (MFA) is commonly employed in literature to model plastic flows. MFA are commonly developed adopting a top-down approach or a bottom-up approach, with different results due to the underpinning assumptions and data limitations. This study aimed at establishing a top-down MFA model for the whole value chain of plastics in the EU27 for the year 2019, focusing on 9 sectors and 10 polymers. The assessment shed light on the main data gaps and inconsistencies concerning available data and it provided estimates for less explored sectors, such as the textiles and clothing, healthcare, and fishing. Estimates indicate that 4.46Mt of plastic recyclates are produced and consumed in the EU27 territory. On average, the EU27 recycling rate was equal to 19%. Total plastic losses amounted to 4% of the total plastic production, mostly occurring in the use phase. Scenarios for the year 2025 were prepared by following expected trends in the plastic value chain and industry targets (e.g., the EU target of 8.8Mt of recycled plastic consumed in EU27 by 2025). Only when multiple actions are combined (i.e., improved waste collection, interventions on mismanaged waste, etc.) the 8.8Mt target could be achieved, with results ranging from 9.11Mt to 11.13Mt of recyclates consumed by EU plastic converters. Results underline that to fulfil the EU ambitions and industry targets, significant efforts are needed to further improve the granularity and details of plastic flows in the EU. Such enhancements could include better sector-specific and polymer-specific data for less explored sectors, coupled with in-depth knowledge of recyclates’ fate, and both losses and mismanaged waste flows. Considering these key commitments for actions at the EU level, an improvement and rethinking of the plastic value chain is mandatory and should be driven by an up-to-date knowledge of all its many hotspots.

5.07.P-Mo364 The United States Federal Plan to Address Microfiber Pollution

***Carlie E. Herring**[1], Krystle Moody Wood[2], Carolynn Box[2], Romell Nandi[3], Gabriella Neusner[4] and Nizanna Bathersfield[3], (1)NOAA Marine Debris Program, (2)Materevolve, (3)USEPA Trash Free Waters Program, (4)U.S. EPA, Office of Ground Water and Drinking Water*

Due to growing concerns over the presence and persistence of microfiber pollution in the environment as well as their potential ecological and human health impacts, the United States Congress mandated that the Interagency Marine Debris Coordinating Committee (IMDCC) develop a Report on Microfiber Pollution. Under Section 132 of the Save Our Seas 2.0 Act of 2020 (P.L. 116-224), the Report on Microfiber Pollution must include: (1) a definition of microfiber; (2) an assessment of the sources, prevalence, and causes of microfiber pollution; (3) a recommendation for a standardized methodology to measure and estimate the prevalence of microfiber pollution; (4) recommendations for reducing microfiber pollution; and (5) a plan for how Federal agencies, in partnership with other stakeholders, can lead on opportunities to reduce microfiber pollution during the 5-year period beginning on such date of enactment. This Report on Microfiber Pollution provides an overview of this issue and efforts completed to date, and the Federal Plan further outlines priority actions to be implemented over the next five years. Through a series of federal agency workshops, a questionnaire, and feedback from experts in the field (in the form of an Expert Advisory Committee composed of representatives from relevant academic, government, and industry sectors), a Federal Plan was drafted to begin mitigating microfiber pollution. This five-year plan focuses on addressing microfiber pollution from production stages (textile manufacturing and production), through use stages (everyday use, fiber mitigation opportunities via filtration devices), and disposal stages. Public feedback on the Report on Microfiber Pollution was solicited during a 30-day public comment period allowing anyone to provide feedback on the report and draft Federal Plan. The Federal Plan will prioritize research needs to further understand the impacts associated with microfibers, engage cross-governmental agencies and cross-sector stakeholders to address this issue, and evaluate solutions to address microfiber pollution from textiles and non-textile sources alike. This presentation will discuss a multi-pronged approach to research, prevent, and drive solutions and mitigation measures for one prominent type of marine debris, microfiber pollution.

5.07.P-Mo368 Self-reinforced Polylactic Acid (SR-PLA) is More Resistant to Releasing Microplastic than Polypropylene (PP) after UV Irradiance

***Zhiyue Niu**[1,2], Ana I Catarino[3], Maelenn Le Gall[4], Marco Curto[5], Elke Demeyer[6], Jana Asselman[2], Colin Janssen[7], Hom Dhakal[5], Peter Davies[4] and Gert Everaert[8], (1)VLIZ, Belgium, (2)Blue Growth Research Lab, Ghent University, Belgium, (3)Flanders Marine Institute, Belgium, (4)IFREMER, France, (5)University of Portsmouth, United Kingdom, (6)Centexbel, Belgium, (7)Laboratory for Environmental Toxicology (GhEnToxLab), Ghent University, Belgium, (8)Ocean & Human health, Flanders Marine Institute, Belgium*

The over-dependence on petroleum-based polymers has led to a series of environmental issues, including the occurrence and persistence of microplastic (MP), in the global ocean. Polymers made from a natural-sourced feedstock, known as bio-based polymers, are hypothesized to be more sustainable alternatives. However, our knowledge remains limited about their degradation and fate in the marine environment. Plastic debris in the marine environment is known to break down to smaller sizes and release MPs under ultraviolet (UV) radiation. A number of studies have provided evidence of the release of MP from larger debris under UV radiation in laboratory conditions, observed via weight loss, changes in average particle size and SEM observations. However, the most direct and quantitative evidence of MP formation, i.e. observation, identification and enumeration of MPs formed after UV radiation, is limited. Until now, only a few studies have assessed the weathering of bio-based polymers and their capacity to form MPs. Here, we aim to assess the MP formation of a bio-based polymer, self-reinforced polylactic acid (SR-PLA), and a petroleum-based polymer, polypropylene (PP), during weathering by UV radiation. To do so, we exposed 3D printed cylinders (surface area=4.7 cm^2) of SR-PLA and PP, immersed in filtered natural seawater, to accelerated UV radiation for 57 and 76 days, simulating 18 and 24 months of mean natural solar irradiance in Europe. Dark controls (i.e. sealed vials from UV, n=6) were incubated in the same conditions for the same duration. To identify, characterise and quantify the formed MPs, we used a combination of fluorescent microscopy, infrared technology (μFT-IR) and image analysis. The average concentration of released SR-PLA MPs (≥50μm) per surface area was 3.9 ± 2.0#/cm^2 in UV exposures and 1.6 ± 0.8#/cm^2 in dark controls. For PP, this was 53.4 ± 46.3#/cm^2 and 0.9 ± 0.9#/cm^2, respectively. For both polymers, higher MP concentrations were found after 76 day UV radiation ($p<0.05$, Dunnett's test) compared to samples kept in dark. The PP cylinders released significantly more MPs than SR-PLA after UV exposure ($p<0.05$, Dunnett's test), indicating that the bio-based polymer SR-PLA is more resistant to releasing MPs than the petroleum-based polymer PP after UV irradiance. We anticipate that our results will contribute to assessing the sustainability of future bio-based polymers and to informing a transition process to more sustainable plastic materials.

5.07.T-01 Mass Flow Analyses and Emissions of Microplastic and Bisphenols From Waste Electronical and Electric Equipment Plastic (WEEEP) in Norway

***Mari Engvig Løseth**[1], Heidi Knutsen[2], Gabriela Castro Varela[3], Alexandros G. Asimakopoulos[3], Sarah Elizabeth Hale[4] and Hans Peter Arp[5], (1)Environmental Chemistry, Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian Geotechnical Institute, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway, (4)Norwegian Geotechnical Institute (NGI), Norway, (5)Norwegian Geotechnical Institute and Norwegian University of Science and Technology (NTNU), Norway*

Waste of electrical and electronic equipment (WEEE) is one of the fastest growing waste streams in the EU. Approximately 20% of WEEE is plastic (WEEEP). Increased recycling of WEEEP is beneficial to reduce virgin plastic production and environmental emissions of microplastics (MPs) from landfills. In Norway, WEEEP is mainly sent to material recycling, however, certain fractions are challenging to handle and recycle as their toxic components pose a substantial threat to the environmental and human health. Plastic containing brominated flame retardants (BFRs) is mainly incinerated. However, recent reports show that increasing amounts are being recycled in Norway, indicating that regrettable recycling of BFRs in plastic may be occurring. Cables are one of most plastic rich WEEE items, often containing up to 50 % polyvinylchloride (PVC), as well as high concentrations of toxic plasticizers like bisphenols to prolong flexibility and lifespan. In Norway, cable plastic is mainly landfilled despite this being the least preferred option of waste management in a circular economy. WEEEP, especially cable and BFR-plastic, have high concentrations bisphenols. The landfilling of WEEEP, such as cable plastic, may thus lead to increased emissions of MPs and

BPs, by dust emissions to atmosphere or leachate to surface and ground water. We present a mass flow analysis (MFA) of BPs and MPs in WEEEP, with focus on BFR- and cable plastic in Norway between 2018 and 2020. Our MFA shows that landfilling of 4 900 tonnes cable plastic resulted in annual accumulation of over 300 kg of BPs, this is predicted to lead to environmental emissions of 50 kg bisphenols and over 5 kg of MPs from landfills. Incineration and thermal destruction efficiently remove 200 kg of bisphenols from the WEEEP MFA, however recycling of 20 000 tonnes of non- BFR- or cable plastic may have contributed to 200 kg bisphenols transferred to plastic recyclates. As such, the present study emphazise a need for improvement of the waste management of WEEEP by reducing landfilling of cable plastic, and tracking the WEEEP recyclates to avoid its use in food packaging or products for vulnerable groups. Some of these issues can be effectively resolved by increased safe and sustainable design of electric and electronic products, through avoiding problematic polymers like PVC and hazardous substances like bisphenols.

5.07.T-02 Towards Including Microplastics in LCA: Effect Factors for Microplastics and Tire Wear Particles for Soil Ecotoxicity

Merve Tunali[1]*, Bernd Nowack*[2] *and Roland Hischier*[2]*, (1)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (2)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Even though the main emphasis on microplastic (MP) pollution is on aquatic environments so far, the MP abundance in soils is expected to be 4 to 23 times higher than in oceans. In addition, emissions to soils were estimated to be 40 times higher than to surface water in Switzerland alone. Even though the number of studies which investigate the effects of MPs on soil organisms is increasing, there is still a crucial gap in quantifying the effects of MPs on soil ecosystems. Thus, it is not yet possible to assess the environmental sustainability of microplastic-producing products, processes, or systems. To fill this gap, the integration of MPs into Life Cycle Assessment (LCA) tools has a crucial importance. For this purpose, the first effect factors of MPs, and tire particles for soil ecotoxicity were derived in this study. A database of soil ecotoxocity studies with micrioplastics was collected from the scientific literature. Ecotoxicity data regarding plants and invertebrates such as earthworms and springtails were collected to include different relevant ecological levels. This hazard dataset with studies published until June 2022 was used to build probabilistic species sensitivity distributions that uses uncertainty factors to transform acute experimental data to chronic data, and different type of dose descriptors to $EC10_{eq.}$ Highest observed no-effect concentration data points were excluded from the MPs database, while they were included in the tire particle database due to the lack of data. Effect factors were then calculated based on the hazardous concentration affecting 20% of the species. Results showed that the hazard data set includes 48 and 18 data points for MPs and tire particles representing 17 and 8 different species, respectively. The mean value of the effect factors for MPs was found to be 0.55 PAF kg/g, while it was much smaller for tire particles with 40.34 PAF kg/g. The effect factors of MPs and tire particles calculated in this study provide the first data towards including MPs and tires into LCA studies for soil toxicity. Full characterization factors to assess the impacts of MP related products, or processes are urgently needed to reveal the effects on soil ecotoxicity, and to support decision-making processes. A further update of the data set should be developed by excluding HONEC values, especially for tire particles once more ecotoxicity values are available in the literature.

5.07.T-03 Life Cycle Inventory and Environmental Fate of Tire-Wear Particle and Textile Washing Microfiber in Japan

Amila Abeynayaka[1,2] *and Norihiro Itsubo*[1]*, (1)Tokyo City University, Japan, (2)Institute for Global Environmental Strategies, Japan*

Full life cycle impacts of plastics (and substitutes) consideration is mandatory to achieve sustainable solutions to end plastic pollution. This requires considerations of fossil-based and biobased feedstocks for plastic production, plastic chemicals, and additives, plastic degradation pathways and intermediates, environmental impacts, ecotoxicological and human health effects, socio-economic costs, etc. Life Cycle Assessment (LCA) is a tool to assess life cycle impacts. However, the present LCA methodological approaches have limitations in including the impacts of microplastics in the LCA. This impact integration into LCA needs both the life cycle inventory (LCI) and life cycle impact assessment methods developments. Tire-wear particles (TWP) and synthetic textile microfiber (TMF) are estimated to be 1.41 and 0.26 million tons/year. The present study estimated TWP and TMF emissions at the prefectural level and 10 km grid level in Japan for six vehicle classes, developed a fate model based on drainage and wastewater treatment systems (WWTPs) in Japan and estimated the fate factors (FF) for several compartments. TWP emissions per unit distance of travel by different vehicle classes have been estimated for Japan. A WWTPs model was developed (ArcGIS) based on the features (treatment level and capacity, location) of the centralized 2114 units and decentralized treatment systems. The TWP and TMF fate in several compartments were estimated using the developed WWTPs model. Estimated TWP emissions for motorcycles and heavy vehicles were 111 to 1664 g/life-of-tire respectively. The total TWP emission for Japan in the year 2019 was 33,796 T/year. The TWP and TMF emission LCIs were obtained for the prefectural and 10 km grid levels (data not given). There are significant differences among the prefectures on the emissions per unit population (and unit GDP). The percentage of combined sewer coverage and WWTPs coverage are the governing parameters for the TWP and TMF FFs to water in Japan respectively. Even though the urbanized prefectures (i.e., Tokyo) emit more TWP the FFs to water become lower (0.23). On the other hand, prefectures like Hokkaido, where the road network is spread over a large area and has less combined sewer coverage, the FFs become higher (0.92). However, in the case of TMF, the FFs in water are correlated with the WWTPs coverage. Further, the FFs of land are dependent on the WWTPs' sludge management practices (data not given).

5.07.T-04 Integrating Ecotoxicological Effects Caused by Additives on Aquatic Species into Life Cycle Impact Assessment

Naiara Machado Casagrande[1,2]*, Carla Ofélia Silva*[3]*, Francesca Verones*[4]*, Paula Sobral*[2] *and Graça Martinho*[2]*, (1)Environmental and Sustainability, NOVA School of Science and Technology, Portugal, (2)MARE - Marine and Environmental Sciences Centre | ARNET - Aquatic Research Network Associate Laboratory, NOVA School of Science and Technology,*

University of Lisbon, Portugal, (3)FCT-NOVA, Caparica, Portugal, (4)Norwegian University of Science & Technology (NTNU), Norway
Additive substances applied in the plastic industries leach from plastic litter and may lead to exposure to aquatic biota. The ingestion of these substances potentially cause lethal or sub-lethal toxic impacts . Currently, LCA lacks environmental indicators to assess the physical and chemical impacts caused by plastic pollution in the entire plastic value chain. Substantial research is ongoing to improve the plastic pollution impact assessment within life cycle impact assessment. We aim to contribute to this effort and present here the effect factors for six groups of additives composed of different chemical substances. The groups of additives which are derived from the EF are Alkylphenols, Bisphenols, Benzophenones, Brominated flame-retardants, Chlorinated phenols, and Phosphates. Their functions in the plastic material are stabilizers, plasticizers, pesticides, flame-retardants, and biocides. Data on the dose-response relationship for laboratory-derived toxicity were gathered for different additive substances tested in the aquatic individuals. After compilation, the additives were classified into the broader groups of chemical categories. Subsequently, we analysed and processed the dose-response data collected to derived species sensitivity distributions for different individual groups of additives and then derive Effect Factors (EF), using $EF = 0.5/(HC50_{EC50})$,. Comparing the dose-response relationship, the higher toxic to the aquatic species are presented by Alkylphenols, followed by Brominated flame retardants and Phthalates. The effect factors provide information on chemical stressors related to the plastic additives on aquatic species of at least three trophic levels. This information is an important advancement for the characterisation factor for aquatic ecotoxicity in Life cycle impact assessment. Advances on this topic contributes to the plastic life cycle assessment which can provide information for stakeholders in decision-making processes as well as guide policies for the application of additives aiming to make the plastic value chain more sustainable.

5.07.P Reducing Plastics Impacts: Integrating Risk Assessment, Life Cycle Analysis and Material Flow Analysis Towards a Circular Economy

5.07.P-Mo365 A Guide for LCA Modelling of Plastics for Safe, Sustainable, and Circular Transition Planning

Heather Margaret Logan[1]*, Steven De Meester*[2]*, Steffen Foss Hansen*[3]*, Alexis Laurent*[3] *and Anders Damgaard*[3]*, (1)ENV, Technical University of Denmark, Denmark, (2)Ghent University, Belgium, (3)Technical University of Denmark, Denmark*
Used in products, packaging, and medical devices, plastics are pervasive in our daily lives. Yet poor design, remiss waste management planning, inadequate recycling capabilities, and negligent usage have led to unsustainable plastic systems, resulting in detrimental environmental and human health impacts. The transition to a circular plastics future is essential for maximizing resource utilization, addressing the plastic accumulation challenges, and maximizing the use and potential of plastics. Today, transition planning and innovative design are supported through Life Cycle Analysis, which assess the impacts of existing systems or forecast the potential impacts of prospective futures.
However, the usefulness and accuracy of Life Cycle Assessments (LCA) are determined by the data and modelling choices used. Recent reviews have found that more than half of the LCAS on plastics in recycling scenarios are incorrectly modelled, as they are failing to transparently account for plastic additives. The impact of LCAs failing to account for additive composition of the plastics, means they miss opportunities to assess the risks of downcycling, degradation, and contamination in circular systems and may be missing human health and environmental impact hotspots. Furthermore, the datasets available for modelling plastics do not account for all the processes needed to accurately model the impacts of plastic production and recycling systems. How then can LCAs inform transitions to circular scenarios or accurately evaluate the impacts of proposed solutions if the baseline is not adequately modelled to create consistent and representative models of plastic systems?
This research aims to address this challenge by proposing a methodological approach for modelling plastic production and recycling systems to better account for the human and environmental impacts for the various processes, flows, and flowables needed for plastic systems. These approaches aide practitioners in modelling variations in the composition of plastics. This methodology proposes modelling approaches for use with major LCA software and databases to create an accurate base for plastic assessments which can then be modified to better represent the variability of plastic compositions. The proposal of this methodology and case studies demonstrates the consistency of the baseline approach and sets flexible framework which can be adjusted based on the chosen modeling methodology.

5.07.P-Mo366 Global Human Health Effects of Plastic Waste Reduction Strategies: A Hybrid Material Flow Analysis and Life Cycle Assessment Framework

Megan Deeney[1]*, Lorie Hamelin*[2]*, Claire Vialle*[3]*, Xiaoyu Yan*[4]*, Rosemary Green*[5]*, Joe Yates*[5] *and Suneetha Kadiyala*[5]*, (1)LSHTM, United Kingdom, (2)Toulouse Biotechnology Institute, Université de Toulouse, France, (3)University of Toulouse, Laboratoire de Chimie Agro-industrielle (LCA), INRAE, France, (4)University of Exeter, United Kingdom, (5)London School of Hygiene & Tropical Medicine, United Kingdom*
Global initiatives are attempting to reimagine linear economies of plastics. Human health impacts across the plastic life cycle are a growing concern but quantification of effects remains scarce. This evidence is critical to ensuring policies for plastic waste reduction maximise co-benefits and mitigate any trade-offs for human health. Using a hybrid Material Flow Analysis (MFA) and Life Cycle Assessment (LCA) approach, our study quantitatively estimates and compares the Disability-Adjusted Life Years (DALYs) associated with the entire plastic life cycle under different policy scenarios between 2016-2040. We build on an existing well-acknowledged MFA, the Plastics-to-Ocean (P_2O) model, that tests the influence of globally implemented waste reduction and circular economy strategies on marine pollution between 2016-2040. P_2O provides data for the mass of plastics for each scenario, for each year, and for each life cycle stage of the global MFA system. Our study uses this data paired with LCA to estimate global health impacts by (i) generating modular unitary building blocks representing the DALYs (and related midpoint

impacts) associated with 1 million metric tonnes of plastic polymers for each process and (ii) combining building blocks to represent each policy scenario. Using industry reports, we estimate specific polymer shares equivalent to the categories of plastic products described in P_2O. We conduct the LCA in Simapro 9.3, with data from Ecoinvent database 3.8 (cut-off) and published literature, using ReCiPe 2016 impact assessment methodology. In Stata 17 software, we combine yearly mass flows for each policy scenario with LCA impact assessment results for each building block. Final analyses compare DALYs between policy scenarios, considering the relative contributions of midpoint impacts. Analyses are ongoing, preliminary results suggest that P_2O policy scenarios reducing virgin plastic production and open burning could provide the greatest co-benefits for health, with possible trade-offs associated with mechanical recycling. Climate change, air pollution and toxicity contribute most to health impacts, whilst data and methodologies to assess macro and microplastic pollution health effects are lacking. Our study will provide a critical analysis of health co-benefits and trade-offs of global plastic waste reduction strategies, generating an interdisciplinary framework that can be extended with emerging research across sustainability concerns.

5.07.P-Mo367 Linking Material Flow Analysis with Plastic Related Impacts: How to Make Progress with What We Know
Valentina Helen Pauna[1]*, Simon Alexander Saxegård*[2]*, Mafalda Silva*[1] *and Cecilia Askham*[1]*, (1)NORSUS AS, Medemblik, Norway, (2)Karlstad University, Norway*
The emission of micro- and nanoplastics (MNPs), its diverse pathways and fate in various ecosystems make the MNP problem a compelling topic in numerous research areas. Furthermore, the MNP discipline continues to rapidly evolve and develop. Therefore, the scientific research regarding the environmental impacts of plastic pollution faces challenges with respect to severe knowledge and data gaps because of the need to quickly develop methods for analyzing MNPs from different perspectives. To address data gaps and link differing perspectives, several international and interdisciplinary initiatives have been underway to bring experts in areas such as mass flow analysis (MFA), risk assessment (RA), ecotoxicology, toxicology, and life cycle impact assessment (LCIA) together to establish data guidelines and to harmonize the efforts of data generators. Our current work aims to use tools, like MFA, to extract relevant information from existing MNP data and link these data to LCIA. In addition, we aim to include new and emerging data that has fulfilled the criterion of our data guidelines, such that they can be used to understand MNP impacts associated with specific product commodities. Some specific cases that will be included are geotextiles, mulch film, slow-release fertilizer, and dolly ropes. This approach could allow us to progress in LCIA and inform stakeholders of possible risks, while also leaving room to include more detailed and accurate data as it is made available.

5.07.P-Mo369 Wash Cycle Design Can Reduce Microplastic Emission from Home Laundry
Shreyas Patankar, *Stephanie Wang, Kevin Landrini, Anneka Vanderpas and Charlie Cox, Ocean Wise Conservation Association, Canada*
Home laundry is a major source of microplastic pollution and is endangering ocean health and, potentially, human health. Globally, the rate of microfibers being released to the ocean is estimated to be around 40,000 tonnes per year, and microfibers of textile origin have been found to be pervasive in even the most pristine environments, such as the Arctic Ocean. To address this pressing concern, we investigate whether adjustments to wash conditions can help to reduce microfiber shedding during home laundry. Building on prior research that studied microfiber shedding variation between different textile materials and constructions, we conducted a series of experiments to systematically measure microfiber shed rates during different wash conditions. Over one hundred washes were conducted using loads of polyester jerseys weighing approximately two kilograms, representative of the weight of a typical consumer laundry load. We found that low intensity wash conditions - generally described as 'gentle' cycles - can reduce microfiber shedding by approximately 70%. Further research is needed to determine the specific relationship between laundry washes and the microscopic breaking and release of microfibers that generates shedding – with a view towards balancing laundry wash quality standards and reduction of microfiber shedding. Future research into life cycle analysis is also needed to understand whether reduction in home laundry microfiber shedding results in increased lifetime of consumer textiles, hence resulting in a net long-term reduction of microfiber pollution in the ocean.

5.07.P-Mo370 Biodegradable Microplastics: How Do Copolymer Blends Fragment and Biodegrade in the Environment?
Patrizia Pfohl[1]*, Markus Rückel*[1]*, Lars Meyer*[1]*, Glauco Battagliarin*[1]*, Patrick Bolduan*[1]*, Thorsten Huffer*[2]*, Michael Zumstein*[2]*, Thilo Hofmann*[2] *and Wendel Wohlleben*[1]*, (1)BASF SE, Germany, (2)University of Vienna, Austria*
For specific applications, biodegradable polymers can serve as an ecologically friendly alternative to conventional polymers, because the microbial oxidation and hydrolysis in the environment constitute a circular process that transforms polymer carbon into biomass and CO_2. For several biodegradable polymers this is shown by monitoring the CO_2 evolution and disintegration over biodegradation time. Here we additionally show that fragmentation is part of the biodegradation process and formed secondary fragments are further biodegraded, not leaving persistent microplastics behind. We apply sensitive microplastic-specific methods to test this hypothesis.
Biodegradation of polymers is not homogeneous, even under standardized conditions. Since biodegradable polymers are often blends, the degradation of the components might differ, e.g. due to variations in the chemical structure, crystallinity and microbial colonization. For a specific biodegradable blend (relevant for food packaging) we found that even the product shape (cryomilled particles, shredded foils, coated paper) influenced fragmentation. This blend consisted of polylactic acid (PLA, susceptible to hydrolysis) and aliphatic-aromatic ester copolymers (e.g. PBAT, susceptible to enzymatic cleavage). To gain a mechanistic understanding of copolymer blend biodegradation we studied fragmentation and biodegradation of several biodegradable copolymer blends under industrial composting conditions (ISO 14855) and compared them against the non-blended polymer matrix. With our previously reported efficient and non-destructive particle extraction processes and μ-Raman as well as

fluorescence microscopy we were able to monitor fragment number, shape, size, and identity during biodegradation. In addition, we used Soxhlet extraction to assess not only the solid polymer, but also the hydrolysed fraction.
The combination of these methods allows to compare fragmentation mechanisms of different copolymer blends and helps to answer the question, if persistent microplastic is accumulated because of biodegradation of these materials. For the investigated case studies, we found that intermittently, up to 0.0012% of the polymer mass were fragments < 25 µm, but at 90% CO_2, less than 10^{-10}. This means that biodegradation of the polymer blends led first to fragmentation, but the previously formed fragments can further degrade until completely transformed into CO_2 and biomass without accumulation of persistent microplastic.

5.07.P-Mo371 Estimation of Emission and Transfer of Microplastics to Tokyo Bay, Japan by Material Flow Analysis
***Kyoko Ono**[1], Wataru Naito[2], Mianqiang Xue[3], Kiyotaka Tsunemi[3] and Isamu Ogura[3], (1)Research Institute of Science for Safety and Sustainability (RISS), National Institute of Advanced Industrial Science and Technology (AIST), Japan, (2)RISS, Natil Inst of Advanced Industrial Science and Technology (AIST), Japan, (3)National Institute of Advanced Industrial Science and Technology (AIST), Japan*
To reduce the discharge of microplastics (MP) into the aquatic environment, it is necessary to properly identify the source. Since it has been pointed out that there were limitations in identifying the sources of MP by observation and measurement, it is considered effective to identify the major source by a material flow analysis approach. The approach is based on reported data of the use or production amount and their estimated emission factor to the environment.
We focused specific sources of MP; i.e. personal care products (PCP), fiber from clothes and tire wearing particle (TWP), for which we could obtain reliable data of use and emission. We estimated potential emission to Tokyo Bay as 10, 38 and 1800 t/year for PCP, fiber and TWP, respectively. These estimated values included uncertainty, so we applied uncertainty analysis using Monte Carlo simulation to reveal range of variation. Also we estimated the amount of transfer to Tokyo Bay assuming deposition and diffusion parameters of the particles.

Track 6: Environmental Policy, Risk Management, and Science Communication

6.01 Advances in Understanding of the Fate and Toxicity of Metals and Metal Mixtures, and its Application in the Regulation of Metals in the Environment

6.01.P-We340 Nickel in the North: Evaluating Nickel Risks Under Arctic-Specific Exposure Scenarios
***Connor B. Stewart**[1], Robert Griffin[2], Hannah Lowes[2], Patrick Gauthier[2], Emily Rogevich Garman[3], Christian E. Schlekat[3], Elizabeth Traudt Middleton[3], Daniel Alessi[2], Anne Cremazy[4] and Tamzin A. Blewett[2], (1)Biological Sciences, University of Alberta, Canada, (2)University of Alberta, Canada, (3)NiPERA Inc., (4)Institut National de la Recherche Scientifique (INRS), Canada*
Nickel (Ni) is an economically and biologically important trace metal, but due to increased demand globally, environmental contamination may arise. The Arctic is not isolated from these impacts, with substantial Ni production in Northern zones leading to contamination of surrounding environments, with global warming increasing accessibility of reserves and thus risk of continued contamination. Many Arctic freshwaters are predicted to have high Ni bioavailability and thus toxic risk due to their abiotic composition (hardness, pH, dissolved organic carbon), while heterogeneity in marine waters may lead to site-specific increases in bioavailability. Freshwater Ni bioavailability and risk under Arctic exposure scenarios will be evaluated with both acute and chronic Ni exposures in the Arctic relevant cladoceran *Daphnia pulex*. This study will evaluate Ni toxicity in waters that mimic Arctic chemical parameters (i.e., hardness, pH), and will evaluate how altered temperature may modify sensitivity. Incorporation of both lethal and sublethal endpoints will allow for assessment of both overt toxicological effects and the mechanism of toxic action (MOA) in *D. pulex* under Arctic exposure scenarios. Alteration of a single hardness ion (magnesium or calcium) to Arctic observed levels reduced 48-hour median lethal concentrations for *D. pulex* neonates from 4.90 mg/L in control waters to 3.76 mg/L and 1.57 mg/L, respectively. Simultaneous modification of multiple parameters (hardness, pH, temperature) will more accurately mimic Arctic waters and is predicted to further increase Ni toxicity compared to single parameter modifications. Nickel risk in Arctic marine waters will be evaluated using the Arctic green sea urchin (S*trongylocentrotus droebachiensis).* S. *droebachiensis* embryos will be assayed for developmental delays, as well as indicators of Ni MOA under Arctic-relevant exposure scenarios. This will allow for comparison with temperate testing which shows S. *droebachiensis* embryos are highly sensitive to Ni contamination, with a 96-hour effect concentration (EC_{50}) of 1.38 µg/L for induction of developmental abnormalities. These results taken together will provide insight into the mechanism and extent of Ni toxicity under Arctic-specific exposure scenarios for both fresh and marine waters, furthering the understanding of the potential risks of Ni in these unique ecosystems.

6.01.T-01 Chronic Metal Mixture Toxicity: Quantitative Reappraisal and Identifications of Data Gaps
***Charlotte Nys**[1], Karel Viaene[2], Koen Oorts[1], Marnix Vangheluwe[1], Violaine Verougstraete[3], Hugo Waeterschoot[4] and Karel De Schamphelaere[5], (1)ARCHE Consulting, Belgium, (2)ARCHE, (3)Eurometaux, Belgium, (4)Chemicals Management, Eurometaux, Belgium, (5)Ghent University - GhEnToxLab, Belgium*
In the Chemicals Strategy for Sustainability, the EU Commission calls to systematically integrate the issue of combined exposure into chemical risk assessments. Hence, there is a need to provide scientific evidence on metal mixture effects as input to the discussions on how to tackle the issue of exposure to unintentional mixtures of naturally occurring substances, like metals and inorganics. The current research builds further on a recently published meta-analysis of mixture effects of Cd, Cu, Ni, Pb and Zn to aquatic organisms at the species-level, but expands the quantitative reappraisal to a broader set of metals.

The quantitative reappraisal aimed to answer the following 3 questions: Q1: Which mixture reference model, either Concentration Addition (CA) or Independent Action (IA), is most accurate for predicting chronic metal mixture toxicity at the species level; Q2: How frequently do significant deviations from the mixture reference models, CA and IA, occur; Q3: How accurate is CA for predicting mixture effects at low effect concentrations? To answer these questions, a literature study was performed to identify relevant recent studies (>2007) and the identified (mixture) concentration response data were analysed in a systematic manner.
In total, 30 chronic metal mixture studies were identified, covering 24 species and 14 metals in 33 combinations. It was shown that CA results in more conservative predictions compared to IA. However, metal mixture toxicity to invertebrates is most accurately predicted by IA, while there are no clear differences between the models for algae. Most experiments showed non-interactive effects or antagonistic effects, while significant synergisms were less frequently observed, certainly when evaluated relative to CA. CA overestimated mixture toxicity at low effect levels (i.e., 10% mixture effect) by 1.3-fold (median value). The present study largely confirmed the findings from the earlier study that considered fewer metals.
Within the current study the following main data gaps were identified: no high-quality data on vertebrates or on mixtures with anionic metals were identified. In addition, more complex mixtures combining 4 or more metals have also been rarely tested. The results of the current study can contribute to the scientific discussions on the implementation of combined exposure into environmental risk assessment (e.g. by possibly refining the) and will also help to prioritize further experimental efforts.

6.01.T-02 Using Bioavailability to Characterise Risks in European Freshwaters; The Example of Copper
***Iain A Wilson*[1]*, Adam Peters[1], Graham Merrington[1] and Stijn Baken[2], (1)wca environment Ltd., United Kingdom, (2)European Copper Institute, Belgium*
Copper is as a naturally occurring essential trace element, that has been regulated in numerous jurisdictions through the use of concentration thresholds. The understanding of the behaviour, fate and ecotoxicity of copper has evolved in the last 20 years, with the concept of bioavailability being now broadly accepted. Despite this, assessments on the exposures of copper have continued to be performed based solely on the dissolved copper concentration. A dataset covering over 17,000 sites in Europe was collated, including bioavailability correction parameters pH, DOC and dissolved Ca. The dataset was used to assess the risk of copper in European freshwaters, with or without consideration of bioavailability. The data was assessed using a variety of compliance metrics used by agencies in Europe, and the conclusions were compared.
When bioavailability is not accounted for, it appears that there is a potential risk to freshwaters across the European continent. This is based on the number of countries with greater than 5 % of sites exhibiting exceedances; the spatial, temporal and extent of exceedances (STE score), and the 95th percentile of the calculated risk quotients (RQ). In contrast, when the assessment is performed on the bioavailable concentration of copper none of the three examined metrics indicates a widespread risk.
This assessment, therefore, shows that if bioavailable concentrations are not utilised in a risk assessment the extent, and magnitude, of the risk of copper to freshwaters in Europe can be significantly overestimated. This overestimation may lead to incorrect decisions being made with respect to copper, and potentially other metals, and lead to policies being applied that are not proportional to the risk associated with the substance. It was noted during the assessment that significantly less sites (and samples) could be assessed accounting for bioavailability (77,617 sites compared to 286,185), with the majority of sites that cannot be further assessed being due to a lack of supporting parameters. Therefore, additional focus should be placed on obtaining the required information to be able to assess the maximum number of sites appropriately following available guidance, prior to any policy making decisions are applied.

6.01.T-03 Development of a Machine Learning Model to Estimate the Biotic Ligand Model-based Predicted No-effect Concentrations for Copper In Freshwater
***Jiwoong Chung*[1]*, Geonwoo Yoo[1], Jinhee Choi[2], Jae-Seong Jo[1] and Jong-Hyeon Lee[3], (1)EH Research & Consulting, Korea, (2)School of Environmental Engineering, University of Seoul, Seoul, Korea, (3)Magok-dong, Korea*
The copper biotic ligand model (BLM) has been used for ecological risk assessment by taking into account the bioavailability of copper in freshwater. The copper BLMs requires many water quality data such as pH, major cation, dissolved organic carbon. It is not easy to get all of these variables in the water quality monitoring programs. It is, therefore, needed to develop an optimized estimator of PNEC based on BLM. To develop the optimized PNEC estimation model based on an available monitoring dataset, an initial model that considers all BLM variables, a second model that requires variables excluding alkalinity, and a third model using electrical conductivity as a surrogate of the major cations and alkalinity have been proposed. Furthermore, deep neural network (DNN) models have been used to predict the nonlinear relationships between the PNEC (outcome variable) and the required input variables (explanatory variables). The predictive capacity of DNN models was compared with the results of other existing PNEC estimation tools using a look-up table, multiple linear and multivariate polynomial regression methods. Three DNN models, using different input variables, provided better predictions of the copper PNECs compared with the existing tools for four test datasets, i.e., Korean, United States, Swedish, and Belgian freshwaters. Consequently, it is expected that the copper BLM-based risk assessment can be applied to various monitoring data sets, as the most applicable model among the three DNN models can be selected according to the data availability of the collected monitoring database.

6.01.T-04 Air-Water Cross-Contamination by Metalliferous Atmospheric Particulate Matter, Fish Metal Toxicodynamics and Human Health Risk for Its Consumption
***Marisa Narciso Fernandes**, Univeridade Federal de Sao Carlos, Brazil*
Seattleable atmospheric particulate matter (SeAPM) containing a mixture of metals, including metallic nanoparticles has increased in the world causing environmental and biota contamination. The bioaccumulation pattern of metals contained in 1 g L^{-1} SeAPM after its dissolution into water was evaluated in Nile tilapia (*Oreochromis niloticus)* for 30 days. The human health risk

for its consumption was assessed using estimated daily intake (EDI). SeAPM was collected surrounding an iron ore processing and steel industrial complex in Vitória city (Espírito Santo, Brazil). Water samples were taken daily for physicochemical analyses and, every 3 days for multielemental analyses. Fish were collected every 3 days for metal bioaccumulation determination in the viscera and fillet (muscle). B, Al, V, Cr, Mn, Fe, Ni, Cu, Zn, As, Se, Rb, Sr, Ag, Cd, Pb, Hg, Ba, Bi, W, Ti, Zr, Y, La, Nb and Ce were quantified in SeAPM, water and fish viscera and fillet by using ICP-MS. Most metals bioaccumulated preferentially in the viscera, except the Hg and Rb which were accumulated mostly in the fillet. The bioconcentration pattern were similar for Fe>Al>Ti>Mn>Pb>V>Zr>La>Ce>Y>Ni>Se>Nb> As>W>Bi in whole body and viscera being higher than in muscle throughout exposure. Rb, Cd and Hg increased slowly in whole-body, viscera and fillet, but continuously. B and Cr increased in whole-body and viscera remaining high during the exposure period. Zn, Cu, Sr, Sn, Ag and Ta did not differ from controls. The differences among metal bioaccumulation were probably related to species ability to cope each metal and/or inefficient excretion. The risk associated with the daily intake of tilapia fillets exposed to 1 g L^{-1} SeAPM would not pose a health risk for adult consumers but indicated that is not safe for children, due to the concentrations of As, La, Zr, and Hg. It is highly worrying mainly considering the emergent metals from which there were no governmental regulations and possible effects are still unknown.

6.01.P Advances in Understanding of the Fate and Toxicity of Metals and Metal Mixtures, and its Application in the Regulation of Metals in the Environment

6.01.P-We339 In Vitro Bioaccessibility Round Robin Testing for Arsenic and Lead in Standard Reference Materials and Soil Samples

Matt Dodd, PhD[1]*, Deanna Lee*[2]*, Ross Wilson*[3]*, Sergei Verenitch*[4] *and Jasen Nelson*[4]*, (1)School of Environment and Sustainability, Royal Roads University, Canada, (2)Health Canada, Canada, (3)Wilson Scientific, (4)British Columbia Ministry of Environment and Climate Change Strategy, Canada*

In vitro bioaccessibility (IVBA) for arsenic (As) and lead (Pb) in soil can be determined using USEPA Method 1340. This method is validated for As and Pb and includes in vivo/in vitro regression equations that enable the use of bioaccessibility data to predict relative bioavailability of As and Pb to better estimate human health risk associated with soil ingestion. NIST 2711a or 2710a are used as standard reference materials (SRMs) in Method 1340. The suitability of using other SRMs were investigated in this study. Following review of various SRMs, BGS119 and EnviroMAT SS-2 were selected based on their cost, availability and the concentration ranges of As and Pb. Five Canadian laboratories participated in Round Robin I to determine As and Pb IVBA in the two SRMs. For BGS119, IVBA ranged from 10.2% to 17.8% for As, while Pb IVBA varied from 67.4% to 86.7%. For EnviroMAT SS-2, As IVBA varied from 16.5% to 27.6% while Pb IVBA ranged from 65.0% to 87.7%. Intra- and inter-lab variability were acceptable with percent relative standard deviations (%RSDs) < 20%. A method for As and Pb IVBA, that included the use of BGS119 as a SRM was drafted for inclusion in the British Columbia (BC) Environmental Laboratory Manual. Round Robin II was conducted using the draft method to determine As and Pb IVBA in the three SRMs (NIST 2710a, 2711a and BGS119) and 10 field-collected soil samples covering a wide range of As and Pb concentrations. Four BC-based laboratories participated, with each reporting three replicate analyses per sample. Total As and Pb concentrations in the soils reported by three of the labs were comparable, however the concentrations reported by the fourth lab were relatively lower. The differences in concentrations were attributed to the use of the <2 mm particle size sieved fraction for the total metal analysis in soils rather than the <150 µm fraction specified in the IVBA method. The calculated IVBA values for the SRMs were within specified control limits while intra- and inter-lab variability were generally acceptable with %RSDs <30%. Arsenic IVBA values for the field collected samples varied from 0.1 to 60.4 % while Pb IVBA ranged from 7.0 to 121.6%. The lowest IVBA values were measured in mine impacted soils, while the highest values were associated with smelter impacted soils. The study demonstrated that reproducible and comparable As and Pb IVBA results can be achieved by the participating labs using the BC Environmental Laboratory Manual method.

6.01.P-We342 Is Assuming Additivity of Single-Metal Toxicity Thresholds a Conservative Approach to Assessing Risk of Ecotoxicity from Elevated Soil Concentrations of Co, Cu, and Ni at Contaminated Sites?

Yamini Gopalapillai[1]*, Steven Siciliano*[2] *and* ***Beverley A. Hale***[3]*, (1)International Copper Association, (2)University of Saskatchewan, Canada, (3)University of Guelph, Canada*

Multiple metal-impacted soils are often realistic scenarios for risk assessments, but tools to address these are currently lacking. The objective of this work was to evaluate whether assuming concentration addition (CA) of metal mixture effects was conservative for prospective risk assessment of soils that were elevated mainly in Ni and Cu and somewhat with Co, Pb, or As. Observed whole mixture toxicity for field soils with aged metal mixtures was compared to the expected whole mixture toxicity, assuming additivity of prospective single-metal thresholds ("toxic units") for the mixture components. Bioavailability adjusted single-metal toxicity thresholds expected for those field soils were the median hazard concentration affecting 5% of species (HC5-50) from the predicted no-effect concentration (PNEC) calculator and calculated from the species-specific dose–response multiple linear relationships (MLRs), all from the European Union Registration, Evaluation, Authorisation and Restriction of Chemicals (EU REACH) dossiers for metals. Generic single-metal toxicity thresholds were based on Canadian Council of Ministers of the Environment soil quality guidelines (CCME SQGs) for agricultural soils. Observed toxicity thresholds were from the community-based risk assessments conducted for Port Colborne and Sudbury, Ontario, Canada. Mostly, prospective single-metal toxicity thresholds were protective relative to the observed toxicity, although that was species or ecological process dependent. The bioavailability-adjusted single-metal thresholds were less conservative than the CCME SQG method, even though the former is based on site-specific EC10 values, and the latter is based on generic EC25 values. When within-site variability in soil properties was used to calculate the 5th and 95th CI for the HC5 sum of toxic units (ΣTUs), CA was conservative for far fewer endpoints. In addition, the prospective ΣTUs were more conservative predictions of the observed whole mixture toxicities for Port Colborne soils than for Sudbury soils. The most appropriate balance of accuracy and conservatism for identifying low-level risk of the whole mixtures in these soils appeared to be the bioavailability-adjusted HC5-50, which was applicable to many endpoints and 2 quite different exposure concentration ratios.

6.01.P-We343 Does the Concentration Addition Model Become a More Conservative Predictor of Aquatic Metal Toxicity with Increasing Number of Metals in the Mixture?

Maria Laura De Donno[1]*, Franz Marius Schmitt*[2]*, Charlotte Nys*[3]*, Karel Viaene*[3]*, Koen Oorts*[3]*, Marnix Vangheluwe*[3] *and Karel De Schamphelaere*[2]*, (1)Animal sciences and aquatic ecology, Ghent University, Belgium, (2)Ghent University - GhEnToxLab, Belgium, (3)ARCHE Consulting, Belgium*

Risk assessment of chemical mixtures is most conveniently regulated following the concentration addition (CA) model. The MAF (Mixture Assessment Factor) has been proposed as a tool to regulate individual chemicals while accounting for unintentional mixture effects predicted by CA. At low chronic effect concentrations, CA on average tends to overestimate mixture effects at the species level. A more accurate alternative for chronic metal mixture toxicity provides the independent action model (IA). A quantifier to assess the deviations of observed toxicity from toxicity predicted with CA is called the MIF (Mixture Interaction Factor), which indicates synergistic (MIF<1) or antagonistic (MIF>1) interactions, relative to CA, if present. However, most research has been conducted with well-studied metals, such as Cu, Zn, Ni, Cd, and Pb, in equitoxic test designs. Less attention has been paid to other metals and environmentally relevant concentration ratios. This study aims to fill this knowledge gap and will further test the hypothesis that IA is generally a more accurate model than CA for metal mixture toxicity. In addition, it will, based on theoretical and mathematical considerations, test the hypothesis that the MIF increases with an increasing number of metals in the mixture.

Ag, As, Ba, Cd, Cr, Cu, Mn, Ni, Pb and Zn have been identified previously as inorganic substances contributing most to predicted mixture risks. The experimental design consisted of testing single metals, and binary, ternary, quaternary and quinary mixtures combinations of those metals. To cover different trophic levels, the test organisms *Raphidocelis subcapitata* and *Daphnia magna* were chosen. For those species, we estimated that in a mixture experiment, five metals are usually sufficient to explain 90% of the toxicity of the mixture pressure (expressed as the sum of toxic units) of the whole mixture.

All tests followed a ray design at environmentally relevant concentrations and concentration ratios based on monitoring data from the European Environmental Agency (EEA) Waterbase. Additionally, an equitoxic ray design based on EC10 values was also tested. Each test was evaluated according to CA and IA, both models were compared for their ability to accurately predict observed toxicity, and the MIF was quantified. This study will contribute relevant experimental data for a better understanding of the joint toxicity of complex, but environmentally and regulatorily relevant metal mixtures.

6.01.P-We344 Chronic Metal Mixture Toxicity: From Data Gap Analysis to the Development of an Environmentally and Regulatory Relevant Experimental Program

Charlotte Nys[1]*, Karel Viaene*[2]*, Koen Oorts*[1]*, Marnix Vangheluwe*[1]*, Violaine Verougstraete*[3]*, Hugo Waeterschoot*[4] *and Karel De Schamphelaere*[5]*, (1)ARCHE Consulting, Belgium, (2)ARCHE, (3)Eurometaux, Belgium, (4)Chemicals Management, Eurometaux, Belgium, (5)Ghent University - GhEnToxLab, Belgium*

In the Chemicals Strategy for Sustainability, the EU Commission calls to systematically integrate the issue of combined exposure into chemical risk assessments. The ‘mixture effects of metals’ project within the Metals Environmental Exposure Data Program (MEED) aims to provide scientific evidence on mixture effects as input to the discussions on how to tackle the issue of exposure to unintentional mixtures for naturally occurring substances. More specifically, it aims to focus on those metals and inorganics that are predicted to contribute most to the overall risks of unintentional mixtures in Europe, i.e. the so-called Inorganic-Priority Contributing Substances (I-PCS). In a previous prioritization exercise using European monitoring data, the following inorganics have been identified as I-PCS: Ag, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Se, V, and Zn. In addition, in a recent meta-analysis, it was observed that there is overall limited (high-quality) data on metal mixture toxicity to aquatic organisms of following I-PCS in freshwaters: Ag, As, Ba, Co, Cr, Hg, Mn, Se, and V. Moreover, there is only limited data for mixtures combining four or more metals.

We present the development of a targeted testing program that aims to cover these data gaps. An experimental program was developed that considers metal mixture toxicity testing with algae *(Pseudokirchneriella subcapitata*) and invertebrates *(Daphnia magna)* at environmentally regulatory relevant concentrations and mixture combinations. The development of the experimental program followed a step-wise approach focusing on the identification of mixture risks of the I-PCS based on species sensitivity data (EC10) from the REACH registration dossiers. The most relevant mixture combinations were identified using a toxic unit-approach applied on the Waterbase, an European aquatic monitoring database. The followed approach ensured the environmental and regulatory relevancy of the experimental program by selecting the most relevant mixture size, metals, metal combinations and metal concentration (ratios) to be tested. The outcome of the experimental program, that is currently ongoing, will increase the scientific evidence on mixture toxicity of inorganics. As such, it will contribute to the discussions on the implementation of combined exposure into environmental risk assessment.

6.01.P-We345 MEED: Progress of the Multiyear Metals Environmental Exposure Data Collection Program to Anticipate Challenges of the EU Zero Pollution Ambition Policy and the Chemicals Strategy for Sustainability

Hugo Waeterschoot[1]*, Marnix Vangheluwe*[2] *and Violaine Verougstraete*[3]*, (1)Chemicals Management, Eurometaux, Belgium, (2)ARCHE Consulting, Belgium, (3)Eurometaux, Belgium*

The Chemicals Strategy for Sustainability (CSS) is one of the main pillars of the European Union Zero Pollution Ambition, a

building block of the Green Deal. A major novelty of this policy initiative is the introduction of a Mixture Assessment Factor (MAF) to demonstrate safe use and lack of impact on ecosystems from the cocktail of chemicals exposures encountered in environmental compartments. The MAF contributes to the overall objective of reducing *exposures of chemicals to levels that are no longer expected to be harmful to health and the environment*. Knowing that the Green Deal and its climate objectives will result in significant increases of metal volumes and uses for renewable energy (e.g. wind mills, solar cells and EV-batteries), it is crucial for the metals sector to demonstrate that exposure levels of emitted metals will not be increasing proportionally. In addition, the sector needs to demonstrate that exposure to metal mixtures in the receiving environments will meet the challenge of the Zero Pollution Ambition and the MAF requirements, now and under future emission scenarios.
Therefore, the EU metals sector designed a comprehensive "environmental exposure gathering programme" (MEED), complemented by scientific concepts that are development to anticipate the Zero Pollution Ambition as well as the objectives of the EU biodiversity policy. The program (2022-2024), which consists of 6 interlinked projects, is halfway. Some important milestones that have been reached include: the confirmation of the extent of the impacts of a default MAF for the metals sector, the identification of metals that contribute the most to the combined risks in soil and aquatic environments, an update of today's regional background levels for metals, a review and reappraisal of existing knowledge on metals mixtures & metals-organics mixtures interactions and the design of a smart testing strategy to fill major gaps in the knowledge of mixture interactions. This poster presents the overall progress and intermediate conclusions of the MEED projects while a detailed assessment of each of the individual milestones are presented in complementary posters.
MEED will deliver a huge amount of data that can be used in REACH registration updates and other EU regulatory programs.

6.01.P-We346 Copper Deficiency in Aquatic Organisms: How Should This be Considered as Part of the PPP Risk Assessment?

***Sarah Priestly*[1]*, Amy C. Brooks, IBERA Certified Environmental Risk Assessor*[1] *and Robert Morris*[2]*, (1)Cambridge Environmental Assessments, United Kingdom, (2)Albaugh*

The EU regulation for authorising plant protection products (Regulation (EC) 1107/2009) uses a tiered risk assessment approach for aquatic organisms. Under this approach, if an active substance fails the lower-tier, more conservative risk assessment, then intermediate or higher tier approaches can be used to demonstrate low risks to aquatic organisms. Higher tier refinements can include the derivation of toxicity endpoints from more realistic test systems, such as mesocosm studies. Assessment factors (AFs) are then applied to those toxicity endpoints to derive a regulatory acceptable concentration (RAC) for use in the risk assessment. There is some flexibility in terms of the AF value applied by regulators to derive the RAC, which can increase or decrease the conservatism of the risk assessment.
Copper is widely used in a variety of industrial applications as well as for plant protection products and it has been documented that Copper is toxic at high concentrations (worst case). However, Copper is also an essential nutrient that is required at low concentrations and if these levels are too low this may cause adverse effects (deficiency). In regulatory risk assessments the focus is usually based on toxicity at these high levels but there is little or no consideration for the impacts of deficiency at lower levels. For example, would the AF assigned by regulators drop the RAC below the required level for normal growth and development and should deficiency be considered by regulators for nutrients such as copper? This issue of essential metals having a U-shaped dose-response curve is mentioned in the EFSA statement on transition metals (EFSA 2021), but not in the context of AF-setting. Based on this, a literature search was conducted to investigate the evidence available for copper deficiency, with particular focus on the critical taxa of aquatic invertebrates and fish. This poster discusses if this could then be used to support use of a reduced assessment factor in the aquatic risk assessment for essential nutrients including copper.

6.01.P-We347 Canadian Federal Water Quality Guidelines for Metals

Sushil Dixit*, Environment and Climate Change Canada, Canada*

The National Guidelines and Standards Office (NGSO) of Environment and Climate Change Canada (ECCC) has recently developed many Canadian federal water quality guidelines (WQGs) for the protection of aquatic life for metals (e.g., aluminum, copper, chromium, iron, lead, manganese and rare earth elements. NGSO uses CCME (Canadian Council of Ministers of the Environment) methods to the extent possible. Because the aquatic toxicity of metals is strongly dependent on physical and chemical characteristics of the exposure water, a careful consideration was given to bioavailability and toxicity of specific metals to aquatic organisms under site-specific conditions. The species sensitivity distribution (SSD), multiple linear regression (MLR) and biotic ligand model (BLM) are among the approaches that we have used for guidelines development and their applications to specific metals will be discussed. The WQGs for aquatic life provide benchmarks for the quality of the ambient environment. Where the WQG is met there is low likelihood of adverse effects to aquatic life. WQGs are regularly used to aid in environmental protection by providing targets for acceptable environmental quality, in evaluating the significance of concentrations of chemical substances currently found in the environment, and as performance measures of the effectiveness of risk management activities.

6.01.P-We348 New Fertiliser Regulation - Are You Prepared?

Andrew Brotherhood*, Agilent Technologies, United Kingdom*

With the new European Union (EU) regulations on fertiliser content (FRP 2019/1009) which came into effect from July 2022, fertiliser manufacturers are potentially faced with the need to stand up to new instrumentation and analytical methods to ensure regulatory compliance. Prior testing and composition requirements almost exclusively covered inorganic fertilisers, but the new fertiliser regulations have been updated to also include the growing organic fertiliser segment. The regulations incorporate additional producers that were not previously subjected to such requirements, so companies should understand the implications of the new regulations, identify instrumentation suitable for associated analyses, and compile methods for speciation and total elemental analysis testing. A variety of approaches, such as those using ultraviolet-visible (UV-Vis) spectroscopy, microwave plasma-atomic emission spectroscopy (MP-AES), and inductively coupled plasma (ICP) instrumentation, including ICP-optical emission spectroscopy (ICP-OES) and ICP-mass spectrometry (ICP-MS), are among the recommended options for performing robust speciation and elemental analyses. Examples of ICP-based instrumental methods applied to determine total elemental content and arsenic speciation are outlined along with the analytical performance standards attainable with such equipment.

6.01.P-We349 Lead Exposure in Marbled Teal and White-headed Duck: What Is the Situation Two Decades After the Ban on Hunting with Lead Shot in "El Hondo" Natural Reserve (Southeastern Spain)?

*María Belén Nieto[1], José Peñalver[2], Pedro María-Mojica[1,3], **Antonio Juan Garcia-Fernandez**[4] and Isabel Navas[5], (1)Health Sciences, Faculty of Veterinary, University of Murcia, Spain, (2)Health Sciences, University of Murcia, Spain, (3)Servicio de Vida Silvestre, Wildlife Recovery Center "Santa Faz", Spain, (4)Toxicology and Risk Assessment Research Group, Faculty of Veterinary, University of Murcia, Spain, (5)Health Sciences-Faculty of Veterinary-IMIB, University of Murcia, Spain*

El Hondo Nature Reserve is comprised of two large reservoirs and their associated wetlands hosting more than 400 species, including marbled teal (*Marmaronetta angustirrostris*) and white-headed duck (*Oxyura lecucocephala*). The wetland was created in the 1920s to provide water for irrigation. Other relevant human activities include hunting and fishing. Millions of lead shots have been widespread in this wetland. Lead (Pb) poisoning in waterfowl due to ingestion of shot pellets from hunting activities has been well documented worldwide. In 2001, a regulation banning the use of Pb shots for hunting in Ramsar sites was approved. Previous studies found high lead pellet densities in sediments 30 years after the ban of hunting.
Ducks were grouped in “*before*” or ”*after*” 2001 (date of death). Thirty marbled teals (15/15) and forty white-headed ducks (25/15) from El Hondo were studied. Samples of liver, brain, kidney, muscle and bone were collected for analyses of Pb. Mass body measurement, sex, age and physical condition were registered. The gizzards were explored to detect the presence of ingested Pb shots. Lead levels were analyzed in 0.1 g of dry tissue after an acid digestion. Pb concentrations were measured by ICP-MS. TORT-2 was used as reference material.
In both species, “*before*” group had mean lead concentrations higher than “*after*” group, however they only were statistically significant in white-headed duck. In this last species Pb mean concentrations in both groups (before and after) were higher than threshold values for lead lethal exposure. However, in marbled teals, animals dead *before* 2001 had Pb concentrations in tissues corresponding to subclinical exposure and those dead *after* 2001 had Pb values corresponding with background lead exposure. Females of white-headed ducks had more Pb shot pellets in gizzards than males. Positive correlation was found between mg of lead in gizzard and lead concentrations in tissues.
In conclusion, Pb concentrations in tissues of marbled teals and white-headed ducks from El Hondo decreased significantly since 2001; however, 22 years after prohibition of Pb ammunition in Spanish wetlands, the impact of lead exposure on health in anatidae remains high, mainly in globally threatened white-headed duck. Other additional measures should be considered to reduce lead exposure in this species.

6.01.P-We350 Development of a Machine Learning Model to Estimate the Biotic Ligand Model-based Predicted No-effect Concentrations for Copper Using Indigenous Species in Korean Freshwater

***Jiwoong Chung**[1], Geonwoo Yoo[1], Jae-Seong Jo[1], Jinhee Choi[2] and Jong-Hyeon Lee[3], (1)EH Research & Consulting, Korea, (2)School of Environmental Engineering, University of Seoul, Korea, (3)Magok-dong, Korea*

Biotic ligand model (BLM) for transition elements is a quantitative ecotoxicity prediction model that can be used to assess ecological risks taking into account the bioavailability of a transition element such as copper. Since a monitoring database operated by the National Institute of Environmental Research (NIER) of Korea provides only a few BLM input variables, the BLM-based predicted no-effect concentrations (PNECs) calculated using estimated values for missing input variables have uncertainty. In this study, a user-friendly tool was developed that simplifies the many input variables and complex procedure required to derive BLM-based PNECs for copper. The electrical conductivity, easily observed by portable measurement, was used as an input variable to surrogate major cations and alkalinity. A deep neural network (DNN) model was used to predict the nonlinear relationship between input variables and PNECs. As a result, copper BLM-based PNECs derived from the sensitivity distributions of 19 native aquatic organisms proposed in the previous study were accurately predicted to within a factor of two. Furthermore, the temporal variation of copper PNECs estimated at detailed monitoring stations in the monitoring database of NIER from 2017 to 2021 were investigated. The copper DNN model requiring only pH, electrical conductivity and total organic carbon can contribute to the application of risk assessment reflecting the bioavailability of copper in various monitoring databases.

6.02 Bird and Mammal Risk Assessment: Now and Preparation for the Future

6.02.P-We351 The Appropriateness of Using the Rabbit (Oryctolagus cuniculus) in the Risk Assessment of Plant Protection Products for Wild Mammals

*Paula Garcia[1], Markus Ebeling[2], **Manousos Foudoulakis**[3], Nina Hallmark[4], Steven Kragten[5], Mary Moxon[6], Joachim Nopper[7] and Katharina Ott[7], (1)Corteva Agriscience, United Kingdom, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany, (3)Corteva Agriscience, Greece, (4)Bayer AG - Crop Science Division, France, (5)Syngenta Agro, Germany, (6)MMTGS Ltd, (7)BASF SE, Germany*

The new EFSA draft Guidance Document on the Risk Assessment for Birds and Mammals proposes to assess the risk of plant protection products (PPP) to generic model species (GMS) for many crop scenarios at tier 1. One of these GMS, defined as

medium herbivorous mammal – and with same body weight and diet composition as the European rabbit *(Oryctolagus cuniculus*) – has a high rate of tier 1 risk assessment failure.
To assess the potential for chronic risk to wild mammals from PPP, two types of information are needed: a) the relevant wild mammal toxicity endpoint and b) the relevant wild mammal exposure scenario. Under the current and the draft new guidance documents, the European rabbit (*Oryctolagus cuniculus*) is used for both: a) as a laboratory test system to derive potential toxicity endpoints for all wild mammals, using the only available laboratory rabbit study (prenatal developmental toxicity) and b) as the relevant potential focal species to assess the risk to medium herbivorous mammals at higher tier risk assessment refinement.
In this platform, we reflect on whether (or when) the use of the rabbit is still appropriate for a realistic, relevant, and robust wild mammal risk assessment in the context of PPP.
We will present and discuss the peculiarities and limitations of the rabbit prenatal developmental toxicity study when used for wild mammal risk assessment, after conducting a novel analysis of the relevance of the maternal and fetal observations, and their potential contribution to the (un)successful recruitment into wild mammal reproductive population.
We will also assess the relevance of the rabbit as the focal species at higher tier risk assessment refinement, after conducting a thorough literature review on rabbits focusing on: European distribution, biology and population dynamics, feeding and habitat preferences, impact of agriculture on rabbits, impacts of rabbits on agroecosystems and rabbit population management in European farmland.
The platform will expand on the methods used and the conclusions available so far and will be supported by relevant posters where further details will be presented.

6.02.P-We352 Effect modelling for Higher Tier Bird Risk Assessment – A Case Study
***Andre Gergs**[1], David Heckmann[1], Markus Ebeling[2] and Thomas G Preuss[1], (1)Bayer AG - Crop Science Division, Germany, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany*
The Guidance Document on the risk assessment for birds and mammals as published by EFSA in 2009 is currently being updated. The new draft guidance document lays out the prospect of using toxicokinetic-toxicodynamic (TKTD) effect modelling for higher tier assessments but also highlights that currently no case studies on the application of those models for the bird risk assessment are availabe. Here, we present a case study where effect models have been applied as a higher tier option for the bird risk assessment of the fungicide fluopyram.
Reproduction studies with Bobwhite quail and fluopyram, following the OECD guideline 206, revealed that offspring weight is significantly affected by the dietary exposure of the adult quails, which provides the most sensitive endpoint for the bird risk assessment of the compound.
Dynamic energy budget (DEB) models and a pyhsiologically-based toxicokinetic (PBK) model were developed to address this endpoint in a higher tier risk asssesment approach. The effect models should adequately represent the process or mechanism leading to the effect. We, thus, tested two different hypotheses for mechanisms that may lead to reduced offspring weight upon the fluopyram exposure of the hen, i.e., the energy hypothesis and the exposure hypothesis. The two hypotheses required different sets of effect models wich were tested for their ability to adequately describe the effects observed in the reproduction studies. Also, a novel egg injection toxicity study was carried out to explore potential effects of chemcial residues in the egg.
Our results indicate that the reduction of offspring weight upon exposure of adult quail to fluopyram is likely an effect caused by egg residues rather than a direct (energetic) effect posed on the hen. The model validation with independent data revealed that the combined DEB-TKTD and PBK modelling adequately predicts the observed effects in the reproducton study without any further vertebrate testing. The combined effect model was succesfully calibrated and validated and can thus be used for the higher tier risk assesment. The overall modelling approach also offers the potential to replace bird reproduction studies in cases where egg residues and offspring effects are likely to drive the risk assessment.

6.02.P-We353 Integrating Emerging Science to Improve Assessments of Chemical Risk to Wildlife, Challenges and Workshop Recommendations
***Nico van den Brink**[1,2], John E. Elliott[3], Elizabeth Power[4], Clare Lauren Kilgour[4] and Mark S. Johnson[5], (1)Division of Toxicology, Wageningen University & Research, Netherlands, (2)Dept of Toxicology, Wageningen University & Research, Netherlands, (3)Environment and Climate Change Canada, Canada, (4)Azimuth Consulting Group Inc., Canada, (5)U.S. Army Public Health Center*
In several jurisdictions, Environmental Risk Assessment (ERA) of chemicals includes evaluating the potential risks of chemicals for terrestrial wildlife (mammals, bird, reptiles and some amphibians).. In such assessments, the potential for adverse effects from exposures to anthropogenic chemicals at contaminated sites, for new pesticides, and for chemicals in production and/or proposed for wide-scale use is evaluated and assessed. Although ERA has included wildlife-related assessment for decades, the tools and methods to evaluate wildlife related risks have not markedly changed, despite the advancement of new scientific insights and tools. In 2019, the Wildlife Toxicology World Interest Group of SETAC initiated a virtual workshop, based on a special session at the annual SETAC North America meeting in Toronto, Canada. This meeting was organised on the prospect to improve risk assessments for wildlife and facilitate better implementation in chemical regulations. The workshop focused on regulations in the USA, Canada, and Europe that incorporated risks to wildlife species. Following that meeting, four work groups focussed on different aspects of the ERA for wildlife, i.e. problem formulation (WG1), exposure assessment (WG2), effects assessment (WG3), and risk characterization (WG4). In this presentation, we provide an overview of the workshop and results, focussed on the regulations that drive risk assessment. Key focus areas for further development will be presented that may help to improve the quality of predicting of risks of chemicals to wildlife, including recommendations for future research and decision making.

6.02.T-01 Use of the Time Weighted Average Factor in Pesticide Risk Assessment for Birds and Mammals

Emily McVey[1], Rachel Sharp[2], Alf Aagaard[3], Ana Lopez Antia[4], Maria Arena[2], Pierre-François Chaton[2], Gabriella Fait[2], ***Alberto Linguadoca[2]*** *and Philippe Berny[5], (1)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands, (2)European Food Safety Authority, Italy, (3)Danish Environmental Protection Agency, Denmark, (4)Spanish Research Council (CSIC), Institute of Environmental Assessment and Water Research (IDAEA), Spain, (5)VETAGRO-SUP, France*

The use of time-weighted average (TWA) concentrations for exposure estimations in risk assessment of pesticides has been a topic of discussion and debate. In recent decades, it has been recognized that although many chronic toxicities are likely a result of extended exposure situations, there situations wherein it cannot be assumed the toxicity observed will be the same for different exposure patterns with the same AUC exposure level. That is to say, it cannot be determined by most standard toxicity studies whether the observed toxicity is indeed a result of a certain level of long-term exposure, rather than, for example, a short or peak exposure at a critical time-point or stage and dedicated toxicological test designs are needed to determine whether these may be the case**.** The Working Group on the Revision of the EFSA Bird and Mammal Guidance document took this into account during the revision of the birds and mammals risk assessment guidance.

6.02.T-02 Focussing on What Matters: A Suggestion for Addressing Vulnerability in Bird Focal Species Selection in Higher Tier Risk Assessments

Steven Kragten[1]*, Arnd Weyers[2], Dennis Sprenger[3], Benedikt Gießing[4], Raquel Sainz Elipe[4] and Christian Wolf[4], (1)Syngenta Agro, Germany, (2)Bayer AG - Crop Science Division, (3)Corteva Agriscience, Germany, (4)Tier3 Solutions, Germany*

In the registration process for plant protection products (PPP), a higher-tier risk assessment is triggered if no acceptable risk is indicated at the first tier. One higher tier refinement option is the use of a focal species (FS). The fundamental concept is that a risk assessment for the selected FS should protect other species of the same feeding guild as represented by the FS.

The draft revision of the Guidance Document for Birds and Mammals Risk Assessment proposes an approach for FS selection, under which feeding guild, body weight and diet composition are considered more important than frequency of occurrence in study fields (FO_{Field}). In addition, it is noted that "*A vulnerable species which is infrequently observed but nevertheless clearly present may be considered a more appropriate focal species for the risk assessment…*". This implies that the most vulnerable species within a feeding guild in the crop would be a suitable FS. Using the example of birds, we here ask the question: what indicates the vulnerability of a bird species occurring in the relevant crop?

Weyers et al. suggested to aid in FS selection, calculating a species-specific "daily dietary dose" or DDD, which provides an indication of the relevance of a bird species for higher tier risk assessment. The approach by Weyers et al. did not provide criteria to identify a vulnerable species as proposed by EFSA. Here, we present a refinement to the approach by Weyers et al. that helps evaluating if a species is vulnerable, based on real data from FS studies, which can be used as a surrogate for PT in theoretical DDD calculations for the purpose of ranking FS according to 'vulnerability'.

The example data used demonstrates that FO_{Survey} values indicate that three of eight species might make frequent use of this crop for foraging. This is then confirmed by the obtained PT data. The FO_{Survey} data are of course not a direct equivalent of PT as the highest FO_{Survey} does not necessarily translate into the highest PT. Nevertheless, this example demonstrates that FO_{Survey} may be a suitable parameter for estimating the magnitude of the differences in utilisation of a crop among the most relevant species in the absence of PT data.

This approach can possibly be used under the new guidance document for birds and mammals risk assessment and can contribute to a more harmonized approach between Member States on this topic.

6.02.T-03 PT Studies: Practical Implications of the Draft Updated Guidance Document on 'Risk Assessment for Birds and Mammals'

Susanne Jähnig[1]*, Ines Hotopp[2], Benedikt Gießing[1], Olaf Fuelling[1], Andrea Rossbach[1] and Christian Wolf[1], (1)Tier3 Solutions, Germany, (2)tier3 solutions, Germany*

In 2021, EFSA has released the draft revised guidance document on 'Risk Assessment for Birds and Mammals' (hereafter GD). The GD aims to clarify methodologies and requirements for field studies. We review some of these requirements with particular focus on field studies that are aimed at assessing the 'proportion of diet an animal obtained from pesticide treated area' (PT). According to the draft GD, it needs to be justified that the selected study area sufficiently represents a worst-case exposure scenario especially if the crop of concern is less abundant or if neighbouring habitats are divers. However, it is not specified when crops are considered abundant nor how diverse habitats are defined.

Furthermore, according to the new requirement that at least ten consumer individuals are necessary for a valid PT study, the method that focuses on the selection of individuals for radio-tracking which represent the wider farmland population, is getting obsolete.

In contrast to the draft GD, we would like to recommend conducting multiple PT sessions on non-consecutive days for the same individual instead of a successive order. By adding additional days between single PT sessions, a better representation of intra-individual variation of PT estimates can be expected.

Additionally, in the current version of the draft GD, the crop attractiveness is calculated using the difference between PT_{90} and PT_{50}. The problem is that the same difference between both PT values can be attained by either mostly low or mostly high PT-values. This is the case when the crop is either used to a great extent or when the crop is only used to a small extend by most individuals. In order to solve this issue, we recommend to calculate the difference between the mean and PT_{50}/PT_{90}. In this case, the sign of the difference between PT_{50} and mean indicates whether the crop is attractive or unattractive, while the difference between PT_{90} and mean indicates – inversely proportional – the extent of attractiveness.

In summary, some aspects of the requirements for PT field studies are only rudimentary described in the draft GD and hold the potential to cause ambiguity among authorities on how to evaluate them. The provision of more details would help to avoid any uncertainty linked to the interpretation of given field study requirements. Furthermore, we hope that the integration of our proposed approaches regarding multiple PT sessions and the evaluation of crop attractiveness improves the draft GD.

6.02.T-04 Risk Mitigation Measures of Pesticide-treated Seeds for Birds
***Manuel Ortiz Santaliestra**[1], Elena Fernández Fernández Vizcaíno[1], Vicente Alcaide[2], Mondéjar-López María[3], Mario Fernández-Tizón[1], Niza Enrique[3], Oussama Ahrazem[3], Rafael Mateo Soria[4] and Francois Mougeot[1], (1)Instituto de Investigación en Recursos Cinegéticos, Spain, (2)Instituto Regional de Investigación y Desarrollo Agroalimentario y Forestal (IRIAF) JCCM, Spain, (3)University of Castilla-La Mancha, Instituto Botánico, Departamento de Ciencia y Tecnología Agroforestal y Genética, Spain, (4)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos, Spain*
Treatment of sowing seeds with pesticides is a widespread agricultural practice that minimizes risks to operators and non-target species by reducing the amount of released pesticides but poses a particular risk to granivorous birds that feed on those seeds during the sowing season. It is therefore important to implement risk mitigation mesures (RMM) to minimize the impact of this specific practice to birds. Over the last decade we have shown how granivorous birds are exposed in the wild to triazole fungicide through the consumption of treated seeds, and that this consumption can reduce their reprodcutive output. We evaluate three different, non-exclusive, RMMs to reduce the risk of triazole-treated seeds for granivorous birds associated with typical Mediterranean agro-ecosystems. The first RMM, focused on reducing toxicity, wasthe use of a non-toxic alternative treatment consisting of garlic essential oil encapsulated in chitosan nanoparticles (GEO/NPCH), whose antifungal activity and efficacy as seed treatment have been demonstrated. Toxicity tests showed no effects on exposed red-legged partridges associated with the ingestion of GEO/NPCH-treated seeds, which contrasts with the physiological alterations observed for conventional triazole treatments. A free-choice test showed no preference by partridges in the consumption of untreated, GEO/NPCH-treated or triazole-treated wheat seeds. The other two RMM were focused on reducing exposure by enhancing the availability of uncontaminated food. We supplemented recently sown fields with non-treated seeds and monitored the bird feeding behaviour using video-trapping cameras. Some species like pigeons occurred preferentially in supplemented fields, although they also feed in the sown treated seeds. Finally, we related the ingestion of triazole fungicides by hunted red-legged partridges to the diversity of landscape in the area where birds were hunted. Increased habitat diversity contributed to reduce the total intake of triazoles during the sowing season, likely because of a higher availability of natural food sources. Altogether our results reflect that RMM can be implemented at different levels. Habitat-based RMM are the most appropriate because they benefit different taxa and can be complemented with the use of non-toxic products like GEO/NPCH. Supplementation is however is less efficient as it can act as an ecological trap by attracting birds that may end up feeding on treated seeds.

6.02.P Bird and Mammal Risk Assessment: Now and Preparation for the Future

6.02.P-We354 New EFSA Guidance Document update on Birds and Mammals: Industry view
***Manousos Foudoulakis**[1], Markus Ebeling[2], Steven Kragten[3], Alex Blakey[4], Joerg Hahne[2], Arnd Weyers[5], Thomas Bean[6], Joachim Nopper[7], Dennis Sprenger[8], Sonja Haaf[9], Paula Garcia[10] and Judith Neuwohner[11], (1)Corteva Agriscience, Greece, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany, (3)Syngenta Agro, Germany, (4)Environmental Safety, Syngenta, United Kingdom, (5)Bayer AG - Crop Science Division, (6)FMC Corporation, Newark, (7)BASF SE, Germany, (8)Corteva Agriscience, Germany, (9)Environmental Safety, ADAMA Deutschland, Germany, (10)Corteva Agriscience, United Kingdom, (11)Nufarm Europe GmbH, Germany*
The Guidance Document (GD) on the risk assessment for birds and mammals (B&M) for pesticides (EFSA 2009) is now in the process of being officially updated by EFSA and will be finalised in 2022. SETAC Europe 2023 is an appropriate forum to share new information and to address controversial topics and/or the lack of harmonization in interpretation among regulators topics. Industry will contribute by sharing the experience from risk assessors who have been using the EFSA GD on a daily basis, highlighting those areas where the update should put more emphasis on or requires further guidance.
According to the impact analysis conducted by industry, it will not be possible to demonstrate acceptable risk for many of the currently registered active ingredients and plant protection products based on the screening step and the Tier I step of the exposure assessment, and this will trigger the need to generate a large amount of additional higher tier data. Numerous changes have been proposed in the new draft EFSA GD while its impact cannot be evaluated as protection goals are still pending. At least a 30-month period is considered necessary to generate reliable scientific data to address the new requirements. As for the bigger picture, significant legal, procedural, resource and knowledge gap, logistical and animal welfare concerns increase uncertainty. Focused actions by industry will contribute to minimize contradictory interpretations by risk assessors, increase the acceptance of, provide clarity and a path forward to a successful guidance. In the opinion of risk assessors from industry, the main refinement parameters that require more discussion before their implementation in routine risk assessment in the future are the following: the Benchmark Dose approach and the selection of the ecotoxicologically relevant reproductive endpoint, the use of the fTWA and agreed Tier 1 risk assessment, the selection of focal species of birds and mammals and further clarity or discussions on the higher tier options and modelling.

6.02.P-We355 Avian Reproduction Studies: Experimental Design and Statistical Methodology

Recent guidance from EFSA (2021) promotes the use of regression or benchmark dose methods to derive estimates of effect concentrations, BMD10, and BMD20 and their 95% lower confidence limits (BMDL10, BMDL20) in risk assessment of avian reproduction studies (OECD TG 206, OCSPP 850.2300). The previous study protocol called for a NOEC determination on selected endpoints using an experimental design with three application rates and a control with 18 replicate pens for each treatment level with each pen containing 2 or 3 individuals. Such a design is often inadequate for reliable dose-response and precise BMDx estimation.
A working group comprised of representatives from EFSA, USEPA, European Crop Protection Association, and independent scientists, collected a large database of studies conducted under existing and modified test designs to use as a basis for an extensive computer simulation study to explore alternative experimental designs and statistical methods that improve BMDx and BMDLX estimation. A secondary goal in this investigation is to keep the number of animals used to a minimum.
The analysis concludes that some responses from some studies cannot be fit reliably by most commonly used dose-response regression models and a NOEC must be used. EFSA guidance also acknowledges this possibility. Alternative experimental designs have been evaluated that indicate both adequate statistical power for NOEC determination in addition to adequate sensitivity of BMDx and BMDLx estimates for most study responses. The recommended designs require little or no increase in the number of animals compared to the older protocol, with an increased reliability of the hazard characterization estimates. Based on case studies and simulations, we recommend (1) generalized non-linear mixed models (GNLMM) for BMD estimation that allow for variance heterogeneity or overdispersion that is often observed in these studies and (2) model averaging in preference to model selection. Included in these recommendations are model acceptance and goodness-of-fit criteria and alternative ways to implement.

6.02.P-We356 Experience to Date Deriving Endpoints for Birds and Mammals using the EFSA draft guidance (2021)
Helena Crosland *and Amy C. Brooks, Cambridge Environmental Assessments (CEA), United Kingdom*
In 2021 the European Food Safety Authority (EFSA) released the draft of an updated bird and mammal guidance. The public consultation gave an opportunity to identify areas of potential concern – where changes in the guidance may result in less favourable outcomes to the risk assessment for Plant Protection Products, or where questions still remained as to how to apply the guidance. In the time since its release, experience has been gained in practically applying the draft guidance to the reproductive risk assessment for birds and mammals in terms of deriving toxicity endpoints.
Under the draft new guidance, ecologically relevant endpoints for both birds and mammals need to be derived. This requires reviewing the effects observed in the toxicity studies to determine which are population relevant and which aren't, with the guidance providing some advice on how to make these decisions. Additionally, benchmark dose modelling must now be performed to determine whether valid 10% effect levels (BMDL10) can be calculated and used in the risk assessment.
This poster aims to summarise our experiences to date, the challenges faced, the approaches chosen, and the uncertainties still present in the light of the updated guidance. Topics intended to be covered include the use of BMD modelling and the selection of ecologically relevant endpoints for both birds and mammals.

6.02.P-We357 Software and Model Evaluations in Benchmark Dose Estimation (BMD) and BMDL for Avian Reproduction Studies
Xiaoyi Sopko[1]*, Hao Wang*[2]*, Zhenglei Gao*[3]*, Inka Marie Spyridonov*[4] *and John W. Green*[5]*, (1)Corteva Agriscience, (2)ISU, (3)Bayer AG - Crop Science Division, Germany, (4)BASF SE, Germany, (5)Ecostatistical Consulting, JohnWGreen-ecostats.com*
The draft of EFSA avian and mammal guidance recommends BMDL as the default Reference Point (RP) to replace LOEC/NOEC. BMDL is defined as the lower bound of the 95% confidence interval of the BMD, or benchmark dose, where the chemical dose or concentration produces a predetermined effect (10% in quantal data, and 5% in continuous data) in the response rate of an adverse effect (EFSA, 2017). Estimation of BMDL can be carried out with a range of different statistical approaches, whereby the choice of approaches can have notable influence on the final outcome. Agency-accepted software adopt different statistical approaches in the estimation of BMDL which can result in different conclusions for the same avian endpoint. The goal of this presentation is to evaluate the different statistical methodologies adopted by various software packages and assess the impact of on the final DL10 estimate.
Comparisons will be made amongst BMD software packages including but no limited to PROAST, BMDS, and ToxicR. Their impacts on the final BMD(L)10 estimates are investigated through comparing the software packages on a set of simulated datasets and case studies for quantal data. ing simulated data, comparisons are made using the following metrics: 1) accuracy of the estimated BMD10 from each software package; 2) The normalized width of the confidence interval/credible interval from which BMDL10 is calculated; 3) identification of scenarios in which software fails to produce quality results. These comparisons provide some metrics to measure the robustness of each software.
Assessment across software packages and models confirms that through model averaging, BMD can be estimated with small amount of bias under scenarios with relatively good model fit. Even when there is a large discrepancy of BMD estimated between the model set, model averaging can still find the synthetic true BMD (from data simulation) with good accuracy. The subsequently estimated confidence intervals tend to be more sensitive to the model sets and model averaging method used. It could be sensitive to poor model fits which indicate the need for the ability to remove individual models when fit is clearly poor. Finally, we assess other factors like design bias and superiority of modeling quantal data over modeling transformed quantal data as continuous using the model averaging framework.

6.02.P-We358 Draft Birds and Mammals Guidance, (2021): The Impact of fTWA Restricted Use on Long-Term Avian Risk Assessments Using LD50/10 Endpoints.

***Kate Brougham**, Environment, TSG Consulting, United Kingdom*

The regulatory approval of pesticides in the European Union requires applicants to conduct an ecotoxicological risk assessment for wild birds and mammals in accordance with the Guidance Document on Risk Assessment for Birds and Mammals on request from EFSA (EFSA Journal 2009; 7(12): 1438). However, the EFSA Working Group (WG) for Birds and Mammals is currently revising the EFSA, (2009) guidance document and, in September 2021, EFSA launched the public consultation on the updated draft. In the current EFSA birds and mammals guidance (2009), when toxic effects are considered to be caused by long-term exposure, a default time-weighted average factor (f_{TWA}) of 0.53 (estimating TWA over 21-days and assuming a default half-life (DT_{50}) of 10-days) is applied to the screening and Tier 1 assessment. The 2021 updated draft birds and mammals guidance proposes significant restrictions on the use of f_{TWA} in the long-term birds and mammals risk assessment including its use when the LD50/10 endpoint is used in the avian long-term assessment. We evaluate the impact of this restriction by considering the effect of removing the f_{TWA} from the risk assessments of compounds that have been evaluated by EFSA under the existing EFSA, (2009) birds and mammals risk assessment.

6.02.P-We359 Laying Hen Studies and Time-to-effect in Reproductive Risk Assessments for Birds

***Markus Ebeling**[1], Alex Blakey[2], Manousos Foudoulakis[3], Stephanie Plautz[4] and Magnus Wang[5], (1)Environmental Safety, Bayer AG - Crop Science Division, Germany, (2)Environmental Safety, Syngenta, United Kingdom, (3)Corteva Agriscience, Greece, (4)BASF SE, (5)WSC Scientific, Germany*

For pesticides in the EU, the current reproductive risk assessment for birds is usually based on 21-d TWA (time-weighted average) concentrations in feed items (EFSA GD 2009).

The draft revision of the bird and mammal risk assessment guidance (2021) states that no TWA can be used for “effects on chick development” unless “significant evidence is provided to indicate that these effects are definitively linked to a long-term exposure”.

Effects on chick development can be induced by several pathways, e.g. changes in nutrient provisioning in eggs or in ovo exposure to toxicants. Contrary to mammals where the developing embryo is constantly provisioned by its mother, bird embryos only get what their mothers transfer into the egg before it is laid. Thus, it is the exposure of the mother for which the question of a link to long-term exposure is relevant in the TWA-context.

Ebeling et al (2022) have proposed to employ laying hen metabolism and residue studies for evaluating if the mechanism behind effects on chick development may be related to in-ovo exposure to residues transferred into the egg. In laying hen studies, adult chicken hens are exposed to a test substance over multiple days, typically by gavage. Some studies also include a depuration phase. The primary purpose of these laying hen studies is to inform the consumer risk assessment about residue levels in eggs, but these studies also inform about the kinetics of residue build-up in the eggs laid over the treatment phase.

When it can be argued (or demonstrated, for instance with an egg injection study) that the in-ovo exposure to such residues is the causative mechanism for effects on embryo development, then the time-to-plateau of the egg residues can be used to indicate the appropriate length of the TWA window. Where possible, PBK modelling may further refine such assessments and also allow direct incorporation of field-relevant exposure patterns as an alternative to a TWA-factor in the bird risk assessment.

In this poster we share the outcome of a data mining exercise in the regulatory study archives of our companies, and present examples for cases where the time course of egg residues is likely to inform an assessment of whether TWA can be applied to chick development endpoints.

6.02.P-We360 Time Weighted Average Factor (fTWA) Assessments for Birds and Mammals under the Draft New Bird and Mammal Guidance: Experiences to Date

***Amy C. Brooks**[1], Helena Crosland[1] and Alan Lawrence[2], (1)Cambridge Environmental Assessments, United Kingdom, (2)Independent Consultant*

The potential risks to wild birds and mammals from foraging in areas treated with pesticides must be assessed in the EU under Regulation (EC) 1107/2009. Currently, the risk assessment is performed using the EFSA (2009) guidance, but this is in the process of being revised, with a draft new guidance being released by EFSA in 2021 and the final version expected to be released by the end of 2022. Within the draft guidance, a number of changes are proposed compared to the EFSA (2009) guidance, including the use of time-weighted average factors (fTWA) in reproductive risk assessments.

Under EFSA (2009), fTWAs could be used for reproductive risk assessments, with a default value of 0.53 being applied (relating to a DT_{50} of 10 days and an averaging period of 21 days) to dietary items such as crop plants, weeds, insects, etc where foliar uses of pesticides were proposed. The assumption behind this was that the toxic effects observed in reproductive toxicity studies were driven predominantly by long-term, rather than short-term, exposure, and therefore residue decline over time could be taken into account in the risk assessment. Conversely, if effects were expected to be driven by the initial maximum level of exposure, then taking into account residue decline over time (and thus a F_{twa}) would not be appropriate.

Under the draft new guidance (EFSA 2021), the fTWA is no longer used by default in the reproductive risk assessment for birds and mammals. Instead, an assessment must be made as to its appropriateness based on the effects observed in the mammalian and avian toxicity studies. The aim of this poster is to present our experiences to date in performing these assessments, highlighting potential issues and where further clarity of guidance is recommended where relevant.

6.02.P-We361 A Population Genetic Analysis of Common Voles in Pome Fruit Orchards and Adjacent Meadows

*Susanne Hein[1], Felix von Blanckenhagen[2], Tina Grimm[3], **Joachim Nopper**[1] and Sonja Wich[1], (1)BASF SE, Germany,*

(2)RIFCON, Hirschberg, Germany, (3)Rifcon, Germany
The common vole, *Microtus arvalis*, is often identified as a relevant focal species for which the chronic risk of the use of plant protection products is required to be assessed. In such a risk assessment, populations are the entity of concern. Consequently, to understand the chronic risk to common vole populations, it is essential to understand how populations are exposed.
We studied the population dynamics of common voles in orchards and adjacent meadows. During a field study in 2005, tissue samples from 554 live-trapped common voles were taken, DNA extracted from the samples and microsatellites of 10 loci analyzed. The frequency of exchange of individuals between habitats was assessed by analyzing genetic variability and gene flow within and between habitats in two consecutive seasons (spring and summer).
Habitat and seasonal differences in allele numbers and occurrence indicate a higher degree of immigration into orchards in spring than from orchards into meadows. In spring samples, allele numbers and the number of private alleles were higher in meadows than in orchards while this proportion reversed in the summer samples. On average, 51.8% of all new alleles observed in the summer samples of the orchard plots have previously been observed in spring samples from meadows, whereas 40.5% of newly observed alleles in late samples of meadow plots have previously been observed in spring samples from orchards. An analysis of likelihood of genotypes showed that 11.3% of all animals were likely to migrate from meadows into orchards whereas 7.2% were more likely to migrate into the opposite direction. The results indicate gene flow between vole (sub)populations from different habitats and consequently, an exchange of individuals between orchards and meadows. Depending on the habitat details, off-crop meadows can serve as starting point for common vole colonization of orchards in spring.
In conclusion, common vole (sub)populations in orchards are no distinct, closed populations but rather exchange with populations from adjacent habitats. Further, agricultural practices in orchards do not restrict the genetic variability of common voles. Consequently, considering this exchange with the off-crop habitat is leading to a more realistic risk assessment. The results of this study can aid in determining suitable landscape compositions for more realistic risk assessments, e.g., when using individual based population modelling with common voles for risk assessments.

6.02.P-We362 How to Demonstrate Representativeness of Field Studies using GIS – An Example with Common Vole in Grassland in Germany

***Ines Hotopp**[1], Anja Russ[2] and Olaf Fuelling[2], (1)tier3 solutions, Germany, (2)Tier3 Solutions, Germany*
The representativeness and transferability of field studies is often questioned by authorities. However, the current EFSA guidance on the risk assessment for birds and mammals (2009) and also the new draft guidance (2021) give no method or measure on how do to prove that a study is representative or that its results can be transferred to another area. Geographic information systems (GIS) can be used to show that a study location is representative for a wider area, even a regulatory zone. Here, we give an example using the common vole in grassland in Germany. The analysis uses temperature and precipitation to describe climatic conditions, the proportion of different crop types to describe the agricultural landscape. As the study area, a region at the FNU Research Centre, North of Frankfurt (Germany), was selected. For the climatic conditions, the mean monthly temperature and the mean monthly precipitation sum were calculated. Agricultural landscape and occurrence of grassland were described using the EU crop map (2018) by d'Andrimont et al. (2021) calculating the proportion of the crop types. As common voles are ubiquitous in Germany, there was no need to analyse their occurrence. The parameters were calculated for 25 km grid cells overlaying the country and the study area. For each parameter, the mean of the study area, consisting of four grid cells, was compared to the whole of Germany by calculating the proportion of grid cells with similar conditions. The study area was representative of Germany for the chosen parameters with parameter values lying in the same range as values for most other grid cells. Climatic conditions, agricultural landscape and occurrence of the crop of interest were in a range common for Germany. For these parameters, the method chosen here worked well. However, a few factors should be considered when applying GIS methods: GIS data for specific crops, especially less common crops are hard to acquire. The resolution and the timeliness of data can cause problems. There are no standardized practices on how to analyse the representativeness of a study area. Using GIS is an option with many possibilities. However, the applicability of spatial data is still limited by data fragmentation and decentralized generation, because of competing interests and variety of formats. There is an urgent need for centralized access to data.

6.02.P-We363 Availability of Pesticide Treated Seeds on the Soil Surface for Birds and Mammals After Drilling

***Joerg Hahne**[1], Manousos Foudoulakis[2], Steven Kragten[3], Kai Ristau[4], Dennis Sprenger[5] and Magnus Wang[6], (1)Environmental Safety, Bayer AG - Crop Science Division, Germany, (2)Corteva Agriscience, Greece, (3)Syngenta Agro, Germany, (4)BASF SE, Germany, (5)Corteva Agriscience, Germany, (6)WSC Scientific, Germany*
For seed treatments, the current long-term tier 1 risk assessment for birds and mammals is based on the assumption that animals have *ad libitum* access to treated seeds. This is a highly conservative assumption as seeds are typically drilled into the soil, while only a small fraction of seeds may remain on the soil surface. Therefore, one of the key factors to realistically assess the risk from treated seeds to birds and mammals is their availability on the soil surface after drilling. To quantify the seeds' availability, De Snoo and Luttik (2004) reported soil incorporation rates in different crops, for different periods of the season and for different drilling techniques. These numbers are frequently used to conceptualize the risk for birds and mammals from exposure to treated seeds: Assuming that each and every seed available at the soil surface is eaten, the area which needs to be searched upon until a critical (toxic) level is reached, can be calculated. If this area is unrealistically large, compared to the foraging behavior of a species, the risk can be considered acceptable.
Due to advances in drilling technology, the seed incorporation efficiency has increased, leading to fewer numbers of treated seeds on the soil surface. Based on several field trials conducted after 2004 an updated database of incorporation efficiencies and exposure of treated seeds on the soil surface, respectively, will be presented, focusing on cereals, oilseed rape and sunflower.

Using this updated information will result in a more realistic and representative birds and mammal risk assessment for treated seeds.

6.02.P-We364 Bird and Mammal Generic Field Studies – Early Application of Reliability Criteria According to the Draft Update to the EFSA Guidance Document

Christopher Taylor[1], *Apostolos Koutsaftis*[2], *Graeme Last*[1], *Sarah Butler*[1] *and Steven Kragten*[3], *(1)ERM Regulatory Services, United Kingdom, (2)ERM Regulatory Services, Netherlands, (3)Syngenta Agro, Germany*

Under mandate from the European Commission, a revision to the EFSA Guidance Document for the Risk Assessment for Birds and Mammals (EFSA Journal 2009; 7(12):1438) has been made and circulated for stakeholder commenting. Amongst the updated content in this revised Guidance Document is a much-expanded section on the assessment of 'Tier 3' generic field studies. This includes a dedicated set of evaluation criteria to assess the reliability and relevance of these study types. A dedicated 'Annex D' evaluation template is provided as part of the Guidance Document revision with the intent that future generic field study evaluation is conducted using this template.

The aim of the work presented here was to evaluate the suitability of this set of reliability criteria for the evaluation generic birds and mammals field studies. In total there are 21 distinct reliability criteria covering areas including general study information, study conditions, the organisms studied, the study methodology, and the statistical design and biological responses assessed. Each criterion is to be scored as one of 'fulfilled', 'not fulfilled', 'not reported' or 'not applicable' and, based on these, an overall reliability score assigned to the study.

The 21 reliability criteria were individually considered and further methodology to fully identify information required to fulfil each criterion was developed based on expert interpretation and judgement. In preparation and application of this methodology it was found that expanded methodology and 'weighting' of individual criteria was essential to the appropriate evaluation of each study. It was also found that some of the individual reliability criteria have no clear or straightforward answer as to what is sufficient for complete fulfilment and in these cases further expert judgement and/or clarification of the criterion is needed. Furthermore, the weighting of individual criteria to influence the overall reliability score for a study is not well instructed and can vary greatly depending on the extent of criterion fulfilment, as well as the objectives and primary endpoints derived from the study. In conclusion, further clarification and/or development of robust standard evaluation procedures is essential to most appropriately evaluate the reliability of these study types according to the new reliability criteria.

6.02.P-We365 Residue Studies for B&M RA: Controlling the Uncontrollable

Helena Crosland[1], *Gabriel Weyman*[2] *and Alan Lawrence*[3], *(1)Cambridge Environmental Assessments, United Kingdom, (2)Gabe Weyman Consulting, United Kingdom, (3)Independent Consultant*

In 2021 EFSA launched the public consultation on the draft updated guidance document on Risk Assessment for Birds and Mammals. This updated guidance included greater detail relating to the performance and evaluation of residue studies for the purpose of refining residue decline on food items for higher tier bird and mammal risk assessment. This is a welcome addition, as designing and performing such studies often raises a large number of complex problems to solve. However, experience to date of designing and monitoring such studies has highlighted many examples where reality does not conform to the guidance document requirements, or where the available guidance does not provide answers.

This poster aims to outline some of these issues, such as: locating sufficient amounts of a matrix for sampling (e.g. the natural lack of abundance of earthworms in some agricultural fields, particularly in Southern Europe); how to appropriately investigate residues in seeds; how to appropriately measure residues in plant matter when applying desiccating herbicides (and implementation in the risk assessment); what is an appropriate spatial and temporal distribution of trial sites; and how to deal with extreme weather events (what is the 'new normal' in the context of climate change?).

A consideration of potential solutions to these issues will be made, as well as reference to any useful information provided within the new draft guidance.

6.02.P-We366 The Harvest Mouse (Mictromys minutus) as Focal Species in the Risk Assessment

Olaf Fuelling[1], *Ines Hotopp*[2] *and Anja Russ*[1], *(1)Tier3 Solutions, Germany, (2)tier3 solutions, Germany*

Hitherto, the in-field risk assessment of birds and mammals to plant protection products was considered protective for off-field populations. The EFSA's draft guidance on birds and mammals, though, underlines the need to consider some small mammal species in the risk assessment that are mainly found in the off-field area. In addition, a small granivore of 6 g should be considered in the crops with BBCH >39. One of the species that is thus becoming the focus of interest is the harvest mouse (*Micromys minutus*).

The granivorous harvest mice are widespread in Europe and Asia. As highly specialized stalk climbers, their original habitats were in reed beds and high grass fields. Secondarily, they occur in cereal and beet fields, shrub-land interspersed with tall grasses and also in orchards. However, harvest mice are not commonly encountered in widespread surveys. They have a very patchy distribution, with 75 % of suitable habitat unoccupied with no clear justification for habitat colonization. Due to three-dimensional habitat use, harvest mice are usually underrepresented in standard small mammal traps set up on the ground. Also, the count of their elevated nests in tall vegetation is not an accurate measure to provide information on the actual population size, although detecting nests can be seen as prove of (recent) harvest mice occurrence.

Here, we discuss methods to identify off-field habitats and in-field occurrence of harvest mice that may be suitable for focal species studies with small granivorous species. Non-invasive methods like camera trapping, baited aerial tubes combined with species identification based on DNA from faeces samplings seem to be appropriate and timely methods for population studies of the harvest mouse to inform the risk assessment.

6.02.P-We367 Rabbits: Ecology, Management and Implications for Risk Assessment of Plant Protection Products
Steven Kragten[1], *Joachim Nopper*[2] *and Felix von Blanckenhagen*[3], *(1)Syngenta Agro, Germany, (2)BASF SE, Germany, (3)RIFCON, Germany*
The draft of the new Guidance Document on the risk assessment for birds and mammals in Europe (EFSA 2021) proposes to assess the risk of plant protection products (PPPs) to new generic model species (GMS) for many crop scenarios at Tier 1 with implications for the need of higher tier risk refinement.
CropLife Europe (CLE) conducted an impact assessment on 34 registered active substances covering 76 different representative uses (GAPs). The medium herbivorous mammal scenario had in almost 50% of all cases the lowest TER values for crop/species scenarios that failed. For risk assessments for the same use but following Guidance Document EFSA 2009 this was only the case for 20% of the failing scenarios. This indicates that under the new guidance document, the medium herbivorous mammal will often fail at tier 1 and will therefore often require refinement.
For higher tier risk assessment, the selection of focal species is a crucial step. The European rabbit (*Oryctolagus cuniculus*) is the medium herbivorous mammal with the lightest body weight in Europe and therefore potentially more exposed to PPPs compared to other species. However, based on scientific data, the relevant focal species has often been determined to be the brown hare (*Lepus europaeus*) and this has been accepted by several Member States. Because the new guidance document will result in many more failures of the medium herbivorous mammal scenario at Tier I (e.g. due to the increase in the number of scenarios for which medium herbivorous mammals are considered to be relevant, the use of BMDL10 instead of NOAEL, restricted use of the time-weighted average factor, assuming that herbivorous mammals feed on crops instead of weeds), the necessity to determine the relevant focal species in a higher tier risk assessment becomes increasingly important.
To better describe the relevance of the European rabbit in the risk assessment for PPPs, we here present the results of a thorough literature review on rabbits focusing on: European distribution, biology and population dynamics, feeding and habitat preferences, impact of agriculture on rabbits, impacts of rabbits on agroecosystems and rabbit population management in European farmland. Based on the information provided in the scientific literature, proposals will be made to facilitate the focal species selection for the medium herbivorous mammal scenarios for particular European regions as well as for particular crops and BBCH scenarios.

6.02.P-We368 Review of the Relevance of the Rabbit Prenatal Developmental Toxicity Study for Wild Mammal Risk Assessments
Mary Moxon[1], *Paula Garcia*[2], *Nina Hallmark*[3] *and* ***Manousos Foudoulakis***[4], *(1)MMTGS, (2)Corteva Agriscience, United Kingdom, (3)Bayer AG - Crop Science Division, France, (4)Corteva Agriscience, Greece*
The current EFSA guidance document for the assessment of risk for birds and mammals from exposure to plant protection products containing pesticides in accordance with Regulation (EU) 1107/2009, was first published in 2009 and the updated draft published in 2021 is currently under review.
The 2021 draft guidance outlines a tiered risk assessment scheme which includes evaluation of endpoints relevant for the maintenance of mammalian populations in the wild. The data on the relevant endpoints are derived from reproductive/long-term toxicological studies conducted in laboratory mammals as required for human safety assessment. Several studies on reproduction and development are routinely conducted for pesticides; all are generally conducted in the rat with one evaluation of prenatal development conducted using the rabbit. The rabbit is a required species because of its known susceptibility to some teratogenic chemicals which have no activity in the rat. However, the rabbit when used as a laboratory test species presents unique challenges affecting data study outcomes. Unlike the rat, individual rabbits do not respond in a consistent manner. In addition, it is worth considering that the rabbit has a unique digestive system and a known vulnerability to stress leading to outcomes which may be misinterpreted as toxicity.
That the rabbit is an important species for the detection of certain chemical teratogens is without doubt. But, is the rabbit a relevant species for the identification of systemic/maternal toxicity? Are all fetal observations that are considered human relevant also ecotoxicologically relevant?
In this poster we share the outcome of a novel analysis of the different parameters measured in the rabbit prenatal developmental toxicity study (OECD TG 414). Building on the 2021 draft EFSA Guidance document, we use these challenging questions and the answers to derive updated recommendations on the ecotoxicological (non-)relevance of the different study observations in this laboratory study as the basis for the endpoint for chronic wild mammal risk assessment.

6.02.P-We369 Seed Treatment Risk Assessment Scheme in the New EFSA Draft GD for Birds and Mammals: A Critical Review
Dennis Sprenger[1], *Manousos Foudoulakis*[2], *Joerg Hahne*[3], ***Steven Kragten***[4] *and Kai Ristau*[5], *(1)Corteva Agriscience, Germany, (2)Corteva Agriscience, Greece, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany, (4)Syngenta Agro, Germany, (5)BASF SE, Germany*
The current guidance document for birds and mammals (EFSA 2009) includes a risk assessment scheme covering exposure to treated seeds and emerging seedlings.
For the exposure to treated seeds, EFSA predicted a high failure rate at tier 1 and acknowledged that it is not possible to provide a standardised approach for a refined assessment. This has led to highly inconsistent evaluations by regulators for the same data set since the implementation of EFSA 2009.
In this presentation we highlight how the risk assessment for seed treatments in the new EFSA draft GD (EFSA 2021) compares to EFSA 2009.

For tier 1, we aim at presenting an impact assessment to evaluate how proposed changes in EFSA 2021 (e.g. no fTWA factor for treated seeds, use of BMD analysis on toxicity endpoint selection) affect toxicity-to-exposure ratios (TERs) compared to EFSA 2009.
For higher tier, we review proposed refinements in the EFSA draft GD, reflect the critical factors driving exposure of birds and mammals to treated seeds and seedlings under field conditions, and propose additional refinements to render the higher tier risk assessment more realistic.
Our preliminary analysis concludes that while EFSA 2021 includes positive elements for the emerging seedling scenario, there is no improvement over EFSA 2009 for the treated seeds scenario. With a more conservative tier 1, and fewer refinement options, we predict that even more products will be triggered into a weight-of-evidence (WoE) analysis for higher tier compared to EFSA 2009. At the same time, however, no detailed guidance is provided on how to conduct a WoE analysis and on how to evaluate WoE data from a regulator's perspective. This is considered problematic as WoE analysis are typically comprehensive, require significant resources, and rely on expert knowledge on agronomic practices and the ecology of exposed bird and mammal species.
In the light of activities to reduce pesticide exposure in Europe, seed treatments present an effective technology to reduce exposure to non-target organisms. However, the proposed risk assessment scheme in the EFSA draft GD leads to high uncertainty for producers and farmers about the availability of this technology in the future.
We therefore promote an open discussion with key stakeholders and call for a timely revision by EFSA of the seed treatment risk assessment for inclusion in the final GD.

6.02.P-We370 Reduced Reproductive Performance in Birds Feeding on Triazole-treated Seeds
Claudia Santamaria[1]*, Manuel Ortiz Santaliestra*[2]*, Marta Herrero Villar*[3]*, Samuel González López*[4] *and Rafael Mateo Soria*[5]*, (1)Institute for Research in Hunting Resources (IREC), Spain, (2)Instituto de Investigación en Recursos Cinegéticos, Spain, (3)Institute for Game and Wildlife Research, IREC (CSIC-UCLM), Spain, (4)Instituto de Investigación en Recursos Cinegéticos (UCLM-CSIC-JCCM), Spain, (5)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos, Spain*
During the last decades, there has been a decline in farmland bird populations across Europe. This regression has been attributed to agricultural intensification, which is characterized, among other components, by the use of pesticides. Triazoles are a group of fungicides used as seed coating treatments in crops, and wildlife associated with agro-ecosystems can easily come into contact with these compounds, especially granivorous birds that consume sown seeds. Triazoles are the most commonly found pesticides in digestive contents of red-legged partridges during the sowing season in autumn. Triazoles used for cereal seed treatment have been shown to affect the reproductive success in birds, reducing fertilization rate or brood size. The objective of this study was to measure reproductive effects on the red-legged partridge feeding on seeds treated with the formulated product Raxil Plus, one of the main products used for treatment of winter cereal seeds in Spain that contains tebuconazole and prothioconazole as active ingredients. We fed partridges with wheat seeds treated with 0% (control), 20% (low dose) or 100% (high dose) of the product labelled application rate. The animals were exposed during 20 days in late autumn, and reproductive parameters (i.e. fertilization, hatching and chicken survival rates) were later monitored in spring. In addition, gonadal size was measured in 12 partridges euthanized at the beginning and end of the breeding period. Fertilization, hatching and chick survival rates were significantly reduced in couples that had been fed with Raxil-treated seeds between three and six months before. These results agree with those found in other studies, which observed a 23% decrease in hatching rate and reduced brood size in partridges exposed to triazoles. In addition, the right testicle of birds that had consumed treated seeds was smaller than that of controls. The fact that triazole exposure in autumn may cause reproductive effects several months later supports the disruption of steroid-regulated processes as the mechanism of toxicity and reveals how the intensive use of triazole-treated seeds in agriculture could affect farmland bird populations through the impairment of their reproductive capacity.

6.02.P-We371 Revised Residue Per Unit Dose Values for the Food Item "Seeds" At Late Crop Growth Stages for Use in Bird and Mammal Risk Assessments of Plant Protection Products
Joachim Nopper[1]*, Manousos Foudoulakis*[2]*, Paula Garcia*[3]*, Michail Gioutlakis*[4]*, Sonja Haaf*[5]*, Steven Kragten*[6] *and Kai Ristau*[1]*, (1)BASF SE, Germany, (2)Corteva Agriscience, Greece, (3)Corteva Agriscience, United Kingdom, (4)RIFCON, Germany, (5)Environmental Safety, ADAMA Deutschland, Germany, (6)Syngenta Agro, Germany*
The draft of the new guidance document on the risk assessment for birds and mammals in Europe (EFSA 2021) provides default residue values, expressed as mg active substance/kg fresh weight, normalized to an application rate of 1 kg active substance/ha, for bird and mammal food items to be used in wildlife risk assessments. Some of these default 'Residue-per-Unit-Dose' (RUD) values for, e.g., monocot and dicot foliage, or fruits are based on large numbers of residue studies that were provided by industry and reviewed by EFSA.
The RUDs for crop and weed seeds are based on published literature (Fletcher et al. 1994) for residues measured in the plant category "leaves, leafy crops, forage crops and small seeds" and were last evaluated in 2002 (EC 2002). It was not possible for the authors to reproduce these RUD values that are still used today, since access to the data on individual residue trials, e.g., their location, the analysed matrix and crop, are lacking. Moreover, since current seed RUDs are based on an evaluation that was published in 1994, the values are likely based to a large extent on legacy chemicals that have long been withdrawn from the European market and may have been generated outside the EU. Altogether, data are of unclear relevance for regulatory purposes and current EU agricultural conditions.
To update the RUDs for the food item "seeds" at relevant crop growth stages of treated crops (BBCH ≥ 70) – i.e., not for (treated) seeds on the soil surface – we evaluated available residue studies that were conducted by industry for regulatory purposes in which residues on seeds were measured. Only data from GLP studies that were conducted in Europe were used. Trial data were

further processed when sampling took place directly after the last application. RUDs were then calculated using the maximum residue measurements after the last application accounting for the applied rate of the substance.
The analysis of the residue trials revealed significantly lower seed RUDs compared to the default seed RUDs given in the current EFSA guidance document (EFSA 2009), which are the same as in the new draft guidance document (2021) as well as the first guidance document on the risk assessment for birds and mammals in Europe (EC 2002). Consequently, new, and more realistic default RUDs for seeds are proposed that should be considered in future risk assessments.

6.02.P-We372 Use of the Open-Source Software Open Systems Pharmacology Suite (PK-Sim® and MoBi®) in Environmental Risk Assessment
Stephan Schaller[1]*, Vanessa Baier*[1]*, Alicia Paini*[1]*, Colin G Scanes*[2]*, Audrey Bone*[3]*, Markus Ebeling*[4]*, Thomas G Preuss*[4]*, Johannes Witt*[4] *and David Heckmann*[4]*, (1)esqLABS, Germany, (2)Department of Poultry Science, University of Arkansas, (3)Bayer AG - Crop Science Division, (4)Bayer AG - Crop Science Division, Germany*
Environmental risk assessment of chemical substances covers the prediction and evaluation of the likelihood and magnitude of the potential adverse effects these substances may produce on wildlife, ecosystems and soil and water-based biological communities. Physiologically-based kinetic (PBK) modelling has emerged as a tool in several sectors (pharma, veterinary, medicine, cosmetics, and agrochemicals including pesticides) where they play a pivotal role for understanding and quantifying the chemical mode of action for risk assessment or precision medicine. PBK models are a mathematical representation of the animal body, describing the adsorption, distribution, biotransformation (metabolism) and elimination of a xenobiotic. PBK models can be built using different sources of data, such as *in vivo, in vitro* and *in silico* kinetic data. As new approach methodologies (NAMs) such as *in vitro* to *in vivo* extrapolation (IVIVE) are emerging also in environmental studies, the application of PBK modeling is key when it comes to interpretation and extrapolation of the data from *in vitro* toxicity assays to *in vivo* exposure doses.
The open-source software Open Systems Pharmacology Suite (OSPS, with tools PK-Sim and MoBi) is specifically tailored towards user friendly, robust, and workflow-supported (GUI-based) modelling and simulation. It combines the ease and efficiency of the GUI-based professional PBK tool PK-Sim with the customizability of the GUI-based mechanistic modeling tool MoBi (similar to Sim-Biology). PK-Sim provides physiology databases of multiple animal species and human populations (including maternal-fetal and preterm neonates). MoBi allows mechanistic modeling in all its detail and full user-based customization of the PBK models, allowing extensions of compartmental structures to any level of detail and the addition of complex kinetic/dynamic mechanisms for an integrated quantitative in-vitro in-vivo (QIVIVE) extrapolation framework.
With this work, we discuss the use of the OSPS platform in support of regulatory decision making under the toxicology and environmental risk-assessment paradigm, showing the development of a generic bird PBK model. The strengths, gaps, uncertainties, and limitations of the platform will be discussed as well as how the validity and credibility of predictions/simulations is achieved. We aim to support a higher degree of confidence in the application of such models in a regulatory context.

6.02.P-We373 What Does It Take to Make an Egg: A DEB Egg Laying Module for Birds Applied to the Bobwhite Quail
Benoit Goussen[1]*, Nina Marn*[2]*, Konstadia Lika*[3]*, Starrlight Augustine*[4]*, Markus Ebeling*[5]*, David Heckmann*[6] *and* ***Andre Gergs***[6]*, (1)ibacon, Germany, (2)Ruder Boskovic Institute, Croatia, (3)Department of Biology, University of Crete, Greece, (4)Akvaplan-niva AS, Norway, (5)Environmental Safety, Bayer AG - Crop Science Division, Germany, (6)Bayer AG - Crop Science Division, Germany*
Understanding and managing risks builds on understanding the ecology and functioning of the system and/or organisms which are at risk. Birds inhabiting grasslands and wetlands, especially linked to agricultural or other commercial activities, are potentially exposed to harmful chemicals via water, food, or both. This positions birds as relevant model organisms for risk management, which, in turn, requires detailed knowledge on their ecology, metabolism, and relevant physiological processes. Particularly, growth, development, and reproduction are endpoints which are relatively easy-to-observe and to interpret. However, for many bird species the reproductive system builds up and major tissue remodelling happens at each reproductive season, coupled with increased food ingestion prior to and during reproduction. Despite research on this topic picking up, there is no clear scientific consensus on the energetic specifics behind these processes. We here used data available in the literature and reports to elucidate the energy fluxes linked to reproduction, by expanding a Dynamic Energy Budget (DEB) model for birds. The expansion of the standard DEB model consisted in a process-based explicit egg-laying module. We formulated and tested two assumptions for the energy allocation of extra assimilates observed in birds prior to and during the reproduction period. The first hypothesis assumed that the energy and nutrients are used directly for egg production. The second hypothesis assumed that the energy is mostly spent fuelling the increased metabolic costs incurred by building up and maintaining the reproductive system and ultimately by the egg laying process itself. We focused on one of the most studied and used bird species in risk assessment, the northern bobwhite quail (*Colinus virginianus*). Our results suggest that the second hypothesis is the more probable energy pathway. The model predictions capture well the development of the northern bobwhite quail and reproduce accurately most of the observed variability in egg size, egg-laying rate, and inter-individual physiology. As such, this model can be used as the physiological building block in the environmental risk assessment of birds exposed to anthropogenic stressors. Reliable models with an ability to predict physiological responses of individuals are relevant not only for experimental setups, but also for wild quail management and conservation.

6.02.P-We374 DEB-TKTD Analysis of Avian Reproduction Study: The Bobwhite Quail Exposed to Fluopyram
Benoit Goussen[1]*, Starrlight Augustine*[2]*, Nina Marn*[3]*, Konstadia Lika*[4]*, Markus Ebeling*[5]*, David Heckmann*[6] *and* ***Andre Gergs***[6]*, (1)ibacon, Germany, (2)Akvaplan-niva AS, Norway, (3)Ruder Boskovic Institute, Croatia, (4)Department of Biology, University*

of Crete, Greece, (5)Environmental Safety, Bayer AG - Crop Science Division, Germany, (6)Bayer AG - Crop Science Division, Germany

Mechanistic modelling to analyse the effect of chronic exposure of chemicals to birds is rapidly gaining interest in the environmental risk assessment field. Lately, the new draft guidance document on risk assessment for birds and mammal from EFSA includes the possibility to use toxicokinetic-toxicodynamics (TKTD) models. In particular, the use of a TKTD module in combination with a physiological model like the Dynamic Energy Budget (DEB) model is recommended. In this study, we integrated a TKTD module into a DEB model with an egg-laying module for bobwhite quail (*Colinus virginianus*) to accurately predict the reproduction endpoints as well as the early development of chicks in both control and exposed situations. We calibrated the DEB module based on literature and control data and the TKTD module based on an avian reproduction study for the standard test species *C. virginianus* exposed to fluopyram. The model described generally very well the growth, development, and reproduction of the F0 generation for control and all different treatments. However, the model failed to capture accurately the wet weight of the F1 generation at hatch and at 14 days unless it was assumed that the mother transferred some of the contaminant into the eggs and that this impacted the offspring. This first analysis confirmed the need of an additional stress factor to capture the effect observed on the F1 generation. We therefore implemented an exploratory simplified TD module for the embryo and chick whereby the level of effect of the offspring is related to the level of contaminant in the mother. This additional module enabled the model to accurately capture the effects observed on the chicks of a mother exposed to fluopyram. Such approach highlights the added value of developing relevant process-specific modules (egg-laying in this case) and has the potential to make better use of existing and future data sets, providing means for a more accurate extrapolation of effects to birds from pesticide exposures in the field.

6.02.P-We375 Challenges of the Assessment of Possible Synergistic Effects in Pesticide Formulations with More Than One Active Ingredient Using Acute Mammalian In Vivo Test Results

*Sonja Wich[1], Stephanie Plautz[2], Christel Schopfer[1] and **Joachim Nopper**[1], (1)BASF SE, Germany, (2)BASF SE*

The draft EFSA guidance document on risk assessment for birds and mammals that was released in Sept 2021 requires an assessment of possible synergy for pesticide formulations containing more than one active ingredient. Acute oral toxicity studies using rats are often available for both active ingredients and formulations. However, these studies are typically conducted for classification and labeling purposes using the acute toxic class method (OECD 423) with a few female animals. The objective of this method is not the calculation of a definite LD50. Instead, the endpoint is expressed within a range of tested doses corresponding to the toxicity classes (e.g., 300 mg/kg bw < LD50 < 2000 mg/kg bw).

To assess whether additive or synergistic effects of several active ingredients in the formulation are expected, the EFSA Guidance document requires the comparison of LD50 values for the respective formulation. If the comparison between the predicted and experimental LD50 values, defined as MDR, deviate by more than a factor of 3, potential synergistic interaction between the ingredients is assumed and additional safety factors in the acute and chronic risk assessments are proposed.

Robust and definite LD50 values are required to generate reliable MDR values for a valid risk assessment. Otherwise, many conclusions of possible synergy are likely, where none actually exists, with associated risk assessment implications. We show exemplarily the challenges of calculating the MDR with non-definitive LD50 values. Innovative methods to evaluate possible synergy mechanism in wild mammals beyond MDR calculations using OECD 423 data for the formulation of interest are under exploration.

6.02.P-We376 Challenges of Using Predicted Environmental Concentrations in Pore Water and Soil to Predict Secondary Poisoning Risk Assessment in Birds and Mammals

*Garcia Lucas[1], **Sebastian Multsch**[2], Nadine Kämmer[1], Susanne Hein[1] and Barbara Birk[1], (1)BASF SE, Germany, (2)APD/EFM, BASF SE, Germany*

The bioaccumulative potential for substances with a log K_{ow} >3 and the risk of secondary poisoning for vermivorous birds and mammals is supposed to be assessed using the pore water approach as described in the revised draft GD (EFSA 2021). Within this new approach, the predicted environmental concentration in earthworms ($PEC_{earthworm}$) is calculated by combining two different routes of exposure: direct exposure of earthworm tissue from substance residues in pore water (PEC_{pw}) as well as by dietary exposure via consumption of soil (PEC_{soil}). This is rendered possible by the newest revision of the soil exposure assessment as presented in EFSA (2017), where a PEC_{pw} is explicitly established along with PEC_{soil}. In this new framework, PEC_{pw} and PEC_{soil} are calculated by considering specific pedoclimatic scenarios to define realistic worst-cases, whether they are predefined scenarios (tier 1), or corresponding to a selected vulnerability level (95^{th} percentile concentrations from spatialized simulations in the cropping area of interest in tier 2 and 3A). Specific scenarios must be established as the pedoclimatic conditions leading to realistic worst-case PEC_{pw} and PEC_{soil} are mutually exclusive: PEC_{pw} is maximum when the availability of the compounds in the liquid phase is high, PEC_{soil} when the substance remains in the modeled soil profile by adsorbing to the solid phase. This aspect is mainly driven by the Organic Matter (OM) content which governs the partitioning of the substance between liquid and solid phases of the soil, and its subsequent mobility. This results in vastly different modeling scenarios when conducting risk assessments either based on PEC_{pw} or PEC_{soil}: from tier 2 onward, the OM content at the 95^{th} spatial percentile scenarios for PEC_{pw} and PEC_{soil} can differ by a factor of 4.8 to 5.8. Consequently, the combined use of PEC_{pw} and PEC_{soil} needs to be considered carefully. Using the direct outputs of the soil exposure assessment for PEC_{pw} and PEC_{soil} would lead to an unrealistically conservative earthworm exposure that would consider two mutually exclusive worst-case scenarios, which combination wouldn't be possible in the first place. In this poster we demonstrate the conservativeness of considering both worst-case PEC_{pw} and PEC_{soil} in comparison to more consistent and realistic PEC_{pw} /PEC_{soil}-pairs.

6.02.P-We377 Evaluation of Determining the Bioconcentration Factor in Earthworms in the Context of Secondary Poisoning – Dry Soil vs. Pore Water Approach

*Nadine Kämmer[1], Susanne Hein[1], Barbara Birk[1], **Joachim Nopper**[1] and Stephanie Plautz[2], (1)BASF SE, Germany, (2)BASF SE*

Assessing the risk of secondary poisoning to earthworm-eating birds and mammals is a mandatory part of registration dossiers of plant protection products. The current EFSA Guidance Document for Risk Assessment for Birds and Mammals (2009) as well as the recently revised draft version (2021) describe two approaches to conduct the risk assessment: the dry soil and the pore water approach. An integral part of both approaches is the calculation of a theoretical bioconcentration factor (BCF) in earthworms that is then used to calculate a theoretical predicted environmental concentration (PEC) in earthworms. However, the calculations of the bioconcentration factor for the two approaches lead to widely different values. Within the dry soil approach, the BCF is calculated as $(F_{water} + F_{lipids} * k_{ow})/f_{oc*}k_{oc}$, where F_{water} and F_{lipids} are the volume fraction of water and lipids, respectively, k_{ow} is the octanol-water partitioning coefficient, f_{oc} is the fraction of organic carbon content in soil and k_{oc} is the organic carbon normalized soil adsorption coefficient. In the pore water approach, BCF is calculated as $(F_{water} + Flipids * k_{ow})/RHO_{earthworm}$, where $RHO_{earthworm}$ represents the bulk density of an earthworm, which is equal to 1. Both k_{oc} and f_{oc} are not included in the equation for the BCF anymore and therefore the estimation of the BCF in the pore water approach is solely driven by the k_{ow} of a substance. Further, the term $F_{water} + F_{lipids} * k_{ow}$ assumes a constant uptake of a substance into the earthworm, which seems biologically not applicable. For a more realistic BCF the relationship between k_{ow} and $f_{oc*}k_{oc}$ might be therefore an essential part of the BCF calculation. We show the challenges of determining robust BCF values when using the BCF equation from the pore water approach in contrast to the BCF equation from the dry soil approach.

6.02.V Bird and Mammal Risk Assessment: Now and Preparation for the Future

6.02.V-01 Challenges of Benchmark Dose Analyses for Risk Assessors

*Christian Dietrich and **Magnus Wang**, WSC Scientific, Germany*

For benchmark dose (BMD) modelling as a method of parametric statistical modelling, certain prerequisites such as data following a certain distribution or having homogeneous variance must be fulfilled in order to be able to conduct the method correctly. Often, the fulfilment of these prerequisites is insufficiently checked or not checked at all. For example, in the case of biological data used for benchmark dose analyses, it is often not clear how they are actually distributed. Incorrect assumptions about the data distribution or even the selection of models that do not make biological sense can lead to the results of the analysis being significantly distorted. Moreover, routine data transformations can distort the data to such an extent that, in the end, a correct basic assumption is no longer fulfilled. The extent of the distorted results due to false assumptions can go in any direction: Too wide or too narrow confidence intervals of the BMD can be the result, whereby the corruption of the width affects both the robustness of the analysis and the BMDL (lower limit of the BMD confidence interval) as a reference point for the risk assessment.

The difficulty of handling data correctly to carry out valid BMD analyses already existed for the frequentist paradigm in the EFSA Guidance on the use of the benchmark dose approach in risk assessment (2017), still exists for the Bayesian paradigm in the updated EFSA Guidance (2022) and will be further explored here by showing examples of what can go wrong.

6.03.A Data-Driven Environmental Decision-Making: Generating Relevant Datasets for Regulatory Assessment of Endocrine-Disruption

6.03.A.T-01 New transgenic medaka model to detect disruption of thyroid signalling

***Elise Pesce**[1], Andrew Tindall[2], Gregory F. Lemkine[2], Laurent Sachs[3], David Du Pasquier[2] and Marion Garde[4], (1)LABORATOIRE WATCHFROG, France, (2)Watchfrog S.A., France, (3)UMR 7221 CNRS/MNHN Muséum National d'Histoire Naturelle, France, (4)Laboratoire Watchfrog, France*

Endocrine disruption caused by chemicals has been considered as a major issue over the last few decades for both human and wildlife health. Identifying endocrine disrupting chemicals in order to limit their usage is therefore a priority. EU authorities has defined a testing strategy to determine the potential endocrine activity on EATS (Estrogen, Androgen, Thyroid, Steroidogenesis) axis. Regarding thyroid disruption, three OECD guidelines using *in vivo* non-mammalian models are validated, all of them are based on amphibian metamorphosis. In the most recent assay, the XETA (*Xenopus Eleutheroembryo Thyroid Assay*, OECD N°248), an amphibian (*Xenopus laevis*) transgenic line expresses a fluorescent protein which is quantifiable and proportional to thyroid axis activity.

To date no OECD test guideline based on fish are available for the detection of Thyroid Active Chemicals (TACs). We aim to fill this gap by developing a new test for the detection of TACs using medaka eleutheroembryos *(Oryzias latipes).*

This test involves a transgenic line, expressing Green Fluorescent Protein (GFP) under the control of the *thyroglobulin* promoter (the precursor of thyroid hormones). We first identify the medaka sequences presumably involved in the regulation of the expression of *thyroglobulin*. A transgene was then built by cloning this putative promoter upstream of the *gfp* coding sequence. Series of micro-injections were performed in one-cell embryos in order to develop transgenic lines. Screening the offspring reveals that four stable transgenic lines were obtained with different transmission rates but all having fluorescent thyroid follicles. The most promising line showed variation of total fluorescence when exposed to TACs, reflecting the negative feedback loop of Hypothalamic–Pituitary–Thyroid axis.

This novel transgenic medaka fish line tg(*tg:eGFP*) provides a promising tool for endocrine disruption assessment of chemicals in fish. Developing an assay based on this transgenic medaka offers the possibility to combine this assay with the REACTIV and/or

RADAR assays (OECD TG n°251). This strategy could lead to reduce the time, number of eleuthero-embryos and cost associated with EATS assessment in fish.

6.03.A.T-02 Refining in vivo Fish Tests by inclusion of Thyroid Hormone System Sensitive Endpoints to improve Regulatory relevant Data

***Henrik Holbech*[1]**, *Lucia Vergauwen[2], Lisa Annie Baumann[3], Peter Matthiessen[4], Taisen Iguchi[5], Thomas Braunbeck[6] and Dries Knapen[2], (1)University of Southern Denmark, Denmark, (2)University of Antwerp, Belgium, (3)Vrije University Amsterdam, Netherlands, (4)Pembrokeshire, United Kingdom, (5)Yokohama City University, Japan, (6)University of Heidelberg, Germany*

Several research projects and OECD member countries are working together to include thyroid hormone system (THS) sensitive endpoints into OECD fish test guidelines. Here we present an update of these efforts with emphasis on the results of the EU Horizon 2020 project ERGO and a proposal for a forthcoming OECD validation of selected endpoints. The ERGO project aims at breaking down the wall between mammalian and non-mammalian vertebrate regulatory testing by identifying, developing and aligning THS sensitive biomarkers and endpoints for linkage of effects between different vertebrate classes. A part of this work is dedicated to development and validation of potential THS sensitive endpoints in fish. Such does not yet exist but are highly warranted because fish tests are included as standard information requirements in many regulations. For example, OECD TG 210 the Fish Early Life-stage Toxicity Test (FELS) is required under the EU REACH regulation for chemicals imported or produced >100 tonnes per year and in the data requirement for active substances in plant protection products. With the the addition of hazard classes for endocrine disrupters under the Classification, Labelling and Packaging Regulation (CLP), information on endocrine activity and adversity from standard fish tests become even more relevant. ERGO-generated fish data support project 2.64 (inclusion of THS sensitive endpoints in OECD fish Test Guidelines) which is on the OECD Work Program under the Validation Management Group for Ecotoxicity Testing (VMG-Eco) and co-lead by Denmark, Belgium and Germany, as well as project 1.35 of the OECD Adverse Outcome Pathways development programme workplan which is co-lead by the same countries and the US. ERGO project partners have developed and evaluated a number of endpoints sensitive to THS disruption, many of which are supported by well-established AOPs, using TG 210 as model for in vivo fish tests including the developmental period. Based on the outcome of seven TG 210 tests as well as a large number of embryonic tests, four endpoints have been selected for further evaluation. These endpoints are: 1) swim bladder inflation, 2) thyroid hormone (T3, T4) levels, 3) thyroid histopathology, 4) eye development and they are all supported by OECD VMG-Eco to bring to validation. We present the status of the work and suggest a way forward for OECD validation.

6.03.A.T-03 An Amphibian Metamorphosis Assay Dietary Restriction Study: Lessons for Data Interpretation

***Joseph Marini*[1]**, *Jeffrey C. Wolf[2], Valentin Mingo[3], Stephanie Jamieson[1], Lee Sayers[1] and James Robert Wheeler[4], (1)Smithers, (2)EPL, Sterling, (3)Corteva Agriscience, Germany, (4)Corteva Agriscience, Netherlands*

The Amphibian Metamorphosis Assay (AMA) is a key in vivo endocrine screen to identify potential thyroid active chemicals. The Test Guidelines (TGs) in-study decision logic and associated guidance consider treatment-related effects on thyroid gland histomorphology to automatically result in the assay being considered positive for thyroid activity, independent of the direction of change or conflicting results in the other biological endpoints. European Union guidance for assessing endocrine disrupting properties of pesticides and biocides classifies the endpoints from the TGs as those that provide direct and indirect endpoints for the evaluation of thyroid activity. Here, it is assumed that accelerated and asynchronous development, as well as histopathologic effects are specific for a chemical-induced thyroid hormone interaction in the absence of overt toxicity.

The goal of this study was to evaluate how a non-chemical stressor, dietary restriction, might affect the outcome of the AMA, and in particular, developmental effects that are currently considered to be mediated specifically through the thyroid endocrine axis. To this end, an AMA was conducted with 5 different feeding regimes equivalent to 50 (reference), 30, 20, 10 and 5% of the TG recommendation. All endpoints were evaluated and their specificity for the determination of thyroid activity was assessed. Statistically significant reductions in growth and development were observed between the 50% and 30, 20, 10 and 5% rations. Findings in the thyroid glands included ration-dependent reductions in the prevalence and severity of follicular cell hyperplasia and follicular cell hypertrophy, and a ration-dependent increase in the prevalence and severity of thyroid atrophy in tadpoles of the 10% and 5% groups.

The results indicate that treatment-related histopathologic effects in the thyroid are not necessarily specific for thyroid endocrine activity and can alternatively be induced by non-hormonal factors as the initiating event. Therefore, the interpretation of data from AMA studies should be adjusted accordingly. We recommend the decision logic presented in the TGs should be changed to reflect an element of agreement between the thyroid histopathology findings and direction of change of the apical endpoints, to conclude on the thyroid endocrine activity of a test substance.

6.03.A.T-04 Amphibian Studies to Investigate the ED Properties Through the Thyroid Modality: A Comparison of Their Statistical Power

Simone Rizzuto, *Alessio Ippolito, Aude Kienzler, Alberto Linguadoca, Laura Villamar-Bouza and Maria Arena, European Food Safety Authority, Italy*

The ECHA/EFSA ED Guidance, in accordance with the OECD Guidance 150, recommends using specific amphibian studies to investigate the ED properties through the Thyroidal (T) modality, based on the available evidence indicating that amphibian metamorphosis is under the control of the hypothalamic–pituitary–thyroid (HPT) axis, and that regulatory toxicity tests on amphibians are standardized and well consolidated. Currently, two validated amphibian standard toxicity tests are available: the amphibian metamorphosis assay (AMA, OECD TG 231), and the larval growth and development assay (LAGDA, OECD TG 241). An extended AMA (EAMA) assay was developed until reaching stage NF62.

AMA studies are developed to conclude on whether a tested substance shows endocrine activity. If AMA is positive, a mode of action should be postulated and additional data should be granted to investigate ED adversity, by providing a level 4 CF study (i.e., LAGDA), in line with the general agreement that level 3 studies (AMA) should serve to screen for endocrine activity and not for the derivation of a precise endpoint for adverse effect (NOEC/EC_X). This raises a potential concern on whether the statistical power of level 3 tests may be insufficient to conclude on potential adverse effects.
A recurring debate is whether conducting a LAGDA is necessary to confirm or clear off concerns identified by a positive AMA. Critical views suggest that both AMA and LAGDA perform a larval assessment of key diagnostic responses for thyroid effects, questioning the added biological value of LAGDA. The direct value in terms of statistical power is also questioned, since the number of tested animals equal across AMA and LAGDA. A similar common debate in the regulatory context is whether it is safe to exclusively rely upon the results of AMA studies to draw conclusions on endocrine adversity. Specifically, a key, unexplored aspect of this debate is whether null results can be deemed conclusive of the absence of effects, considering that aspects of the AMA design may limit our ability to statistically detect effects on diagnostic responses of the T-modality. Here we address this knowledge gap by testing the hypothesis that the statistical power for key diagnostic responses of the T-modality differ across different study designs (i.e., AMA, LAGDA and EAMA). Our results may improve our knowledge and understanding of the testing strategy for the regulatory ED assessment of pesticide active substances.

6.03.A.T-05 Amphibians in Thyroid Disruption Assessment: From Testing Strategies to the Identification of Thyroid-related Effect Patterns
Laurent L.-M. Lagadic[1], *Katherine K. Coady*[2], *Oliver Körner*[3], *Tara Miller*[4], *Lennart Weltje*[5] *and James Robert Wheeler*[6], *(1)Bayer AG - Crop Science Division, Germany, (2)Environmental Safety, Bayer AG - Crop Science Division, (3)Edmund-Rumpler-Strasse 6, Germany, (4)Syngenta, United Kingdom, (5)Ecotoxicology, BASF SE, Germany, (6)Corteva Agriscience*
Metamorphic development of amphibians is controlled by thyroid hormones and test guidelines (TGs) have been developed by the US EPA and OECD with *Xenopus laevis* to evaluate thyroid-mediated activity and adversity. Within the OECD Conceptual Framework for testing and assessment of endocrine disruptors, the *Xenopus* Eleutheroembryonic Thyroid Assay (XETA) and the Amphibian Metamorphosis Assay (AMA) are level-3 screening assays providing data about selected endocrine mechanism(s)/pathway(s). The AMA also includes apical endpoints that can inform on potential adversity, especially when the test is run according to a fixed termination stage design (*i.e*., the Extended AMA or EAMA). The Larval Amphibian Growth and Development Assay (LAGDA) is an OECD level-4 assay that has a limited validation dataset for the assessment of the thyroid modality and does not always allow for the distinction between endocrine and non-endocrine modes of action. Since the LAGDA is not typically conducted for the initial assessment thyroid-mediated activity and is not generally considered a reliable test for investigating thyroid-mediated adversity, testing strategies generally rely on a combination of the XETA, AMA and/or EAMA, as well as *in vivo* mammalian mechanistic studies and *in vitro* assays focusing on specific thyroid molecular targets such as the sodium-iodide symporter (NIS) and thyroperoxidase (TPO). In certain conditions, partly described in Annex A of the ECHA-EFSA guidance for the identification of endocrine disruptors, animal testing can be avoided by combining the XETA with selected *in vitro* assays and an understanding of the mammalian toxicology dataset. This presentation will describe how OECD level-3 amphibian assays can be combined with *in vitro* and other *in vivo* data into integrated test strategies for regulatory assessment of thyroid-mediated activity and adverse effects. In the AMA and EAMA, there is an interplay between endocrine activity and adversity endpoints. The direction, concomitance, and severity of changes of the developmental and histological parameters measured are therefore essential to the identification of endocrine-related effect patterns specific to the thyroid modality. The decision logic of OECD TG 231 should be changed to reflect an element of agreement between thyroid histopathology findings and direction of change of the apical endpoints.

6.03.B Data-Driven Environmental Decision-Making: Generating Relevant Datasets for Regulatory Assessment of Endocrine-Disruption

6.03.B.T-01 Evaluation of Interactions of Endocrine Disrupting Chemicals (EDCs) with Human and Zebrafish Nuclear Receptors (NRs) using Reporter Cell Lines
Anna Toso[1], *Clementine Garoche*[2], *Abdelhay Boulahtouf*[2], *Marina Grimaldi*[2], *Aurelie Escande*[3] *and Patrick Balaguer*[4], *(1)Ecole doctorale CBS2, France, (2)INSERM IRCM, France, (3)University of Montpellier, France, (4)INSERM, France*
Reporter gene cell lines expressing Nuclear Receptors (NRs) are widely used to study the effects on human and wildlife of Endocrine Disrupting Chemicals (EDCs), substances that can interfere with their endogenous hormonal pathways. Given the large number of chemicals to be studied in the environment, the development of *in vitro* tools makes it possible to significantly reduce animal testing. However, as the OECD guidelines for EDC testing require the use of reporter cell lines expressing only human NRs, the scientific gap regarding the effects of EDCs on wildlife is filled by extrapolating mammalian data to other species. Our group has developed cell lines expressing reporter genes of human (h) or zebrafish (zf) NRs with the aim of studying interactions of chemicals with NRs of different species and improving the regulatory testing approaches. These cell lines can be used to study in a species-specific manner hundreds of chemicals for their endocrine-disrupting properties towards different molecular endpoints. Our method consists of transfecting the NR reporter gene of interest toghether with a luciferase gene whose expression is under the control of the receptor. In this way, it is possible to evaluate the effects of chemicals on the NR as they are able modulate the luminesce signal. Our results showed that, depending on the NR studied, interspecies differences are more (e.g. Progesterone Receptor, Peroxisome X Receptor) or less pronounced (e.g. Androgen Receptor, Glucocorticoid Receptor). Furthermore, as part of biological monitoring, NR-expressing cell lines can be used to analyse environmental extracts (e.g. water and air samples) to assess the effects of environmental chemicals on NRs in addition to chemical analysis. Our results showed that

the analysis of environmental samples with NR-expressing cell lines confirmed some interspecies differences observed with pure chemicals and allowed us to choose the most appropriate cell lines according to the purpose of the research. In conclusion, our work broaden knowledge on the effects of several environmental chemicals on different NRs and species. Biological assays using reporter cell lines expressing NR of different species can be used as a screening tool to assess the effects of numerous EDCs and at the same time greatly reduce animal testing, which is particularly important in view of the 3R principle.

6.03.B.T-02 Nuclear Receptor-Mediated Endocrine Disruption in Marine Invertebrates: A Case Study with the Mediterranean Mussel *Mytilus galloprovincialis*

Angelica Miglioli[1,2]*, Beatrice Risso*[2,3]*, Lydia Besnardeau*[4]*, Michael Schubert*[4]*, Remì Dumollard*[4] *and Laura Canesi*[1]*,*
(1)University of Genova, Italy, (2)Lbdv, Institut de la mer de Villefranche-sur-mer, France, (3)University of Geneva, Switzerland, (4)Institut de la mer de Villefranche-sur-mer, France

Endocrine Disrupting Chemicals (EDCs) are a global threat to populations of marine invertebrates. Although it is well-known that the main action of EDCs is to mimic endogenous hormones and bind to their Nuclear Receptors (NRs), the scarce knowledge of NRs functions and transactivation dynamics in most invertebrate clades prevents the understanding of NR-mediated endocrine disruption in these organisms.
In this light, the present work characterized the NR superfamily of the Mediterranean mussel *Mytilus galloprovincialis* (*Mg*), investigating potential developmental functions, ligand affinities and susceptibility to endocrine disruption.
*Mg*NRs were isolated from the mussel genome, their developmental expression dynamics were obtained from RNA-seq data, and expression patterns were assessed by In situ Hybridization (ISH) and Hybridization Chain Reaction (HCR). Pharmacological manipulations largely focused on *Mg*RXR (Retinoid X Receptor) and its heterodimeric partners (HPs) using 9-cis-Retinoic Acid as positive control (RXR agonists), UVI3003 (RXR antagonist) as negative control, and Tributyltin (TBT) as model EDC.
36 canonical *Mg*NRs were identified with most of them fitting in the current nomenclature and classification. All *Mg*NRs were dynamically expressed at different developmental stages, in particular the members of NR subfamily 1, 2, 3 and 4. Most *Mg*NRs showed discrete localization in neurogenic and shellbiogenic tissues suggesting a pivotal role of the superfamily in governing mussel larval morphogenesis.
*Mg*RXR pharmacological modulations with both TBT and RA caused developmental arrest at the pre-Veliger stage. Such adverse effect could be consistently reversed by co-exposure to RXR antagonist hence demonstrating the specificity of the phenotype to *Mg*RXR disruption.
*Mg*RXR modulation also inhibited multiple elements of the neuroendocrine pathway governing early shell biogenesis thus showing a potential link between NRs and the neuroendocrine signaling in a mollusk.
Interestingly, TBT and RAs did not induce the same neural phenotype. Given the subordination of RXR transcriptional activity to the one of its HPs, it is parsimonious to theorize that the binding of both chemicals to *Mg*RXR might not necessarily induce the transactivation of the same heterodimers.
Altogether, the findings of this work represent a step forward in the understanding of NR signaling and susceptibility to endocrine disruption in bivalve mollusks.

6.03.B.T-03 Are Changes in Vitellogenin Concentrations in Fish Reliable Indicators of Chemical-induced Endocrine Activity?

Rebecca Jayne Brown[1]*, Grace Panter*[1]*, Edward Salinas*[2]*, Lennart Weltje*[3]*, James Robert Wheeler*[4]*, Natalie Burden*[5]*, Yvonne Wolf*[6] *and Laurent L.-M. Lagadic*[7]*, (1)wca environment Ltd., United Kingdom, (2)BASF SE, Germany, (3)Ecotoxicology, BASF SE, Germany, (4)Corteva Agriscience, Netherlands, (5)NC3Rs, United Kingdom, (6)Environmental Safety, Bayer AG - Crop Science Division, Germany, (7)Bayer AG - Crop Science Division, Germany*

The egg-yolk precursor protein vitellogenin (VTG) is widely used as a biomarker for endocrine-mediated activity via estrogen (E), androgen (A) or steroidogenesis (S) pathways. Reliable and robust measurements of VTG are therefore required to support decision-makers in the regulation of chemicals for their environmental endocrine activity. VTG concentrations are inherently variable and equivocal results from fish studies are common and can lead to additional fish testing to refute or confirm a previous result. A comprehensive review of VTG data was conducted, including 98 substances (general chemicals as well as substances with known endocrine activity) focusing on regulatory test species; namely fathead minnow, zebrafish and Japanese medaka. The review confirmed the high variability in VTG response with coefficient of variations for interlaboratory variation being between 201-543% in males and 76-206% in females. VTG induction in male and female fish was tabulated for substances with E receptor (ER) agonist activity (based on potency estimates from the ER bioactivity model) and substances which inhibited VTG induction based on aromatase inhibition (AC50). Substances with a higher ER agonist bioactivity score were more likely to induce VTG in males to levels which were greater than the female control response and/or to induce VTG in females (in at least one study). Most of the substances which caused inhibition of VTG were inhibitors of aromatase *in vitro*. Exceptions to this were most notably for substances with multiple mechanisms of action. There were also a few examples of substances which did not have evidence for endocrine activity *in vitro* causing repeatable, concentration-dependent effects on VTG, and these were substances with active metabolites, or which potentially affect steroidogenesis other than via aromatase. To increase confidence in the VTG measurement we recommend improvements to the consistency of VTG analysis, and greater transparency in reporting of VTG measurements (including quality control criteria for assay performance). This review supports the application of New Approach Methodologies (NAMs) by demonstrating that endocrine effects in *in vitro* studies with mammalian cell lines are predictive for *in* vivo effects on VTG in fish, suggesting that NAM data could be used more broadly in decision making to help reduce animal testing.

6.03.B.T-04 Population Models in a Hazard Assessment: Population Relevance of the Effects of Endocrine Active Substances

Alice Tagliati[1], *Charles Hazlerigg*[1], *Thomas G Preuss*[2] *and Laurent L.-M. Lagadic*[2], *(1)Enviresearch Ltd, United Kingdom, (2)Bayer AG - Crop Science Division, Germany*

All agrochemicals being authorised for use in the EU need to be assessed against the criteria for being identified as an Endocrine Disruptor (ED), namely whether they have an adverse effect that is the result of an endocrine-mediated mechanism. For non-target organisms, the adverse effect being considered is at the population level (e.g. population abundance). However, those endpoints reported in recommended studies on endocrine active chemicals are commonly at the individual level (e.g. significant effects on fecundity in fish). Whilst the ECHA-EFSA guidance on how to assess for an EDC indicates that population modelling may be used to link observed effects on individuals in laboratory studies to population-level effects relevant for the assessment criteria, it provides no practical guidance on how this might be done. Here we present how population modelling could be used as an initial screening step for assessing the population relevance of adverse effects observed on individuals in the laboratory. Using the Adverse Outcome Pathway (AOP) concept, this method could be applied to any molecule being considered under EC1107/2009 for use in the EU.
Results from three fish population models available from the literature: zebrafish (*Danio rerio*), stickleback (*Gasterosteus aculeatus*) and brown trout (*Salmo trutta*) are presented. Selected apical endpoints assessed in higher level ED studies, namely fecundity, fertilisation rate, sex ratio (male and female skew), behaviour and growth, were implemented both individually and in combination at different magnitudes. We used a magnitude of effect of 10, 20, 50 and 90% change in an endpoint to assess both population abundance and biomass against the control simulations (no effects imposed on any endpoint) using the two criteria from EFSA.
Aim of this work is to demonstrate how population modelling can be used to extrapolate the relevance of ED-mediated effects on individuals to whole populations, thereby better linking the assessment endpoint (adverse effect on population abundance or biomass) with the protection goal (population) of an ED assessment under EC 1107/2009 and Commission Regulation (EU) 2018/605.

6.03.B.T-05 AOP Linking RAR/RXR Overactivation to Feeding Disruption

Audrey Phan, *Marie Smutna, Aleksandra Sokolova and Klara Hilscherova, RECETOX, Masaryk University, Czech Republic*

Retinoid signaling disruption has been overlooked in regulation. However, in the last few years, there is an increasing interest in retinoid-disruption related adverse effect in (eco)toxicology because of regulatory needs. Indeed, the known conserved mechanisms of retinoid signaling across species and the environmental occurrence of retinoids are contributing to the potential high risk when retinoid signaling disruption occurs.
In the line of AOP development, we focused on a specific adverse outcome, craniofacial malformation. After conducting a weight of evidence analyses, a lack of data linking craniofacial malformation to regulatory endpoints was identified. Here, we focus on linking malformation to feeding disruption in early larval stages and survival at late larval stages. As posterior swim bladder inflation could also play a major role in buoyancy and thus feeding behavior, we also assessed this endpoint. Results show that the derived EC50 for craniofacial malformation, EC50 for no inflation of the posterior swim bladder, and IC50 for feeding disruption were comparable. The data indicate that in the context of teratogenicity induced by RAR overactivation, a combination of effects occurring in parallel leads to decreased feeding. We also link the feeding behavior disruption at the early larval stage (7dpf) to mortality at the later larval stage (14dpf). 14 dpf zebrafish larvae showed ~90% mortality at ATRA 1ug/L regardless the exposure time: 6-48hpf; 6-72hpf; 6-120hpf.
To conclude, we demonstrated quantitatively that the teratogenicity induced by the overactivation of RAR/RXR leads to a disruption in feeding behavior and mortality. By adding a regulatory-relevant endpoint to a putative AOP and by providing quantitative data, we bring together data that could fit a future framework implementing AOP into risk assessment.

6.03.P Data-Driven Environmental Decision-Making: Generating Relevant Datasets for Regulatory Assessment of Endocrine-Disruption

6.03.P-We378 Investigations into the Induction of Thyroid Hormone Liver Metabolism in Zebrafish (*Danio Rerio*) Embryos

Maximilian Rinderknecht[1], *Lisa Gölz*[1], *Lisa Annie Baumann*[2] *and Thomas Braunbeck*[1], *(1)University of Heidelberg, Germany, (2)Environment and Health, VU University, Amsterdam, Netherlands*

Hepatic TH metabolization consists of two major pathways: Deiodination and conjugation. The conjugational pathways comprise glucuronidation by UDP-glucuronosyltransferases (UGTs) and sulfation by sulfotransferases (SULTs), both of which increase water solubility and thus facilitate biliary excretion. In addition, sulfated THs are also inactivated by deiodinase 3 at a much higher rate than the parent hormone itself. Expression of conjugation enzymes is influenced by a variety of nuclear receptors, such as the aryl hydrocarbon receptor among others. These receptors accept a wide range of exogenous agonists, and their activation generally leads to an increase in the expression of enzymes involved in the metabolization of xenobiotics. As an off-target effect, UGT and SULT expression can also be increased to levels that negatively affect TH homeostasis. While disruption *via* this pathway has been observed in multiple mammalian species, it has so far not been explored in detail in fish. In the context of the 3R principles, it would be highly beneficial to determine whether this mechanism leads to similar outcomes in fish and other lower vertebrates. Specifically, the applicability of zebrafish (*Danio rerio*) embryos as a model predictive of the identification of altered hepatic TH clearance would help to reduce animal testing in mammals. To properly evaluate the induction of hepatic TH metabolism in zebrafish, multiple endpoints need to be investigated at different steps in the pathway, ranging from molecular key events to physiological changes. In addition, multiple model substances, which are known agonists of the nuclear receptors involved in UGT and SULT expression, need to be tested to determine the impacts of different molecular events. For this, both a wildtype as well as a transgenic zebrafish line with fluorescent thyroid follicles were exposed. As endpoints, gene expression analysis of multiple thyroid- and metabolism-related genes, fluorescence intensity and area measurements of the transgenic zebrafish thyroid follicles as well as eye histopathology were selected to cover mechanistic events as well as biologically relevant apical endpoints in development. Taken together, results of these experiments provide insight into the mechanisms of and effects on hepatic TH metabolism in zebrafish embryos, which can then be compared to literature data on other vertebrates to establish both similarities and differences between species and vertebrate classes.

6.03.P-We379 OECD Endorsement of an AOP Network of 5 AOPs Linking Thyroid Hormone System Disruption to Impaired Swim Bladder Inflation in Fish

***Lucia Vergauwen**[1], Evelyn Stinckens[1], Daniel L. Villeneuve[2], Lisa Annie Baumann[3], Avril Hanbridge[4], Thomas Braunbeck[5], Henrik Holbech[6] and Dries Knapen[1], (1)University of Antwerp, Belgium, (2)U.S. Environmental Protection Agency, (3)Vrije University Amsterdam, Netherlands, (4)AquaTT, Ireland, (5)University of Heidelberg, Germany, (6)University of Southern Denmark, Denmark*

Over the last 10 years, through the success of several projects, five adverse outcome pathways (AOPs, AOP-Wiki IDs 155-159) have been developed linking thyroid hormone system disruption (THSD) to adverse effects on swim bladder inflation and survival in fish. The ECO20-UA project (2013-2016), funded by the Cefic Long-Range Research Initiative, investigated whether the AOP framework could provide a mechanistic basis for predicting chronic fish toxicity using non-animal alternatives. The AOPs were developed up to the point that they allowed selection of key events and development of alternative assays to identify thyroid hormone system disrupting chemicals (THSDCs). The follow-up ECO20.2 project (2016-2018) applied the alternative assays developed during ECO20 to a set of selected compounds, predicted acute and chronic toxicity, and performed Fish Embryo Acute Toxicity (FET) and chronic Fish Early-Life Stage (FELS) toxicity testing to validate the predictions. In the ERGO project (2019-2023), funded under the Horizon 2020 programme, the AOPs were completed and submitted for review by OECD. The AOPs have now been endorsed by the Working Group of the National Coordinators of the Test Guidelines program (WNT)/ Working Party on Hazard Assessment (WPHA) and will soon be published in the OECD Series on Adverse Outcome Pathways. We are now working on a broader network of THS AOPs to support cross-vertebrate extrapolation of mechanisms and effects of THSDCs for informing both on environmental and human health. Pre-validation of fish assays is also ongoing within ERGO. The endorsement and publication of these AOPs by OECD supports the addition of new endpoints to existing OECD fish Test Guidelines (TGs). This is facilitated by the close integration of AOP and TG development at the OECD level. Project 1.35 (Lead: BE, partners: US, DK, DE) on the OECD AOP development programme workplan overseen by EAGMST was initiated in 2015 and comprises the development of AOPs for THSD in fish. Project 2.64 (lead: DK, partners: BE, DE) on the OECD work plan for the Test Guidelines Programme overseen by VMG-Eco was initiated in 2019 and uses the AOPs as support for adding thyroid-sensitive endpoints to existing fish TGs. Such refined TGs will improve the evaluation of THSDCs and will be included in approaches for extrapolation of THSD effects across mammalian and amphibian species. The contents of this abstract neither constitute, nor necessarily reflect US EPA policy.

6.03.P-We380 Potential Endpoints to Identify Thyroid Hormone System Disruption in Zebrafish Embryos

***Lisa Gölz**[1], Thomas Braunbeck[1], Henrik Holbech[2], Dries Knapen[3], Lucia Vergauwen[3] and Lisa Annie Baumann[4], (1)University of Heidelberg, Germany, (2)University of Southern Denmark, Denmark, (3)University of Antwerp, Belgium, (4)Environment and Health, VU University, Amsterdam, Netherlands*

Identifying thyroid hormone system disruptors (THSD) is warranted because of the crucial role that thyroid hormones (THs) play in the normal development of vertebrates. Thus, selection of a sensitive animal model and identification of suitable endpoints for detecting THSDs are key for guiding regulatory decisions. OECD fish test guidelines so far lack TH system sensitive endpoints. However, the TH system regulates a wide range of measurable molecular and morphological endpoints in fish, including swim bladder inflation, thyroid- and eye-related gene expression, and the development of thyroid follicles and eyes. This study aimed to investigate whether these endpoints are suitable for detecting THSD in the zebrafish (Danio rerio) embryo by using the existing OECD test guideline 236 (FET, fish embryo toxicity test). We performed experiments with multiple THSDs with different modes-of-action, such as propylthiouracil (PTU), potassium perchlorate (PCL), iopanoic acid (IOP) and the natural thyroid hormone triiodothyronine (T3). The basic protocol of OECD TG 236 was followed, and different TH system sensitive endpoints such as gene expression, detection of cellular changes in the eyes (e.g., cell size, cell layer structure and organization, number of photoreceptors, pigmentation etc.), as well as morphological changes (e.g., alterations of thyroid follicular morphology in transgenic fish) were added. For thyroidal analysis, transgenic zebrafish embryos expressing the reporter gene tg:mCherry were used. Results demonstrate that zebrafish embryos react sensitively to THSD. Changes in the expression of the eye- and thyroid-related genes in the zebrafish embryos were observed and different modes of THSD resulted in various alterations of thyroid follicle morphology and fluorescence intensity in the transgenic line. Furthermore, strong alterations of eye morphology and cellular structure, combined with changes in photoreceptor patterning, could be recorded by (immuno-)histopathology. Results confirm growing evidence that zebrafish embryos are sensitive to THSD treatment and represent a promising tool for assessing TH system- related effects in fish. The FET protocol according to OECD TG 236 proved to be a suitable basis for implementing TH system sensitive endpoints in fish, as it covers important stages of early development, many of which are regulated by THs.

6.03.P-We381 The Early Life Stage Amphibian Thyroid Assay (ELSATA), a Thyroid-Focused Alternative to the Larval Amphibian Growth and Development Assay (LAGDA)

*Adric D. Olson[1], **Lennart Weltje**[2], Maike Habekost[3] and Douglas J. Fort[4], (1)BASF Corporation, (2)Agricultural Solutions - Ecotoxicology, BASF SE, Germany, (3)BASF SE, Germany, (4)Fort Environmental Laboratories*
The Larval Amphibian Growth and Development Assay (LAGDA, OECD TG 241) was designed as a higher tier *in vivo* assay meant to provide data on adverse effects of substances on thyroid-mediated endpoints. As a level 4 test within the OECD Conceptual Framework on Endocrine Disrupters Testing and Assessment, it is a final step of testing in the ECHA-EFSA testing scheme for the thyroid modality, to be utilised in case a Level 3 Amphibian Metamorphosis Assay (AMA, OECD TG 231) indicates thyroid activity of a substance and thus, the need for the generation of additional data. However, the LAGDA is not limited to generating endpoints related to the thyroid modality, as the second half of the study is focused on the estrogen, androgen and steroidogenic (EAS) modalities. Considering that the triggering of a LAGDA is based on concerns around the thyroid axis, questions have been raised as to the value of this additional 10-week period in the study for identifying any additional effects related to (anti)thyroidal activity of substances. Initiation at NF stage 10 considers embryo-larval and pre-metamorphic development, already providing a means for assessing potential alternative modes of action and discriminating non-endocrine from endocrine toxicity. Additionally, for the purpose of an assessment on the thyroid modality, generating unrelated data causes needless animal welfare concerns. In an effort to focus on the core strength of LAGDA, we have investigated a modified version of the study which only considers endpoints related to the thyroid modality. In doing so, animal welfare is emphasized, as fewer individuals are used for a shorter total duration, crucially without decreasing the amount of thyroid-specific data generated. Results from the evaluation of this Early Life Stage Amphibian Thyroid Assay (ELSATA) will be presented.

6.03.P-We382 Use of *Xenopus laevis* Developmental Stage-matched Control Data in Amphibian Metamorphosis Assays to Assess Inter-laboratory Variation in Endpoint Data
***Joseph Marini**[1], Lee Sayers[1], Maria Estebaranz-Yubero[2], Apostolos Koutsaftis[3], Oliver Körner[4], Sonja Haaf[5], Angela Goßmann[6] and Douglas J. Fort[7], (1)Smithers, (2)ERM Regulatory Services, United Kingdom, (3)ERM Regulatory Services, Netherlands, (4)Edmund-Rumpler-Strasse 6, Germany, (5)Environmental Safety, ADAMA Deutschland, Germany, (6)ibacon, Germany, (7)Fort Environmental Laboratories*
The analysis of continuous quantitative *Xenopus laevis* endpoints such as snout-vent length (SVL), hind limb length (HLL), hind limb length normalized by snout-vent length (nHLL), and wet weight is performed to assess statistically significant differences between the negative control and active substance treatments in the Amphibian Metamorphosis Assay (AMA) for the detection of potential thyroid modes of action according to Guidelines OECD 231 and OPPTS 890.1100. However, the current statistical analysis of these parameters at Day 7 and 21 is routinely performed by using the replicate means or medians of the individual endpoint values without taking into consideration the different stages of development within each control or treatment replicate. Furthermore, these endpoints are well known to be directly impacted by developmental stage in tadpoles and so using stage-matched data may have an impact in the interpretation of the biological results. This is also the case for tadpole thyroid gland histopathological findings, where it is already recognized in both Guidelines that the most appropriate approach is to use NF developmental stage-matched tadpoles for evaluation. Consequently, individual control HLL, nHLL, SVL, and wet weight values for the Day 7 and 21 termination events from multiple Contract Research Organizations have been extracted and evaluated according to NF developmental stage. Stage-matched and non-stage-matched data were also evaluated against several study parameters such as food and water quality. The analysis presented here aims to develop a NF developmental stage-matched Historical Control Database that allows the assessment of potential impact in the outcome of statistically significant results of these thyroid screening parameters, as well as the variability of NF developmental stage-matched control data across different GLP AMA-performing laboratories.

6.03.P-We383 Impacts of Non-endocrine Factors on Amphibian Metamorphosis Assay (AMA) Results
***Jeffrey C. Wolf**[1], Douglas J. Fort[2], Valentin Mingo[3] and James Robert Wheeler[4], (1)EPL, (2)Fort Environmental Laboratories, (3)Corteva Agriscience, Germany, (4)Corteva Agriscience*
The *in vivo* Amphibian Metamorphosis Assay (AMA) has become a key experimental tool for determining the potential of a tested chemical to interact with the hypothalamic-pituitary-thyroid axis of amphibians and other taxa. The 21-day AMA, which is performed using *Xenopus laevis* tadpoles, features a suite of growth and development endpoints that include Nieuwkoop and Faber (NF) developmental stage, snout to vent length (SVL), hindlimb length (HLL), normalized hindlimb length (normalized by SVL; nHLL) wet body weight (WBW), and thyroid histopathology. According to the current wisdom, WBW and SVL are considered to be growth-related types of endpoints, while NF stage, nHLL, and thyroid histopathology are linked more closely to metamorphic development, which is known to be thyroid hormone dependent. Previous AMA studies have demonstrated that experimental exposure of *X. laevis* tadpoles to a thyroid hormone agonist tends to cause increases in NF stage and HLL, decreases or no change in growth endpoints, and decreased histopathologic evidence of thyroid activity. On the other hand, thyroid hormone antagonist exposure generally causes the opposite effects instead. Pe odically, however, the results of AMA studies indicate effects which do not line up according to either of these patterns, and the reasons for such incongruous outcomes are often not immediately apparent. The goal of the current presentation is to describe the findings of three recent AMA-type experiments performed independently, that together shed light on ways in which non-endocrine, non-thyroidal factors can influence the AMA study results. This is a cautionary tale that also illustrates the importance of assessing all available endpoints when conducting AMA studies, and the use of a weight of evidence approach for data interpretation.

6.03.P-We385 Development of a Set of AOP Network-Supported IATAs for Thyroid Hormone System Disruption
***Dries Knapen**[1], Lucia Vergauwen[1], Karine Audouze[2], Anna Beronius[3], Shalenie den Braver-Sewradj[4], Ann-Cathrin Haigis[1], Ellen Hessel[4], Karolina Jagiello[5], Achilleas Karakoltzidis[6], Ioanna Katsiadaki[7], Sharon Munn[8], Nafsika Papaioannou[6], Elisavet*

Renieri[6], Alessandra Roncaglioni[9], Dimosthenis Sarigiannis[6], Anita Sosnowska[10], Sabrina Tait[11], Jagoda Treider[5], Henrik Holbech[12] and Miriam Jacobs[13], (1)University of Antwerp, Belgium, (2)Université Paris Cité, France, (3)Karolinska Institutet, Sweden, (4)Dutch National Institute for Public Health and the Environment, Netherlands, (5)University of Gdansk, Poland, (6)Aristotle University of Thessaloniki, Greece, (7)Centre for Environment Fisheries and Aquaculture Sciences (Cefas), United Kingdom, (8)European Commission Joint Research Centre, Italy, (9)Istituto di Ricerche Farmacologiche Mario Negri, Italy, (10)QSAR Lab, Poland, (11)Instituto Superiore di Sanità, Italy, (12)University of Southern Denmark, Denmark, (13)UK Health Security Agency, United Kingdom
The Partnership for the Assessment of Risks from Chemicals (PARC) is a research and innovation programme funded by Horizon Europe, bringing together nearly 200 partners from 28 countries as well as EU agencies to support next-generation chemical risk assessment and risk management incorporating both human health and the environment in a "One Health" approach.
One of the activities in this context is the development of integrated approaches for testing and assessment (IATAs) for endocrine disruption (Task 6.1.1). The PARC endocrine disruption IATA development process is closely aligned with work on adverse outcome pathway (AOP) development for endocrine and metabolic disruption (Task 5.3.2) to ensure that the methods that are considered for inclusion in the IATAs are supported by key event descriptions of well-developed AOPs.
Thyroid hormone system disruption (THSD) has been identified as one of the priority areas for IATA and AOP development in PARC. Effects on the hypothalamic-pituitary-thyroid axis are considered low-hanging fruit because of the relatively large number of AOPs available or under development for this system, and the ongoing efforts to assess and validate *in vitro* assays for the assessment of THSD conducted at the JRC, the OECD Thyroid Disruption Methods Expert Group, the US Environmental Protection Agency, and within the EURION project cluster under the Horizon 2020 programme.
We present an update on the joint work of developing AOPs and IATAs for THSD in Tasks 5.3.2 and 6.1.1 of PARC. An existing cross-species AOP network for THSD consisting of 50 AOPs taken from the AOP-Wiki, initiated by 13 molecular initiating events and leading to 9 adverse outcomes, provided a starting point. Data and knowledge gaps were identified based on this inventory of available AOPs. Pivotal key events relevant to THSD were identified, and the associated methods were evaluated in terms of data interpretation, available prediction models, test method readiness, and performance. These methods were then mapped to the AOP network, and priorities for further AOP development were determined as a function of IATA development priorities. A set of conceptual IATAs was subsequently outlined, addressing adverse effects that are relevant to either human or environmental health. These IATAs will be further developed and refined in the future in close collaboration with relevant stakeholders, and evaluated through dedicated case studies.

6.03.P-We386 Conceptual Framework for Assessing Metal Interactions with the Endocrine System of Aquatic Organisms
*Kevin Brix[1], **Stijn Baken**[2], Douglas J. Fort[3] and Charles Tyler[4], (1)EcoTox, (2)European Copper Institute, Belgium, (3)Fort Environmental Laboratories, (4)University of Exeter, United Kingdom*
Regulatory attention on endocrine disrupting chemicals has increased in recent years leading to the ongoing development of criteria and guidance in the European Union to assess the endocrine disrupting (ED) potential of chemicals. These documents, and those developed in other regulatory jurisdictions or in the scientific literature, are largely focused on the ED potential for organic compounds. The applicability of this guidance to metals and inorganic substances is unclear. The available information on the ED properties of metals and metal compounds (hereafter referred to as metals) mainly originates from non-guideline studies in the scientific literature with some conflicting information. Certain studies suggest that some metals may exhibit ED activity in animal experiments intended to evaluate environmental risk. Consequently, concerns have been raised that ED metals may be considered as a new class of hormone-active substances. Some of these assessments, however, are based on a misunderstanding of what constitutes endocrine disruption under current regulatory frameworks. Additionally, some of the experimental evidence stems from studies at exposure concentrations in excess of those that elicit toxicity clearly not related to putative endocrine mediated effects. Although certain metals can cause reproductive and developmental effects, the question remains whether metals specifically and adversely affect endocrine systems at environmentally or physiologically relevant concentrations. Furthermore, their natural occurrence and for some metals their essentiality, including direct roles supporting normal endocrine function, further increases the complexities in the ED assessment of metals. The objective of this presentation is to propose an overall framework for assessing metal interactions with the endocrine system of aquatic organisms. More specifically, we will highlight key issues associated with ED assessment of metals, we will synthesize the available knowledge, identify data gaps, and discuss how this knowledge could facilitate a meaningful ED assessment of metals.

6.03.P-We387 Potential Information Requirements for Endocrine Disruption Assessment Under REACH: The Reliance on Animal Data
***Rhiannon Smith**[1], Grace Panter[1], Natalie Burden[2] and Rebecca Jayne Brown[1], (1)wca environment, United Kingdom, (2)NC3Rs, United Kingdom*
Assessment of substances for Endocrine Disruption (ED) is being introduced in the EU as a specific information requirement under the Registration, Evaluation, Authorisation and restriction of Chemicals (REACH) regulation. An independent review estimated potential resource and animal use of two policy options proposed by the European Commission for assessing ED under EU REACH. Here, we discuss potential challenges of implementing the proposed strategies and the balance between *in vivo* testing and other approaches. Further updates to the strategy for ED assessments made prior to this SETAC conference will be taken into account.
The policy options set out the information requirements including potential ways to waive certain studies for ED assessments, though these depend on the availability of higher tier *in vivo* testing or non-specified data showing pathway activity. Many substances would not have sufficient existing higher tier data to fulfil the information requirements, particularly for environmental

assessments. There are also concerns that non-*in vivo* methods (or New Approach Methodologies - NAMs, e.g., quantitative structure activity relationships [QSARs], *in vitro* assays) have not been sufficiently validated or are unlikely to be applicable to industrial chemicals.
The policy options specify data from *in vitro* NAMs under Annex VII information requirements (substances manufactured or imported at >1 tonne) as a trigger for *in vivo* testing and to inform on mode of action analysis. There is concern that the high number of (currently unvalidated) assays will lead to equivocal results, interpretation issues and potentially unnecessary animal testing. Also, *in vitro* test results are largely disregarded at Annex VIII (10-100 tonnes) or IX (100-1000 tonnes), which have direct *in vivo* information requirements, including ecotoxicology endocrine test guideline studies in fish and amphibians. These studies are highly complex, resource and animal intensive. The policy options show little scope for implementing NAMs that might obviate animal testing, such as mammalian *in vitro* assays informing on non-target vertebrates, or reducing the number of animals where possible. The estimated animal use based on either of the policy options is considerable and arguably unachievable considering current laboratory capability and capacity. Further work is required to ensure robust evaluations whilst considering the scale of new animal testing for ED assessments under EU REACH.

6.03.P-We388 Control Performance of Medaka Extended One Generation Test Designs
***Natalie Burden**[1], Scott G. Lynn[2], Valentin Mingo[3], Constance Mitchell[4], Edward Salinas[5], Inka Marie Spyridonov[5] and James Robert Wheeler[6], (1)NC3Rs, United Kingdom, (2)U.S. Environmental Protection Agency, (3)Corteva Agriscience, Germany, (4)Health and Environmental Sciences Institute (HESI), (5)BASF SE, Germany, (6)Corteva Agriscience, Netherlands*
Evaluation of endocrine activity and disruption in human and wildlife involves conduct of specific assays used to evaluate relevant pathways. Multiple *in vivo* test guidelines (TGs) have been validated for mammals, amphibians, or fish, focusing on the estrogen, androgen, thyroid, and steroidogenesis (EATS) pathways. They are now being conducted widely to satisfy regulatory requirements to identify chemicals that have the potential to interact with endocrine pathways. However, these assays are often costly and require the use of a substantial number of laboratory animals, and their outcome can lead to significant regulatory actions. It is therefore critical that the assays are sufficiently reliable and robust.
The Medaka Extended One Generation Test (MEOGRT; OECD TG 240/EPA OCSPP 890.2200) is one such *in vivo* assay designed to provide comprehensive data on adverse effects and endocrine-relevant endpoints for key aspects of the fish life cycle. Exposure starts with spawning fish (F0), covers multiple life stages of their progeny (F1) and continues until hatching (two weeks post-fertilisation) in the second generation (F2). Potential adverse effects on population-relevant parameters are assessed including survival, growth, sex ratio and reproduction (fecundity/fertility). In addition, to provide mechanistic information and linkage between results from other studies where there is evidence for a chemical having the potential to interact with endocrine pathways, liver vitellogenin mRNA (or protein) is measured, phenotypic secondary sex characteristics (SSC) are assessed as related to genetic sex, and gonad histopathology is undertaken.
This poster presents control data from 28 studies conducted in line with the MEOGRT Test Guideline (TG 240/OCSPP 890.2200) or in the spirit of the MEOGRT, including 14 Medaka Multigeneration Tests (MMT) conducted prior to adoption of TG 240 (which includes those used to validate the TG). Reliable historical control data ranges will be developed for the core study endpoints and the associated validity and performance criteria. Additionally, the historical control data will be explored to investigate cross-laboratory and study differences, potential sources of variability, and the power of the test design. The overarching aim is to form a knowledge base that could be used to improve test design, performance, and interpretation of the data. *This abstract does not necessarily represent US EPA policy.*

6.03.P-We389 Distinguishing Non-endocrine from Suspected Endocrine Responses: Importance of Experimental Design
***Douglas J. Fort**[1], Jeffrey C. Wolf[2], Carol Mackie[3], Stijn Baken[4], Kevin Long[3], Craig A. Poland[3], Kevin Brix[5] and Micheal McGrath[6], (1)Fort Environmental Laboratories, (2)EPL, (3)Regulatory Compliance, United Kingdom, (4)European Copper Institute, Belgium, (5)EcoTox LLC, (6)Necon Technologies, Ireland*
Experimental design in ecotoxicological endocrine disruption (ED) studies is vitally important to discriminate between direct endocrine-related effects and effects from other mechanisms of action that may involve indirect compensatory endocrine responses. Further, understanding mechanisms of action is critical to properly classifying a substance as having or not having potential ED properties. ED classification has serious regulatory consequences including banning of substances in some regulatory frameworks, such as those in the EU.   both fish and amphibians, the effect of non-endocrine factors such as bioenergetics, dietary iodine availability, systemic toxicosis, oxidative stress, and treatment-induced stress must be considered in the study design. In addition, the design of amphibian-based studies should be sufficient to detect divergence in developmental rates, as this provides a line of evidence regarding the role of the HPT axis. As an example, we will discuss how careful experimental design of an amphibian test provided support for the hypothesis that the effects of Cu on development and metamorphosis in *X. laevis* are suspected to be the result of non-endocrine systemic toxicity occurring in early development prior hypothalamic-pituitary-thyroid (HPT)-driven metamorphosis. In his case, additional histopathological assessment beyond that required by standard OECD protocols allows for a better discrimination between direct and indirect related ED effects in the test organisms.

6.03.P-We390 The Importance of Integrating all of the Evidence to Identify Endocrine Disruption: A Case Study with Bisphenol A
***Ellen M. Mihaich**[1], Christopher Borgert[2], Michael Bunge[3], Margaret E. McArdle[4] and Kevin Sondenheimer[3], (1)ER2, (2)Applied Pharmacology & Toxicology, (3)Covestro, Germany, (4)Exponent*
The challenge of identifying endocrine-disrupting chemicals (EDC) has been at the forefront of regulatory discussion and debate

in the European Union and internationally since the late 1990's. According to the World Health Organization's International Programme on Chemical Safety, an EDC must (1) alter the function of the endocrine system; and (2) as a consequence of that alteration, cause an adverse health effect in humans or wildlife. This definition requires a causal link between the endocrine mode of action (MoA) and the adverse effect that can often be difficult to discern when several potential pathways converge on the same adverse effect. While expanding sets of assays and tools are being developed that provide new and targeted information to better differentiate between endocrine and non-endocrine patterns of responses, the use of this type of data in regulatory decision making is often inconsistently employed. The extensive database for bisphenol A (BPA) provides an excellent case study to illustrate the use of some of these new approach methods for linking mechanistic information to apical outcomes of relevance in a hypothesis testing weight of evidence (WoE) framework. The WoE evaluation for BPA included the integration of data from high throughput screens, regulatory guideline studies and published literature, corresponding to levels 1-5 of the OECD conceptual framework. While BPA exhibits weak estrogenic activity in *in vitro* receptor binding studies and can increase male VTG in fish, the profile of adverse effects that have been measured in BPA-exposed aquatic vertebrates and are used in ecological risk assessments (*i.e.,* effects on survival, growth, development, and reproduction) are not all definitively linked to a weak estrogenic mode of action. The use of bioactivity screens and a consideration of the mechanistic potency of BPA, in relation to endogenous hormones, suggests that the lead mode of action is related to non-specific, systemic toxicity rather than an endocrine specific mode of action.

6.03.P-We391 Efficacy of Dietary Administration in the Amphibian Metamorphosis Assay: Influence of Solvent Loaded Test Substance on Nutritional Quality and Control Performance Criteria

Douglas J. Fort[1]*, Angelika Langsch*[2]*, Markus Junker*[3]*, Beate Fast*[4] *and Rainer Otter*[4]*, (1)Fort Environmental Laboratories, (2)Regulatory Affairs and Advocacy, Industrial Petrochemicals Europe, BASF SE, Germany, (3)GBP/RA, BASF SE, Germany, (4)BASF SE, Germany*

Based on a recent regulatory request to perform an OECD TG 231 Amphibian Metamorphosis Assay (AMA) of bis(2-propylheptyl) phthalate (DPHP) administered via diet, an investigation of the efficacy of dietary administration of test substance was performed. The efficacy study was comprised of two phases: evaluation of the physical influence of the loading process via solvent and 10, 1, and 0.1 mg/L test substance or surrogate (sunflower oil) on the Sera Micron Nature® (SMN) diet, and 2) performance of a modified AMA in which Nieuwkoop and Faber (NF) stage 51 *Xenopus laevis* larvae were exposed to dechlorinated tap water using one concentration of the sunflower oil in the diet for 21-days. Sunflower oil served as a surrogate with similar physicochemical characteristics to DPHP. Based on the results of phase 1, the addition of acetone or acetone with DPHP or sunflower oil and subsequent solvent removal physically altered the diet. Specifcally, reduced transmittance, density and dietary pellet were observed indicative of alteration of the nutritional quality of the diet. Since physical impact was identified in the acetone treated diet and magnified with the addition of the DPHP or sunflower oil, treatments used in the modified AMA were acetone alone and 0.1 mg/L sunflower oil dissolved in acetone. These treatments were evaluated against an SMN benchmark using standard AMA endpoints. Both the ace ne treated SMN and 0.1 mg/L sunflower oil treated diets had significantly reduced survival rates, 67% and 70% relative to the SMN benchmark (100%). Clinical signs of gastrointestinal impaction were noted in the dietary treatments, but not the SMN benchmark. Increased occurence of tail flexure was also observed in the acetone treated diets (29-38%) compared to the SMN benchmark. Treatment of the MN with acetone (NF stage 58.3) or 0.1 mg/L sunflower oil dissolved in acetone (NF stage 58) decreased the median developmental stage relative to the SMN benchmark (NF 60). Development stage frequency distribution was also decreased relative to the SMN benchmark. Aside from the adversity identified by the present evaluation, the inability to determine doses administered and route of exposure, and lack of historical control data to support this design compound the inefficacy. Ultimately, dietary ex sure of a test substance in an AMA study will not provide meaningful data that can be appropriately interpreted and warrants traditional aqueous exposure.

6.03.P-We392 Historical Control Histopathology Data from Amphibian Metamorphosis (AMA) and Fish Short Term Reproduction (FSTRA) Assays

Jeffrey C. Wolf[1]*, Douglas J. Fort*[2]*, Valentin Mingo*[3] *and James Robert Wheeler*[4]*, (1)EPL, (2)Fort Environmental Laboratories, (3)Corteva Agriscience, Germany, (4)Corteva Agriscience*

The Amphibian Metamorphosis Assay (AMA) and the Fish Short Term Reproduction Assay (FSTRA) are *in vivo* ecotoxicological bioassays that are used to determine if exposure to a tested chemical might have the potential to interact with the endocrine systems of aquatic vertebrates. Specifically, the AMA is designed to investigate potential effects of a chemical on the hypothalamic-pituitary-thyroid (HPT) axis, while the FSTRA investigates effects on the hypothalamic–pituitary–gonadal axis (HPG). Translational extrapolation of effects to wildlife and humans is facilitated by the highly conserved nature of endocrine physiological mechanisms among the vertebrate taxa, and results of these screening assays can help to determine if a substance does or does not appear to display endocrine activity, which in the former case can then be investigated by more definitive testing. It's important to recognize that apparent effects in these assays are not always attributable to endocrine perturbation, but instead may be consequences of treatment-induced stress or non-endocrine toxic responses. Differentiating endocrine from non-endocrine effects can be challenging, but answers may be provided by careful examination of data from various AMA or FSTRA endpoints. As a decision-making tool, HCD are most fairly and effectively used in combination with other criteria in a weight of evidence approach, rather than merely as a gatekeeper to exclude undesirable data points or nullify clear treatment-related effects. A major goal of this endeavor is to present histopathology HCD from a sizeable number of guideline-adherent AMA and FSTRA studies, so that such data become publicly available and can thereby be used to help interpret future study outcomes. A second goal is to perform a granular exploration of the AMA and FSTRA control data in order to identify background lesions, assess the utility of particular diagnostic findings for distinguishing endocrine from non-endocrine effects, and help determine if specific improvements to the guidance and interpretation procedures may be warranted. This information will be used to inform suggestions for the interpretation of histopathology data from AMA and FSTRA studies.

6.03.P-We393 Evaluation of Yeast-based Reporter Gene Assays Using Thyroid Hormone Receptors of *Homo sapiens* and *Xenopus tropicalis*

Masahiro Ogawa[1]*, Junya Kitamoto*[1]*, Yuto Hanaichi*[2]*, Mayuko Nakashima*[2]*, Sayoko Ito-Harashima*[3]*, Megumi Terada*[1]*, Takashi Yagi*[2] *and Masanobu Kawanishi*[2]*, (1)Life Science Research Institute, Kumiai Chemical Industry, Japan, (2)Graduate School of Science, Osaka Metropolitan University, Japan, (3)Graduate School of Agriculture, Osaka Metropolitan University, Japan*

Thyroid hormones are a critical role in cardiac function and brain development, and the act of thyroid hormones is mediated through the activation of nuclear thyroid hormone receptors (TRs). Although in vitro reporter gene assays are widely used to detect endocrine disruptors, a TR-responsive reporter gene assay has not been established except for a few human cell-based bioassays. In the previous study, we developed yeast-based TR responsive reporter gene assays. In this study, we investigated whether thyroid hormones and anti-thyroid hormone compounds were effectively detectable using four yeast-based reporter gene assays for TRα and TRβ in human and *Xenopus tropicalis*.

In 96-wells plates, yeasts were incubated with the various concentrations of test substances for 16 hours. The antagonistic activities of chemicals were examined by competition between the chemical and thyroid hormone simultaneously added at the various concentrations. To distinguish antagonist activity from the cytotoxicity, the yeast strains established in W303a and corresponding mutants for each receptor that constitutively expressed the lacZ reporter were used for comparisons.

In both of TRα and TRβ assays in human and *Xenopus tropicalis*, β-galactosidase activity was induced by thyroid hormones in a dose-dependent manner. All anti-thyroid hormone compounds tested in this study inhibit thyroid hormone-induced in human TR assays, but some compounds had no antagonistic effects in the assays for *Xenopus tropicalis*. Further studies are needed to determine whether other compounds can be evaluated in our assays.

6.03.P-We394 Influence of Storage Method, Storage Duration, and Freeze-Thaw Cycles on Measured Plasma Vitellogenin Concentrations for Fathead Minnows

Julie Krzykwa, *and Joseph Marini, Smithers*

Plasma vitellogenin (VTG) concentration is one of the primary apical endpoints of regulatory test methods using fish models where estrogen/androgen/steroidogenesis modalities are evaluated (e.g., OECD 229/230/234 and OCSPP 890.1350). As VTG is relied upon as a biomarker of exposure to endocrine active compounds, there has been a focus on the high variation observed in reported VTG levels, in the impacts this variation may have regarding assay robustness/animal usage/repeat testing, and how the methodology utilized by different labs to assess VTG concentrations may be a factor in the observed variation. One potential source of variation is sample storage. It is currently unclear how storage methodology and storage duration influence the stability and subsequent analysis of fathead minnow plasma VTG. While relevant guidelines outline a storage procedure for plasma samples (i.e., store with a protease inhibitor at -80 °C), not all laboratories are using the described procedure. In addition, these guidelines provide no clear indication of the stability of samples under this storage regime. The paucity of information regarding the effects of storage method and duration makes it difficult to determine if these factors may be influencing the previously noted variation in VTG concentrations. Therefore, the objective of this project was to evaluate the impacts of storage method, storage duration, and freeze-thaw cycles on plasma vitellogenin concentrations. To achieve this objective, composite plasma samples from male and female fathead minnows were stored under multiple storage scenarios (i.e., with/without a protease inhibitor at -20°C or -80°C) and sample VTG concentrations were measured via ELISA at 0.14 (1 day), 2, 6, and 15 weeks after collection for VTG concentration. The results of this project indicate that storage time and method have an impact on measured plasma VTG concentrations and may be a contributing factor to the high inter- and intra-laboratory variation in control VTG concentrations. In addition, this dataset confirms that freeze-thaw cycles should be avoided if possible; however, if freeze-thaw cycles are anticipated in advance samples should be stored neat.

6.03.P-We395 Thyroid Hormone System-disrupting Effects Of Carbamazepine on Zebrafish − A Case Study for the Performance Of OECD TG 210 (FELS) with Implementation of Thyroid-related Endpoints

Giulia Cafiero[1]*, Maximilian Rinderknecht*[1]*, Thomas Braunbeck*[1] *and Lisa Annie Baumann*[2]*, (1)University of Heidelberg, Germany, (2)Vrije University Amsterdam, Netherlands*

In recent years, research on endocrine disruptors (EDs) has picked up speed again, since the focus has now included chemicals with disrupting effects on the fish thyroid hormone (TH) system. The hypothalamus-pituitary-thyroid (HPT) axis is crucial for the maintenance of homeostatic functions and numerous developmental processes. Its role can be studied in models such as zebrafish, where changes of TH levels may lead to changes in eye and swim bladder development. As the HPT axis processes are highly conserved among vertebrate classes, cross-species extrapolation is being considered to comply with the 3R principles of replacement, reduction and refinement of animals used for experimental purposes. For environmental screening, current test guidelines (TGs) for thyroid-active compounds are restricted to protocols with amphibians, although fish represent the most frequently used model for ED testing. Nevertheless, the thyroid modality is not covered in existing fish TGs. The zebrafish (*Danio rerio*) is a well-established model in ED testing and is currently being evaluated as a model for the assessment of thyroid hormone system-disrupting chemicals (THSDCs). Various thyroid-related parameters have been identified as relevant endpoints so far: thyroid follicle histopathology, eye development, swim bladder inflation and TH level measurement. The ERGO project, as part of the EU H2020 EURION cluster, is focused on optimizing existing fish TGs for screening for the effects of THSDCs, such as the fish early-life stage toxicity test (FELS, OECD TG 210). For the present case study, zebrafish embryos were exposed during the first 33 days post-fertilization to carbamazepine, an anti-convulsant drug that has been shown to accelerate liver metabolism and thereby increase TH excretion, lowering TH levels in mammals. In order to compensate the lack of adequate hormone level, due to higher liver clearance of the hormone, thyroid follicles are expected to proliferate. Consequently, to confirm this effect at the morphological level, juveniles were subjected to histopathological analysis of thyroid follicle morphology and epithelium thickness. Moreover, eye development, which is also under the control of THs, was investigated by measuring different retinal layers. These analyses provide further information on the effects of carbamazepine on the HPT axis in fish and on the sensibility of thyroid follicles and eye development as endpoints for THSDCs screening using OECD TG 210.

6.03.P-We396 The Rapid Estrogen ACTivity In Vivo (REACTIV) Assay and the Rapid Androgen Disruption Activity Reporter (RADAR) Assay

Andrew Tindall[1]*, Ioanna Katsiadaki*[2]*, Marion Sebire*[2]*, Hiroshi Yamamoto*[3]*, Gitte Petersen*[4]*, Marlo K Sellin Jeffries*[5]*, Lisa Annie Baumann*[6] *and Gregory F. Lemkine*[1]*, (1)Watchfrog S.A., France, (2)Centre for Environment Fisheries and Aquaculture Sciences (Cefas), United Kingdom, (3)National Institute for Environmental Studies (NIES), Japan, (4)DHI Water and Environment, Denmark, (5)Texas Christian University, (6)University of Heidelberg, Germany*

In June 2022 a novel level three OECD test guideline was published for the Rapid Androgen Disruption Activity Reporter (RADAR) assay, TG 251. It describes a 72 h *in vivo* assay for the detection of androgen axis active chemicals using transgenic medaka (*Oryzias latipes*) eleutheroembryos, non-compliant with the EU definition of a laboratory animal.

A complementary assay for the detection of alterations in estrogen axis signalling is currently under OECD validation. The Rapid Estrogen ACTivity *In Vivo* (REACTIV) assay is based on the same concept as the RADAR assay, the use of transgenic medaka eleutheroembryos that reveal the level of activity of the hormonal axis of interest by the expression of GFP. In the case of the REACTIV assay, the axis of interest is the estrogen axis and its activity is translated into fluorescence using a portion of the *choriogenin h* gene promoter to drive the expression of GFP coding sequence under the control of liganded estrogen receptors. The use of aquatic eleutheroembryos allows quantification of the effects of test chemicals acting via a range of modes of action (MoA). The chosen reporter, the choriogenin h promoter, as a terminal step in estrogen axis signalling, indicates the net effect of disruption of the estrogen axis via one or multiple mechanisms.

Laboratories from six countries took part in the REACTIV assay interlaboratory validation exercise. The chosen test chemicals covered a wide range of MoA. The transferability of the assay and its ability to identify chemicals acting on estrogen axis signalling, either at the receptor level or on downstream steroidogenesis was demonstrated. The six expected inert chemicals were all correctly identified as inactive on the estrogen axis. The results obtained by the lead laboratory for chemicals tested with the REACTIV and RADAR assays during the OECD validation exercises showed that all ten chemicals were correctly identified as active or inactive. Chemicals with different MoA showed differing response profiles in the two assays.

The REACTIV assay is a 24 h assay that allows the quantification of estrogen axis activity. It provides crucial data on endocrine activity for a weight of evidence approach. By comparing the results in the presence and absence of testosterone the REACTIV assay can help to elucidate the MoA of a test chemical. A greater precision for identifying the MoA is achieved when the REACTIV assay is performed in parallel with the complimentary RADAR assay.

6.03.P-We397 Lessons Learnt from Three Years of Applying the XETA Test Guideline

David Du Pasquier and ***Gregory F. Lemkine****, Watchfrog S.A., France*

The Organization for Economic Cooperation and Development has set up a conceptual framework for the testing and assessment of endocrine disrupters (EDs). Different *in vitro* and *in vivo* standardized methods (test guidelines, TG) are categorized into five levels of increasing biological complexity. Detection of thyroid active molecules is addressed by mammalian and amphibian testing. The mammalian testing strategy mainly relies on measurements of plasma concentrations of thyroid hormones (THs) as well as on histopathological analysis of the thyroid. Amphibian testing takes advantage of the THs' exclusive control of anuran metamorphosis. In June 2019, the OECD validated the *Xenopus* Eleutheroembryonic Thyroid Assay (XETA) in the test guideline program in order to support the identification of thyroid active chemicals. The XETA utilizes *X. laevis* eleutheroembryos to detect modulation of thyroid signalling by thyroid active chemicals. The assay is transcription-based and uses a transgenic tadpole line expressing the Green Fluorescent Protein (GFP) under the control of a promoter directly regulated by TH. The response measured is fluorescence of embryos. The technical transfer of the assay to contract research organisations (CROs) was a prerequisite to the application of the XETA, the test guideline has been easily implemented in several CROs in a short time frame. The use of the XETA has been supported by the publication of an annex describing how to include the XETA in the assessment strategy of the ECHA/EFSA Guidance. To date reglementary studies have been perfomed to assess the T-modality for approximately 30 chemicals using the XETA. During these studies, some practical points of consideration have appeared including how to consider sub lethal effects, affecting behaviour or obviously testifying of toxicity, in the definition of the Maximum Tolerated Concentration and how to ensure testing concentrations close as possible to the MTC. The objective of the present communication is to highlight theses developments that allowed the use of the XETA in chemical assessment since its validation in 2019. The developement and rapid implementation of the XETA into the reglementary assessment of chemicals has paved the way to developing assays using embryonic stages of aquatic vertebrates. These are ethical and novative tools that perfectly fits into the strategy of a mechanistic approach for the comprehensive assessment of endocrine activity on targeted EATS.

6.03.P-We398 Elucidating the Effects of Acute and Chronic Exposure of 2,4-dichlorophenoxyacetic Acid on Freshwater Fish Innate Immunity

Emily Cornelius Ruhs[1]*, Brian Anton*[2] *and Gavin Dehnert*[3]*, (1)Department of Ecology and Evolution, University of Chicago, (2)University of Wisconsin, Madison, (3)VCGRE, University of Wisconsin, Madison*

Aquatic herbicides, such as 2,4-Dichlorophenoxyacetic acid (2,4-D) formulations, are commonly used on invasive species for management throughout the United States. Ecologically relevant concentrations of 2,4-D impair essential behaviors such as locomotion and prey capture, reduce survival, and act as an endocrine disruptor; however, there is limited knowledge of its effects on the health of non-target organisms. Here, we aim to broadly investigate the acute and chronic exposure impacts of 2,4-D on condition, immune function, and fever-avoidance behaviors of fathead minnows (Pimephales promelas), a model organism. To elucidate the effects of 2,4-D, we took a multi-faceted approach. First, we exposed adult male and female fathead minnows to three different ecologically relevant concentrations of 2,4-D (0.0, 0.4, and 4.0mg/L) and took blood samples at three acute time points (6, 24, 48, and 96 hours) and one chronic time point (31 days). Male fatheads had significantly increased mean total white blood cell counts after 6-hours of exposure at 0.4 and 4.0 mg/L compared to control fish; however, individual cell types did not change with treatment. Female fatheads exposed at 4.0mg/L had increased heterophils at a chronic timescale, but no other significant changes were observed. Second, we are assessing the ability of male fathead minnows to have a "healthy" behavioral fever response after exposure to lipopolysaccharide (LPS) and when exposed to 2,4-D. We expect that control fish would prefer warmer water environments during a stimulated fever response to naturally raise their body temperatures to clear an infection. However, we expect fish exposed to 2,4-D will not be able to make the same behavioral choices due to neurological impairment as compared to the control fish. Finally, we are exploring innate immunity-associated gene expression changes after chronic exposure to 2,4-D throughout development. Results from these experiments will shed light on freshwater fishes ability to maintain an adequate immune system and clear pathogen infections while exposed to commonly used herbicides. Moving forward, our group will build on these preliminary studies with an ultimate goal of elucidating the morbidity impacts of herbicide exposure on fishes health and immunity. These studies will help management agencies accurately make data driven management practices and create risk assessments for herbicide treatments in aquatic ecosystems in the Great Lakes, and beyond.

6.03.P-We399 Testing for Endocrine Disruption - Existing Gaps and Recommendations from a CRO Perspective
***Johannes Völker*[1]**, *Armin Peither[2], Lisa Gutmann[2], Séverin Semal[2], Birgit Höger[2], Jörn Schreitmüller[2] and Stefan Hoger[2], (1)IES, Switzerland, (2)Innovative Environmental Services, Switzerland*
Testing for endocrine disruption is an essential part of regulating chemical substances in the EU and USA. Accordingly, contract research organisations (CROs) face a high demand for endocrine testing. Since 2019, IES ltd. has been increasingly conducting key *in vivo* bioassays out of Level 3 or 4 of the OECD conceptual framework for testing and assessing endocrine disruptors, such as the Fish Short Term Reproduction Assay (FSTRA; OECD 229, OPPTS 890.1350), the Amphibian Metamorphosis Assay (AMA; OECD 231, OPPTS 890.110) or the Fish Sexual Development Test (FSDT; OECD 234). Especially for the registration of plant protection products (PPPs) in Europe, the FSTRA and AMA represent critical assays to screen for endocrine disruption given that the indication of an effect triggers higher tier tests resulting in additional costs and use of animals and, in case of a confirmed endocrine disrupting effect, a ban of the substance on the European market. Based on our long-term experience and during the implementation of the FSTRA and AMA, we identified gaps in the description of the applied test procedures in both the OECD and OPPTS guidelines, which may affect the reproducibility and comparability of the outcomes. Given the high importance of these tests for the registration and re-registration of PPPs, existing gaps should be discussed and closed for future testing. Thus, to identify weaknesses of the current procedures, we compared our control data for all relevant endpoints (fecundity, nuptial tubercle score, vitellogenin for the FSTRA and determination of the Nieuwkoop-Farber stage (NF-stage), measurement of the hind limb and snout-vent length for the AMA) with control data from the EPA Endocrine Disruptor Screening Program. Based on this comparison, we will discuss critical steps of these key bioassays to screen for endocrine disruption and provide recommendations to improve the testing procedure, such as choosing suitable test concentrations due to the lack of reliable toxicity data.

6.03.P-We400 Investigation of Possible Endocrine Sensitive Endpoints in Snail Embryos and Juveniles
***Jane Ebsen Morthorst*[1]**, *Gunnar Carlsson[2], Stefan Orn[2], Ketil Hylland[3], Henrik Holbech[1], Gaëtan Tucoo[4] and Pernille Ambus Hansen[4], (1)University of Southern Denmark, Denmark, (2)Swedish University of Agricultural Sciences (SLU), Sweden, (3)University of Oslo, Norway, (4)Biology, University of Southern Denmark, Denmark*
Today, test methods and endpoints able to identify chemicals interfering with the endocrine system and thereby disrupt fundamental processes such as development, reproduction, and metabolism, in invertebrates are lacking. Invertebrates, accounting for 95% of all living animal species, are suffering from rapid global decline;50% of freshwater mollusk speciesare threatened with extinction. Chemical pollution, including endocrine disrupting chemicals (EDCs), is considered as a key driver, but understanding the scale of the problem is hampered by lack of knowledge; there are very few data available on fundamental endocrinology and neuroendocrinology including regulation of reproduction, development and metabolismof most invertebrate groups. Invertebrates have also received increasing attention in regulatory chemical testing. The 3Rs concept involves Replacing vertebrate animal experiments when possible, Reducing the number of vertebrate animals used, and Refining experiments to minimize the impact on vertebrate animals by developing new approach methodologies (NAMs) including less sentient species (e.g. invertebrates) or life-stages (embryonic life-stages).
The great pond snail (*Lymnaea stagnalis*)is a freshwater gastropod mollusc widely distributed in Europe, and it is used as test organism in the OECD test guideline 243, which is a reproduction test designed to assess effects of exposure to chemicals on the reproduction and survival. Currently, we are developing an assay with *L. stagnalis* embryos and juveniles and investigating potential endocrine sensitive endpoints.
Here, we discuss the lack of knowledge about fundamental endocrinology molluscs and present our preliminary experiences and data.
This knowledge is highly necessary for the optimization of existing and/or development of new OECD test guidelines, and for understanding better the potential harmful effects of chemicals on invertebrate populations in the environment.

6.03.P-We401 Underlying Mechanisms of Drug-Induced Endocrine Disruption to Gastropod Shell to Be Unravelled by Fundamental Molecular Diagnostics

Konstantinos Panagiotidis, *Giang Huong Duong, Hazzel Tabernilla and Alice Baynes, Department of Life Sciences, Brunel University, United Kingdom*

Due to a lack of detailed knowledge relating to the endocrinology of molluscs, current OECD tests lack mechanistic underpinning. Therefore, current freshwater gastropod OECD tests (242 and 243) can only determine reproductive toxicity in adult snails. Consequently, existing OECD tests are unable to identify if a chemical is an endocrine disruptor (ED) to molluscs. In the last decade, molecular and chemical exposure investigations have shown that molluscs do not poses a nuclear androgen receptor, and do not respond to exogenous androgen (e.g. testosterone) exposure. However, molluscs do have some steroidogenic genes which are homologous to vertebrates. These include 5-alpha reductases (5αR) known to convert testosterone to the more potent dihydrotestosterone in vertebrates. As yet, the function of these steroidogenic genes in molluscs is unknown. Previous work in our lab has shown that 5αR genes are not only expressed in adult and embryonic *Biomphalaria glabrata* tissues, but that developmental exposure to pharmaceutical 5αR disruptors (dutasteride or finasteride) results in a highly reproducible and dose-dependent disruption to embryonic shell morphology. Here we present further investigations narrowing down the sensitive window of dutasteride disruption in developing *B. glabrata*. To further understand this developmental disruption, we also need to map gene expression profiles in the developing embryos. However, basic molecular information, such as suitable endogenous control "housekeeping" genes during embryo development are still lacking in this species. Candidate endogenous control genes and primers were identified from the literature. Their expression stability across four stages of embryo development (days 2-5 postoviposition) and albumen gland tissues has been investigated using RT-qPCR and the stability algorithm BestKeeper. Preliminary analysis suggests Ubiquitin as the most stable endogenous control gene out of the candidates tested. Optimisation and refinement of primers of the most appropriate control genes are being re-validated. The development of robust endogenous control genes will allow us to link 5αR gene expression patterns to the sensitive window of dutasteride disruption, furthering our understanding of this possible ED sensitive phenotype in gastropods. These control genes will enable expression analysis of other transcripts during gastropod early development for mechanistic research and could inform future ED test development.

6.03.P-We402 Assessment of Sediment Samples from Lake Tai, China via Effect-Based Methods Including Metabolic Activation

Feifei Xue[1]*, Andreas Schiwy*[2] *and Henner Hollert*[3]*, (1)Evolutionary Ecology and Environmental Toxicology, Goethe University Frankfurt, Germany, (2)Evolutionary ecology and environmental toxicology, Goethe University Frankfurt, Germany, (3)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany*

The quality of ecological environment of Lake Tai, the third-largest freshwater lake in China, is facing huge challenges due to existing input of chemical pollution since last few decades. Among numerous emerging pollutants, endocrine disruptive chemicals (EDCs) with the ability to disrupt the mammalian hormonal system attracts more attention. Different methods have been used to detect those compounds. As a supplementation of chemical target analysis, *in vitro* chemically activated luciferase gene expression (CALUX®) was proposed as a standard testing for endocrine disruptors in Europe. However, the currently used cell-based CALUX® assay may not provide full potential of adverse effects of environmental samples because of its limited metabolization capacity. We standardise the testing system by adding the rat liver S9 mix as an exogenous metabolic system to the *in vitro* CALUX® assay for (anti-)estrogenic (ERα) and (anti-)androgenic receptor (AR) assessment as the first step. To exploring comprehensive toxicological potential of Lake Tai, sediment samples from three sampling sites were taken and subsequently tested with *in vitro* CALUX® assay without and with S9 metabolic module. By the neutral red retention assay, 0.01 protein mg/ml of S9 mix was more suitable as working concentration compared to 0.05 protein mg/ml, 0.1 protein mg/ml. Furthermore, *in vitro* CALUX® assay combined with S9 metabolization were completed systematically with tamoxifen, flutamide and other new chemicals of benzo(a)pyrene as the agonist in the ERα CALUX® assay and stanozolol as androgen agonist in the Anti-AR CALUX® assay. The establishment and improvement of standardization of *in vitro* CALUX® assay with metabolic fraction not only provide more comprehensive ecotoxic evaluation to environmental samples as powerful screening tool, but also implies that the addition of S9 mix could overcome the disadvantage of the lack of metabolic bioactivity of various cell-based mode of action bioassays.

6.03.P-We403 Peer-Group Assessment of the Results from an Interlaboratory Study for Effect-based In Vitro Methods to Determine Estrogenic Effects in Environmental Surface Water

Martin Jähne[1]*, Karina Hettwer*[2]*, Kirstin Frost*[2] *and Steffen Uhlig*[2]*, (1)new_diagnostics, Germany, (2)QuoData, Germany*

Estrogens are well known for their potential of causing adverse effects on aquatic organisms in extremely low concentrations of exposure (ng to pg per liter) and are already monitored for many decades, accordingly. Hence, environmental quality standards for priority substances under the European Water Framework Directive for 17-α-Ethinylestradiol (EE2), 17-β-Estradiol (E2) and Estrone (E1) have been suggested and reviewed. The use of effect-based *in vitro* methods (EBM) for the determination of hormonal effects contributes beneficial information on the assessment of the quality status of environmental water ecosystems especially in the case of estrogenicity. Since the publication of the ISO 19040 standards in 2018 the respective *in vitro* assays are in use for the analysis of estrogenicity of surface water in routine laboratories. The implementation of internal and external quality assurance procedures is an essential requirement for providing confidence and reliability in the reported estrogenicity data by the responsible laboratory. Thereby it still remains challenging to compare and harmonize the generated data due to the use of mammalian and yeast biosensor systems exhibiting different biological responses with respect to the relevant estrogens. To provide an opportunity to implement an external quality assurance measure which also meets the requirements of the ISO/IEC

17025 an interlaboratory study was performed to determine the estrogen equivalent concentration (EEQ) in artificial environmental samples.
Several European laboratories participated in the study by using different effect-based *in vitro* methods. Due to the different biological responses of the *in vitro* methods a combined evaluation was not feasible. However, as the number of participants per method type was too small for a reliable evaluation of laboratory performance, a novel mathematical-statistical approach has been applied that considers peer groups. Using this approach, the peer group effect due to the use of different effect-based *in vitro* methods (ISO 19040-1 and other, ISO 19040-2, ISO 19040-3 and other) as well as the overall robust mean across peer groups were considered. Following this approach, the assessment of laboratory performance as well as the characterization of differences between peer groups (method effects) was obtained.

6.04 Deriving and Implementing Ecologically Relevant Environmental Quality Standards

6.04.P-Th392 pH normalization of effect values of ionisable drugs for aquatic EQS derivation taking Diclofenac as an example

*Odile Sellier[1], Peter Von der Ohe[2], Heinz Köhler[3], **Marion Junghans**[4] and Alexandra Kroll[4], (1)University of Genève, Switzerland, (2)German Environment Agency (UBA), Dessau-Rosslau, Germany, (3)University of Tuebingen, Germany, (4)Swiss Centre for Applied Ecotoxicology, Switzerland*

Around 80% of prescribed drugs are ionizable. Ionizable substances tend to be more toxic and bioavailable with an increasing fraction of the unionized species. However, aquatic toxicity tests are mostly performed at pH adapted to the test organisms rather than to the requirements of the ionizable substance. We hypothesize that heterogeneity in aquatic toxicity effect data is at least partially caused by differences in bioavailability at different pH. Using the weak acid diclofenac, a widely prescribed anti-inflammatory drug as an example, we examine the influence of pH on published effect data and derivation of environmental quality standards (EQS) for freshwater by applying a logD-based correction to effect values.
Around 50-67% of available effect data had to be excluded from the dataset due to lack of analytical verification and reported pH values. This also led to exclusion of rarely tested species and certain groups of organisms. We therefore recommend pH values and exposure concentrations to be determined and fully reported in toxicity studies.
Amphibians are the most sensitive group in the logD corrected acute dataset but are not represented in the chronic dataset. This data gap should be addressed to make the suggested EQS more robust. Likewise, bivalves are the most sensitive group in the logD corrected chronic dataset but are not represented in the acute dataset. This data gap is, however, less relevant due to the chronic type of exposure to diclofenac and other drug substances in surface waters.
Correction of effect values for logD at pH 6 and pH 8 results in a similar decrease in the standard deviation of log10 acute and chronic effect values in both cases. The wide range of pH values allowed in guidelines and used in toxicity tests apparently results in artificial heterogeneity in toxicity data.
The original threshold value (HC5) derived from a species sensitivity distribution (SSD) based on chronic data and pH-corrected data are similar to the lowest effect concentrations in the chronic dataset. The application of an AF of 5 to the respective HC5 results in an EQS_{SSD} of 0.057 µg/L for non-corrected data, 0.004 µg/L for pH6-corrected data, and 0.097 µg/L for pH8-corrected data.
We conclude that the decrease in data variability upon pH/logD correction and the substantial differences between EQS derived for different pH values show that pH/logD correction should be mandatory for ionisable substances for hazard assessment and EQS derivation.

6.04.P-Th393 Updating the Environmental Quality Standard for nickel in the UK

*Christian E. Schlekat[1], Adam Peters[2], Iain A Wilson[2], Graham Merrington[2], **Elizabeth Traudt Middleton**[1], Emily Rogevich Garman[1] and Helen Wilkinson[3], (1)NiPERA Inc., (2)wca environment Ltd., United Kingdom, (3)Environment Agency (England), Bristol, United Kingdom*

Nickel was identified as a Priority Substance under the Water Framework Directive (WFD) and an Environmental Quality Standard (EQS) was set in 2013 that applies throughout Europe. The EQS was set as a “bioavailable nickel” concentration, and the assessment of compliance against it should take account of bioavailability. The EQS was set based on a Species Sensitivity Distribution (SSD) for nickel that is normalised to the local site-specific water chemistry conditions using the Biotic Ligand Model (BLM). The ecotoxicity database that is used as the basis for the SSD, and the underlying models that define the bioavailability normalisation within the BLM, are based on information that was available in 2010. There have been several advances in the science that supports this approach over the past decade, in terms of additional ecotoxicity data that mean a greater diversity of species could be included, and the applicability of the underlying bioavailability normalisation models to broader ranges of water chemistry conditions. Since the UK left the European Union it is free to make an independent evaluation of the nickel EQS if the EU update is deemed inappropriate. This study describes the update of the approach and the derivation of the revised EQS for the UK, and provides a provisional assessment of compliance with the updated EQS for UK freshwaters.

6.04.P-Th394 Metals Ecotoxicity Species Sensitivity: From Native Waters to Laboratory Waters

***Carol Mackie**[1], Kevin Long[1], Kevin J Rader, PhD[2], Richard F. Carbonaro[2,3], Douglas J. Fort[4] and Robert Dwyer[5], (1)Regulatory Compliance Limited, United Kingdom, (2)Mutch Associates, (3)Manhattan College, (4)Fort Environmental Laboratories, (5)Risk Decision Sciences*

An informal meeting was held at the 2022 SETAC North America Annual Meeting in November to consider the following question: are metals ecotoxicity results impacted by sensitivities or stresses introduced when organisms are tested in waters not

resembling their natural environment? This meeting was conducted under the auspices of SETAC's Metals Interest Group (MIG). A total of 28 ecotoxicologists/chemists participated.
There is much interest in determining the sensitivity of organisms (e.g., fish; invertebrates, including snails and mussels; and algae) collected from their natural habitat and transported to a laboratory for subsequent ecotoxicity testing with metals and other substances. This has drawn considerable interest particularly for rarely tested and/or endangered species (e.g., sturgeon). However, as the number of good quality publications increase in this area of research, concerns arise on their suitability for use in risk assessment, in classification, and on development of specific water quality criteria requirements for metals.
Several critical factors in determining the suitability of these studies were discussed in the meeting including: (1) study design requirements; (2) reproducibility of studies in the laboratory with organisms collected at different times or environments; (3) water quality differences between natural waters and laboratory waters; and (4) performance quality criteria.
It was agreed that further research and evaluation of available data were required and that this could be taken forward to a second meeting to discuss future potential activities such as review of existing studies and design of targeted new studies.

6.04.T-01 Deriving an EQS for Aluminium in UK Surface Waters
Adam Peters[1]*, Iain A Wilson*[1]*, Graham Merrington*[1]*, Barrie Howe*[2]*, Simon Roe*[2] *and Helen Wilkinson*[2]*, (1)wca environment Ltd., United Kingdom, (2)Environment Agency (England), Bristol, United Kingdom*
Aluminium is ubiquitous in the environment, although the levels in surface waters may be enriched by anthropogenic activities that result in emissions from both point and diffuse sources. Aluminium can be present in a wide variety of different forms in aquatic systems ranging from truly dissolved simple inorganic complexes, colloidal complexes with organic matter, inorganic colloids, precipitates, and clay minerals. Several of these forms can contribute to adverse effects on aquatic organisms, either by direct toxicity or by physical effects such as smothering or precipitation on gill membranes. Consequently, deriving an acceptable limit that can be practically applied for regulatory purposes is challenging not only because of the different forms that may cause effects, but also because of the need to be able to identify those forms analytically in a manner that is practical for routine regulation.
A number of (bio)availability models have been developed for aluminium based on semi-mechanistic biotic ligand modelling (BLM) principles and empirical multiple linear regression (MLR) approaches to predict the toxicity of aluminium to a variety of standard laboratory test species. Some data is also available that can be used to evaluate the performance of these models both for other species and for natural, field collected, waters. These validation studies are required by many regulators to demonstrate that the bioavailability models will be protective of real ecosystems in natural waters.
This study describes the evaluation of the available evidence on aluminium toxicity to aquatic organisms to derive an EQS that can be practically implemented by UK authorities in regulating discharges containing aluminium into the aquatic environment.

6.04.T-02 On the Derivation and Implementation of Environmental Quality Standards for Sediments.
M. Carmen Casado-Martinez[1]*, Alexandra Kroll*[2]*, Michel Wildi*[2]*, Marion Junghans*[2] *and Benoit JD Ferrari*[3]*, (1)Centre Ecotox, Switzerland, (2)Swiss Centre for Applied Ecotoxicology, Switzerland, (3)Ecotox Centre, Switzerland*
The Swiss Centre for Applied Ecotoxicology (Ecotox Centre) has derived environmental quality criteria for surface waters for many substances, including pesticides, biocides, pharmaceuticals and industrial chemicals. The derivation is largely based on the EU Technical Guidance for Deriving EQS (TGD for EQS), because the protection goals of the Swiss water protection law and ordinance and the Water Framework Directive (WFD) are comparable. In contrast to the WFD dossiers, sediment and human health via the consumption of fisheries products are not part of the EQS derivation in Switzerland. In the last years, the Ecotox Centre has been working on a sediment quality assessment strategy for Switzerland. The objective is to harmonize and improve practices in sediment quality monitoring and assessment, which mainly addresses the chemical status so far. In this context, sediment quality criteria have been derived for both traditional sediment contaminants and other contaminants including pesticides, pharmaceuticals and personal care product ingredients.
At last SETAC Europe Annual Meeting in Copenhagen, we summarized our experience on the derivation of environmental quality standards for sediments as a poster contribution in the session "Contaminated sediment: an environmental compartment of concern". We would like to take the opportunity of this year's session dedicated to the derivation and implementation of ecologically relevant environmental quality standards to put on the spotlight the derivation and implementation of environmental quality standards for the sediment compartment. Building on our last year's contribution, we would like to highlight the difficulties in the derivation of sediment quality guidelines due to the (lack of) availability of relevant ecotoxicological data and the quality and reliability of available data from spiked-sediment toxicity tests, potential issues with implementation of the derived EQS for sediments, and other topics that still deserve further developments such as the incorporation of bioavailability in compliance check, how to address endocrine potential, or how to derive sediment EQS for protecting against secondary poisoning.

6.04.T-03 The ecological relevance of Environmental Qualtity Standards for biota
Lies Teunen[1]*, Maarten De Jonge Dr.*[2]*, Adrian Covaci*[3]*, Claude Belpaire*[4]*, Ronny Blust*[5] *and Lieven Bervoets*[3]*, (1)Biology, University of Antwerp, Belgium, (2)Flanders Environment Agency, Sint-Denijs-Westrem, Belgium, (3)University of Antwerp, Belgium, (4)Research Institute for Nature and Forest (INBO), Belgium, (5)ECOSPHERE, University of Antwerpen, Antwerpen, Belgium*
Aquatic environmental pollution is a transboundary problem. Therefore, substantiated international environmental standards are imperative. For 11 (groups of) pollutants that tend to strongly biomagnify, mostly due to their hydrophobic of lipophilic characteristics, European Environmental Quality Standards exist (e.g. PFOS, PBDEs, PAHs, mercury, dioxins). These compounds

need to be monitored in biota (EQS_{biota}), preferably occupying high trophic levels. Even though large and frequent exceedances of the current standards are reported on a global scale, for multiple compounds, no imminent environmental effects are detected. This led to a doctoral research evaluating the ecological relevance of the current EQS_{biota}. Firstly, an extensive 4-year monitoring campaign was performed at 44 sampling locations covering the main water bodies in the northern part of Belgium (Flanders). Study species were European perch (*Perca fluviatilis*), European eel (*Anguilla anguilla*), Dreissenid mussels (*Dreissena sp.*) and Asian clam (*Corbicula fluminea*). This resulted in an overview of the general pollution distribution and extend of the exceedance of the current EQS_{biota}. Secondly, the potential human health risk of the calculated concentrations was evaluated. Thirdly, critical accumulated concentrations in biota were determined using biotic indices reflecting the overall water quality of each sampling location. Finally, all three approaches were integrated, which suggested that the current EQS_{biota} for Hg and PBDEs might be too low to protect the ecological water quality, while the standard for HBCD may be too high. The results from this study provide an important baseline for the further evaluation of the current EQS_{biota}. Furthermore, it was brought to light that bioaccumulated concentrations of PFOS and dioxins in Flanders are very high, potentially causing both environmental and human health risks.

6.04.T-04 Thresholds for the terrestrial environment: proposal for an aggregated Environmental Quality Standard
***Sandrine Andres**[1] and Pia Kotschik[2], (1)INERIS, France, (2)German Environment Agency (UBA), Dessau-Rosslau, Germany*
The EU Soil Strategy for 2030 '*Reaping the benefits of healthy soils for people, food, nature and climate'* envisages that all soils in the EU should be in a healthy condition by 2050. For this, one of the legal instrument would be a possible EU Soil Health Law for protecting, sustainably managing and restoring EU soils. In the preparation of this law, the European Commission included in its consultation process questions related to the use of thresholds: this concerns for example the identification through measurements and monitoring of soil health and threats of early warnings of exceedances of critical thresholds to guide sustainable soil management. The harmonization at EU level of the threshold values for contaminants that would trigger a risk assessment is also questioned.
Currently different values are derived for the purpose of risk assessment including ground organisms, above ground organisms or human health. For the purpose of soil monitoring however, and from the experience gathered with the implementation of the Water Framework Directive, it appears that a single value might be useful and simplify the development of analytical and management activities.
However, whereas the Water Framework Directive has set the scene for the definition of safe level that should not be exceeded in water, soil and biota to protect the human health and the ecosystems, such a definition does not exist for terrestrial environment. Methodological developments would be needed to achieve an equivalent approach for soil. This work is a feasability study, which reviews the different protection goals that need to be considered and the possible approaches to combine them in a single value. Whereas the Soil Health law remains in preparation, this study does not question the relevance of protection goals that is a policy decision, but rather highlights the feasability of including the definition of a single agregated threshold value that could help for the implementation of monitoring requirements in soil, early warning on chemicals of concern and the identification of local exceedence.
Example on data rich and data poor chemical indicates that whereas these differences exist also for aquatic toxicity, they are more marked for terrestrial toxicity endpoints. The definition of an aggregated threshold value is however feasible, but technical adaptations would benefit to be further refined.

6.04.P Deriving and Implementing Ecologically Relevant Environmental Quality Standards

6.04.P-Th395 Enhancing the Role of Open Literature in Regulatory Environmental Risk Assessment
***Simone Rizzuto**, Maria Arena, Domenica Auteri, Fernando Alvarez, Franco Ferilli, Aude Kienzler, Alessio Ippolito, Alberto Linguadoca, Rachel Sharp, Csaba Szentes and Laura Villamar-Bouza, European Food Safety Authority, Italy*
Regulatory environmental risk assessment (ERA) of chemicals is often targeted by academic researchers and by the general public for relying mainly on industry dossier studies, and for not being sufficiently receptive of literature studies. In the case of plant protection products (PPPs), data requirements include standard GLP studies (e.g., OECD, ISO), as well as all relevant scientific peer-reviewed open literature on the active substance, its relevant metabolites and the representative formulation(s) published within the last 10 years before the date of submission of the dossier. In 2011, EFSA published a guidance document providing instructions on how to minimize bias in the identification, selection and inclusion of peer-reviewed open literature in dossiers, according to the principles of systematic review. Thus, in principle, studies published in the peer-reviewed open literature could directly inform the regulatory ERA of PPPs, mainly in addressing their hazard characterization. One of the pillars of the EU chemical strategy for sustainability is the concept of 'one substance, one assessment'. In this framework, the assessment of hazard data performed in the context of the environmental risk assessment of PPP for substance/product authorization can be relevant for the selection of Environmental Quality Standard (EQS). Depending on the relevance and the reliability of the measured endpoints, the results from such non-regulatory studies could be used either quantitatively (e.g., when an endpoint addressing a data requirement can be estimated from the study), or qualitatively (e.g., as supporting information in a weight of evidence approach or to further investigate any remaining uncertainties) in the hazard characterization, together with the available dossier studies. Nonetheless, it is currently rather uncommon for the regulatory ERA of PPPs to be driven by endpoints obtained from the open literature.
In this contribution, an analysis of the most frequent issues hindering relevance and reliability of literature studies in regulatory ERA, was conducted over several studies gathered during literature reviews of active substances/formulations. This input aims at: (i) delineating the issues often observed in the relevance and reliability assessment of open literature studies; (ii) offering possible

ways to produce useful outcomes for the regulatory process, while maintaining the freedom to investigate specific and independent research questions.

6.04.P-Th396 A Framework for the Co-building of Reference Values Using Multi-agent Approach Implementing Exposure-impregnation Models

*Virgile Baudrot[1], Thomas Kleiber[1], **Sandrine Charles**[2] and James Maino[3], (1)Qonfluens, France, (2)UMR CNRS 5558, University Claude Bernard Lyon 1, France, (3)Cesar Australia, Australia*

Embedding laboratory or mesocosm studies within monitored landscape in order to assess the real impact of stressors at the ecosystem scale is a huge challenge for ecotoxicological modelling. Assessing the ecological risk of chemical compounds is critical to avoid the decline and potential extinction of some populations that may subsequently threaten other species for example in food chains. Simultaneously, being able to control population dynamics is also important when a population outbreak in specific time and space may compromise agricultural activities and human health.
Ecological Risk Assessment studies have to deal with multiple exposure stressors (chemical and micro-biological) within multiple life-history contexts. In this talk, we propose a unified modelling framework for ecotoxicology, agroecology and eco-epidemiology (see Figure 1).
However, although these models are often intended to help decision-making, their use too rarely translates into direct application [1]. The obstacles are distributed between the lack of relevance (i.e., scales and variables of the model not appropriate to the decision-making framework), the low credibility (i.e., not following the standards of scientific rigor) and the lack of legitimacy (i.e., lack of trust of the users in the results). Therefore, we propose a first step of a methodology using social-science to parameterized and questioned the model.
Our results illustrate the robustness of this framework through its application within two contexts: (i) the impact of Bt-maize on Non-Target Lepidoptera in Catalonia (Spain), and (ii) the outbreak of Fall Armyworm resistant population at the continental scale of Australia. We also performed a sensitivity analysis in both cases to identify the most influential processes and provide recommendations of reference values for ecosystem management practices.

6.04.P-Th397 Solution-focused Mixture Assessments at the Landscape Level and Key Notions to Improve Water Quality Under the Water Framework Directive

***Leo Posthuma**[1], Matthias Hof[2] and Jaap Slootweg[1], (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Wageningen University & Research, Netherlands*

Surface water of good quality is vital for human health, ecosystems and their services, which provides the motivation of the 'toxic-free environment' aspiration. However, a low percentage of water bodies in European countries is tagged with having good water quality, with the Netherlands having a score of only 1% at the landscape-level. The main challenge is clear: "how to reach a 100% soon?" and how to avoid the backlash that >20 years of Water Framework Directive (WFD) policies apparently yield high 'failure' scores?
This challenge was addressed in the EU-projects *SOLUTIONS* and the Dutch project "*Knowledge Impulse on Water Quality*" by close consideration of field facts on exposures, risks and impacts in comparison to policy principles and operational solutions. Upon close reading of the WFD and the *Chemical Strategy for Sustainability* (CSS), and collecting and analysing monitoring data for Dutch surface waters over a prolonged period, this presentation will suggest some key innovations to forward WFD practices. The key innovations are based on implementing a 'distance to target' metric to summarize spatial or temporal trends in chemical pollution of surface waters next to the well-known environmental quality standards, and to provide water managers with two main new tools: (1) the solution-focused assessment paradigm, to help forward thinking into feasible solutions, and (2) a website with tools that assist in using that paradigm to evaluate efficacy of past solutions and explore likely outcomes of novel ones. The innovations were designed together with water quality management practitioners.
Given >80k visitors to the mixture risk website in the first few days upon publication marks an apparent broad public interest. Case studies further show spatial and temporal trends in chemical pollution. Given examples of positive effects of management on water quality and biodiversity, it appears key to utilize "distance to target" (DTT) approaches next to the current "*one out all out*" (OOAO) approach to report and assess real, gradual, trends in chemical water quality and enable the design of effective measures.

6.04.P-Th398 Criteria to Assess the Relevance and Reliability of Environmental Threshold Concentrations (ETCs) for Pharmaceuticals

***Caroline Moermond**[1], Marlene Ågerstrand[2], Thomas Backhaus[3], Cristiana Cannata[4], Todd Davidson[5], Gemma Janer[6], John Jensen[7], Gerd Maack[8], Samuel K Maynard[9], Ad M. J. Ragas[10], Els Smit[1] and Jan Wölz[11], (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Stockholm University, Sweden, (3)University of Gothenburg, Sweden, (4)Radboud University Nijmegen, Netherlands, (5)Bristol Myers Squibb, (6)Novartis Pharma, Spain, (7)Department of Ecoscience, Aarhus University, Denmark, (8)German Environment Agency, Germany, (9)Global Sustainability, Astrazeneca UK, United Kingdom, (10)Environmental Science, Radboud University, Netherlands, (11)Research & Development, Pharmaceuticals, Bayer AG - Pharmaceuticals, Germany*

Environmental Threshold Concentrations (ETCs) are threshold values below which concentrations are 'unlikely to represent a risk to surface waters' (European Medicines Agency) and other environmental compartments. ETCs indicate the maximum concentration for which 'safe use of a chemical' (REACH) can be assumed, given the available data and the context of the particular legislation. ETCs include PNECs (Predicted No Effect Concentrations), EQSs (Environmental Quality Standards), and other similar terms used in environmental science, risk assessment and risk management. For pharmaceuticals (similar to other substances), multiple ETC values might be available from regulatory frameworks and scientific literature. When performing a risk assessment, often the question is which of these values should be used, i.e., which is most relevant and reliable given the intended use? In this poster, we present a method to assess the relevance and reliability of ETC values.

6.04.P-Th399 Updating the EQS for Zinc in the UK

Adam Peters[1], *Iain A Wilson*[1], *Graham Merrington*[1] *and Christopher Cooper*[2], *(1)wca environment, United Kingdom, (2)International Zinc Association, Belgium*

Environmental Quality Standards have been set for zinc in UK waters for several decades. Zinc was identified as a specific pollutant under the Water Framework Directive in the UK and standard updated accordingly. The EQS for zinc was last updated over a decade ago and advances in the understanding both of zinc toxicity to aquatic organisms and the bioavailability modelling that is used to ensure that the EQS applied is ecologically relevant to local conditions mean that it may be appropriate to update the EQS. Updates to the bioavailability modelling approaches used may mean that the standard can be applied over a broader range of water chemistry conditions than was previously possible, meaning that the true risk posed by zinc can be evaluated for more of the surface waters resulting in a more ecologically relevant EQS. The updated standard will be compared against the existing EQS for zinc in UK freshwaters, in terms of the size and taxonomic diversity of the database, the proportion of UK water chemistry conditions covered, and the likely levels of compliance if it is updated. This presentation summarises the updates made and their implications for the EQS for zinc in the UK.

6.04.P-Th400 Updating the Metals Bioavailability Assessment Tool for Assessing EQS Compliance for Bioavailable Metals in the UK

Adam Peters[1], *Iain A Wilson*[1], *Graham Merrington*[1] *and Helen Wilkinson*[2], *(1)wca environment, United Kingdom, (2)Environment Agency (England), United Kingdom*

Several metals have Environmental Quality Standards set as bioavailable concentrations in the UK. Biotic Ligand Models are usually used for predicting metal toxicity under local water chemistry conditions, but they are data intensive, complex, and required skilled personnel to use them. Consequently, simplified tools are often used by regulators to make compliance assessment more practical and cost effective. The Metals Bioavailability Assessment Tool (MBAT) was developed for UK regulatory authorities to assist in compliance assessments against the EQS for copper, manganese, nickel, and zinc as a simple spreadsheet-based tool that could be easily operated, and if necessary could be implemented directly within automated Laboratory Information Management Systems. This tool therefore needs to be updated if the underlying EQS values for any of the metals are updated, for example to take account of new ecotoxicity information, or to extend the range of water chemistry conditions that the bioavailability approach can be applied over. This presentation describes changes made to the tool, including the approaches used to implement these changes, for possible future updates to metal standards in the UK.

6.04.P-Th401 Which Distribution to Choose for Deriving a Species Sensitivity Distribution?

Miina Yanagihara[1], *Kyoshiro Hiki*[2] *and Yuichi Iwasaki*[3], *(1)KWR Water Research Institue, Netherlands, (2)National Institute for Environmental Studies (NIES), Japan, (3)National Institute of Advanced Industrial Science and Technology (AIST), Japan*

Species sensitivity distributions (SSDs) are used to assess ecological risk and provide critical information to derive defensible guideline values. SSDs are typically estimated by fitting a statistical distribution to ecotoxicity data and several distributions have been used following existing guidelines. However, it has not been quite clear yet which statistical distribution should be chosen for SSD estimation, and how the choice of the distribution affects the hazardous concentration for 5% of the species (HC5). This study aimed to compare three different SSDs (estimated using log-normal, log-logistic, and Burr Type III distributions), based on an information criterion and HC5 values derived from the three SSDs. The ecotoxicity data for 192 chemicals were collected from a database and selected based on the criteria proposed in previous studies. The SSDs were estimated by fitting the three distributions, and a distribution model with the smallest value of the corrected Akaike's information criterion (AICc) was selected as the best model in terms of prediction. HC5 values estimated from sub-optimal models were compared with those estimated from the best models. As a result, out of 192 chemicals, log-normal, log-logistic, and Burr type III distributions were selected as the best models for 99, 61, and 32 chemicals, respectively, based on AICc. The log-normal distribution served as the best model in half of the cases (52%), and this finding provides some support to the fact that the log-normal distribution has been widely used for SSD estimation. The ratios of HC5 values estimated from log-normal distribution to those estimated from log-logistic distribution fell within the range −0.5 to 0.5 ($\log_{10}$-transformed values), suggesting the differences between the HC5 values estimated from these two distributions were relatively smaller. In contrast, for example, when the Burr type III distribution was selected as the best model, the ratios of HC5 values estimated from the best model to those estimated from the sub-optimal models fell outside the range −0.5 to 0.5 ($\log_{10}$-transformed values) in 18 SSDs. These results suggest that applying only a single distribution for SSD estimation can lead to an under- or overestimation of HC5. More details will be discussed in the presentation.

6.04.P-Th402 Organic Wastes Applied to Land—Australian Approaches to Assessing Risks and Establishing Acceptable Levels

Jackie Wright, *Environmental Risk Sciences, Australia*

Resource recovery is encouraged by regulators in Australia through zero waste and circular economy policies. Such policies have driven proposals for reuse of a wide range of different organic wastes including biosolids, food and garden organics (FOGO), and organic wastes recovered from general kerbside garbage (i.e. municipal solid waste, MSW).

Pre-existing Australian regulations require all businesses to minimise the risk of harm to the environment from site activities. Wastes recovered in alignment with zero waste and circular economy policies, however, contain a wide range of chemicals that present an unknown risk of harm in a waste recovery context. Careful assessment of material characteristics, processing methods,

and application to land (including rates, number of applications) is, therefore, needed as part of ensuring minimal environmental harm from chemicals in recovered waste.
Detailed risk assessments have been undertaken for a range of different waste types. Chemical criteria calculations undertaken as part of these risk assessments have used standard methods, where possible, but have also required literature reviews to determine otherwise unknown values for parameters including chemical characteristics and uptake factors into fruits, vegetables, crops and livestock. In addition, criteria to determine if materials are of acceptable quality for resource recovery have been back calculated to determine the concentration of a chemical in a waste material that will not pose an unacceptable risk (as defined in national guidance in Australia) when such waste material is applied to land.
The approaches used to constrain chemical criteria have been applied to a range of waste types and groups of chemicals. Regulators have made use of these detailed risk assessments to set policy and to make regulatory decisions for specific sites. The approaches used to constrain novel chemical criteria will be presented along with the challenges, including variability of chemical concentrations in the wastes and obtaining robust values for critical parameters.

6.04.P-Th403 A Proposal for Ecotoxicological Risk-based Reference Values for Plant Protection Product Residues in Agricultural Soils: Soil Guidance Values
Mireia Marti-Roura[1]*, Gilda Federica Dell'Ambrogio*[1]*, Sophie Campiche*[2]*, Alena Tierbach*[1]*, Janine Wong*[1]*, Jean Mathieu Renaud*[1]*, Benoit JD Ferrari*[3] *and Marion Junghans*[1]*, (1)Swiss Centre for Applied Ecotoxicology, Switzerland, (2)Envibiosoil, Switzerland, (3)Ecotox Centre, Switzerland*
The widespread use of Plant Protection Products (PPPs) in agriculture and their persistence in the ecosystem is continuously raising concern about their impact on ecosystem health, including the soil compartment. For PPPs authorization, a prospective risk assessment is performed to guarantee that their application does not lead to unacceptable adverse effects to the soil ecosystem. This assessment is based on single-substance assessment on a limited number of non-target species directly after the application. No retrospective risk assessment is currently performed for evaluating the potential impact of synthetic PPP residues and their mixture in the soil compartment on the long-term.
To fill this gap, we propose a concept where ecotoxicological risk-based reference values will be compared to an annual PPP residue monitoring in in-crop areas. Such values, called Soil Guidance Values (SGV), would serve as generic screening values to identify which sites need further assessment. This further assessment would imply a refinement of the SGV to a site-specific assessment (e.g. considering soil type, climate) and the application of a toolbox of bioindicators to assess the trend of the effects of PPP residues on key soil organisms and functions.
Based on a previous review on several soil regulatory frameworks, specific recommendations are suggested on how to derive SGV with the aim of protecting relevant agro-ecological soil functions in the long term. Some of the recommendations include: the reliability and relevance assessment of ecotoxicological chronic data for in-soil invertebrates, microorganisms and plants considering toxicity only through exposure to PPP residues in soil; the normalization of toxicity data to standard soil organic matter content; and, when possible, the use of ecosystem-relevant derivation methods (e.g. species sensitivity distribution (SSD), mesocosms, field studies) in order to decrease the uncertainty of the effects of the PPP residues in soil ecosystems. In order to show the implications of the recommendations proposed for the derivation of SGV, two PPPs were used as case studies (diuron and fluazinam) and compared to soil reference values derived according to different regulatory frameworks in Europe.
Finally, to address the combined toxicity of multiple PPP residues, it is envisioned to develop a concept for a mixture assessment in a further step.

6.05 Environmental Assessment of Nanomaterials, Research to Regulation: From hazard and risk to grouping and similarity approaches

6.05.T-01 Trimetal-Based Nanomaterials Induced Toxicity to Plants: Does It Differ From Mixed and Single Element Nanoparticles
Yuchao Song[1]*, Martina G. Vijver*[2] *and Willie Peijnenburg*[3]*, (1)Inistitute of Environmental Sciences, Leiden University, Netherlands, (2)Leiden University, Netherlands, (3)National Institute for Public Health and the Environment (RIVM), Netherlands*
Metal alloys nanomaterials are entering the market and as an example trimetal-based nanomaterials (TNMs) are nowadays used within products. It is essential to raise the question if the toxicity of advanced nanomaterials like TNMs differs from the joint effects as manifested by exposure to the single components. To this end, a trimetal-based nanomaterial: bismuth cobalt zinc oxide (BiCoZnO) was tested and it had a mass ratio of 90% ZnO NPs, 7% Bi_2O_3 NPs and 3% Co_3O_4 NPs. Nanoparticle-exposed lettuce seedlings (*Lactuca sativa L.*) showed decrease in relative root elongation (RRE) and biomass after 21 days. The EC_{50} values of TNM was 3.0 mg L^{-1} and of the same magnitude as the EC_{50} values found for ZnO NPs (EC_{50} = 2.2 mg L^{-1}) and mixture of components NMs (EC_{50} = 5.4 mg L^{-1}) to lettuce when the endpoint was RRE after 240 h of exposure. The toxicity of ZnO NPs was mostly due to ion release and the actual concentration of released zinc ions was lower for TNMs in comparison to the ion concentrations released by the ZnO NPs. The TNMs tested over time (480 h) gave more toxicity compared to ZnO NPs consisting of one single element. Our results confirmed that the crystal structure of the nanomaterials influenced the dissolution: dissolution was lower than in the single element applications and the toxicity of the metal alloy was also decreased. The metal alloy nanomaterials are having a high synthetic complexity compared to its mixture of single element component NMs, but key principles learned and understood from this study can be applied to aid the effect assessment of trimetal-based nanomaterials.

6.05.T-02 Determination of the Hydrophobicity Index of Nanomaterials: Method, Testing and Applications

Cloe Desmet[1], *Francesco Roncari*[1], *Andrea Valsesia*[1], *Marisa Sarria Pereira de Passos*[2], *Claudia Cella*[1], *Juan Riego Sintes*[1] *and Pascal Colpo*[1], *(1)European Commission Joint Research Centre, Italy, (2)EU Commission JRC, Italy*

Standardised quantitative methods for the determination of hydrophobicity cannot be applied to nanomaterials. A method to fill this gap was developed, which enables the determination of the *hydrophobicity index* (Hy) of NMs. In the context of its submission as an OECD Test Guideline it was tested through an interlaboratory comparison exercise, and its applications as an indicator for environmental behaviour were assessed.

The method is based on a measurement of the affinity of NMs to rationally engineered hydrophobic and hydrophilic surfaces (collectors), monitored by Dark-Field microscopy (DFM). Three types of collectors with different surface properties are produced. Particles are dispersed in an aqueous medium and injected through a fluidic cell. The binding of particles is recorded by DFM and a camera. The number of bound particles as a function of time determines their affinity to the collector. Hy is defined as the logarithm of the ratio between the NMs binding rate on the hydrophobic collector (directly related to the hydrophobicity of the NM), and the one on the hydrophilic collector with a surface charge opposite to the one of the NM (where the binding rate is maximum due to the electrostatic attractive interactions). It is a direct measurement of the tendency of the NM to be attracted to a hydrophobic surface as compared to water. Au, Ag, TiO_2, SiO_2, GaN, ZnO and CeO NMs with different types of surface treatment were characterised, as well as nano- and microplastics. The method was tested through an Inter-laboratory Comparison exercise by nine participants, for four materials. The large majority of the results are falling in the ± 1 STD difference from the average.

The correlation with environmentally relevant parameters was studied for a set of characterised NMs. A batch test experiment was adapted to measure the hetero-aggregation in reference soil. Bioassays were also performed with two freshwater green microalgae presenting different cell wall compositions. Binding, cell growth and oxidative stress were assessed after 24 hours of exposure with the different NMs. The results demonstrated an impact of Hy on the different markers. Further studies should be performed but Hy could provide information on the affinity of NMs to environmental matrices and organisms and help in the environmental hazard and exposure assessment as requested by REACH.

6.05.T-03 Findable, Accessible, Interoperable and Repeatable use of Historical Ecotoxicological Data for Nanomaterial Governance

Andrew Barrick[1], *Jean-Marie Marion*[1], *Isabelle Métais*[1], *Hanane Perrein-Ettajani*[1] *and Amelie Chatel*[2], *(1)Universite Catholique de L'Ouest, (2)Université Catholique de l'Ouest, France*

Development of novel manufactured nanomaterials is outpacing research capabilities to define environmental risk. Implementing predictive modelling using physicochemical properties is one of the proposed methods to streamline risk assessments for manufactured nanomaterials. The efficacy of this approach hinges on access to robust historical data, which is currently lacking for most ecotoxicological platforms. Centralization of data following FAIR principles can facilitate environmental risk assessment. The aim of NanoInformaTIX is to leverage existing data for ecotoxicity data used in the FP7 project NanoRETox and the Horizon2020 projects NanoREG and NanoREG2 to establish parametric models predicting adverse outcomes. Data were compiled to develop a FAIR database and investigate whether existing data can characterize how physicochemical properties influence bioaccumulation and ecotoxicity for manufactured nanomaterials. Results demonstrated an existing need for standardization in reporting for ecotoxicity data. This presentation highlights the integration of FAIR data practices that can be used to augment predictive modelling in ecotoxicology. This presentation highlights current capabilities of nanomaterial ecotoxicity to address 21st century issues and proposes suggestions for FAIRification of ecotoxicological data. This presentation also provides perspectives on database management to maximize scientific investment for contaminants of emerging concern.

6.05.T-04 Towards Harmonisation of Testing of Nanomaterials for EU Regulatory Requirements on Chemical Safety - A Proposal for Further Actions

Eric A. J. Bleeker[1], *Elmer Swart*[1], *Hedwig Braakhuis*[1], *Maria Luisa Fernandez-Cruz*[2], *Ilse Gosens*[1], *Frank Herzberg*[3], *Frank Von der Kammer*[4], *Keld Alstrup Jensen*[5], *Steffi Friedrichs*[6], *Jolinde Kettelarij*[1], *José M. Navas*[7], *Kirsten Rasmussen*[8], *Kathrin Schwirn*[9] *and Maaike Visser*[1], *(1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)INIA-CSIC - Spanish National Institute for Agricultural and Food Research and Technology, Spain, (3)Federal Institute for Risk Assessment (BfR), Germany, (4)Vienna University, Austria, (5)NRCWE, (6)AcumenIST, (7)Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA-CSIC), Spain, (8)European Commission Joint Research Centre, Italy, (9)German Environment Agency (UBA), Germany*

Over the recent years, EU chemicals legislation, guidance and test guidelines have been developed or adapted for nanomaterials to facilitate safe use of nanomaterials in society. However, so far the priority needs for development and adaptation of Test Guidelines (TGs) and Guidance Documents (GDs) are largely tailored toward the needs for the adaptation of the REACH legislation. This raises the question of whether other (EU) regulatory areas have specific needs for nanomaterials that have been overlooked in earlier assessments and that may require additional adaptations or developments of OECD TGs or GDs. In this presentation we provide an overview of the information requirements across different EU regulatory areas. For each information requirement, we identified the potential needs (from an EU perspective) for further action to develop or adapt guidance and test guidelines to nanomaterials. In total we identified 136 information requirements across different EU regulatory areas. A need for further action was identified for in total 62 information requirements. Details of these needs are provided in the presentation. Further, the analysis shows that there are multiple overarching issues that are relevant for multiple information requirements and across multiple regulatory areas. These include the needs to 1) resolve issues around nanomaterial dispersion stability and dosing in toxicity testing for especially human health endpoints, 2) further develop tests or guidance on degradation and transformation of organic nanomaterials or nanomaterials with organic components, and 3) further develop tests and guidance to measure (a)cellular reactivity of nanomaterials. We propose to prioritize work toward three topics. Efforts toward addressing these overarching issues will result in better fit-for-purpose test methods for (EU) regulatory compliance. Moreover, it secures validity of the hazard and risk assessments of nanomaterials. The results of this study underscore the need for increased (innovation) policy – science – regulatory interaction to optimally exploit the full potential of nanomaterials and their contribution to technological solutions to address societal challenges.

6.05.T-05 How to Categorize and Assess "Advanced Materials": The InnoMat.Life / HARMLESS approach

Wendel Wohlleben[1]*, Michael Persson*[2]*, Blanca Suarez-Merino*[3]*, Anders Baun*[4]*, Susan Dekkers*[5]*, Dirk Brossell*[6]*, Burkhard Stahlmecke*[7]*, Otmar Schmid*[8] *and Andrea Haase*[9]*, (1)BASF SE, Germany, (2)Chalmers University of Technology, Sweden, (3)TEMAS Solutions, Switzerland, (4)Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark, (5)TNO, Netherlands, (6)BAuA, Germany, (7)University Duisburg-Essen, Germany, (8)Helmholtz Center Munich, Germany, (9)Federal Institute for Risk Assessment (BfR), Germany*

In July 2022 the OECD WPMN released their description of Advanced Materials (AdMa). AdMa are made by rational design, using precise control of its composition and internal structure, and/or are transformed through advanced manufacturing techniques. Advanced Materials have exceptional properties (e.g., mechanical, electric, optic, magnetic) or specific functionalities that differentiate them from the rest of materials (e.g. self-repairing, shape change, transformation of energy). While numerous lessons can be learned from the nanosafety area, it is unclear if nanomaterials are an appropriate point of departure to develop approaches to AdMa risk screening. As another point of departure, the roadmap of the Advanced Materials Initiative (AMI2030) describes the many intended uses and very diverse types of AdMa that industry will commercialize in the coming decade. In the absence of a unifying technological AdMa feature (such as, for nanomaterials, a length scale), a categorization and screening is needed, which must also differentiate AdMa from conventional materials. Here we present such a categorization framework which helps to identify specific concerns for screening and assessment and supports criteria to guide SSbD development of AdMa. The scheme first categorises materials in three dimensions: 1. Does the material consist of particles? 2. Is the material nano-enabled? If consisting of particles, does the revised EU recommendation of a regulatory definition of nanomaterials (2022) identify it as nanomaterial? 3. Manufacturing processes or materials considered as "advanced" identified by several criteria? In this way, the three-dimensional categorisation can be easily displayed as table with four quadrants, and some black (conventional), some red (AdMa) entries. The scheme then asks if the AdMa changes (alleviates or aggravates) the typical SSbD challenges and benefits of a conventional materials that serves the same purpose, as guided by the material categories and industry sectors. To prevent regrettable substitutions, potential new concerns are first addressed by comparing the targeted composition against JRC's CLP-derived criteria for materials of (very high) concern.
The scheme was compared against other approaches in an OECD WPMN - HARMLESS workshop in November 2022.

6.05.P Environmental Assessment of Nanomaterials, Research to Regulation: From Hazard and Risk to Grouping and Similarity Approaches

6.05.P-We404 Prioritising Nano- and Microparticles - Identification of Physicochemical Properties Relevant for Toxicity to *Raphidocelis subcapitata*

Karsten Schlich*, Ruben Schlinkert and Kerstin Hund-Rinke, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany*

Advanced/innovative materials are an undefined group of nano- and micro-particles encompassing diverse material compositions, structures and combinations. Due to their unique properties that enable specific functions during applications, there are concerns about unexpected hazards to the environment. By applying algae growth inhibition tests according to OECD 201 with *Raphidocelis subcapitata*, and extensive material characterisation, we aimed to identify indicators of concern. This allows a better prediction of the hazardous properties of these materials in the future. 45 nano- and microparticles of various organic and inorganic species (single constituents and complex compositions; materials releasing toxic ions and others), morphologies (spheroidal, cubic, flaky, elongated/fibrous) and sizes (10 nm – 38 µm) were systematically investigated.
The chemical identity (toxic ion releasing materials vs. other materials) and agglomeration behaviour, which is affected by size (nm vs. µm) and morphology (fibres vs. others), were obvious drivers of ecotoxicity on algae. Differences in morphology had an impact on agglomeration behaviour. Fibres formed agglomerates of varying sizes with entrapped and attached algae. Small compact (e.g., spheroidal) particles attached to algae. A high coverage resulted in high ecotoxicity, while less toxic materials attached to a much lesser extent. No agglomeration of algae and particles was observed for particles with a µm size independent on their chemical identity (organic/inorganic). Small toxic components of large hybrid materials did not affect ecotoxicity. Considering the identified effects and the material characteristics, charts were developed to indicate the expected toxicity of advanced/innovative materials toward algae. Due to the different toxicity mechanisms, materials releasing toxic ions are separated from the other materials. For the former, a dependency on the producer/production process and applied substances not reflected solely by solubility measurements in test media must be considered. For the latter, morphology, size and agglomeration behaviour are considered. Examples for the various clusters are presented, and remaining open questions are defined. The approach can also support read-across and the justification of sets of nano/micro-forms. On the identified criteria three sets of nano-forms for TiO_2 materials are presented and justified by the EC_{50} values.

6.05.P-We405 Assessing the Fate and Behaviour of Particulate Emissions From Graphene-based Corrosion-resistant Coatings in Aquatic Environments

Andy Booth[1], *Trond Nordtug*[2], *Knut Thorshaug*[2], *Juan Yang*[2], *Christelle Denonville*[2], *Patricia Carvalho*[2], *Branson Belle*[2] *and Sergio Armada*[2], *(1)Climate and Environment, SINTEF, Norway, (2)SINTEF, Norway*
Novel anti-corrosive coating formulations containing GO and APTES-functionalised GO developed for the aerospace industry were subjected to environmental fate assessment comprising abrasion testing, particulate emission characterization and particulate behaviour studies in aqueous media. Coatings containing APTES/SolGel and GO corrosion inhibitors were applied to aluminium plates (Al 2024 T-3) and subjected to a tribological sliding test (reciprocating TE88-tribometer), which produced dust from all samples and varying damage to coating surfaces. The particulate material generated was characterised for particle size distribution (PSD), shape and morphology. Small (1-20 µm) and large (>100 µm) particles were present in all samples and each coating exhibited a different PSD. SEM images indicated there were no significant differences between any of the coating types. UV spectrophotometry calibration curves were established for GO in synthetic freshwater and seawater (33, 35 and 37 ppm), with and without dispersant (5%). Environmental fate assessment measured (i) sedimentation, (ii) agglomeration and particle size, and (iii) dispersion stability. All end points were measured at regular time intervals up to 330 mins. Studies with the abrasion dust were performed only in freshwater owing to low quantities being available. The GO dispersion was less stable and sedimented more in seawater compared to freshwater, suggesting GO sediments more rapidly in the marine environment and stays in dispersion for a longer in freshwaters. The mean particle size diameter decreased gradually over time, indicating large particles and aggregates gradually settled out. Increased salinity resulted in increasing sedimentation and decreasing dispersion concentration. The dispersant produced a more stable GO dispersion in all media types. In general, mean particle size diameter increased rapidly within a few minutes in freshwater and seawater, before decreasing over time as formed agglomerates sedimented. Zeta potential varied over time, possibly reflecting the continuous removal of larger aggregates through sedimentation. Values remained more stable for freshwater and the dispersant increased GO dispersion stability. Dust abrasion samples exhibited differences in PSD and behaviour over time. GO and APS-GO results in the generation of smaller dust particles which are more stable in aqueous dispersion, while absence of GO produced in larger particles that sedimented quickly.

6.05.P-We406 Embriotoxicity of a Novel Bio-based Nanomaterial with Anti-corrosion Properties on Tropical Marine Species

Mariana Bruni Marques do Prado e Silva[1], *Fernando Perina*[2], *Roberto Martins*[1] *and Denis Abessa*[3], *(1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)University of Aveiro, Portugal, (3)São Paulo State University, Brazil*
Metallic corrosion is the main cause of degradation of materials immersed in seawater. Currently, this problem is minimized by the addition of corrosion inhibitors (CI) in order to delay the corrosion process. However, such molecules are toxic to the biota, requiring their replacement by eco-friendly alternatives with good anti-corrosion efficacy, such as the biological based corrosion inhibitors (bio-CI), namely sodium gluconate (SG). In the framework of the NANOGREEN project (https://t.ly/XXi6), Zn-Al layered double hydroxides (LDH) have been used to immobilize SG, aiming to develop a new generation of anti-corrosion nanoadditives that can simultaneously reduce the typical early leaching of CIs and extend the corrosion protection of metallic immersed substrates over time. Since LDH-SG is a novel nanomaterial, the present study aims at assessing the toxicity of LDH-SG and its free counterparts (SG; Zn-Al LDH) on the embryonic development of two tropical marine species, the sand dollar *Mellita quinquiesperforata* and the mussel *Perna perna*. Organisms were exposed using the standard guideline NBR 15350 with adaptations for *M. quinquiesperforata* (36 h exposure), and NBR 16456 for *P. perna* (48 h exposure) to determine the embryonic development inhibition. For *M. quinquiesperforata* the tested exposure concentrations were 0.41, 1.23, 3.7, 11.1 and 33.3 mg/L, while the *P. perna* the concentrations tested were 1.23, 3.7, 11.1, 33.3 and 100 mg/L. For the three tested compounds, NOEC values ranged between 1.23 mg/L (*M. quinquiesperforata*) and <1.23 mg/L (*P. perna*), while the LOECs ranged between 3.7 mg/L (*M. quinquiesperforata*) and 1.23 mg/L (*P. perna*). For the sand dollar embryos, EC_{50} of SG, ZnAl-LDH, and LDH-SG were 37.12 (21.51 - 64.08), 5.766 (3.754 - 8.856) and 1.376 (1.078 - 1.755) mg/L, respectively. In the case of the mussels, EC_{50} were 3.739 (2.267 - 6.168) and 0.2645 (0.2198 - 0.3183) mg/L for SG and ZnAl-LDH, respectively; embryos exposed to LDH-SG did not develop in all concentrations tested. These findings contradict recent results obtained for temperate species, for which an opposite trend - soluble CIs are more toxic than the nanostructured forms - has been observed for several invertebrate species. Further studies are advised to confirm the current results and provide sound information to support the development of truly environmentally friendly CIs suitable for all major marine compartments.

6.05.P-We407 SustainablE Nano Strategies for Water Remediation – SENSE Project

Patricia V. Silva[1], *Roberto Martins*[2], *Ana Rita R. Silva*[2], *Carlos Pinheiro*[2], *Joaquim P. Ferreira*[3], *João Tedim*[4] *and Susana Loureiro*[2], *(1)Department of Materials and Ceramic Engineering & CICECO - Aveiro Institute of Materials, University of Aveiro, Portugal, (2)CESAM & Department of Biology, University of Aveiro, Portugal, (3)Ciceco & Cesam, University of Aveiro, Portugal, (4)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal*
Sea-level rise and eutrophication threaten freshwater bodies worldwide, posing severe economic, environmental, and human health risks. Coastal areas are in particular danger due to their location and higher urbanization. It is predicted that coastal regions will suffer from seawater intrusion, causing freshwater and terrestrial systems salinization. The excessive nutrient loadings from industrial and domestic effluents and leaching from agricultural fields may increase the risk for eutrophication in these areas, which can consequently cause the deterioration of water quality. Research has been focusing on remediating waters, however, no definitive process has been yet implemented, with some strategies causing deleterious effects to organisms. Therefore, efforts are being made to find environmentally safe alternatives such as nanotechnology-based tools like layered double hydroxides (LDHs). LDHs are anionic nanoclays with ion-exchange properties, composed of positively-charged layers with mixed metal hydroxides, and stabilized by anions and water molecules in the interlayers. The stabilizer anion can be exchanged by anions present in the

surrounding media, such as chlorides or phosphates, making these nanomaterials promising remediation solutions for waters at risk of salinization or eutrophication. The project SENSE aims to provide scientifically based evidence of the efficacy of LDHs to remediate waters potentially impacted by salinization and eutrophication. Waters of the Estarreja region (Aveiro district, northern Portugal) will be used as a case study due to its low-lying coastal lagoon location and historically contaminated waters from the intense industrial and agricultural activities. The experimental design consists of laboratory and *in situ* assays to test the ability of LDHs to remediate chlorides and phosphates from waters, and ecotoxicological bioassays to evaluate the potential toxicity of the remediated waters on freshwater species. Therefore, the outputs of SENSE may provide evidence of the efficient application of LDHs in real scenarios and support its environmentally safe application. These data will be fundamental to help the implementation of this potentially innovative, low-cost, and environmentally safe alternative for water remediation in the market and for improving nanoregulation and risk assessment of these emerging nanoforms.

6.05.P-We408 Are "Smart" Engineered Nanoclays Toxic to Zebrafish?

Diana Isabel Oliveira Carneiro[1,2]*, Daniel Alexandre Bruno*[3]*, Évila Pinheiro Damasceno*[1]*, André Borges*[4]*, Susana Loureiro*[1]*, Maria D Pavlaki*[5] *and Roberto Martins*[1]*, (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)University of Aveiro, Portugal, (4)University of Aveiro, Department of Biology, Portugal, (5)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal*

Layered Double Hydroxides (LDH) are known as "smart" (i.e., stimuli-responsive) anionic nanoclays or hydrotalcite-like systems and have received a lot of attention in several fields in the last decade due their structures and unique physical and chemical properties. LDH are composed by positively charged mixed-metal hydroxide layers intercalated with anions and water molecules. Also, LDH have versatile physicochemical advantages including excellent biocompatibility, pH-sensitive, high stability and layered structure. The extraordinary properties of LDHs have been exploited in multiple areas, such as nanomedicine (e.g., drug delivery), environmental remediation (e.g., absorbents), industry (e.g., anticorrosive and anti-fouling coatings), among others. Although these nanomaterials are low toxic to humans, mammals and marine organisms, studies focused on the possible effects on freshwater organisms are yet scarce. The zebrafish *Danio rerio* are at the forefront of eco-toxicology research, since it is a well-established freshwater model organism widely used to assess the effects of several chemicals (e.g., nanomaterials, pharmaceuticals). Thus, the present study aimed to assess the physiological, behavioral, and biochemical alterations in *Danio rerio* after exposure to Mg-Al LDH-nitrates. *Danio rerio* eggs were exposed to concentrations ranging from 13 to 100 mg/L of Mg-Al LDH according to the OECD 236 FET protocol, where mortality and malformations were documented daily during 96 h. Following the same principle, neurotoxicity and oxidative-stress related biomarkers, as well as DNA damage (comet assay) were assessed at the end of 96 h exposure. For the behavioral assay, embryos were exposed to Mg-Al LDH for 120 h and locomotory activity of larvae was tracked using the Zebrabox (Viewpoint, Lyon, France).

No mortality or malformations were observed at the concentrations tested for the 96 h of exposure. These results provide input for the near-future environmental risk assessment of this nanoclay, showing Mg-Al LDH as a class of promising eco-friendly nanomaterials.

6.05.P-We409 Aquatic Ecotoxicity Assessment to Support the Environmentally Safe Application of Layered Double Hydroxides (LDHs)

Patricia V. Silva[1]*, Ana Lopes*[2]*, Fabio Yu Chen*[2]*, Fábio Campos*[3]*, Évila Pinheiro Damasceno*[3]*, João Tedim*[4] *and Susana Loureiro*[3]*, (1)Department of Materials and Ceramic Engineering & CICECO - Aveiro Institute of Materials, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)CESAM & Department of Biology, University of Aveiro, Portugal, (4)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal*

Layered double hydroxides (LDHs) are nanoclays with lamellar structure, composed of positively-charged layers with di- and trivalent metal cations, and stabilized by anions and water molecules in the interlayers. These nanomaterials possess high anion exchangeability and memory effect, making them highly attractive for a wide range of applications, such as in remediation, medicine, and pharmaceutical. Despite being considered an eco-friendly nano-technique, the ecotoxicological assessment of LDHs is in its infancy; therefore, their potential effects on non-target organisms need to be tested. Furthermore, emphasis should be given to studying their potential ecotoxicity towards aquatic species due to their applications in water remediation and antifouling paints. Additionally, the lack of ecotoxicity studies of LDHs needs to be overcome to facilitate their implementation in the market and aid their nanoregulation. Considering this, this study aimed to assess the ecotoxicity of ZnAl-NO_3 and MgAl-NO_3 LDHs (slurry form) in several test model freshwater species: the microalgae *Raphidocelis subcapitata* (algal growth inhibition test; OECD, Test No 201), the macrophyte *Lemna minor* (growth inhibition test; OECD, Test No 221), the water flea *Daphnia magna* (acute immobilization test; OECD, Test No 202) and the zebrafish *Danio rerio* (fish embryo toxicity test; OECD, Test No 236). Overall, results showed that LDHs caused very low toxicity to the test species. These results were compared with our previous data on the ecotoxicity of the calcined and non-calcined forms of the same ZnAl-NO_3 and MgAl-NO_3 LDHs (data presented in SETAC Copenhagen). The toxicity differed between the slurry, calcined and non-calcined forms of each LDH, suggesting that the final form in which the LDHs are produced can significantly influence their ecotoxicity. This is essential information to provide to the manufacturer of these nanomaterials and supports the need for collaboration between academia and industry. Furthermore, this study provides data that may help support the environmentally safe application of these LDHs and might be used for risk assessment and nanoregulation purposes of these nanomaterials.

6.05.P-We410 Comparing Pre-guideline Literature Data on Dispersion Stability for CeO2 Nanoparticles to Current Guideline Requirements – Can We Use Literature Data for Concluding on the Endpoint and Grouping?

Nele Deleebeeck*, Francesco Fratepietro, Laura Lefèvre and Michiel Claessens, Arcadis Belgium, Belgium*
Dispersion stability is an important parameter determining the environmental fate of nanoparticles. This parameter depends on physicochemical characteristics of the nanoparticles and the suspension medium, as well as on the concentration of nanoparticles and other substances or particles in the medium. It is considered a required endpoint for nanoparticles under REACH, with OECD releasing in 2017 the OECD guideline 318 for standardised testing of dispersion stability of nanomaterials in simulated environmental media and publishing further guidance in OECD Series on Testing and Assessment No. 318 in 2020 (updated in 2021). Obviously, a lot of non-guideline data were generated and published in literature before these OECD documents were published. This is also the case for CeO2, where during a literature survey, various studies reporting on dispersion stability of CeO2 nanoparticles were identified and evaluated. These studies provide evidence for rapid removal of uncoated CeO2 nanoparticles from natural waters through homo- or hetero-aggregation and consequent sedimentation. They further provide insight into the effect of various conditions on dispersion stability of CeO2 nanoparticles, such as ionic strength and the presence of natural organic matter, suspended solids, or natural colloids. Although none of these studies were guideline studies, a conclusion was drawn on this mandatory REACH endpoint by setting up a weight of evidence approach including the most relevant studies. In this poster, we are discussing 1) how the (pre-guideline) literature data compare to the current requirements set out in the OECD guidance documents, 2) to what extent conclusions on the endpoint can be drawn in the absence of guideline data, 3) what benefits guideline data would have for the assessment of CeO2 nanoparticles, and 4) what the implications are for grouping, taking into account the role of dispersion stability in the potential effects in the environment resulting from direct interaction of the nanoparticles with various types of organisms.

6.05.P-We411 A Method for the Production of WWTP-Transformed Silver Nanoparticles for Use in Accumulation and Toxicity Studies

Andy Booth[1]*, Julia Farkas*[2]*, Ralf Kaegi*[3]*, Brian Sinnet*[3]*, Marianne Unaas Rønsberg*[2]*, Anastasia Georgantzopoulou*[4]*, Marianne Molid*[2] *and Sebastian Kuehr*[4]*, (1)Climate and Environment, SINTEF, Norway, (2)SINTEF, Norway, (3)Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (4)Norwegian Institute for Water Research (NIVA), Norway*
Most studies investigating the accumulation and toxicity of engineered nanomaterials (ENMs) utilise pristine test materials. However, in the natural environment, ENMs rapidly undergo a range of transformation processes depending on their intrinsic physicochemical properties and the specific conditions they are exposed to in different environmental matrices. A primary transport route for ENMs from consumer products to the environment are wastewater treatment plants (WWTPs), which represent harsh conditions that can drive transformation of ENM properties. Silver nanoparticles (AgNPs) are known to rapidly sulphidise in WWTPs, changing their properties significantly and therefore more relevant for use in accumulation and toxicity studies. However, producing such materials and isolating them for use in exposure studies is a challenge. In the current study we outline a method for producing bulk quantities of fully sulphidised WWTP-transformed AgNPs for use in such studies. Effluent (10 L) was collected from Høvringen WWTP (Trondheim) and passed through a 0.45 µm filter. The sulphide (HS^-) content of the filtered effluent was then determined iodometrically. A stock solution of HS^- was prepared using sodium hydrosulphide hydrate (NaHS) and the concentration also verified iodometrically. In the next step, 10 mg of AgNPs were added to 10 L of filtered WWTP effluent and the sulphidisation process allowed to proceed. The remaining free HS^- concentration was determined iodometrically every 2 hours over a 6 hour period until a stable concentration was recorded or until all the HS^- had been reacted. Where all the available HS^- has been reacted, full AgNP sulphidisation is assumed to be incomplete. In this case, the HS^- stock solution is added to the AgNP-effluent solution at a concentration calculated to be sufficient to sulphidise all the AgNPs present. Further sulphidisation of the AgNPs is allowed to proceed (up to 6 hours) and then the HS^- concentration determined iodometrically to ensure that a stable excess of HS^- is present. At this point, the fully sulphidised AgNP-effluent solution is ready for utilisation in accumulation and toxicity tests using aquatic organisms. The approach is scalable to large volumes of effluent water allowing assessment of WWTP-transformed AgNPs in flow through systems for accumulation and toxicity testing.

6.05.P-We412 Environmental Behavior and Hazard of a Novel "Smart" Engineered Nanomaterial

Roberto Martins[1]*, Joana Figueiredo*[2]*, Fernando Perina*[1]*, Diana Isabel Oliveira Carneiro*[1]*, Tânia Oliveira*[3]*, Frederico Maia*[3]*, João Tedim*[4] *and Susana Loureiro*[1]*, (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)Smallmatek, Small Materials and Technologies, Portugal, (4)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal*
Layered double hydroxides (LDH), also known as anionic plate-like nanoclays, are a class of stimuli-responsive (or "smart") inorganic engineered nanomaterials. They have been used in several industrial and material engineering applications due to their physico-chemical properties, such as high surface area and capacity to control the exchange of a wide range of anions, depending on the presence of specific triggers (e.g. pH changes). The effects of LDHs, and, in particular, Mg-Al LDH stabilized with nitrates (Mg-Al LDH-NO_3), have been scarcely or even not yet studied in marine organisms. Therefore, this study aims at assessing the behavior in seawater, the exposure effects, and the marine hazard of Mg-Al LDH-NO_3.
The behavior of Mg-Al LDH-NO_3 was assessed in terms of electrochemical stability (through zeta potential), hydrodynamic size (dynamic light scattering), anions release (nitrates spectrophotometric quantification), and dissolution (Mg and Al determination, ICP-OES). Ecotoxicological tests were carried out using 14 marine species from different trophic levels: bacterium (*Aliivibrio fischeri, Idiomarina seosinensis, Halobacillus locisalis*), microalgae (*Chaetoceros calcitrans*, *Isochrysis galbana, Phaeodactylum tricornutum Tetraselmis chuii*), rotifers (*Brachionus plicatilis*), bivalves (*Scrobicularia plana, Mytilus galloprovincialis*), crustaceans (*Artemia salina*) and echinoderms (*Paracentrotus lividus*). Exposure concentrations ranged from 0.41 to 100 mg/L (dilution factor of 3), depending on the species, plus a negative control of artificial saltwater. The lowest no observed effect

concentration (NOEC) was then used to derive the predicted no effect concentration (PNEC) dividing the NOEC by an appropriate assessment factor (100).
Aqueous dispersions of Mg-Al LDH-NO_3 are unstable. In artificial saltwater, larger aggregates tend to sink in the first 24 h, particularly in the highest tested concentration (100 mg/L). The release of nitrates is fast in the first hours of exposure until reaching a plateau. Dissolution of Mg-Al LDH is minimal over the exposure period. This nanomaterial was not toxic to all tested species (lowest NOEC=0.41 mg/L for *P. lividus*). The PNEC for Mg-Al LDH-NO_3 was set at 4.1 µg LDH/L. The study suggests that Mg-Al LDH is a safe and sustainable by design nanomaterial. These insights will be critical for academic and regulatory purposes and will contribute for the implementation of the EU Chemicals Strategy for Sustainability.

6.05.P-We413 "Smart" Anti-Corrosion Nanomaterials: What We Know About Them?
Tânia Oliveira[1], Diana Isabel Oliveira Carneiro[2], Joana Figueiredo[3], Fernando Perina[2], Olga Kaczerewska[4], Muhammad Muqeet Iqbal[4], Frederico Maia[1], Susana Loureiro[2], João Tedim[4] and ***Roberto Martins****[2], (1)Smallmatek, Small Materials and Technologies, Portugal, (2)CESAM & Department of Biology, University of Aveiro, Portugal, (3)Department of Biology, University of Aveiro, Portugal, (4)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal*
Layered double hydroxides (LDH) are regarded as "smart" or stimuli-responsive engineered nanomaterials due to their anionic exchange capacity. The anion nitrite has an outstanding anti-corrosion performance in steel substrates and its immobilization in Mg-Al or Zn-Al LDHs can be use to mitigate the early leaching of conventional corrosion inhibitors. Despite their industrial relevance, the fate, behavior and hazard of Mg-Al LDH-NO_2 or Zn-Al LDH-NO_2 in the marine compartment are not yet known. Therefore, this study aims at presenting the physical and electrochemical characterization and the behavior and hazard of Zn-Al LDH- NO_2 and Mg-Al LDH-NO_2 in the marine compartment.
Physical and electrochemical characterization included scanning electron microscopy, X-ray diffraction and impedance measurements. Environmental behavior in artificial saltwater (ASW) included colloidal stability (zeta potential), hydrodynamic size (dynamic light scattering), nitrites release (spectrophotometric quantification), and dissolution (Zn, Mg and Al determination, ICP-OES). Ecotoxicological tests were carried out using bacterium (*Aliivibrio fischeri, Idiomarina seosinensis, Halobacillus locisalis*), microalgae (*Chaetoceros calcitrans*, *Isochrysis galbana, Phaeodactylum tricornutum Tetraselmis chuii*), rotifers (*Brachionus plicatilis*), molluscs (*Mytilus galloprovincialis*, *Phorcus lineatus, Scrobicularia plana, Steromphala umbilicalis*), crustaceans (*Artemia salina*) and echinoderms (*Paracentrotus lividus*). Exposure concentrations ranged from 0.41 to 100 mg/L (dilution factor of 3), depending on the species, plus a negative control of ASW.
The immobilization of nitrites into LDH was confirmed through XRD and chemical analyses. Aqueous dispersions of both LDH are unstable. In artificial saltwater, larger aggregates tend to sink in less than 24 h. Tested LDHs are not toxic under the range of tested concentrations (E/I/LC_{50} > 100 mg/L) for most species, except for *P. lividus, I. galbana,* and *P. lineatus* (E/I/LC_{50} = 5.4, 45.2, 93.0 mg/L, respectively), in the case of Zn-Al LDH-NO_2, and *I. galbana*, in the case of Mg-Al LDH-NO_2 (IC_{50} = 38.4 mg/L). The sea-urchin *P. lividus*set the lowest NOEC (<0.41 mg/L) for both LDHs, a value that does not allow the successful derivation of the hazard endpoint. Despite this, the Mg-Al form seems safer, and such findings contribute to increasing the foreground knowledge towards a new generation of efficient and truly eco-friendly anti-corrosion additives.

6.05.P-We414 Direct Quantification of Hydrophobicity: A Case Study of Environmentally Relevant Silver Nanoparticles
Francesco Roncari[1], Salimar Cordero[2], ***Cloe Desmet****[1], Andrea Valsesia[1], Pascal Colpo[1] and Boris Lau[2], (1)European Commission Joint Research Centre, Italy, (2)Department of Civil and Environmental Engineering, University of Massachusetts Amherst*
Among the physical and chemical properties of nanomaterials, hydrophobicity is recognized to play a key role in their environmental impact. This parameter is involved in abiotic and biotic processes and could be used in the prediction of nanoparticles' (NPs') behaviour in the environment, in terms of aggregation, toxicity and bioaccumulation. Through a dark field microscopy (DFM)-based method, this paper characterized the change in hydrophobicity of silver (AgNPs) induced by sulfidation and by the formation of a corona of natural organic matter (NOM). DFM results, measured as a Hydrophobicity index (Hy), were compared with the dye adsorption method results (log HR).
The sulfidation of the AgNPs and/or the adsorbed NOM/ "Lipid-free" (LF-NOM) increased their own hydrophobicity, increasing the Hy values. The tendency of sulfidized AgNPs to become more hydrophobic is demonstrated by both methods. Log HR results were not able to differentiate the hydrophobicity of AgNPs with varying natural organic matter (NOM) coronas. This study shows that the DFM-based method, can effectively measure the hydrophobicity of environmentally relevant NPs and it has a potential to be used as fate predictor.

6.05.P-We415 Using a Meta-analysis Approach to Assess Silver Nanomaterial Hazard to Terrestrial Soil Ecosystems for Safety-by-design Practices
Sarah Roberts*, Richard Cross, Elma Lahive, David J Spurgeon and Elise Morel, UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*
Extensive research has been conducted on the ecotoxicological risks of silver nanomaterials (AgNMs) on freshwater organisms and hazard thresholds are established based on species sensitivity distributions (SSD). Similar hazard thresholds for released AgNMs for terrestrial soil organisms have not been so well established. To address this knowledge gap, this study collected existing dose-response data of different Ag forms from the literature, including a benchmark (AgNM-300K), ionic ($AgNO_3$) and environmentally relevant (Ag_2S) forms of Ag. For AgNM-300K, 546 soil toxicity values were gathered in a database from 29 articles published between 2013-2021, across soil-dwelling organisms. Data availability by taxa followed the order microbes >

enchytraeids > springtails > earthworms > nematodes > plants. Alongside toxicological endpoint data, the database captured exposure characterisation and AgNM fate measurements within the exposure medium. This allowed variation in toxicological endpoint data across species endpoints for the different Ag forms to be assessed, including the influence of environmental parameters on driving Ag toxicity. To obtain estimates of hazardous concentrations affecting 5% of species (HC_5), SSDs based on predicted no effect concentrations (PNECs) were constructed. Results show that AgNM-300K produced higher HC_5 values when aged (HC_5 = 0.05 mg/kg) compared to 'as manufactured' state (HC_5 = 0.03 mg/kg) and to $AgNO_3$ (HC_5 = 0.04 mg/kg) in soils. In relation to existing soil toxicity thresholds for persistent, bioaccumulative and toxic substances, AgNM-300K HC_5 concentrations fall within the 'very toxic' category (PNEC < 0.1 mg/kg). In a safe-by-design context, the difference between primary particle characteristics and their hazard need to be elucidated, and this approach demonstrated that although differences may be detected, the chemical composition drives hazard more compared with particle properties for soils. Further to establishing the most up to date HC_5 values for Ag in soils, we were able to use the database to explore apparent reproducibility of commonly used assays tested in the same species and under similar conditions and identify species most sensitive to this nanomaterial. This knowledge can support recommendations for sensitive and reproducible assays suited for inclusion in soil hazard assessment, with regulatory relevance and for guiding a safety-by-design approach for manufactured NMs for the protection of soil ecosystems.

6.06.P Evidence Led Approaches to Identifying Chemical Priorities and Groupings for Effective Risk Management

6.06.P-We416 A Method for Ranking and Prioritising Chemicals Without The Need For Significant Resources

Kate Bromfield[1], *Stephanie Jervis*[2], *Alex Cliff* [1], *Steve Corrin*[1] *and Anna Ramarosandratana*[3], *(1)Hazard Evaluation, New Zealand, (2)Hazel Evaluation, New Zealand, (3)NSW Environmental Protection Authority, Australia*

We present a methodology designed to rank hazardous chemicals without requiring the user to expend significant computational or human resources.

The ability to compare chemical toxicity is increasingly problematic for the non-expert. Current existing methods require manual collection of data and expert knowledge to interpret. Inconsistent methodologies, gaps in available data, and outdated information seriously hamper attempts to compare like with like. In addition, the volume of chemical information released on a daily basis surpasses the ability of resources to process it.

Data, incorporating select environmental toxicity parameters and human health impacts, are drawn from internationally recognised chemical databases such as the United States Environmental Protection Agency (USEPA) and the European Chemical Agency (ECHA). Algorithms enable users to quickly and simply refine groupings of chemicals to a high priority subset, based on customisable filters. The curated and qualified chemical information enables substance comparisons via transparent and uniform hazard criteria and provides unique visuals to facilitate communication of results to stakeholders.

This method does not replace or supersede existing systems used to make regulatory or other decisions. Rather it enables users to rapidly identify and refine areas for further research, thus maximising resource allocation.

6.06.P-We417 Identification, Grouping, and Prioritisation of Water-Soluble Polymers in Household Products

Hattie Cerridwen Catherine Brunning[1], *J Brett Sallach*[2] *and Alistair B.A. Boxall*[1], *(1)University of York, United Kingdom, (2)Department of Environment & Geography, University of York, United Kingdom*

Polymers are long-chain molecules which typically exist as a distribution of homologues across a range of molecular weights. Due to their large size, polymers have previously been exempt from regulatory initiatives such as REACH. However, given their widespread usage and environmental emissions, there is a need to incorporate polymers into environmental risk assessment schemes. The huge number and variety of water-soluble polymers (WSPs) in current use presents a significant challenge for risk assessment, especially given the lack of transferability of many existing assessment methods. In addition, data on formulation, usage volumes, and even substance identity and composition, remain unavailable for many polymers. It is thus essential to develop approaches for identifying, grouping, and prioritising WSPs in current use. Here we present a prioritisation approach for identifying WSPs in current use that have the greatest exposure and pose the greatest risks to the environment.

An inventory of polymers found in household products was built using publicly available ingredients data. Polymers were grouped by chemical structure and function in products, and formulation concentrations were estimated from patents. Estimates of market penetration were based on frequency of occurrence in the studied products. These data were combined with literature usage data to obtain worst-case predicted environmental concentrations (PEC). PECs for the top ten polymer groups were further refined based on wastewater treatment fate from literature data, and resulting PEC estimates were combined with predicted no-effect concentrations to obtain risk quotients (RQs) for prioritisation.

A total of 339 individual polymers were identified across 1,353 products and subsequently divided into 26 groups. Based on limited ecotoxicity data, estimates of aquatic RQs indicate that polyethers and copolymers, polyquaterniums, and polyol ethoxylate esters (e.g. polysorbates) may be of highest potential concern. This study provides key knowledge of the types of WSPs which may be present in the environment, a method for identifying these and other ingredients and estimating usage volumes from publicly available data without prior knowledge of chemical identity, and a basis for grouping of WSPs for risk assessment, as well as initial estimates of environmental exposure and risk.

6.06.P-We418 A National Scale Prioritisation and Early Warning System for Chemicals of Emerging Concern

David Brown[1], *Helen Wilkinson*[1], *Nathalie Tonge*[1], *Mark Sinton*[1], *Jonathan RAY Newman*[1], *Ian Martin*[1] *and Kerry Sims*[2], *(1)Environment Agency (England), United Kingdom, (2)Chief Scientists Group, Environment Agency (England), United Kingdom*

The UK Government's 25-year Environment Plan highlights the need for early identification of chemicals of concern, so that effective intervention can be undertaken prior to damage being caused to the environment, wildlife or human health. To address

this chemical challenge the Environment Agency (EA) have developed a Prioritisation and Early Warning System (PEWS) for England. Our aim has been to establish a system which ensures the appropriate regulatory focus on individual and groups of substances of emerging concern. This is based on a suitable level of risk assessment, considering each substance in terms of readily available use, fate and ecotoxicological/toxicological parameters and monitoring data.
The PEWS process includes nomination and sifting of substances, screening of substances for potential risks to human health via the environment, and to surface waters (both freshwater and marine), groundwater, soils, biota and sediments. Chemicals are then prioritised for environmental regulation if there is considered a sufficient level of risk. For some substances, the process demonstrates a need for further human biomonitoring and environmental monitoring to help understand current concentrations and increase certainty in prioritisation.
In this presentation we describe the progress of the development and use of a National scale early warning system. We illustrate how use of the system furthers our understanding of substances which have been screened for potential risks to date, and the link from PEWS to potential regulatory intervention, where this process has shown that to be appropriate for a chemical. We demonstrate a case study of veterinary medicines in the environment, showing the connection from assessing the science to identifying regulatory gaps. We highlight the outstanding technical challenges and some of the approaches that we are undertaking over the year ahead to overcome these.

6.06.P-We419 Harmonizing Non-Target-Screening Results for Aggregated Analysis
Kevin S. Jewell[1], Franziska Thon[1], Susanne Becher[1], Björn Ehlig[2], Jonas Skottnik[1], Thomas Scharrenbach[1], ***Jan Koschorreck[3]****,* *Arne Wick[4] and Thomas A Ternes[5], (1)German Federal Institute of Hydrology, Germany, (2)German Federal Institute of Hydrology, Germany, (3)German Environment Agency (UBA), Germany, (4)G2-Aquatic Chemistry, German Federal Institute of Hydrology, Germany, (5)G Qualitative Hydrology, German Federal Institute of Hydrology, Germany*
Non-Target-Screening (NTS) by high-resolution mass spectrometry in surface water is widely used for the monitoring of organic pollutants. At the moment, datasets often remain locally isolated and pooling data to help the identification of unknown detections is slow and not scalable. The current project sets out to develop a system of harmonizing and linking *pre-processed* NTS data from different methods and software through the use of 1) a standardized format for the *processed* results, 2) harmonization scripts to convert existing data to this format and 3) an algorithm to compare all data and link detections of the same compound, so-called alignment. To make use of this harmonized data, a frontend web-application (*NTSPortal*) was developed to allow searching of the data and displaying maps (spatial distributions) and time-series of the aggregated results. A common web-standard data serialization format (JSON) was chosen for the standard format for the processed NTS data. This format is the standard format for many database systems and search libraries, allowing existing software to be used. For this project, ElasticSearch was used to make the data searchable. A harmonization script to transform processed data into JSON was written in R. The alignment process was performed on the data after it was loaded into ElasticSearch. An R package was written to recall individual features (detections) from the database, make comparisons by clustering using m/z, retention time and MS^2 spectral similarity, and write back to link features by using common IDs. To validate the whole procedure, several metrics were defined to help assess the quality of the alignment. The two most important ones being: a) Fraction of “orphan” features and b) Fraction of “falsely grouped” features. The database currently contains 1.3 million features from 1087 measurements, 12 sampling stations across Germany and 2 matrices (water and suspended particulate matter). These were clustered into 17,854 grouped features. 70% of features had an associated MS^2 spectrum. Of these, 26% were “orphans” and 7% were “falsely grouped”. Using the interactive web front-end, a user can search for a feature by attributes such as m/z and MS^2 fragments and see the occurrence patterns of matching features regionally and at a selected sampling stations over time. These first experiments show the feasibility of aggregating processed NTS data from across different regions and matrices.

6.06.P-We420 A Combined Passive Sampling and Non-Targeted Analysis Approach to Prioritise Organic Pollutants in Coastal Environments
Rosie J Lennon[1]*, John Wilkinson[2] and Alistair B.A. Boxall[1], (1)University of York, United Kingdom, (2)Environment and Geography, University of York, United Kingdom*
Coastal environments will be exposed to hundreds of chemicals arising from multiple sources, but only a proportion of these are likely to cause ecological harm. Therefore, there is a need for an approach specific to marine ecosystems, so that future work can be targeted at those substances that pose a potential hazard and risk. Here, we present a prioritisation framework combining passive sampling using Chemcatchers®, non-targeted LC-QToF MS analysis and QSAR modelling to prioritise organic chemicals in the Firth of Forth (Scotland) in terms of their potential risk to the European shag (*Gulosus aristotelis*). Chemcatcher data were collected from two sites in proximity to European shag colonies during 2021. Seven datasets relevant to the exposure pathway were chosen to inform three parameters: persistence (P) (qualitative DT_{50} data for sediment and water); bioaccumulation (B) (bioconcentration factor for higher trophic levels); and acute toxicity (T) (quantitative fish LC_{50} values and an extended Cramer classification for acute human toxicity). Using these data, each chemical was attributed to one of seven prioritisation categories (vB-vP-T; P-vB-vT; vP-B-vT; vP-vB; vB-vT; vP-vT; P-B-T) based on EPA and REACH guidelines. For comparison, the same method was repeated for 111 POPs that are to be monitored in the same study system. In total 404 chemicals were detected, with data obtained for 395. Of these, 17/395 chemicals fell into either vB-vP-T, P-vB-vT or vP-B-vT categories, with 13 specifically vB-vP-T. A further 113/395 chemcatcher chemicals were categorised as either vP-vT or vT-vB, whereas no chemicals were assigned to either the vP-vB or P-B-T category. Comparatively, 50/111 POPs were assigned to the vB-vP-T category and 37/111 to either vP-vT or vT-vB. The majority of vB-vP-T chemcatcher chemicals contained either a long hydrocarbon chain or at least one benzene ring, whilst the structure of non-prioritised chemicals was varied. This framework identified 17 chemicals that had similar P-B-T properties to well-known classes of POPs, such as PCBs and PBDEs. In particular, 13 chemicals were classed as

vB-vP-T and will be taken forward into a spatial bioaccumulation model to assess their potential impact on European shags resident at both sampling sites. With many QSAR models available, this approach is malleable to a range of mixed-chemical exposure pathways to prioritise and identify potential contaminants of emerging concern in coastal environments.

6.06.P-We421 Ad hoc Assessment of Non-target Screening Data in the Aquatic Environment: Prospects and Challenges for Science and Regulation

Alexander Badry[1]*, Anna Lena Kronsbein*[1]*, Kevin S. Jewell*[2]*, Nicole Bandow*[1] *and Jan Koschorreck*[1]*, (1)German Environment Agency, Germany, (2)German Federal Institute of Hydrology, Germany*

Analytical advances using high-resolution mass spectrometers such as suspect- and non-target screening (NTS) provide valuable information on contaminants of emerging concern (CECs) in the aquatic environment. NTS data are challenging for authorities as regulatory guidance is still missing for the use of semi-quantitative data. Monitoring programmes, in turn, frequently lack regulatory information on CECs such as regulatory status, sale/production volumes or hazard information. The myriad of chemicals on the European market currently outpaces the capacity of chemical regulators to assess hazards and risks for many CECs. A recognised problem is that testing requirements for the placing of chemicals on the market in Europe are not harmonised between chemical legislation. Up to now, there is no centralised database available that provides regulatory information on chemicals irrespective of their legislation. In Germany, the German Environment Agency (UBA) represents the competent authority for environmental risk assessment in chemical legislations. In the project *water monitoring of the future*, we aim to combine NTS data from the aquatic environment with regulatory information from UBA in an Elasticsearch-based database called NTS Portal. The ultimate goal is to provide an ad-hoc risk assessment of CECs independent of their respective uses by linking monitoring data (e.g. detection rates), use information (e.g. tonnages) and hazard-based parameters from OECD/ISO guidelines (e.g. PBT/PMT, fate, effects). In addition to the assessment of individual substances we also aim to characterise priority mixtures, point sources and trends in water and suspended particulate matter samples. Here we provide examples for an ad hoc assessment of substances that were identified and prioritised using established NTS workflows and compare our approach to established prioritisation approaches, e.g. from NORMAN. Linking regulatory information with monitoring data in a centralised database is crucial for dealing with the myriad of registered/authorised substances on the European market and will ultimately strengthen the connection between regulation and science.

6.06.P-We422 Substantiating Chemical Groups for Read-Across Using Molecular Response Profiles

Rosemary Elizabeth Barnett[1]*, Bruno Campos*[2]*, Claudia Rivetti*[2]*, Thomas N Lawson*[1]*, Carlos Barata*[3]*, Adam Biales*[4]*, John Colbourne Prof*[1]*, Mark Cronin*[5]*, Silvia Lacorte*[3]*, Gavin R Lloyd*[6]*, Matthew Smith*[7]*, Andrew D Southam*[7]*, Mark R. Viant*[1]*, Ralf J.M. Weber*[6] *and Geoffrey Hodges*[2]*, (1)Michabo Health Science, United Kingdom, (2)Unilever - Safety and Environmental Assurance Centre (SEAC), United Kingdom, (3)Spanish Research Council (CSIC), Institute of Environmental Assessment and Water Research (IDAEA), Spain, (4)U.S. Environmental Protection Agency, (5)Liverpool John Moores University, United Kingdom, (6)University of Birmingham, United Kingdom, (7)Phenome Centre Birmingham, United Kingdom*

The chemical grouping and read-across paradigm is a key approach to support the evaluation of environmental and human health hazards posed by chemicals, whilst reducing or even avoiding animal testing. It provides a process by which toxicity endpoint data can be read across from a data-rich to a data-poor substance(s) and is underpinned by the concept that structurally similar substances generally elicit similar toxicological effects. However, structural similarity alone is typically not sufficient, and additional supporting data such as a shared mode of action can strengthen a grouping hypothesis and hence justify a read-across. The overall aim of this study is to demonstrate how multi-omics measurements can be used to increase confidence in a grouping hypothesis by using bioactivity signatures that are reflective of a chemical's mode of action.

We investigated six substances with two known modes of action, including three phthalates; benzyl butyl phthalate (BBP), dibutyl phthalate (DBP) and diisobutyl phthalate (DiBP) and three uncouplers of oxidative phosphorylation; 2,3,4,5-tetrachlorophenol (TCP), carbonyl cyanide 3-chlorophenylhydrazone (CCCP) and carbonyl cyanide 4-(trifluoromethoxy)phenylhydrazone (FCCP). Conventional structure-based grouping approaches were first applied to formulate a grouping hypothesis. Next, short-term exposures were conducted in *Daphnia magna* at EC_{10} (48 h immobilisation) concentrations to produce multi-omics data (LC–MS metabolomics and TempO-Seq transcriptomics). A bioactivity-based grouping—measuring the similarity between the 'omics responses—was then derived from these data using hierarchical cluster analysis.

Conventional structure-based grouping approaches struggled to assign the uncouplers and phthalates into two anticipated groups with the structurally diverse uncouplers often assigned into 2–3 different classes. Despite varying magnitude in the number of perturbed features between treatments, bioactivity-based grouping using multi-omics data placed the substances in two distinct groups, one containing the uncouplers of oxidative phosphorylation and the other the three phthalates.

This study demonstrates that molecular (multi-omics) data can successfully be applied to calculate substance similarities, thereby increasing confidence in category formation with biologically-based knowledge. This finding is relevant to chemical risk assessment to increase the efficient use of available data.

6.06.P-We423 Demonstrating the Reliability of Metabolomics-based Chemical Grouping: Towards Acceptable Practice

Mark R. Viant[1]*, E Amstalden*[2]*, T Athersuch*[3]*, M Bouhifd*[4]*, T Ebbels*[3]*, V Haake*[5]*, A Kende*[6]*, F Lai*[6]*, Pim Leonards*[2]*, Pei Pei Lim*[6]*, Gavin R Lloyd*[1]*, Tomasz Sobanski*[4]*, C Sands*[3]*, L Swindale*[6]*, Ralf J.M. Weber*[1]*, T Walk*[5]*, F.-M. Zickgraf*[7] *and H Kamp*[5]*, (1)University of Birmingham, United Kingdom, (2)Vrije University Amsterdam, Netherlands, (3)Imperial College London, United Kingdom, (4)European Chemicals Agency, Finland, (5)BASF Metabolome Solutions, Germany, (6)Syngenta, United Kingdom, (7)BASF SE, Germany*

Metabolomics has reached a critical point in determining its value to regulatory toxicology. Building on 20 years of research, the first metabolomics data to support grouping/read-across was recently submitted to ECHA, metabolomics best-practices for various applications including grouping were published in *Nature Communications*, and the OECD Omics Reporting Framework has been developed. Given these and other examples of its increasing relevance to chemical safety regulations, an assessment of the reproducibility of metabolomics in the context of chemical grouping is required. The aim of the Cefic-funded MATCHING study (MetAbolomics ring-Trial for CHemical groupING) is to determine whether this technology can demonstrate high reproducibility in grouping, and hence high reliability, or whether refinements in analytical or data analysis practices are needed. Through this fully-blinded evaluation, the second aim is to propose 'acceptable practice' for metabolomics-based grouping. The international consortium comprises seven industrial, government and academic metabolomics ring-trial partners, BASF SE, and the European Chemicals Agency (ECHA) as an independent advisor. First, 8 substances were selected for the trial, and all ring-trial partners were fully-blinded to their identities, modes of action, and the number of categories. Plasma samples for the ring-trial were then derived from 28-day rodent tests (8 substances, each 'low' and 'high' dose, plus vehicle controls), aliquoted, and distributed to partners. Each metabolomics laboratory then applied their preferred LC-MS metabolomics workflows to acquire, process and statistically analyse the plasma samples. This included attempting to group the 8 substances into categories based on their metabolomics signatures, and then reporting their findings to ECHA to ensure the blind conditions of the trial were respected. To date, five ring-trial partners have reported, and all have discovered the identical grouping of the 8 substances into 3 unique categories (remaining two reports expected by December 2022). Further analyses into the metabolic biomarkers driving the groupings are underway. In addition, both the consistent and differing elements of the consortia's metabolomics workflows are being examined to propose acceptable practice for metabolomics-based grouping. In conclusion, the findings from the MATCHING study have demonstrated high reliability of metabolomics-based chemical grouping.

6.06.V Evidence Led Approaches to Identifying Chemical Priorities and Groupings for Effective Risk Management

6.06.V-01 Converging Degradation Pathways as a Basis for Grouping & Read-Across

***Ralf Arno Wess**, Innovative Environmental Services, Switzerland*

Since the REACH legislation, Read-Across became a frequently used option for predicting toxicity and properties of chemicals. While (Quantitative)-Structure-Property-Relationships ((Q)SPR) have achieved some regulatory acceptance (e.g., for concluding of explosive properties or estimating vapour pressure of substances with a melting point above 200 °C), the derivation of biological effects is often not very solid and gets refused.

Formaldehyde Releasers are a good example for a straight-forward applicable Read-Across. The cleaving of formaldehyde is often intended and an important primary degradation step, while the remainder of the parent molecule normally does not degrade very fast and shows little bioactivity. Nonetheless, more complex grouping may be based on converging pathways where the relevant metabolite or transformation product is formed after some antecedent degradation steps may be an option. As an illustration of the principle, the poster shows an example: A variety of substances are potentially able to converge in the metabolic pathway of benzene, i.e., the formation of Hydroxyhydroquinone, potentially the critical molecule in the benzene toxification (metabolic activation).

6.07 Getting the Soil Loop Rolling: Ecotoxicology, Risk Prediction, Monitoring and Back

6.07.T-01 ERAMYC - Assessing the Sensitivity of *Arbuscular mycorrhizal* Fungi to Chemicals in Soil

***Tiago Luz**[1], Luís Oliveira Filho[2], Patrícia Ferreira[3], Tanel Vahter[4], Pia Kotschik[5], Silvia Pieper[5], Susanne Walter-Rohde[5], Sonia Purin da Cruz[6], Susana Rodríguez-Echeverría[7], Matthias Rillig[8], Mari Moora[4], José Paulo Sousa[7] and Osmar Klauberg-Filho[2], (1)University of Coimbra, Portugal, (2)Santa Catarina State University, Brazil, (3)Cloverstrategy, Instituto Pedro Nunes, Portugal, (4)University of Tartu, Estonia, (5)German Environment Agency, Germany, (6)Federal University of Santa Catarina, Brazil, (7)University of Coimbra, Centre for Functional Ecology, Portugal, (8)Freie Universität Berlin, Germany*

Arbuscular Mycorrhizal Fungi (AMF) are organisms that live in symbiosis with most plant species, being responsible for supporting key soil functions and providing important ecosystem services. Due to their ecological relevance and sensitivity to chemicals, AMF have been indicated by the European Food Safety Authority (EFSA) as a potential group of non-target test organisms to be used in the risk assessment of Plant Protection Products.

The existing ISO protocol 10832 describes a method to evaluate the effect of chemicals on AMF, but considers only spore germination (pre-symbiotic phase). Germ tube formation and asymbiotic hyphal growth are important phases of the fungal life cycle and are essential for establishing symbiosis. However, other processes like root colonization could be affected by chemicals in the soil and are not investigated when following the existing test protocol.

ERAMYC is a project which integrates a consortium of experts with the aim to 1) improve the existing protocol for the pre-symbiotic phase by including additional AMF species, test conditions and procedures embracing the symbiotic phase of AMF species; 2) standardize the developed test protocol through a ring-test with different chemicals; 3) develop a draft OECD Test Guideline and evaluate experimental results in reference to the existing framework for the risk assessment of soil organisms exposed to chemicals.

To comply with these objectives, two phases of preliminary experiments were performed. In the first phase, experiments were conducted without chemicals to evaluate the performance/suitability of the selected AMF species in different soils under specific environmental conditions and selected host plants. The second phase included the use of test chemicals to assess how the different AMF species and respective parameters react to the selected chemicals.

The use of seeds pre-soaked in water and a total AMF colonization higher than 40% in controls have been required to validate the experiments. Results of previous studies have shown that Chlorothalonil had effects on both the pre-symbiotic and symbiotic phases in the AMF *Gigaspora albida* and *Rhizophagus clarus*. In the symbiotic phase, arbuscular colonization was, in most cases, more sensitive when compared to total colonization and total extra-radicular mycelium length. However, this patern can be different when testing an herbicide or/and a fungicide with a different mode of action.

6.07.T-02 The Influence of Soil Organic Matter Content on the Toxicity of Pesticides to Soil Invertebrates: A Review
Bart Gerrit van Hall[1]*, Christopher Sweeney*[2]*, Melanie Bottoms*[2] *and Cornelis A.M. van Gestel*[3]*, (1)Vrije University Amsterdam, Netherlands, (2)Syngenta, United Kingdom, (3)Amsterdam Institute for Life and Environment (A-LIFE), Vrije University Amsterdam, Netherlands*
Lipophilic organic chemicals can adsorb to soil organic matter (SOM), reducing their bioavailability to soil invertebrates. As such, the European Food Safety Authority (EFSA) suggests that for lipophilic pesticides (Log Kow > 2), the endpoints derived from laboratory toxicity tests performed in artificial soil containing ~10% SOM should be divided by a factor of 2 to correct for the lower SOM contents in agricultural soils (~5% SOM). These corrected endpoints can then be used in the subsequent risk assessment. Recently, the application of this factor of 2 has been questioned, as it is based on 14-day earthworm toxicity tests focussing on mortality, instead of 56-day earthworm toxicity tests focussing on reproduction. As such, its suitability for other standard soil test invertebrates (Collembola, Enchytraeidae, Acari), and toxicity endpoints (i.e. reproduction) is questionable. A better understanding of how SOM content influences pesticide toxicity to soil invertebrates is needed to improve the ecological relevance of risk assessment approaches. In the current study, soil invertebrate toxicity data (LC_{50} & EC_{50}) were collected from studies determining the toxicity of organic chemicals in soils with varying SOM content. Relevant studies were identified by performing a literature search and through the use of toxicity databases. The data were used to address the following questions: 1) Can the relationship between toxicity and SOM content be quantified?, 2) Does SOM content influence different toxicity endpoints in a similar way?, and 3) Is the influence of SOM content on sensitivity to pesticides different between species? The results indicate that toxicity-SOM relationships are chemical dependent, not clearly different between lipophilic and non-lipophilic chemicals, differ between endpoints, and are species specific. Hence, the grouping of chemicals based solely on their lipophilicity, as well as having only one correction factor for multiple species, may not be an appropriate approach in risk assessment.

6.07.T-03 How Could the New Soil Exposure Framework Be Implemented into a Future, Tiered Ecotoxicological Testing Scheme?
Sebastian Multsch[1]*, Agnes Schimera*[2]*, Gregor Ernst*[3] *and Bernhard Gottesbueren*[4]*, (1)APD/EFM, BASF SE, Germany, (2)ADAMA Deutschland, Germany, (3)Bayer AG - Crop Science Division, Germany, (4)BASF SE, Germany*
In the EU risk assessment (RA) for soil organisms exposed to plant protection products (PPPs), laboratory derived ecotoxicity endpoints are compared with the predicted environmental concentrations in soil at lower tier. If a potential risk is indicated, higher tier field studies are conducted to investigate whether effects on soil organism communities occur at relevant field application rates under natural conditions.
As EFSA published a new guidance for the exposure assessment of PPPs in soil in 2017, an impact assessment has been conducted by CropLife Europe to investigate possible changes in exposure values of active substances and potential consequences for the soil RA. Key outcomes were that considerably higher exposure values can be expected in all regulatory zones compared with the current FOCUS modelling. Increase was correlated with specific soil parameters (including bulk density and organic matter (OM) content), pre-defined wash-off fractions and obligatory model and scenario specific correction factors. Consequently, a significant increase in the number of active substances failing the lower tier soil RA was observed, triggering higher tier field studies as a refinement.
High soil exposure values were often related to high OM levels in the exposure scenarios with median values of 6.1, 10.3 and 19.4 % in the southern (SEU), central (CEU) and northern (NEU) zone, respectively. However, these median values assumed in EFSA modelling are clearly higher compared to other, measured OM data for EU, and compared to higher tier field studies conducted on typical agricultural soils in CEU, with a median OM content of 3.1 % (n = 54). Further, toxicity endpoints from the laboratory are corrected for lipophilic compounds (Log_{Pow}>2), assuming that toxicity is underestimated in soil with high peat content (and high OM). Thus, direct comparison of exposure and effects may thus under- or overestimate the risk to soil organisms.
To properly refine soil RA based on exposure values from the new framework, a joint understanding and consideration of both, exposure parameters and ecotoxicological effect characterisation is required. Adjustment of modelling soil characteristics to real agricultural soil characteristics, e.g. by using natural soils in an intermediate tier testing, could, together with a reduced assessment factor, quantify the potential risk more realistically and serve as an additional step before the initiation of field studies.

6.07.T-04 Soil Health As Part of Sustainable Agricultural Production Systems
Christian Bogen[1]*, Christoph Georgi*[2]*, Florian Ballhaus*[3] *and Julia Köbele*[2]*, (1)EMEA Public Affairs, Science & Sustainability, Bayer AG - Crop Science Division, Germany, (2)Bayer AG - Crop Science Division, Germany, (3)Tier3 Solutions, Germany*
Soil health is considered an integral part of sustainable agriculture, therefore requiring special attention by farmers when setting up their farming practices. Within the agricultural production context, soil health interacts with the various other tools and methods that are used by farmers to create a successful cropping situation and sustainable production system.
Along other sustainabilty criteria, soil health properties with focus on nutrient balance, organic carbon and earthworm populations have been investigated on two farms in Germany, taking into account the challenges and opportunities of different farming systems and approaches with the aim to improve their sustainability profile, respectively, over the five years of the planned trial period.

While the sustainability is assessed across several key indicators, such as crop yields per ha to reflect the land use footprint, the crop quality, economic assessment of the production scenario, greenhouse gas emissions per volume crop produced, biodiversity of carabids as proxy for natural pest control and biodiversity and their diversity and biodiversity of plants in habitats adjacent to the fields, soil health is specifically considered with focus on nutrient balance, organic carbon and earthworm populations.
The soil health implications within the current crop rotations are presented. The yields, climate and further environmental implications of the different production scenarios with their corresponding choice of tools and methods have been simultaneously assessed, thus enabling a holistic perspective that takes into account the farmers agronomic challenges, decision-making and opportunities for improvement.
The further assessments are taking place over an extended crop rotation, following the corresponding agronomic requirements and the practical implications for the farmer with the aim to cover five subsequent years and to continuously improve the sustainability of the scenarios over time. Along with the recent performance challenges are presented that could appear currently as limiting factors for an improved monitoring or hint towards trade-offs.

6.07.T-05 Assessing the Effectiveness of Risk Mitigation Measures on the Risk Values of PPP Spray Series: A Case Study with Soil Organisms on Vineyards

Fernanda de Santo[1]*, Tiago Luz*[2]*, Patrícia Ferreira*[3]*, Camila Campello*[3]*, Rita Garcia*[4]*, Pedro Marques*[4]*, Paolo Marucco*[5]*, Fausto Freire*[4] *and José Paulo Sousa*[3]*, (1)Universidade de Coimbra, Portugal, (2)University of Coimbra, Portugal, (3)University of Coimbra, Centre for Functional Ecology, Portugal, (4)University of Coimbra, ADAI, Department of Mechanical Engineering, Portugal, (5)Department of Agricultural, Forest and Food Sciences (DiSAFA), University of Turin (UNITO), Italy*

To reduce the impact of Plant Protection Products (PPPs), risk mitigation measures (RMM) are usually suggested and implemented. Some RMM are related to the use of more efficient and target-specific pesticides, the use of new spraying technologies, the development of precise Early Detection Systems (EDS) and of Decision Support Systems (DSS) that reduces the PPP's use by predicting disease outbreaks. These RMM were developed/tested in isolation and in combination in field trials at the H2020 OPTIMA project aiming to develop an optimized novel Integrated Pest Management (IPM) system targeting the goals of the Farm to Fork strategy. In this study, we assess the risk of PPP spray series used in vineyards to earthworms, where those RMM measures were adopted. The aim was to holistically assess the cumulative risk of each spray series and the effectiveness of the RMM (isolated or in combination) in reducing the risk to in-soil organisms. Six field trials (named Ref 0 to Ref 5) were conducted on vineyards (Barbera variety) in Italy, where the different RMM were tested. Each reference consisted of a spray series with 13 application events, where 19-20 active substances (a.s.) were used. Ref 0 was considered the baseline condition. The risk of the spray series from each reference was calculated deriving the daily cumulative ETR values (ETRsum) over the application period of 144 days based on the CA model. The toxicity data (NOEC) were collected in DAR/RAR or derived from laboratory tests. PEC values were estimated using the PERSAM software. The a.s. degradation was assessed by using a first order kinetics reaction. The comparison of the overall risk was done by calculating the "area under curve" and estimating the risk reduction. Considering the IPM system, there was a risk reduction among all references. This was particularly visible on Ref 3 and Ref 5 (71.9% and 57.5%, respectively) where some of the synthetics were replaced by bio-PPPs and anti-drift nozzles were used. The adoption of other RMM also resulted in an overall risk reduction: 6.8% (Ref 1), 26.4% (Ref 2), and 34.6% (Ref 4). However, despite these values and the efficiency of mitigation measures, none of the references tested fell below the trigger value during most of the application period. The RMM, mainly the replacement of synthetic PPPs by bio-PPPs, resulted in a decrease of the overall risk values, showing their significant contribution to reduce the reliance of crop production on chemical PPPs.

6.07.P Getting the Soil Loop Rolling: Ecotoxicology, Risk Prediction, Monitoring and Back

6.07.P-Mo372 Application of a Novel Smartphone-Based Digital Image Colorimetry Technique for the Assessment of Soil Salinity

Michael Muir[1] *and Andrew Innes*[2]*, (1)School of Interdisciplinary Studies, University of Glasgow, United Kingdom, (2)Scotland's Rural College*

Salinization is one of the largest threats facing soils globally as a result of rising sea levels and the use of saline groundwater for crop irrigation. Saline soils have been identified in over 100 countries worldwide, affecting over 1 billion hectares of land. Understanding the scale and extent of soil salinity is essential to enable farmers and land managers to make appropriate decisions about how to effectively apply practices which can help to reduce the impact of problems associated with saline soils. However, soil salinity analysis methods are frequently prohibitively expensive or time consuming, therefore access to low-cost, simple, fast and robust measurement techniques is desirable to help inform land-management approaches and to provide accessible analysis techniques to all practitioners, without cost being a barrier.
In this project, a novel smartphone-based Digital Image Colorimetry (DIC) technique using colorimetric chloride test strips has been developed and compared to other portable and lab-based techniques for the assessment of soil salinity. A survey of a coastal saltmarsh and neighbouring farmland was conducted at the RSPB Mersehead Nature Reserve in Southwest Scotland. The salinity of 70 soil samples was analysed by the new DIC method, as well as 3 other portable and 2 lab-based methods. Comparisons were drawn between the methods in terms of practicality and ease of use, cost effectiveness, accuracy, and precision of measurement. Results presented show that the new DIC method compares very favourably with standard analytical methods for soil salinity, with a correlation coefficient of 0.98 ($p<0.001$) and 0.96 ($p<0.001$) with chloride meter and conductivity methods, respectively. The DIC method also performed better than a portable soil conductivity sensor. An application of the DIC method, and other methods evaluated, is demonstrated by using geostatistical analysis (Kriging) to estimate soil salinity across the ~7km^2 Mersehead site, highlighting significant variation in salinity across the area.

Each technique evaluated had specific benefits, such as accuracy, precision, selectivity or speed, however the low cost, portability and lack of specialist equipment required for the DIC technique makes it suitable for use in agriculture, citizen science or conservation settings where resources may be limited. The example presented demonstrates how smartphones may be used successfully to broaden access to environmental analysis techniques.

6.07.P-Mo373 Assessment of Biomagnification Potentials for a Suite of Per- and Poly-fluoro Alkyl Substances (PFAS) in a Soil-Plant-Mammal Model
Michael Simini[1], *Roman Kuperman*[1], *Linnzi K Wright*[1], *Ruth W Moretz*[1], *Jennifer Guelfo*[2], *Zhao Yang*[2], *Emily E Reinders*[3] *and Guilherme R. Lotufo*[4], *(1)U.S. Army DEVCOM Chemical Biological Center, (2)Texas Tech University, (3)Excet, (4)U.S. Army Corps of Engineers*
Per/polyfluoroalkyl substances (PFASs) have been linked to accumulation in soil, terrestrial plants and mammals in previous studies with the potential for biomagnification in terrestrial food webs. We investigated the uptake of a suite of PFAS compounds in Timothy grass (*Phleum pratense*) and kale (*Brassica oleracea*) from soil to estimate the biomagnification potential in a soil-plant-rabbit food web. Plants were grown in a modified Organisation for Economic Co-operation and Development (OECD) constructed soil amended with of 18 PFAS compounds to generate bioconcentration factors (BCF). The shoot BCFs increased as the C chain length decreased except for Perfluorobutanoic acid (PFBA) and were greater for kale than for Timothy grass. PFBA had the greatest BCF in plant shoots. Root BCFs generally increased with C chain length except for PFBA. PFAS compounds with shoot BCF values ≥2 were selected for the soil-plant-rabbit biomagnification study. For the biomagnification study, kale plants were grown in an environmentally controlled greenhouse in a modified OECD constructed soil amended with 0.01 mg/kg each of 11 PFAS compounds for 56 days. Kale leaves were harvested from mature plants. Certified contaminant-screened Timothy hay was purchased and amended via atomizer with PFAS compounds at concentrations achieved in the BCF studies. Plant material was fed to Dutch-belted rabbits weekly for a 28-day uptake phase and 28-day elimination phase. Accumulation of the 11 compounds in soil, plants and rabbits were analytically determined. Ecologically relevant data developed in this research will fill several knowledge gaps regarding biomagnification potential for PFAS compounds released into the terrestrial environment.

6.07.P-Mo374 Relative Toxicities of PFAS-Free Replacements of Aqueous Film-Forming Foams for Soil Invertebrates
Roman Kuperman[1], *Michael Simini*[1], *Guilherme R. Lotufo*[2] *and Robert Boyd*[3], *(1)U.S. Army DEVCOM Chemical Biological Center, (2)U.S. Army Corps of Engineers, (3)U.S. Army Engineer Research and Development Center*
Legacy aqueous film-forming foam (AFFF) formulations containing per- and polyfluoroalkyl substances (PFAS) have been linked to accumulation in soil invertebrates and terrestrial plants in previous studies with the potential for biomagnification in terrestrial food-webs. Alternative PFAS-free surfactant formulations are being developed and evaluated for their ability to meet current US Department of Defense performance requirements. The relative toxicities of PFAS-free AFFF-alternatives, as compared with legacy AFFF formulations are not known. We have developed ecotoxicological data for seven candidate PFAS-free AFFF formulations and a legacy AFFF formulation by determining reproduction toxicity for soil invertebrates collembolan *Folsomia candida,* earthworm *Eisenia andrei,* and potworm *Enchytraeus crypticus*. Test species were exposed in separate studies to each formulation in a natural soil, Sassafras sandy loam, which has characteristics (low clay and organic matter content) expected to support high bioavailability for these materials. Toxicity data derived from this project will be used to develop Soil Ecotoxicological Risk Factors (SERF) to assess which PFAS-free AFFF formulations would exhibit lesser environmental toxicity, while meeting the current performance requirements.

6.07.P-Mo375 MICROSOIL – Investigation of Alternative Test Methods to Correctly Assess the Impact of Plant Protection Products, Biocides and Pharmaceuticals on Soil Microorganisms
Marie Winter[1], *Gabriele Broll*[2], *Frank Zielinski*[3], *Jens Schönfeld*[3], *Pia Kotschik*[3], *Silvia Pieper*[3] *and Karsten Schlich*[1], *(1)Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany, (2)University of Osnabrueck, Germany, (3)German Environment Agency, Germany*
For the risk assessment of plant protection products (PPP) potential effects on soil microorganisms are addressed by investigating if N-transformation (OECD 216), an important soil function, may be affected. However, by focusing on only one central function of the microbial community, other effects might be neglected.
To determine potential other effects of PPP on functional microbial activity, one objective of the project MIROSOIL is to investigate the sensitivity of three alternative test methods, i.e. substrate induced respiration (MicroResp^{TM}), measurement of enzymatic activities (ISO 20130) and effects on ammonium oxidizing bacteria (ISO 15685, AOB). To gather information about the sensitivity of these methods, six model substances were investigated (fungicides: tebuconazole, pyraclostrobin, propamocarb; herbicide: ethufomesate; antibiotic: tiamulin hydrogen fumarate; biocide: DDAC). For sensitivity assessment, results are compared to OECD 216 data.
Up to now, tests were performed in the sandy soils LUFA 2.1 and RefeSol 04A. Three to four nominal test concentrations, e.g. 1x, 5x and 10x of the intended application rate, were tested. Measurements for each test method were performed after 14 and 28 days. If effects above 25% occurred after 28 days, the test duration was extended up to 84 days.
MicroResp™ indicated in general a low sensitivity, substance-independently. The group of AOB was strongest inhibited by the test substances. Especially for DDAC (LUFA 2.1 test results), concentration related effects > 25% were determined after 28 days of exposure. For ethofumesate in Refosol 04A, the extracellular enzymatic activities, e.g. phosphatase, altered over the exposure period between stimulation and inhibition. In general, effects > 25% occurred on specific time points, followed by recovery of the respective enzyme activity on the following measurements.

Upcoming experiments with RefeSol 02A will help to identify potential influence of soil properties to the ecotoxicological results. To encounter the impact on the group of fungi, arbuscular mycorrhiza (ISO 10832, *Funneliformis mosseae*) will be investigated under substance exposure. These assessment results of the different soil organisms referring to functional diversity will be complemented by ARISA (Automated Approach for Ribosomal Intergenic Spacer Analysis) structural analysis and presented at the conference.

6.07.P-Mo376 The Influence of Soil Organic Matter Content on the Toxicity of Pesticides to the Springtail *Folsomia candida*

Bart Gerrit van Hall[1], *Christopher Sweeney*[2], *Melanie Bottoms*[2] *and Cornelis A.M. van Gestel*[3], *(1)Vrije University Amsterdam, Netherlands, (2)Syngenta, United Kingdom, (3)Amsterdam Institute for Life and Environment (A-LIFE), Vrije University Amsterdam, Netherlands*

In the environmental risk assessment (ERA) of lipophilic pesticides (Log Kow > 2), an assessment factor (AF) of two is applied to toxicity endpoints to compensate for differences in soil properties between artificially constructed soils and agricultural soils. This AF is based on earthworm toxicity tests focusing on mortality, and therefore its applicability to other soil invertebrates and toxicity endpoints is questionable. Hence, a better understanding of how soil organic matter (SOM) content influences pesticide toxicity endpoints of other soil invertebrates is needed to improve the ecological relevance of ERA approaches. In the current study, the influence of SOM content on pesticide toxicity to springtails was investigated. Standardized reproduction toxicity tests were performed using the springtail *Folsomia candida*. Animals were exposed to five persistent pesticides with a range of lipophilic properties in four soils (three artificial soils, one natural soil) with different SOM contents, using survival and reproduction as endpoints. The data were used to determine LC_{50}, EC_{50}, and NOEC values, and the relationships between toxicity endpoints and SOM content were analysed through linear regression analysis. The results show that, for all tested pesticides, the acute and chronic toxicity was lower in soils with higher SOM content. For chlorpyrifos (Log Kow = 4.70), SOM influenced lethal effects more than sub-lethal effects, while for lindane, cyproconazole, and imidacloprid (Log Kow = 3.50, 3.09, and 0.57, respectively) the toxicity-SOM relationships were similar for both toxicity endpoints. For carbendazim (Log Kow = 1.48), no dose-response curves could be constructed. Overall, the results indicate that toxicity-SOM relationships differ between pesticides, which implies that having a single AF for all lipophilic pesticides may not be fully appropriate. Additionally, the current research shows that SOM content also influences the toxicity of pesticides which are considered non-lipophilic under current legislation.

6.07.P-Mo377 The Power of Soil Water in Ecotoxicological Testing with Springtails Following OECD 232 Using Natural Soils

Eva Aderjan[1], *Zarah Kazemi*[2], *Eiko Wagenhoff*[1] *and Andreas Duffner*[1], *(1)Eurofins Agroscience Services Ecotox, Germany, (2)University Koblenz-Landau, Germany*

In 2017, the European Food Safety Authority (EFSA) issued a scientific opinion addressing the state of the science on risk assessment of plant protection products for in-soil organisms, stating that a standardised arable soil closer to the scenarios in the exposure assessment would be preferred over the OECD artificial soil. As most agricultural soils do lack of extreme properties for practical and fertility reasons, factors influencing a successful control performance in reproduction testing with *Folsomia candida* are less soil properties like texture or pH value but more the soil water availability. If the matric potential (soil water tension) exceeds pF 2.18 (-150 hPa), reproduction of *F. candida* is completely stopped and will only restart, when soil moisture conditions are wetter. This means, when investigating the toxicity of substances on in-soil organisms in natural soils not only soil properties like organic matter or species specific sensitivity can influence the results, but also the soil moisture status. Beside biotic stress due to different water availability, the exposure scenario for in-soil organisms is also influenced by precipitation and drought events, due to differences in sorption behaviour and therefore bioavailability of a substance.

To meet the demand of alternative natural soils for standardised tests, a sensitivity testing was performed with four reference soils that are representative for agricultural use for species *F. candida* according to OECD 232. The toxicity of an appropriate reference substance on *F. candida* exposed in natural soils was tested in comparison with OECD artificial soil. Additionally, a co-stressor of differences in the soil moisture status was included.

The results show, that the usage of a wide range of agricultural soils with diverse properties are suitable for laboratory testing according to OECD 232. A key factor for a successful testing with diverse natural soils is an appropriate actual soil water availability that can be ensured with pF values as a measure for soil moisture instead of the maximum water holding capacity. In general, the exposure scenario and toxicity of plant protection products for in-soil organisms in natural agro-ecosystems is influenced by the fate of a substance and their bioavailability in the habitat soil. This bioavailability is influenced by a multitude of factors and the results presented will reveal the role of the soil water status and soil sorption properties.

6.07.P-Mo378 Use of Natural Soils as Intermediate-tier for Non-target Soil Organisms Risk Assessment of Plant Protection Products at EU Level

Franck Brulle[1], ***Julie Ravat***[2], *Claire Blondel*[1], *Emilie Perrat*[1], *Emilie Farama*[1], *Pierre-François Chaton*[1] *and Vanessa Mazerolles*[1], *(1)French Agency for Food, Environment and Occupational Health & Safety (ANSES), France, (2)U3EiV, French Agency for Food, Environment and Occupational Health & Safety (ANSES), France*

According to the European regulation (EC) No 1107/2009, an ecotoxicological regulatory risk assessment (RA) for Plant Protection Products (PPP) typically follows a tiered approach, based on a large range of organisms tests. Regarding non-target soil meso- and macroorganisms the first-tier RA is based upon chronic toxicity data from laboratory studies using standard artificial substrates. These laboratory studies are performed in controlled conditions following recommendations of dedicated guidelines (*e.g.*: OECD, ISO). Toxicity values are then compared to the predicted environmental concentrations in soil. In case of

unacceptable risk, field studies can be performed to assess the potential effects on soil organisms communities in realistic conditions. However, to date no other refinement options are formally available.
The use of artificial soils for Tier 1 RA has many benefits, as these soils are easy to use and allow good reproducibility between laboratories. However, due to their high organic matter content, clay composition and soil texture, these soils may not be representative of agricultural soils / natural soils and potentially drive to confounding effects that bring uncertainty in a RA context.
The guidance on the risk assessment of PPP for soil organisms is going to be revised in the upcoming years. Meanwhile, an EFSA scientific opinion (2017) proposed a new framework for risk assessment of soil organisms. This opinion also identified intermediate tier approaches as a focus for future research that need development, standardized test designs and further guidance. Among all recommendations provided, it is encouraged to identify and use natural agricultural soils in standard laboratory testing to characterize parameters potentially modulating toxicity of PPP in order to better extrapolate toxicity data from the laboratory to field situation.
Through a scientific literature analysis, the aim of this poster is to (i) identify relevant and reliable toxicity data using natural soils for standard soil organisms (e.g. *Eisenia fetida*/*andrei*; *Folsomia candida* and *Hypoaspis aculeifer*) using natural soils; (ii) compare these toxicity endpoints to the ones currently used in the EU risk assessment for PPP and determine which parameters mostly influence toxicity results; (iii) identify if the outcome of the RA would be different and propose recommendations for further research and development to better address non-target soil organisms RA in the upcoming years.

6.07.P-Mo379 Intermediate-Tier Approach for In-Soil Meso- And Macroinvertebrates Risk Assessment for Plant Protection Products Registration: Species Sensitivity Distributions (SSD), Application and Limits
***Emilie Perrat**, French Agency for Food, Environment and Occupational Health & Safety (ANSES), France*
In the frame of the European regulation (EC) No 1107/2009, a regulatory risk assessment (RA) is performed for all Plant Protection Products (PPP). According to this regulation, a large range of organisms is required and current guidances on ecotoxicology RA usually followed a tiered approach. For soil organisms when exposure cannot be excluded, a first-tier RA is required based on chronic toxicity data from laboratory tests in controlled conditions (*i.e.,* following recommendations of dedicated guidelines or academic standards) using artificial soils. Some refinements using natural soils are proposed. These laboratory studies are conducted on three species groups: earthworms, collembola, and mites, represented by three standard species, *i.e., Eisenia spp.*, *Folsomia spp.,* and *Hypoaspis aculeifer,* respectively. Ratio between toxicity value and predicted environmental concentration in soil is compared to the threshold value for acceptability of effects under intended use conditions. In case of unacceptable risk after first-tier RA, higher-tier assessment with field studies can be performed to assess the potential effects on invertebrate soil communities in more realistic conditions. To date, no other refinement options are available in the current SANCO guidance document (2002). However, in the EFSA opinion (2017), a new framework with revised community protection goals was proposed including intermediate-tier approaches, which still need development, standardized test designs and further guidance.
One of these approaches is to address the sensitivity of species belonging to one or more taxonomic groups using the Species Sensitivity Distributions (SSD). This method is based on laboratory data to estimate the Hazardous Concentration affecting 5% of the tested species (HC_5). In many publications, SSD are built based on a combination of different parameters: *e.g.,* toxicity data from active substance and/or PPP; different types of substrates; different endpoints measured; etc. However, their reliability remains questionable for RA purposes.
This poster seeks to (i) identify toxicity data available in scientific literature to perform an intermediate-tier approach with a proof-of-concept method conducted on various active substances (ii) identify technical limitations and gaps (iii) propose recommendations to build more reliable SSD concerning the soil organisms RA (iv) suggest development to further address the soil meso- and macrofauna RA in the upcoming years.

6.07.P-Mo380 Further Testing of the Fungicide Fluazinam – Effects on Three Non-Target Species
***Micha Wehrli**[1], Gilda Federica Dell'Ambrogio[2], Miriam Langer[3,4], Dominique Grandjean[5], Florian Breider[5], Benoit J.D. Ferrari[2] and Jean Mathieu Renaud[2], (1)University of Gothenburg, Sweden, (2)Swiss Centre for Applied Ecotoxicology, Switzerland, (3)University of Applied Sciences and Arts Northwestern Switzerland - FHNW, Switzerland, (4)Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (5)Ecole Polytechnique Fédérale de Lausanne – EPFL, Switzerland*
Plant Protection Products (PPP) are extensively applied chemicals, to protect crops against pests and are one of the primary pillars of high production modern age agriculture. However, PPPs applied in agriculture can have unintended toxic effects on non-target organisms. As a result, modern agriculture represents a constant struggle between chemical driven high yield of edible crops, and the challenge of sustainable production.
Due to their toxic nature, PPP are subject to a risk assessment before they are authorized for the use in agriculture. In Europe, the risk assessment is performed by the European Food and Safety Authority (EFSA) and for soil, it is mostly based on chronic effects of single products on few standard surrogate species.
In this study, we chose to focus on the fungicide fluazinam, because its authorization is based on limited ecotoxicological data. First, reproduction effects for the springtail *Folsomia candida* are expressed as unbound values. Secondly, laboratory results suggested high toxicity on the reproduction of the earthworm *Eisenia fetida*. However, field studies did not show any adverse effects. These contradictory results lead to some controversy concerning the risk of fluazinam application. As such, the risk was considered as acceptable by European and Canadian regulatory agencies but not acceptable by Norway, which decided to ban the substance.

To generate further data on the ecotoxicity of fluazinam, we performed reproduction tests on three terrestrial species *Folsomia candida, Folsomia fimetaria* and *Enchytraeus crypticus.* Testing was carried out, under standard laboratory conditions, using LUFA 2.2 soil as testing substrate and following standard OECD guidelines. Additionally, test concentrations were measured at the start and at the end of the test using an LC-MS/MS system. Preliminary results indicate a high sensitivity of *E. crypticus* and *F. fimetaria*, with effects detected below the lowest relevant measured environmental concentration. The results of this study provide further evidence that fluazinam might present an unacceptable risk for soil organisms and its use should be re-evaluated to establish a safe application pattern. The study also demonstrates that other non-target species than the ones routinely tested in the authorization procedure like *F. fimetaria* and *E. crypticus* can have a higher sensitivity to certain PPP.

6.07.P-Mo381 Use of natural soils to refine the risk to earthworms in India – A Case Study

***Stefan Kimmel**, Corteva Agriscience, Germany*

At present there is no specific guidance for intermediate steps to refine the risk assessment for earthworms. Currently, guidance includes only 2 tiers: Tier 1 laboratory studies (OECD 222) and Tier 2 field studies if a potential risk is triggered.
At Tier 1 the assessment of toxicity to earthworms performed in an artificial soil substrate. This substrate does not necessarily reflect the behavior of chemicals in the range of natural soils found in the environment. This presentation describes an intermediate refinement using representative natural soils from India. To refine the hazard assessment of a fungicide, the potential adverse effects in a range of natural soils was tested to increase the environmental realism and relevance of the studies. Representative batches of natural soils from across India were selected based on different soil textures and classes. Reproductive performance of the earthworms under a range of test concentrations in the natural soils was compared to untreated controls as well as artificial soil according to modified OECD 222 to enable more realistic evaluation and standardization of the tested natural soils. The results will be presented alongside how this approach might be incorporated within existing risk assessment frameworks for soil organisms.
This case study demonstrates the value of tailor-made study designs to develop appropriate approaches for refined risk assessment of soil organisms.

6.07.P-Mo382 The Effect of the Estimation of Different Hypotheses Test with Different Transformation on the Estimated Endpoint - Consequences of Wrongly Used Tests on an Endpoint and its Reliability

***Thomas Gräff**, Sabine Duquesne, Pia Kotschik, Klaus Swarowsky, Rene Sahm and Silvia Pieper, German Environment Agency, Germany*

In higher tier test systems, natural assemblages are tested experimentally and exposed to chemicals to understand their effects on communities representative of field situations. For terrestrial higher tier studies, the regulatory endpoint of interest is the NOEC. For aquaitc mesocosm studies, it is also the NOEC and as well the NOEAC that are the relevant endpoints; they enable to apply the threshold and the recovery options, respectively . Due to the high diversity of natural communities, data from higher tier test systems always present a high variance and low numbers of replicates. The endpoint estimation is based on multiple hypotheses tests and the test with the highest statistical power should be selected. For both types of test systems, terrestrial field experiments or aquatic mesocosm experiments, abundance data sets have to be analysed. These data sets are count data and follow the Poisson distribution which is skewed to the right. Parametric tests of the t-test familiy show a much higher power compared to unparametric tests like Jonckheer- Terpstra or U- test . The preconditions for these parametric tests are rmal distribution and/or variance homogenity. In case of William's test, additionally a linear trend is needed. For aquatic experiments, it is quite common to transform the data with the natural logarthim procedure ln(a*X + 1). In most cases, those preconditions are not prooven after the transfomation, i.e. it is not checked if the transformed data set fullfills the criteria of the specific statistical test. For terrestrial higher tier tests, data transformation is not usual but also sometimes applied. In these cases, unparametric tests like the U-test, showing a very low power, are used for effect determination. For both types of studies, other statistical tests showing higher statistical power without dependency on data transformation are available. Possible alternatives for parametric tests analysing count data are GLM and GLMM with internal error correction based on Poisson or quasi-Poisson distribution in combination with Dunnett test or CPCAT.
In the present study, several data sets of terrestrial and aquatic higher tier test systems were analysed with different hypotheses tests to estimate the NOEC. Preconditions were also checked, if required. The tests delivering the most protective results under specific conditions were analysed. Different transformation methods were applied, when specific preconditions were required.

6.07.P-Mo383 Alternatives for CP-CAT Test to Evaluate Soil Organism Feld Trials

*Ludwig A. Hothorn[1], Gregor Ernst[2], **Zhenglei Gao**[2], Anja Gladbach[2] and Changjian Jiang[3], (1)Institute of Biostatistics, Leibniz University, Germany, (2)Bayer AG - Crop Science Division, Germany, (3)Data Science, Bayer AG - Crop Science Division*

The draft OECD guidance (OECD, 2021) recommend the statistical evaluation of species abundances less than five by means of the CP-CAT test (Lehmann, 2016). The rationale for this choice was: "The theoretical distribution assumption of earthworm abundance field test data follows a Poisson model". The CP-CAT test is a combination of 1) Marcus' closed testing procedure in a complete family version for unrestricted comparisons against a control group and 2) a permutation version of the likelihood ratio test for the difference of Poisson means. NOEC estimates are appropriate for small sample sizes, as the proposed n=6 and strict Poisson distributed variable. But the above rationale violates the Box' principle 'All models are wrong, some are useful' by focusing on exactly one theoretical distribution with the strange condition 'variance=mean'. The sum of Poisson variables follows the Poisson distribution when they are independent, which is already violated by averaging the sub-sampling trap counts for a field plot and particularly for the aggregation into higher taxonomic levels. Even empirically over-dispersion and particularly severe over-dispersion were observed in historical control data for selected species in Fig. 24 of the UBA report (UBA, 2020).

Simulations reveal both violation of the alpha level and sub-optimal power when applying CP-CAT test to under/over-dispersed data. Moreover, the current CP-CAT test is numerically only available in a two-sided version, confidence limits are not available, random effect modeling of sub-samples is not available and adjustment against baseline covariate is not possible.
Therefore, alternatives were selected that are robust against various violations of the theoretical Poisson distribution, particularly different dispersion parameters in the multiple concentration groups. Candidate tests include a non-parametric Dunnett-type test based on global ranking relative effect size (Konietschke, 2012), the most likely count transformation model (Siegfried, 2020) and generalized estimation equations using variance-sandwich estimators for clustered count data.

6.07.P-Mo384 An Alternative for OECD Decision Tree Approach to Evaluate Soil Organism Field Trials
Ludwig A. Hothorn[1], Gregor Ernst[2], ***Zhenglei Gao[2]****, Anja Gladbach[2] and Changjian Jiang[3], (1)Institute of Biostatistics, Leibniz University, Germany, (2)Bayer AG - Crop Science Division, Germany, (3)Data Science, Bayer AG - Crop Science Division*
In the draft new OECD guideline for the earthworm field testing (OECD, 2021) a decision tree approach is proposed for the evaluation of soil organism field trial in Fig. 2(page 18). The first branch divided into rare abundance data or continuous as well as abundance data when no. taxa>5. The latter is relevant for the majority of raw the data, namely abundances >5 (and their aggregations to upper taxonomic level) and continuous endpoints like biomass on its various classification levels.
After first branching, the next two branches propose pre-tests on normal distribution (e.g., Shapiro-Wilks test) and homogeneity of variances (e.g., Levene test) (Fig. 2). Based on these decisions an appropriate test out of the method list (Williams or Dunnett, Bonferroni-Welch-t tests, stepdown JT test, Bonferroni U-test, Bonferroni median test) should be selected. Using such pre-tests to decide between proper parametric and non-parametric test is not appropriate and can lead to misleading conclusions. Alternative robust tests without the need of all pre-tests are proposed: I) robust against variance heterogeneity in balanced and unbalanced designs, namely using sandwich variance estimators (Herberich, 2010) for multiple contrast test of Dunnett, Williams and DunnettWilliams-type (Jaki, 2013), II) robust against violation of normal distribution, particularly count data with not too tiny counts, namely robust parametric, non-parametric and most likely transformed multiple contrast tests. A list of compatible tests is proposed (in difference to Fig. 2 list). A tiny slice of an extensive simulation study is presented.
A real data example (a soil organism field study, Ernst, 2022) is used, to demonstrate these alternative approaches by means of two one-sided 95% confidence limits derived based on using the plot as randomized unit (linear model) and using the subplot within the plots (linear mixed effect model). These intervals are plotted for consecutive monitoring times to interpret species-specific decrease and their possible recovery afterwards.
In summary, recommendations for a routine analysis using CRAN R packages are developed, and an outlook on the analysis of abundance data with very low count numbers is given.

6.07.P-Mo385 Design and Evaluation of Ecotoxicological Field Studies with Soil Organisms (Collembola) for the Registration of Plant Protection Products (PPP) in the EU
Agnes Schimera[1]*, Jörg Hanisch[2], Katja Henkes[2], Zhenglei Gao[3], Oliver Jakoby[4], Johannes Lückmann[4], Michael Thomas Marx[3], Frank Staab[5], Pernille Thorbek[5] and Lijuan Yan[6], (1)ADAMA Deutschland, Germany, (2)Rifcon, Germany, (3)Bayer AG - Crop Science Division, Germany, (4)RIFCON, Germany, (5)BASF SE, Germany, (6)BASF Services Europe, Germany*
For the registration of PPPs in the EU, ecotoxicological risk assessments (RA) for soil organisms are required. The tiered approach starts with comparing calculated environmental concentrations and ecotoxicological endpoints from laboratory studies. In case of failure, a higher tier RA can be conducted, which regularly results in field studies, focusing on recovery of non-target soil organisms within one year after application of the respective product. As shown in a previous impact assessment, the new EFSA exposure framework for calculation of environmental concentrations increases the number of compounds failing the first tier RA, i.e., requiring field studies.
However, no official OECD Test Guidelines have been adopted for such field studies; ISO guideline 11268-3 adapted with literature data is used to conduct field studies on earthworms. Collembola field studies are generally conducted following this guidance, yet there is a lack of guidance for evaluation and interpretation of results. High natural variability of data may lead to discussions on biological relevance and statistical significance, with a preprogramed high uncertainty on the outcome from regulatory perspective.
We have analysed and reviewed historical control data to investigate natural variability in Collembola populations in farmland, between studies and over time. Species abundance for different taxa and sampling points shows the variability in abundance for studies conducted in a similar agricultural environment. The results shall support data interpretation of field studies and help to distinguish between natural variability and biologically relevant test item effects. Available and new statistical methods (including CPCAT, GLMMs and power analysis) to detect potential treatment effects are evaluated, and suitable approaches for statistical evaluation of abundance data are proposed.
Our results can support the development of a future OECD test guideline for soil mesofauna field studies and help with data interpretation. However, with regards to the high complexity of the data and difficulties in interpretation, a full field study should be the last step in the RA and not directly following Tier 1 studies. Expecting that more compounds will fail the first tier RA, intermediate tier testing is required to clearly distinguish between low-risk compounds and compounds that potentially pose a risk.

6.07.P-Mo386 Regulatory Field Studies With Soil Mesofauna – On The Way to a Guidance for Harmonized Assessment of Pesticide Impacts in the Field
Gesa Amelung*, Pia Kotschik, Thomas Gräff, Klaus Swarowsky and Silvia Pieper, German Environment Agency, Germany*
If the tier 1 pesticide risk assessment for soil organisms indicates an unacceptable risk, current data requirements ((EU) No

283/2013 and 283/2013) give the option to perform higher tier studies on soil mesofauna. Due to practical reasons, field studies with soil mesofauna usually focus on natural collembola and or mite communities. However, no official guidance is available for such studies up to now. This results in high uncertainties and inconsistencies in the conduction and evaluation of respective studies. Currently, European Member States are discussing the development of a respective guideline. To contribute to this process, we evaluated field trials with soil mesofauna submitted to authorities during active substance and plant protection product evaluation. The analysis aimed to gain an understanding on how relevant effects on assessed endpoints can be determined reliably. Statistical analyses helped to evaluate whether endpoints in aggregated form or those related to single species were more relevant to identify effects of the tested substances. Data was retrieved from studies on soil natural mesofauna communities, usually exposed to pesticides under field conditions for 12 months. In case of very persistent test substances, studies were prolonged in order to cover the possible effect duration. We investigated the variability of determined soil mesofauna species versus grouped endpoints additionally to the determination of the statistical power of the studies. Poisson distributed data were analysed via Closure Principle Computational Approach Test (CPCAT) in order to identify statistically significant deviations in responses of soil mesofauna in treated plots compared to control plots. Additional statistical test methods (e.g. Dunnett or William test) were performed depending on the data quality. Analyzing poisson distributed data with CPCAT enabled to detect significant effects at lower concentrations than common statistical methods, which are less suitable for poisson distributed data. Analyses of aggregated endpoints was based on higher individual densities and was often statistically more robust – but in some cases the impact at species level was blurred. Discussion of the biological relevance of the statistically significant difference is important as well as of non-significant effects at large effect size.

6.07.P-Mo387 Software Development for Soil Ecological Risk Assessment in Korea
Seung-Woo Jeong[1]*, Songhee KIM*[2]*, Duckhyung Kim*[2]*, Hyunjun Jung*[2]*, Dokyung Kim*[3] *and Youn-Joo An*[3]*, (1)Environmental Engineering, Kunsan National University, Korea, (2)Kunsan National University, Korea, (3)Konkuk University, Korea*
The International Standard Organization (ISO) recently suggested an ecological risk assessment strategy for contaminated sites, so called the TRIAD approach that includes three lines of evidence such as chemical (Chem-LoE), ecotoxicity (Ecotox-LoE), and ecology (Eco-LoE). he three LoE are calculated each as a 0-1 number and ultimately integrated to obtain the final integrated risk (IR) for the contaminated site. Every tiered work has been conducted by hands or using excel worksheets. There is no computer program to automatically calculate the TRIAD approach to contaminated sites. This study constructed a computer program, called KERAS (Korean ecological soil risk assessment program) to include the three tired approaches. e KERAS begins the first two main gates, “Preliminary survey” (PE) and “Ecological risk assessment” (ERA). PE was ready to decide whether a contaminated site should be subject to a further ERA or not, given Korean government situations. PE ncludes program pages to collect contamination information such as contaminants, concentrations, land uses, ecological and environmental indices. PE decides “further ERA” if the site is located within ecologically sensitive area. PE decides “further ERA” if the site is located within an ecologically sensitive area. If PE decides “further ERA is needed”, an appropriate soil sample size can be computed by statistical power through the EP survey preparation page. . If PE decides “further ERA is needed”, an appropriate soil sample size can be calculated by statistical power through the investigation preparation page of PE. ERA includes input pages of each site investigation data for chemical, ecological and ecotoxicity areas. These inputs were automatically calculated to produce each chemistry, ecological and ecological risk, and ese three risks can be integrated into the site’s IR. KERA i also able to display graphically Chem-LoE, Ecotox-LoE, Eco-LoE and IR on each site.

6.07.P-Mo388 Prioritisation of Tomorrow‘s Pollutants in Soils
Tatjana Schneckenburger[1]*, Thomas Gräff*[1]*, Lisa Noll*[2]*, Olivia Roithmeier*[1] *and* ***Pia Kotschik***[1]*, (1)German Environment Agency, Germany, (2)Pesticides Unit, German Environment Agency, Germany*
Soils provide 95% of our food and inhibit an enormous number of living organisms. However, soils underly multiple uses – half of Germany`s land is used for agricultural production, which is treated with pesticides to ensure good growth of cultivated crops. However, chemical inputs into soils may cause threat on soil functions like soil fertility, harm in-soil organisms and thus threat our food security and human health. The number of registered and used substances used as plant protection products in the EU and Germany is high and their impact on soils is hardly monitored. Usually, monitoring activities only focus on well-known substances, such as heavy metals. Recent monitoring studies show several residues of pesticides in soil samples. Whereby healthy soils are one goal described within the EU soil strategy as well as in the Sustainable Development Goals of the United Nations, a definition of a healthy soil is missing. However, proposals for the definition of soil health include also indicators for chemical pollution.
Guidance values for chemical pollution are urgently needed as soil pollution by chemicals may disturb soil functions, harm in-soil organisms, leach into groundwater, may be taken-up by plants serving as food source for humans and may also be taken up by humans directly. Therefore, it is important to get a deeper understanding of chemicals in soil, released via air or directly via the application of biosolids, fertilisers, plant-protection products, etc. The aim of this work is to identify candidates of organic substances used as plant protection products most harmful for in-soil organisms by a prioritisation concept. Here, we present the selection of relevant parameters describing potential harmful properties of active substances, based on their physical and chemical properties as well as ecotoxicological profiles.
Moreover, we introduce the results of our first theoretical approach based on a simple mathematical model with data available from various data bases. In the course of the European Soil Strategy and the revision of German Soil Legislation this concept is expected to be helpful in providing new insights into soil pollution and requirements for monitoring and regulation.

6.07.P-Mo389 Inventory Analysis of the Contamination of Agricultural Land with Biocides, Pharmaceuticals and Plant Protection Products in Germany

Pia Kotschik[1]*, Daniela Gildemeister, Marie Reppe*[1]*, Daniel Sättler*[1]*, Stephan Marahrens*[1]*, Karlheinz Weinfurtner*[3] *and Silvia Pieper*[1]*, (1)German Environment Agency, Germany, (2)IME Fraunhofer, Germany*

Agricultural soils in Germany are exposed to a variety of substances. However, the overall residue contamination situation is unknown. Several substances are applied directly or indirectly to soils and can accumulate there - depending on the respective soil and substance properties. Published studies on agricultural soil pollution in Germany are limited and often restricted to single (often well known) substances or substance groups.

Organisms living in such soils are exposed to numerous chemicals from different uses over a long period of time. However, the risk assessment for active substances of plant protection products (ppp), biocides and pharmaceuticals as well as industrial chemicals under the different European regulations does not consider multiple exposure of substances. In reality, substances under different regulations used within several products reach the soil, e.g.; by spraying series of different ppp, which are applied within one growing season (Knillmann et al, 2021). This has already been identified as one of the major deficits of the single substance assessment in the approval procedures of ppp (Topping et al., 2020; Frische et al., 2018), but is also common practice in the approval procedures of biocides and pharmaceuticals. So far, it is unclear to what extent multiple exposure is relevant in the field situation and whether neglecting the realistic exposure leads to an underestimation of resulting risks in the individual approval procedures of chemicals.

In 2021, a project funded by the German Environment Agency was initiated, with the aim of obtaining a first screening of the pollution level of agricultural soils in Germany together with the investigation of their biological conditions. Knowledge of the current contamination situation of agricultural soils is necessary to check the plausibility of models for regulatory substance approval. Moreover, current assumptions underlying risk assessment schemes for soil organisms can be checked against the situation in the field. An overview of the actual contamination situation in connection with a status survey of the soil organism community can therefore provide a valuable contribution to the further development of risk assessment of pharmaceuticals, biocides, ppp and industrial chemicals and could significantly influence approval decisions in the future. This poster summarizes results of the fist sampling period in spring 2022 in terms of chemical residues as well as biological parameters.

6.07.P-Mo390 A Conceptual Framework for Biomonitoring Plant Protection Product Residues in Soil

Jean Mathieu Renaud[1]*, Mireia Marti-Roura*[1]*, Sophie Campiche*[2]*, Gilda Federica Dell'Ambrogio*[1]*, Alena Tierbach*[1]*, Marion Junghans*[1] *and Benoit JD Ferrari*[3]*, (1)Swiss Centre for Applied Ecotoxicology, Switzerland, (2)Envibiosoil, Switzerland, (3)Ecotox Centre, Switzerland*

Plant protection products (PPP) are an extensively used tool to protect agricultural crops from pests. To avoid adverse effects of PPPs on non-target organisms, a prospective soil risk assessment is performed prior to their (re-)authorization, focusing on single active ingredients and their products and their effects on single species. Transient effects from which the communities can recover after a short period of time are accepted within the authorisation. So far, neither mixture effects from multiple applications nor potential indirect effects on soil communities are explicitly considered. Therefore, retrospective risk assessment of PPP, especially for long-term effects of PPP residues, to validate these assumptions is needed.

Since soil is a complex matrix, which affects PPPs bioavailability and organism’s fitness, the total soil concentrations of chemicals might not directly correlate to effects on soil organisms. To improve the retrospective risk assessment of PPP residues in soil, chemical and biological monitoring should be combined. Current approaches, such as the TRIAD method, designed for site specific risk assessment, can provide an important basis but needs to be adapted to fit a monitoring approach.

For the biomonitoring of PPP residues, a “deconstructed” TRIAD approach is proposed. Since it is not possible to do detailed biomonitoring at all agricultural sites, chemical analysis in combination with generic ecotoxicological risk-based reference values (Soil Guidance Values - SGV) could be used as a screening tool to identify sites potentially at risk. Sites potentially at risk are flagged for more detailed monitoring where, the generic SGV is refined based on specific site properties and ecotoxicological and ecological indicators are applied. Detailed monitoring should be conducted over multiple years (i.e. 5 years), to evaluate the long-term trends of PPP residues and their impact on soil fertility.

Finally, the long-term risk can be evaluated by combining data collected from chemical, ecological and ecotoxicological lines of evidence. The information generated can be used to evaluate and calibrate the bioindicator toolbox as well as the SGV values.

6.07.P-Mo391 Development of an Indicator to Reflect the Specificities of Habitat and Ecosystems in Chemical Risk Assessment

Sandrine Andres[1]*, Pia Kotschik*[2]*, Laure Malherbe*[3]*, Aurelien Carré*[4]*, Eldbjørg Sofie Heimstad*[5]*, Helene Lunder Halvorsen*[6]*, Mamadou-Bailo Balde*[3]*, Maja Nipen*[7]*, Gertie Arts*[8]*, Jeanne Vuaille*[9] *and Xenia Trier*[10]*, (1)INERIS, France, (2)German Environment Agency, Germany, (3)Ineris, France, (4)MNHN, France, (5)Norwegian Institute for Air Research (NILU), Norway, (6)Environmental Chemistry, Norwegian Institute for Air Research (NILU), Norway, (7)MILK, Norwegian Institute for Air Research (NILU), Norway, (8)Environmental Risk Assessment, Wageningen University & Research, Netherlands, (9)EEA, (10)European Environment Agency, Denmark*

Indicators are required to answer the very different needs coming from environmental policy, strategies and aims. This scoping study was conducted with the aim to develop an ecosystem indicator to support the assessment of the progress made in implementing the goals of the European Green Deal. In this scoping study, a methodology was designed reflect the consequences of chemical pressure on terrestrial ecosystems raised by human activities (*e.g.,* farming) taking into account different land use types like specific or protected habitats or intensively used areas such as agricultural landscapes,

In this conceptual study, our leading approach is based on the risk, which can be summarised as a combination of hazard (toxicity) and exposure, but we introduce the specificities of a given habitat for both farmed and natural areas, by applying a protection factor within an indicator. The study focuses on terrestrial ecosystems as an example, and identifies relevant methodologies and datasets related to chemical concentrations, their effects on ecosystems (habitats and species spatial distribution) to produce risk maps for chemicals that could be applied to various ecosystems.
The work conducted highlights the data required for the development of such an indicator and their public availability through a review of existing databases for occurrence and ecotoxicological effects of chemicals as well as habitats descriptors. A case study was developed using data that originate from regular monitoring surveys conducted in Czechia, which is taken as the study area. The indicator is successively applied to different terrestrial habitats based on laboratory data on surrogate plant soil organism species in combination with occurrence data related to residues of active ingredients from PPPs (45 monitoring points mostly in agricultural land). As a background layer, broad ecosystem types available from COPERNICUS High Resolution Layers, or more simplified mapping material, Corine Land Cover (CLC) 2018 Classes as well as The Agricultural Area Mask - a spatial reference layer aiming at achieving the best possible coverage of the Utilized Agricultural Area - were used for biodiversity and habitat information.
The case study illustrates the applicability of the indicator and the need for further development.

6.08 Passion for Pollinators: A Decade on the New EFSA Bee Guidance Document and Its Implementation for Pollinator Risk Assessment

6.08.P-Tu400 The New Bee Guidance: Using Equivalence Tests in Higher Tier Studies

***Ines Hotopp*[1]**, *Markus Persigehl[2] and Andrea Rossbach[2], (1)tier3 solutions, Germany, (2)Tier3 Solutions, Germany*
The proposed use of equivalence test instead of difference tests in the new draft guidance for the risk assessment of PPPs on bees is a sensible approach assuming an adverse effect as seen in the lower tier studies. Using the hypothesis that there is a risk as null hypothesis, places the burden to proof the opposite on the other side.
However, the use of equivalence tests as suggested by EFSA proves to be problematic.
Here, we compare equivalence and difference testing methods using a control dataset of a honeybee field effect study conducted in northern Germany in 2014. Half of the 48 colonies were assigned to a hypothetical test item – group and the colony strength data was analysed using t- tests, a Generalized Linear Mixed Model (GLMM) and the corresponding equivalence tests. The equivalence tests used a 10% equivalence limit and an alpha of 0.2 as suggested by EFSA. The precise calculation of the equivalence tests was designed to the best of our knowledge and understanding of the draft guidance.
The data reflects the natural variability of honeybee colonies, with initially about 15,000 adult bees. Whilst t-test and GLMM confirmed that 24+24 colonies are sufficient to show “no adverse effect”, the equivalence tests of t-test and GLMM were not able to reject the null hypothesis and classified at least some of the assessments as “high risk”, indicating a power that was too low. 24+24 colonies in combination with an equivalence limit of 10% are not able to proof that there is a “low risk” for an adverse effect. An increase of colony numbers in the same year increases the area covered by the study. Alternatively, the study could be conducted again in the next year. Both options possibly increase the natural variability and thus not increase the power of the study as intended, making it impossible to carry out studies that can be accepted by authorities.

6.08.P-Tu401 Understanding Frequency and Relevance of Non-additive Effects of Pesticide Mixtures to Honey Bees

Verena Taenzler[1], Ismael M Rodea-Palomares[2], Christian Maus[1], Markus Ebeling[1], Arnd Weyers[3], Steven L Levine[4], Zhenglei Gao[1], Daniel R Schmehl[2], ***Mark Miles*[5]** *and Ana R Cabrera[2], (1)Bayer AG - Crop Science Division, Germany, (2)Bayer AG - Crop Science Division, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany, (4)Regulatory Science, Bayer AG - Crop Science Division, (5)Bayer AG - Crop Science Division, United Kingdom*
The toxicity of pesticide mixtures to honey bees has been a concern for decades. When assessing effects of mixtures, the pharmacological principle of additivity defines default expected effects. However, deviations from additivity may occur, namely over-additive (synergistic) or under-additive (antagonistic) effects. Frequency and relevance of synergistic effects of pesticide combinations to pollinators is highly debated. Important considerations are how synergy is measured, and what level of deviation from additivity should be considered “synergy”. There is a lack of appropriate criteria for defining relevant deviations from additivity for bees, and a poor understanding of their frequency. To address these gaps, we investigated a large Bayer database of bee acute toxicity data for binary to quaternary insecticide and fungicide combinations. We computed additivity predictions for these combinations and compared them to the experimental values via Model Deviation Ratios. Moreover, we investigated a large dataset of bee toxicity data from the US EPA Knowledge Base to study the intrinsic testing variability and used this information to propose a numerical threshold to define relevant departures from additivity. Our findings suggest that most acute effects of pesticide combinations to bees can be well predicted by concentration addition, and that the prevalence of synergistic effects is low.

6.08.P-Tu402 Bees and Pesticides – Landscape Ecotoxicological Perspectives on Exposure, Effects, and Mitigation

Maj Rundlöf[1], ***Jessica Knapp*[2]***, Charlie Nicholson[1], Ove Jonsson[3], Clara Stuligross[4], Rosemary L Malfi[4] and Neal Williams[5], (1)Department of Biology, Lund University, Sweden, (2)Lund University, Sweden, (3)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (4)Department of Entomology and Nematology, University of California, (5)Department of Entomology and Nematology, University of California, Davis*
Agricultural use of approved pesticides results in bee exposure to a mixture of pesticides. However, we know less about 1) how this exposure and related risk vary among species and landscape contexts, 2) what the biological outcomes are for bee health in

agricultural landscapes or 3) if agricultural interventions could be used to mitigate potential effects. To explore these questions, we used two field site systems, one in Sweden (24 sites) and one in California (15 sites), covering gradients in agricultural land, and five bee species varying in foraging traits. We sampled pollen from all species and used the pesticide concentrations, weighed by toxicity and summed, to estimated pesticide-related risk, along with measurements of bee performance. We found that *Apis mellifera*, an extensive forager, experienced the highest pesticide-related risk that was independent of the landscape context. Two more limited foragers, *Bombus terrestris* and *Osmia bicornis*, experienced increasing pesticide risk with increasing agricultural land. However, pesticide risk was correlated among bee species. We also found that whilst flower plantings were a source of pesticide exposure, they increased *Osmia lignaria* nesting and mitigated pesticide-related reductions in *Bombus vosnesenskii* reproduction. These context dependencies bring the use of single model species, fields, and pesticide product-focus in the environmental risk assessment into question, but also possible roads for development.

6.08.T-01 Bee Guidance Document of EFSA, 2023

Csaba Szentes[1], *Pauline Iris Adriaanse*[2], *Andres Arce*[3], *Andreas Focks*[4], *Brecht Ingels*[5], *Daniela Jölli*[6], *Sébastien Lambin*[7], *Maj Rundlöf*[8], *Dirk Suessenbach*[9], *Domenica Auteri*[1], *Alessio Ippolito*[1], *Jacoba Wassenberg*[10], *Laura Padovani*[1], *Agnés Rortais*[1] *and Franco Maria Neri*[1], *(1)European Food Safety Authority, Italy, (2)Environmental Risk Assessment, Wageningen Environmental Research (WUR), Netherlands, (3)Ecology and Conservation Science University of Suffolk, United Kingdom, (4)Institute of Mathematics, University of Osnabrueck, Germany, (5)Federal Public Service Health, Food Chain Safety and Environment, Service Plant protection and Fertilising products, Belgium, (6)Austrian Agency for Health and Food Safety (AGES), Austria, (7)French Agency for Food, Environment and Occupational Health & Safety (ANSES), France, (8)Department of Biology, Lund University, Sweden, (9)German Environment Agency (UBA), Section IV 1.3 - Plant Protection Products, Germany, (10)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands*

The bee Guidance Document of the European Food Safety Authority (EFSA, 2013) has been reviewed by a Working Group and the new document is expected to be issued in spring 2023. Nearly all aspects, such us the characterisation of the exposure, the characterization of the hazard, as well as the lower- and higher tier risk assessments have been reviewed and updated applying innovative approaches and the best available knowledge. Specific aspects, such as assessing chemicals prone to time-reinforced toxicity, assessing sublethal effects, predicting the toxicity of mixtures (i.e. pesticide formulations with two active substances) or the risk from metabolites, were also reviewed. The methods, the used data and the data analysis are all transparently reported. The new document offers workable and detailed user-friendly guidance for the necessary risk assessments that fully respect all the agreed elements of the specific protection goals as set by the risk managers.

6.08.T-02 A Stakeholder's View on the Proposed Updated Regulatory Guidance for Bees in Europe: An Industry Perspective

Mark Miles, *Bayer AG - Crop Science Division, United Kingdom*

The European regulation of plant protection products (PPP) requires an evaluation of the risks to human health and the environment before the European Union level approval of active substances and national registration of formulated products (Reg (EU) 1107/2009). The risk to pollinators is evaluated in this context through a dedicated risk assessment guidance document and the European Food Safety Authority (EFSA) published a revised draft guidance for bees in July 2022 which incorporates many new features. The new draft revised guidance proposes a new risk assessment paradigm that enables a direct comparison of the outcome of the risk assessment calculation to the protection goals set by risk managers.

This presentation will review the main changes contained in this new EFSA guidance proposal in the light of the outcome of an impact analysis performed for a range of PPP and uses, and case studies conducted by industry to test the useability and outcomes of applying the new draft proposal to real-life risk assessment situations. The impact analysis was performed for a range of uses of typical PPP across the EU. In the screening assessment 114 active substances/products and 210 uses were included/ At tier I there were 101 active substances/products and 173 uses (spray applications only).

Based on mortality effects the screening and tier I risk assessments in the draft revised EFSA bee guidance (2022) appear to be more discriminatory for herbicides and fungicides than in the previous draft of 2013. The improved pass rate for these low toxicity compounds for honey bee risk may be attributed to more realistic food intake assumptions and a more realistic approach to chronic exposure and risk. However, the opposite appears to be the case for insecticides and the majority of insecticides may require extensive higher tier data packages, including field studies for which the guidance provided in EFSA 2022 is still not prescriptive enough to ensure the notifier can conduct a realistic and valid study and consequently many of the unresolved challenges of EFSA 2013 may still remain. Furthermore, the impact of time reinforced toxicity and sub lethal assessments for low toxicity compounds requires more evaluation using case studies (which will be provided in the presentation).

6.08.T-03 Sublethal Effects in Honey Bee Risk Assessment

Jacoba Wassenberg[1], *Andres Arce*[2], *Brecht Ingels*[3], *Daniela Jölli*[4] *and Csaba Szentes*[5], *(1)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands, (2)Ecology and Conservation Science University of Suffolk, United Kingdom, (3)Federal Public Service Health, Food Chain Safety and Environment, Service Plant protection and Fertilising products, Belgium, (4)Austrian Agency for Health and Food Safety (AGES), Austria, (5)European Food Safety Authority, Italy*

The lower tier risk assessment of plant protection products (PPP) for bees has historically been focused on lethal effects on adult bees and brood. However, a growing body of scientific research has shown the broad array of sublethal effects PPPs can have on bees which has resulted in calls to include sublethal effects in regulatory assessment. The new EFSA guidance document on the risk assessment of plant protection products on bees (EFSA, 2023) addresses this need by incorporating a subset of sublethal effects in the risk assessment for honey bees. While a large array of sublethal effects was found in a narrative review, very few of these effects had been studied according to harmonized guidelines, and a link to the SPG was not available. The EFSA Bee Working Group decided to focus primarily on a subset of sublethal effects in honey bees, in particular those that very obviously alter bee behaviour. The rationale for this is that large scale behavioural changes may interfere with important tasks, such as foraging, which would be expected to have a strong mechanistic link/relationship to colony strength. In the proposed tiered approach, existing data that is already collected in line with the legal data requirements is used as much as possible. Initially, mortality endpoints are used with an additional trigger to predict the no-effect level on foraging behaviour. In a second step, the behavioural observations in the standard laboratory tests on bees are used to calculate the no-effect level on behaviour. Guidance for specific refinement studies is presented, including laboratory and higher tier experiments.

6.08.T-04 Testing Chemicals for Time-reinforced Toxicity on Honeybees Based on GUTS Modelling

***Andreas Focks**[1], Alessio Ippolito[2] and Brecht Ingels[3], (1)Institute of Mathematics, University of Osnabrueck, Germany, (2)European Food Safety Authority, Italy, (3)Federal Public Service Health, Food Chain Safety and Environment, Service Plant protection and Fertilising products, Belgium*

A substance shows time-reinforced toxicity (TRT) when its toxic effects from exposure to low doses for a long period of time are higher compared to effects from exposure to higher doses for a short period of time (i.e. its toxic effects are reinforced by exposure time). This phenomenon was earlier also called ‘accumulative toxicity’. In the environmental risk assessment of chemicals, analyses are limited to studies assessing the effects from fixed exposure durations (acute and chronic). This approach is valid when toxicity is mainly dependent on the dose. However, in case of substances which show time-reinforced toxicity, the impact of low doses may be underestimated if the exposure period tested in the laboratory is shorter than the environmentally relevant length of exposure. In the new bee guidance document of EFSA, appropriate testing of TRT needs to be implemented. This study explores the use of applying the General Unified Threshold models of Survival (GUTS) framework for the assessment of TRT, with special emphasis on comparing the GUTS-RED-SD and -IT models with corresponding data. A number of data sets were analysed, and GUTS-RED-SD and -IT derived LDD_{50} values were compared with experimental observations. It turned out, that LDD_{50} values calculated directly from data for some substances clearly follow the dynamics of the GUTS-RED-IT model, whereas other substances follow the GUTS-RED-SD model. Some compounds show data in between IT and SD model-derived values. This shows the importance to always use both GUTS models and to compare with experimental data. conclusion, we are showing here the advantages of using a mechanistic model as GUTS in comparison to using statistical or empirical models like Haber’s rule. Using only statistical models for the derivation of LDD_{50} values for single time points results in increased uncertainties for later timepoints. Using Haber’s rule for such analyses is scientifically flawed, since under this rule the LDD_{50} of every compound would converge to zero, if the exposure duration would be long enough. The GUTS model has the advantage of “learning” TK and TD from all data points of a test at once, which makes the difference to statistical approaches who use only observations for single time points. Also, GUTS is superior concerning filtering between background mortality and chemical-induced mortality. The recent GUTS-based analyses will inform future strategies for discriminating substances with TRT properties.

6.08.P Passion for Pollinators: A Decade on the New EFSA Bee Guidance Document and Its Implementation for Pollinator Risk Assessment

6.08.P-Tu403 Developments in the Pollinator RA Following the New EFSA GD and ICPPR

***Helena Crosland**[1] and Gabriel Weyman[2], (1)Cambridge Environmental Assessments, United Kingdom, (2)Gabe Weyman Consulting, United Kingdom*

The 2013 European Food Safety Authority (EFSA) guidance on pollinator risk assessment remains un-Noted (i.e. is not officially sanctioned for use in the EU). In July 2022 the EFSA released a draft updated guidance on the risk of plant protection products to bees for public commenting. This allowed stakeholders to identify and comment on new features of the guidance and how they may impact on the pollinator risk assessment for pesticides. In addition, in October 2022 the 15th International Symposium on the Hazards of Pesticides to Bees (organized by the Bee Protection Group (BPG) of the International Commission for Plant-Pollinator Relationships (ICPPR)) was held in the UK. The revised guidance was a hot topic of the conference, which was attended (amongst others) by members of the European Commission (EC), EFSA, the EFSA Working Group on Bee Guidance Revision (WG); and the Organisation for Economic Co-operation and Development (OECD).

Both the public commenting period and the ICPPR conference have helped to clarify some areas of the pollinator risk assessment; however there remain some significant areas of uncertainty. This poster aims to summarize some key concerns raised in the public commenting period and the updates (if any) provided on these topics at the ICPPR conference. For example, the Time Reinforced Toxicity (TRT) assessment and potential impact of this (particularly for low-toxicity substances); the lack of a calculator tool; the state of currently available test guidelines compared to the requirements in the updated guidance document; and the risk assessment for non-*Apis* species. Generally, from the presentations and discussions at ICPPR, it seems that the commenting period succeeded in raising important areas of concern with EFSA and the WG (who intend to work further on some topics), but that the guidance document is unlikely to receive significant revisions before release (which may or may not occur before this poster is written and presented at SETAC EU 2022). The full impact of the revised guidance document on future pollinator risk assessments remains uncertain. We will summarise the certainties and uncertainties remaining by the time of the SETAC EU 2022 conference.

6.08.P-Tu404 Review of the Lower Tiers of the Succeeding Crop Exposure Scenario in the new Bee Guidance Document of EFSA, 2023

Laura Padovani[1] *and Csaba Szentes*[2]*, (1)Risk Assessment Production - Pesticides, European Food Safety Authority, Italy, (2)European Food Safety Authority, Italy*
In the succeeding crop scenario, bees are exposed to pollen and nectar contaminated with residues of a plant protection product (active ingredient and/or metabolites) that are already present in the soil following the treatment of the preceding crop. Residues accumulated in soil from the previous pesticide application might be taken up by the roots of the succeeding annual crop and then translocated via the vascular system to nectar and pollen. This may also happen for the permanent crop next year or for annual crops that are grown twice in a growing season on the same field ("double crops"). In practice, the succeeding crop is relevant when the use of a plant protection product on a primary crop has the potential to lead to the transfer of residues in succeeding crops via uptake from soil due to the characteristics of the compound (persistency and mobility in soil, transport mechanisms in the root zone). In the EFSA Guidance Document on the risk assessment of pesticides on bees (EFSA, 2013), the assessment of the succeeding crop scenario was required for all substances unless the DegT50 (half-life at 20°C and at a soil moisture content at field capacity) is less than 2 days for applications within the same year and 5 days for applications in different years. However, these triggers were later on criticized because almost all substances triggered the need for further assessments. Therefore, the Working Group tasked to review the bee Guidance Document of 2013, has decided to reconsider the lower tiers of the succeeding crop scenario by setting a screening level to identify those substances that would lead to an exposure level that will not cause adverse effects on bees for this scenario. Based on the available data and analysis, it was concluded that for the dietary route of exposure, the succeeding crop scenario cannot be excluded a priori but its relevance should be always considered during the problem formulation. However, for the annual "double crops" and for the permanent crops the following year, it was concluded that this scenario can be excluded based on specific combinations of soil persistence and soil adsorption properties of a substance with toxicity endpoints ≥ 0.1 µg/bee and at a given application rate.

6.08.P-Tu405 Field Studies on Pesticide Residues to Refine Exposure to Bees: Recommendations in the Bee Guidance Document of EFSA, 2023

Laura Padovani[1]*, Csaba Szentes*[2]*, Pauline Iris Adriaanse*[3]*, Jacoba Wassenberg*[4]*, Maj Rundlöf*[5] *and Alessio Ippolito*[2]*, (1)Risk Assessment Production - Pesticides, European Food Safety Authority, Italy, (2)European Food Safety Authority, Italy, (3)Environmental Risk Assessment, Wageningen Environmental Research (WUR), Netherlands, (4)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands, (5)Department of Biology, Lund University, Sweden*
Field studies on pesticides residues in pollen and nectar are used to refine the exposure assessment for bees in the EU regulatory context. However, to date, detailed and comprehensive technical guidance to ensure the practicality, reliability and validity of these studies is lacking. To prevent potential concerns about the defensibility of bee-relevant residue studies during the evaluation of the marketing authorisation, the new EFSA Guidance Document on the risk assessment of plant protection products on bees (EFSA, 2023) includes clear recommendations on exposure refinement for honey bees, specifically on the test principles, the experimental design, the field phase, the analytical phase and the assessment of residues decline in pollen and nectar. In particular, scientific and technical aspects of field studies aimed to measure residues in pollen and/or nectar have been provided to cover the spatial scale (i.e. the minimum number of sites required to refine the exposure assessment and how to select the locations where to conduct the field study), the temporal scale (e.g. the number of samples, the sampling intervals…), the crop selection and the sampling method. In addition, the regulatory community is unequivocally advised on the selection process for the RUD (Residue Unit Dose) values available from the higher tier studies and that can be used in the exposure assessment refinement. Some considerations on the field exposure studies for non-*Apis* bees are also provided.

6.08.P-Tu406 Higher Tier Studies on Pesticide Effects on Bees: Recommendations in the Bee Guidance Document of EFSA, 2023

Jacoba Wassenberg[1]*, Andres Arce*[2]*, Franco Maria Neri*[3]*, Maj Rundlöf*[4] *and Csaba Szentes*[3]*, (1)Board for the Authorisation of Plant Protection Products and Biocides, Netherlands, (2)Ecology and Conservation Science University of Suffolk, United Kingdom, (3)European Food Safety Authority, Italy, (4)Department of Biology, Lund University, Sweden*
EU legislation requires the application of a plant protection product to have no unacceptable effects on bees. In the new EFSA Guidance Document on the risk assessment of plant protection products on bees (EFSA, 2023), risks to honey bees, bumble bees and solitary bees have to be assessed separately. If concerns cannot be excluded in the lower tier risk assessment, which is based on laboratory effect studies, refinement is possible by studying the effects in a more realistic setting. EFSA (2023) provides a strategy for the three different bee groups that is based on the Specific Protection Goals set by the risk managers. Tests can be performed under confined or full-field conditions. Field tests, with bees freely foraging on a treated crop, are considered the highest tier. Feeding tests, in which spiked food is offered directly inside the colony, and cage tests are also included as less demanding options, albeit for a limited purpose for honey bees. EFSA (2023) includes specific recommendations on the test principles, the experimental design, exposure verification, the starting conditions of the test species, the duration of the tests, the endpoints and the statistical analysis.

6.08.P-Tu407 BEEHAVE - Analysing the Significance of Increased Brood Termination Rate on the Colony Strength in Honey Bees

Alexander Singer, Matthias A. Becher, ***Johannes Lückmann****, Oliver Jakoby, Marcus Metz and Daniel Ruf, RIFCON, Germany*
The brood termination rate (BTR) investigated in OECD GD 75 studies for pesticide risk assessments is the determinant of honey bee (*Apis mellifera* L.) mortality during development from egg to adult. However, it is questionable what an increase of the BTR means for the protection of honey bee colonies. The current EFSA Bee Guidance (2013) on pesticide risk assessment, indicates risk to honey bee colonies, if the overwintering colony size in late autumn drops below 5000 bees. Following this guidance,

previous work indicated potential risk to colonies only if high BTRs towards the end of the bee season occurred (e.g. caused by highly brood impacting reference compounds applied in August). In contrast, the updated Specific Protection Goal (SPG) for honey bees in the draft version of the revised EFSA Bee Guidance of July 2022 defines that a reduction in colony size of up to 10% at all time after pesticide application compared to control bee hives is acceptable.
Therefore, we investigated what the BTR means in terms of this novel risk definition (i.e. > 10% colony size reduction). Using the honey bee colony model BEEHAVE, we simulated colony dynamics following an increase in the BTR. Firstly, we estimated natural variability in colony size to understand if a 10% difference to control reliably can be measured in OECD GD 75 test settings. Secondly, we investigated the plasticity of a bee colony and its ability to recover from increased BTRs. Thirdly, we examined in a sensitivity analysis how BTRs of different magnitude and duration affect colony strength relatively to control bee hives. Our results show the consequences of an increased BTR for colony strength relative to control and sheds light on the impact of the suggested new risk definition in the draft guidance.

6.08.P-Tu408 Food Jelly, A Potential Source for Pesticides to Harm Honey Bee Larvae?
Silvio Erler, *Julius Kühn-Institute (JKI), Germany*
Honey bees are of public interest because of their pollination service, and production of honey, wax, and propolis. Further, they are considered as model organisms in pesticide risk assessment on pollinators. Previous studies have investigated residue analysis in different bee matrices like honey, bee bread or wax, and some in larval food jelly. We summarize the findings dealing with pesticide residues in all larval food jellies and elaborate factors influencing the pesticide occurrences as well as possible harmful risks for the larvae. It was demonstrated that residue analysis were mainly done in royal jelly, while only one study focused on residue detection in worker jelly. Overall 30 out of 176 pesticidal substances could be detected in a range of 0.15 to 3860 ppb. The experimental setup, respectively the exposure scenario, was the major factor influencing the pesticide occurrence. A comparison of the detected doses with available reference values from risk assessment on honey bee larvae, showed no lethal effects for larvae. The literature screening revealed that there are still missing information on pesticide degradation within different honey bee matrices, possible effects on larval physiology, contamination pathways and associated accumulation or dilution factors of contaminants.

6.08.P-Tu409 Bee Sensitivity Derived from Acute Contact Tests Biased by Standardised Protocols?
Jan Baas[1], Timm Knautz[2], Annika Barme[2], Tatsuya Sekine[2], Dick Belgers[3], Marcel Jaklowski[2], Marie-Claire Boerwinkel[4], Nina Jansen[5] and ***Ivo Roessink***[6]*, (1)Wageningen University & Research, Netherlands, (2)ibacon, Germany, (3)Team Environmental Risk Assessment, Wageningen Environmental Research, Netherlands, (4)Team of Environmental Risk Assessment, Wageningen Environmental Research, Netherlands, (5)Environmental Risk Assessment, Wageningen Environmental Research, Netherlands, (6)Wageningen Environmental Research, Netherlands*
For non Apis bees acute contact test results are the only source available for comparing the sensitivity of bees. However, these tests are carried out according to the honeybee test template: i.e., an assessment based on a 48-hour test, regardless of the size of the bee. In addition, the volume that is applied on the bee is standardized to a 1 µL droplet. Only the bumble bee is treated with a 2 µL droplet. This raises the question if this influences the outcome of the test, as relative surface area that is covered in a test strongly depends on the size of the bee. In our experiments two questions were addressed: does the droplet size affect the kinetics of the toxicant? And does the droplet size affect the sensitivity of the bee?
Therefore, an assessment was made on how much surface area is covered by using different droplet sizes and solvents for four species of bees (alfalfa leaf cutting bee, red mason bee, honeybee and bumble bee) and how this affects the observed effects. The tests on the covered surface areas were carried out with different droplet sizes with a coloring agent in either the solvent acetone or Triton X-100, both frequently used in acute contact tests. In addition, effect data were generated for the different droplet sizes and exposure to dimethoate. Effects were interpreted with recently developed Toxicokinetic Toxicodynamic (TKTD) BeeGUTS, allowing to separate the kinetics from the dynamics.
It showed that the sensitivity of the bees expressed as their threshold for effects was not affected by the droplet size. However, the kinetics appears to depend on the droplet size. In other words, the ‘effect clock’ ticks faster with increasing ‘relative’ droplet size. So, with the standard tests and an assessment based on the 48 hr. LD50 this would introduce an additional source of bias when testing a standard droplet size on differently sized bees.

6.08.P-Tu410 Improved Test Design for the Evaluation of Semi-Field Studies with Bumblebees (*Bombus terrestris*)
Markus Persigehl[1]*, Guido Sterk[2], Paraskevi Kolokytha[2] and Janna Hanegraaf[2], (1)Tier3 Solutions, Germany, (2)IPM Impact, Belgium*
The revised EFSA bee guidance document defines new requirements for the testing of bumblebees and solitary bees in higher tier semi-field and field studies. The colony strength or population size, as well as the reproductive output were set as Specific Protection Goal (SPG). However, the effect size could not yet be determined.
Between 2016 and 2017, the icppr non-*Apis* working group developed and tested a methodology for a bumblebee semi-field test which was based on endpoints used in honey bee semi-field studies (ring-test). The varying results showed that test methods and end points cannot easily be adopted from established semi-field tests for honey bees (OECD 75 and OEPP/EPPO 170). In particular, the colony assessment and most importantly the production of new queens could not be controlled sufficiently in the test.
Factors influencing the varying development and queen production could be the variability of commercially available bumblebee hives as well as the strong disturbance of colonies during intensive colony assessments during the field phase of the trial.

IPM Impact and tier3 solutions GmbH developed a test design for semi-field studies which reduces the variability between the colonies by using special maximal standardized R&D hives with the same colony size and age structure. It minimizes the impact on the natural development of the colonies and their reproductive success (forming of new queens) by using minimal invasive assessment methods during assessments as well as additional modification of hives.
This semi field test system fulfils the requirement for bumblebee semi-field studies in the revised bee guidance, such as colony strength and provides further reliable parameters.

6.08.P-Tu411 Oomen Studies –How To Find The Right Concentration To Test

Silvio Knaebe[1]*, Pierre Mack*[2]*, Sigrun Bocksch*[2] *and Sylviane Gony*[3]*, (1)Eurofins Ecotox, Germany, (2)EAS Ecotox, Germany, (3)Eurofins Agroscience Services Regulatory, France*

To protect pollinators from unwanted effects from pesticides there is a compulsory risk assessment necessary before a product can be registered for usage.
The risk assessment has a TIERed approach. First risk is calculated with values received in lab studies and default exposure predictions. In a second step exposure can be refined with nectar and pollen residue studies. If there is still risk calculated higher TIER studies can be run. The Oomen feeding study (Oomen et al., 1992, Lueckmann und Schmitzer, 2014, 2019) is the next higher TIER when a risk for brood is identified at lower TIER level, based on data obtained from the lab studies. It is a robust a reliable study design that exposes the brood and nurse bees directly to the pesticide via food.
In the study design bee hives are fed directly with sugar solution that is spiked with a formulated pesticide. In the original publication the proposal for the determination of the testing rate was the concentration in the spray solution recommended for field use. However, this is a very conservative approach and not really a risk refinement. Furthermore, there exist now several publications from regulatory agencies that estimate residue values in nectar and pollen as well as consumption rates of different life stages of honey bees. But there is no guidance from authorities on how to calculate feeding exposure rates and different national authorities might follow different approaches.
Based on information available in the most recent draft pollinator risk assessment guidance document from EFSA a more realistic concentration for feeding concentration for testing should be agreed upon. The treatment concentration should be based on a back calculation from the residue intake (Rint/PEQ) estimated for TIER 2 exposure estimation. In lack of TIER 2 exposure estimation, TIER1 exposure estimation might be considered. It is expected that in most of the cases, the higher of the 90th percentile nectar or pollen concentration should result in a sufficiently high test concentration (i.e. sufficiently high residue intake in the test) (EFSA 2022).
The poster will show a possibility to calculate feeding exposure rates from the guidance document and will give possibilities for refinement of TIER2 studies with available date from exposure studies.

6.08.P-Tu412 Semi-Field Test Design for the Leafcutter Bee *Megachile rotundata*

Julian Fricke[1]*, Ignacio Gimeno Rodrigo*[2]*, Olaf Klein*[1]*, Carmen Gimeno*[2] *and* ***Silvio Knaebe***[1]*, (1)Eurofins Ecotox, Germany, (2)Eurofins Trialcamp, Spain*

Solitary bees came into regulatory focus with the 2014 published draft guidance document for the risk assement of pollinators. Before, only honey bees were tested as a surrogate species. As a consequence, a semi-field test design with the red mason solitary bee *Osmia bicornis* L. was ringtested by the ICPPR non-Apis working group in 2016 and 2017. The result of the ringtests was presented and published by the ICPPR non-Apis working group with a recommendation for a semi-field test design in 2021.
With the knowledge on differences in exposure pathways between the solitary bee *Osmia bicornis* and leafcutter bees (e.g. *Megachile rotundata* F.), it is expected that the same plant protection products will impact those species differently. In addition, a higher sensitivity of Megachile species to selected plant protection products was estimated.
Since there is no established test design for solitary bee studies with *Megachile* so far, the main objective of the test was the methodological development of a standardised Tier II study semi-field design based on the recommended test design for *Osmia*.
In the leafcutter bee study design, bees (*Megachile rotundata* F.) were released as emerged adults in tunnels containing a bee attractive flowering alfalfa (*Medicago sativa* L.) in Spain and were exposed during their reproductive period. The semi-field tunnel study included a water treated control and a reference item (dimethoate) sprayed treatment. After the application of dimethoate, the bees collected all relevant nest and food items from the treated crop and were exposed via contact to the treatet Alfalfa. This included not only pollen and nectar but also treated leaves for nest building. The evaluated endpoints were the establishment of actively nesting females at the nesting units (nest occupation), observations of the flight activity in front of the nesting units and the production of brood cells.
The assessed endpoints were evaluated with respect to their potential for the use in the risk assessment of plant protection products. Results of this semi-field test will be presented and recommendations for the adaptation of the semi-field test design to an additional species will be given.

6.08.P-Tu413 Testing Methods for Honey Bees, Bumblebees and Solitary Bees in the Context of Pesticide Registration

Silvio Knaebe[1] *and Karen Liepold*[2]*, (1)Eurofins Ecotox, Germany, (2)Field, Eurofins Agroscience Service Ecotox, Germany*

Pollinators are an important organism group in general but especially in the agricultural landscape. They fulfil an ecological task that has been recognised since a long time. Pollinators belong to different orders of insects but there are also pollinating birds and mammals. However, across all pollinators, honey bees, bumble bees and solitary bees belonging to the order Hymenoptera are the most important group.
Regulatory authorities for Plant Protection Products (pesticides) require an assessment of the impact on the pollinating species. At present there is regulation in the European Union, North America, Brazil and Japan. The European regulation is being updated at

the moment to take into account the most recent scientific developments. Also, expert groups are active in updating the set of testing methods to be used in revised regulatory context.
The talk will provide state of the art of actual testing methods and their developments, linked to OECD, ICPPR and EPPO. It will also show endpoints used in the risk assessment.
Methods will address the honey bee (*Apis mellifera*) and will illustrate developments for some other species (*Bombus* spp. and selected examples of other solitary bees).

6.08.P-Tu414 Investigating Potential Effects of a Common Fungicide on Honey Bee Colonies Under Field Conditions When Applied According to Best Agricultural Practice in Flowering Oilseed Rape
Christof Schneider[1]*, Inka Marie Spyridonov*[1]*, Pernille Thorbek*[1]*, Alexander Schnurr*[2]*, Matthias Bergtold*[1]*, Sonja Braaker*[1] *and Martin Obermann*[1]*, (1)BASF SE, Germany, (2)Biochem agrar*
As an effective fungicide against multiple crop diseases and due to its low toxicity, both to adult and larval stages of honey bees, boscalid is used in a variety of crops incl. the flowering period in attractive crops like oilseed rape or almonds. This can lead to multiple potential exposure pathways for honey bees, both short term through contact exposure via overspray as well as medium or long-term via bee food items like pollen and nectar, which are stored as honey and bee bread. Thus, focus on boscalid and its effects on honey bees has increased in the past years. Despite the considerable amount of scientific research on potential effects of boscalid on honeybees, to our knowledge, no study has yet addressed potential effects of boscalid on colonies under realistic agricultural conditions. Therefore, our focus was on potential effects of boscalid, applied as the commercial solo-formulation CANTUS®, under field conditions according to best agricultural practice on flowering oilseed rape. Honey bee colonies were located at the edge of both untreated (UT) and treated (T) test fields for 45 days before being relocated to a monitoring site, where the colonies were overwintered until spring of the following year. Parameters measured were mortality, foraging activity, colony development, residue levels in pollen and nectar as well as overwintering success. While residue analyses confirmed exposure to boscalid in the colonies located at the treated fields, no adverse effects were observed in the T test group compared to the UT test group regarding mortality foraging activity, colony development, as well as overwintering success.
To our knowledge this is the first time that such an extensive study was conducted for a substance other than an insecticide and it confirms the low risk indicated based on standard laboratory studies.

6.08.P-Tu415 The Revised EFSA Bee Guidance in Practice: An Insecticide Case Study
Elizabeth Collison[1]*, Vincent Kramer*[2]*, Stefan Kimmel*[3] *and Ed Pilling*[4]*, (1)Corteva Agriscience, United Kingdom, (2)Corteva Agriscience, United States, (3)Corteva Agriscience, Germany, (4)Corteva Agriscience, United Kingdom*
The draft revised guidance on the risk assessment of plant protection products on bees (*Apis mellifera, Bombus* spp. and solitary bees) was published by the European Food Safety Authority (EFSA) for public consultation in July 2022. The proposed risk assessment methodologies in this revision are substantially different to those in the previous EFSA 2013 guidance document at all tiers and include some new schemes such as sublethal effects and time-reinforced toxicity assessments. Whilst the draft revised document presents some working example calculations for hypothetical substances and sensitivity/impact analyses for a very limited number of scenarios and elements of the proposed scheme, to the best of our knowledge there is as yet no case study for an active substance in which the full scope of the revised guidance is considered. Here, we will present a pollinator risk assessment for an EU representative open field use of the active substance sulfoxaflor according to the revised EFSA guidance published in 2022. This assessment will follow the proposed tiered approach and use existing laboratory and higher tier studies that have previously been submitted at EU level by Corteva Agriscience. We intend to compare the outcomes of the risk assessments conducted in accordance with the 2013 and 2022 EFSA guidance documents and, if relevant, identify any areas of the revised guidance that cannot be addressed based on the currently available data.

6.08.P-Tu416 Bees and Microbial Pest Control Products, Case Studies with *Bacillus thuringiensis* ssp. aizawai
Silvio Erler*, Julius Kühn-Institute, Germany*
Microbial pest control products are commonly applied worldwide as alternatives to avoid potential adverse effects of chemical plant protection products. These products are discussed as being highly species-specific, with no or only mild effects on non-target organisms. There is no information on potential interactions between microbial pest control products and bees' response after exposure to combinations or variable environmental conditions. We aimed to evaluate the biosafety of a commercial product containing *Bacillus thuringiensis* ssp. *aizawai* (strain ABTS-1857) using serval experiments with honey bees and other bees as non-target organisms.
Our approaches included 1) laboratory chronic exposure to evaluate the survival of adult and larval honey bees, 2) in-hive feeding under field conditions to examine the effect of *B. t.* on brood development and the core gut microbiome of adult honey bees, 3) semi-field colony-feeding to determine contamination levels of *B. t.* spores in various matrices, 4) a field trial with spray application in a bee-attractive crop to estimate potential environmental accumulation and exposure of honey bee colonies, and 5) laboratory exposure assays to evaluate bees after exposure to mixture of different microbials.
Adult bee and larval survival were negatively affected after chronic exposure depending on the tested concentrations; however, pollen feeding to adults promoted survival of treated bees and delay the effects. Under colony conditions, treated colonies showed a higher brood termination rate and a significantly lower normalized abundance of the core gut microbiome in worker bees. *B. t.* spores were detectable in all matrices at different concentrations, decreasing over time under semi-field conditions. High spore levels were present in honey sacs and pollen pellets immediately after application. No spore reduction was seen in stored matrices like nectar and bee bread. A mixture of *B. thuringiensis* ssp. *azawai* and *B. amyloliquefaciens* was identified to cause reduction in the lethal time compared to the solo-products.

In conclusion, the pest control product containing *B. t.* ssp. *aizawai* (strain ABTS-1857) showed a negative effect on exposed bees under laboratory as well as field conditions, for instance on colony development and caused dysbiosis of the gut microbiome. However, further field-realistic exposure studies in bee attractive crops are needed to evaluate the potential risk of such products on honey bees.

6.09.P Practical Implementation of the Essential-Use Concept Through Alternatives Assessment and Functional Substitution

6.09.P-Mo392 Data for Decision-making: Do REACH Applications for Authorisation Provide Sufficient and Relevant Information to Assess the Essentiality of a Use?
Flora Borchert[1]*, Romain Figuière*[2]*, Ian Cousins*[3]*, Silke Gabbert*[4]*, Christina Rudén*[3] *and Marlene Ågerstrand*[3]*, (1)ACES, Stockholm University, Sweden, (2)Department of Environmental science, Stockholm University, Sweden, (3)Stockholm University, Sweden, (4)National Institute for Public Health and the Environment (RIVM), Netherlands*
The European Commission's Chemicals Strategy for Sustainability stipulates investigating the integration of the so-called essential use concept (EUC) into existing EU chemical regulations, such as the REACH Authorisation which manages the continued use of substances of very high concern (SVHCs). The EUC aims to protect consumers, vulnerable groups and the natural environment from the most harmful chemicals by deciding if their continued use is necessary for health, safety or critical for the functioning of society, given there are no alternatives available that are acceptable from the standpoint of environment and health. A recent analysis by Figuière et al. (2022, under review) has shown that the EUC could be potentially integrated into the Authorisation procedure of the REACH Regulation because sufficient and relevant data are already demanded from companies that apply for authorisation of continue using an SVHC. These data comprise impact assessments on health, social aspects, the (wider) economy and society as a whole, given the guidance of the European Chemicals Agency (ECHA) is followed, and therefore provide information that is health- and safety-related and/or is connected to the functioning of society. Additionally, applicants need to assess alternative substances or techniques that reduce the overall risk to human health and the environment compared to using the respective SVHC. However, it is not known if the information provided in an application for authorisation (AfA) can be used in practice in an essential use assessment. Thus, the aims of this study are to (1) investigate if applicants for authorisation provide sufficient and relevant information that could be used to assess the essentiality of a use, and (2) identify potential gaps and challenges when applying the EUC to further suggest how this concept could fit in the REACH Authorisation procedure. Therefore, we currently analyse a pool of 140 AfAs based on pre-defined essential use criteria for data extraction. Our preliminary investigations suggest that applicants already provide relevant information for an essentiality assessment but that the scope of the overall assessment needs to be re-directed to justify a direct link between the specific function of a substance and its essentiality for health, safety and/or the functioning of society. Further, the hazards of alternatives are not sufficiently assessed to identify safer substitutes which might lead to regrettable substitutions.

6.09.P-Mo393 Analysing Outcomes of the Current Regulatory Processes under REACH and the Stockholm Convention: Implications for Implementing the "Essential-Use" Concept
Romain Figuière[1]*, Zhanyun Wang*[2] *and Ian Cousins*[3]*, (1)Department of Environmental science, Stockholm University, Sweden, (2)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (3)Stockholm University, Sweden*
The "essential-use" concept was first introduced in 1987 in the Montreal Protocol to phase out the use of ozone-depleting chlorofluorocarbons, except for certain "essential" uses. In the Chemical Strategy for Sustainability, the European Commission proposed to use the concept in the decision-making processes of restriction and authorisation under REACH, with the aim to render the processes more efficient and aligned with societal needs. Much work is ongoing to develop criteria for implementing the concept in the EU chemical regulations. This study aims to inform the ongoing EU work on the criteria for the essential-use concept by providing an analysis of existing outcomes of restriction under REACH and of the listing under the Stockholm Convention. This analysis evaluates how existing regulatory outcomes differ from the "essential-use" concept and determines the reasons for eventual discrepancies. To that aim, this study analyses the rationale behind existing restriction outcomes under REACH and under the Stockholm Convention to determine the main reasons justifying granting a specific derogation. The REACH restriction dossier on intentionally added microplastics and the listing of PFOA under the Stockholm Convention served as additional case studies to check whether, by using the same information as evaluated in the respective scientific committees, an outsider would reach the same conclusion when applying the "essential-use" concept. The results suggest that in the majority of the cases derogations were granted for practical and technical reasons. It is unlikely that the implementation of the essential-use concept would influence these situations. However, in some cases, derogations were granted because it was believed that the costs of phasing-out the substance of concern for the particular use were greater than the benefits, or because the emissions, exposure and/or risks from the use of the substance of concern were judged negligible. In those cases, it is likely that the implementation of the essential-use concept would influence the decision-making and thus affect the conclusions regarding derogations.

6.09.P-Mo394 Applying Quantitative Structure Use Relationships (QSURs) to Identify and Evaluate Functional Substitutes
Joel Tickner[1]*, Pamela Spencer*[2] *and Monika A. Roy*[3]*, (1)University of Massachusetts, Lowell, (2)ANGUS Chemical Company, (3)UMass Lowell*
Phillips et al. (2017) described Quantitative Structure Use Relationships (QSURs) as a tool that can "elucidate which features and properties of a chemical give rise to its function and identify chemicals with similar properties and features that could also fulfill that role." Similar to how predictive models in toxicology assessments are used to screen potentially safer alternatives, QSURs

can help expedite risk management decisions on chemicals, particularly when data may be limited. When combined with exposure models, they provide a critical tool for rapid screening of potential alternatives and to compare chemicals that serve a particular function.
The Essential-Use Concept is a developing policy approach that, when implemented, aims to expedite the phase-out of "non-essential" uses of chemicals not necessary for the "health, safety, or critical functioning of society". Here, QSURs may provide useful insights to efficiently support Essential-Use determinations by assessing whether safer functional substitutes exist and whether specific chemical functions or chemicals are indeed "essential". In this presentation, we introduce QSURs and their applicability in supporting functional substitution, both when chemical options exist, as well as in the stage-gate process for new chemicals development. We also outline potential benefits of their use when combined with other screening level data such as New Approach Methodologies (NAMs).

6.09.P-Mo395 Are Analysis of Alternative Methods Suitable for Poly- and Perfluoroalkyl Substances?
Rachel Lucy London[1]*, Juliane Glüge*[2] *and Martin Scheringer*[3]*, (1)Institute for Biogeochemistry and Pollutant Dynamics, ETH Zürich, Switzerland, (2)ETH Zürich, Switzerland, (3)Institute of Biogeochemistry and Pollutant Dynamics, Switzerland*
The upcoming European Poly- and Perfluoroalkyl Substances (PFAS) restriction is unprecedented in scope, thousands of substances will be covered. Many organisations and businesses are currently seeking alternatives to PFAS. When searching for alternatives to PFAS, hazard information about PFAS and about alternatives must be combined and a decision reached as to the most advantageous alternative. Are the current methods used to analyse chemical alternatives suitable for PFAS?
Over the past 40 years a number of Analysis of Alternative methods have been created. This includes decision-tree methods (e.g., Greenscreen, Cradle to Cradle), and weighted-sum methods (e.g., Multi Criteria Decision Analysis, Life Cycle Assessment, or Cost Benefit Analysis).
A decision-tree method and a weighted-sum method were investigated, with a particular interest in how these methods might be adapted to handle substances like PFAS. Hypothetical substance datasets and real substance datasets, from case studies in the scientific literature, were used to investigate the strengths and limitations of these methods.
The investigated methods showed considerable flexibility and there is also overlap between them. However, the ability to determine the acceptability of an alternative is not intrinsic to any method. Decision makers need to be aware of the decision rules and parameter settings that govern the application of these methods. Without appropriate awareness of decision rules to be employed as well as settings of method parameters, this flexibility can lead to unacceptable alternatives being erroneously categorised as acceptable. This poster concludes with recommendations as to the appropriate parameter settings to be used in these methods when they are applied to the analysis of chemical alternatives, and the analysis of chemical alternatives to PFAS in particular.

6.09.P-Mo396 Implementing the Essential Use Concept For Intentionally Added Microplastics in the EU
Stefano Amberg[1] *and Denise M Mitrano*[2]*, (1)ETH Zürich, Switzerland, (2)Environmental Systems Science, ETH Zürich, Switzerland*
Plastic pollution in the environment has been rapidly increasing for decades and the environmental impacts can be related to material size where macro-, micro (< 5mm) and nano (< 1mm) can have different fate, transport and biological interactions. Most microplastics originate from the degradation of plastic litter or release from normal use of polymer-containing materials (i.e., secondary microplastics), but microplastics are also intentionally added in a number of products (i.e., primary microplastics). While the reduction of secondary microplastics can be targeted through improved policies for mismanaged waste, other more targeted measures are needed that focus specifically on intentionally added microplastics. ECHA's proposed regulation of primary microplastics under REACH considers the wide variety of uses, physical and chemical properties, and applications collectively as a group. However, implementing the Essential Use Concept may help to balance environmental health, technical feasibility and innovation of new materials better than the currently proposed approach. Here we present a systematic framework of how microplastics could be categorized and regulated based on their use to stimulate innovation of more competitive and environmentally conscious materials. In some cases, substitutions are both politically and technically feasible. In other cases, substitutions may come with more uncertainty such as significant performance questions and monetary costs. A holistic and transdisciplinary alternatives assessment is therefore needed that considers microplastic risks and benefits in a particular use case as well as the existence, quality, costs, and hazards of replacement materials. This concept is illustrated by three case studies which reflect different tiers of essentiality; 1) microplastics use in rinse-off cosmetics, which score low on essentiality and have microplastic-free alternatives readily available, 2) microplastic infill material for artificial turf, which is debated in its level of essentiality and represents a complex substitution problem and 3) microplastic seed coatings, which are essential for agricultural productivity but still need to be replaced with more sustainable technologies. In all of these cases, the Essential Use Concept bridges the gap from the need to phase out risky materials to incentivizing informed decision-making towards sustainable and innovative alternatives.

6.09.P-Mo397 Managing PMT/vPvM Substances in Consumer Products through the Concepts of Essential Use and Functional Substitution: A Case-Study for Cosmetics
Joanke van Dijk[1]*, Romain Figuière*[2]*, Stefan C. Dekker*[3]*, Annemarie van Wezel*[4] *and Ian Cousins*[5]*, (1)Utrecht University, Copernicus Institute of Sustainable Development, Netherlands, (2)Department of Environmental science, Stockholm University, Sweden, (3)Environmental Sciences, Utrecht University, Copernicus Institute of Sustainable Development, Netherlands, (4)University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Netherlands, (5)Stockholm University, Sweden*
Measures are needed to protect water sources from substances that are mobile, persistent and toxic (PMT) or very persistent and

very mobile (vPvM). PMT/vPvM substances are currently used in a diverse range of applications, including consumer products. The combination of the concepts of essential use and functional substitution has been proposed as a method to phase out substances of concern and support the transition to safer and more sustainable chemicals, a key goal of the European Commission's Chemicals Strategy for Sustainability. The aim of this work was to explore the potential of these concepts to support the phase-out of PMT/vPvM substances from consumer products by taking cosmetic products as an example. In this work, the number and type of cosmetic products containing PMT/vPvM substances were identified. Results show that circa 6.2% of cosmetic products available on the European market contain PMT/vPvM substances. The product group containing PMT/vPvM substances most often were hair care products. Based on their high occurrence, Allura Red (CAS 25956-17-6), Benzophenone-4 (CAS 4065-45-6) and Climbazole (CAS 38083-17-9) were selected as case-studies chemicals for the assessment of alternatives and essentiality.
The framework used in this study allowed to identify uses of Allura Red which are believed to be not necessary for the performance of some cosmetic products. In these cases, the use was considered as non-essential and the chemical should be removed from the application. For other applications of Allura Red, as well as all applications of Climbazole and Benzophenone-4, the technical function of the chemical was necessary for the product performance. However, safer alternatives were identified for all case-study chemicals, making their uses substitutable and therefore also non-essential. Further work is needed to refine the framework, e.g. by evaluating and comparing the reliability of experimental and QSAR hazard data, and by consulting different stakeholders to select the most relevant hazard endpoints and better deal with potential trade-offs of alternatives. This work shows that alternative assessment is a core step to phase out hazardous substances via the essential-use concept. It is therefore key that alternative assessment methods combine hazards-based considerations with life-cycle impacts to prevent problem shifting and assure that chemicals are used both in a safe and sustainable manner.

6.10 Regulation of Contaminants of Emerging Concern: Are We Missing Something?

6.10.T-01 Critical Review of Frameworks for Screening and Risk Management of Chemicals and Advanced Materials

David W. Moore[1]*, Betsy Ruffle*[2]*, Sagar Thakali*[2]*, Andrew D McQueen*[3]*, Deborah E. Edwards*[4]*, Stacey P. Hopkins*[5] *and Trent A. Key*[5]*, (1)U.S. Army Corps of Engineers, (2)AECOM, (3)U.S. Army Engineer Research and Development Center, (4)NewFields, (5)Environmental Property and Solutions, ExxonMobil Global Services Company*

Regulatory programs and frameworks developed for the evaluation of safety and management of risks associated with chemicals and/or materials have evolved over the last half-century. Despite regulatory advancements, identification of new and emerging contaminants in the environment continues, suggesting a need for review of current approaches and strategies to better ensure safety of new chemicals and materials. To identify potential process improvements for facilitating early identification of potentially problematic substances and better inform risk management strategies, twelve existing frameworks relating to evaluation and management of chemical/material risk were reviewed. The selected frameworks represent a broad spectrum of regional, national, and international authorities and purposes, including pre-production evaluation of new substances, classification and hazard communication, identification of persistent pollutants, and identification of safer alternatives. Presentation will include an overview of commonalities and unique features for the reviewed frameworks and a summary of process improvement recommendations to enable more timely identification of potentially problematic substances. The conceptualized risk management framework based on these recommendations will also be presented.

6.10.T-02 Identifying Emerging Substances Gaps; A Prioritisation and Early Warning System for England

Kerry Sims, *Helen Wilkinson, Nathalie Tonge, Mark Sinton, Jonathan RAY Newman, Ian Martin and David Brown, Environment Agency (England), United Kingdom*

Reducing risks from a growing number of chemicals of emerging concern (CECs) is a recognised global challenge. The UK Government's 25-Year Environment Plan highlighted the need for early identification of CECs, so that effective intervention can be undertaken prior to damage being caused to the environment, wildlife, or human health. To address this chemical challenge, the Environment Agency (EA) have developed a Prioritisation and Early Warning System (PEWS) for England. The aim has been to establish a system which ensures appropriate regulatory focus on individual substances and groups of CECs. The PEWS process includes nomination and sifting of substances. Subsequently, substances are screened for potential risks to surface waters (freshwater and marine), groundwaters, soils, biota, and sediments and to human health via the environment. Screening is based on a suitable risk assessment, considering each substance in terms of readily available usage data, fate, toxicological parameters and environmental monitoring data. Screening CECs considers both exposure data (primarily based on EA monitoring data) and chemical hazard data. Screening is undertaken on batches of substances referred to as tranches. As of 2022, 215 individual substances have been screened in eight tranches. The limitations of a single substance approach to screening is recognised, so a group approach has also been adopted. Grouping approaches have been used on quaternary ammonium compounds, glycol ethers, linear alkylbenzene sulfonates, and retrospectively for science communication on neonicotinoids, pet flea and tick treatments, phenolic benzotriazoles, synthetic pyrethroids and flame retardants. The system concludes with chemicals being prioritised for environmental regulation where there is considered sufficient risk.
PEWS has demonstrated further monitoring requirements to clarify current environmental concentrations and increase certainty in prioritisation outputs. This presentation will describe the development and use of PEWS, illustrating some of the substances which have been screened for potential risks to date. It will also cover the links from PEWS to potential regulatory interventions where this process has been shown to be appropriate. PEWS has potential to be expanded to a UK-wide rather than England only system. There is opportunity to compare this approach to other decision-making frameworks utilised to prioritise regulation of CECs internationally.

6.10.T-03 Considerations for Developing Risk Assessment Approaches to Manage CECs and Agriculture: PFAS And Livestock

Jen Martin[1], *Antti Mikkonen*[2], *Greg Symmons*[1] *and Carolyn Brumley*[1], *(1)Arcadis Australia Pacific, Australia, (2)EPA Victoria, Australia*

Building resilience to climate change is a key driver for increasing use of recycled water and biosolids in agriculture settings. However, in 2019-2020 only 16% of wastewater in Victoria, Australia was recycled, with 84% discharged to oceans and waterways, in contrast approximately 87% of biosolids were land applied in agriculture settings.

Victoria has a significant peri-urban agriculture industry that provides a significant volume of the state's food produce and is expected to need to grow by 60% to meet population needs by 2050. In addition, Victoria may not have sufficient water supply to service its needs by 2028. Sourcing irrigation water from recycled water will have a significant impact on protecting key water needs.

The result is a need to balance domestic food production needs through access to recycled water and biosolids, with potential risks to the environment, human health and trade requirements. Emerging contaminants are challenging as their unique physico-chemical properties, toxicokinetic and toxicodynamic profiles and dynamic exposure pathways make development of proportionate regulatory frameworks difficult to establish. This is particularly the case when traditional approaches, that adopted aquatic or terrestrial ecosystem criteria, are not protective of agricultural objectives.

This presentation explores lessons learned from collaboration between research and regulatory organisations to support development of risk assessment and management frameworks for emerging contaminants in agricultural settings. Critical changes to standard approaches were necessary, enabling rapid adoption of research outputs to support regulatory actions. Key changes in approach included: 1) incorporation of detailed regional farming practice information to enable pragmatic advice; 2) development of dynamic livestock exposure models that capture physiological changes and seasonal factors that influence daily dose intake; 3) undertake serum measurement to identify and prioritize relevant PFAS; 4) early investment in species relevant toxicokinetic data (cattle, sheep) to support development of risk assessment and risk management frameworks; 5) early consideration of global trends for health-based guideline values to enable risk management frameworks that would be protective of future international trade needs. The learnings from this work are collated to reflect on unexpected findings and propose new approaches to addressing emerging contaminants in agricultural settings.

6.10.T-04 Long-term Monitoring And Environmental Specimen Banking in Support of Environmental Policy

Jan Koschorreck[1], *Annette Fliedner*[2], *Bernd Göckener*[2], *Alexander Badry*[1], *Anna-Lena Kronsbein*[1], *Kevin S. Jewell*[3], *Robin Schütz*[4] *and Henrik Krehenwinkel*[5], *(1)German Environment Agency, Germany, (2)Fraunhofer IME - Institute for Molecular Biology and Applied Ecology, Germany, (3)German Federal Institute of Hydrology, Germany, (4)University Duisburg-Essen, Germany, (5)University Trier, Germany*

Environmental monitoring data play a key role in the Zero Pollution Ambition of the European Green Deal, setting the pace for more sustainable environmental policies and acting as a watchdog for their success. The study highlights the potential of environmental specimen banks (ESBs) to support environmental and chemical policy. The highly standardized samples from the ESB archives can be used to assess the state of the environment and monitor temporal trends in environmental pollutants and ecological conditions. Retrospective trend assessment using modern methods of environmental analysis allow to reassess the evolution of ecosystem health over the past decades, to better understand its current state in this context, and to derive more meaningful predictions for its future evolution. Recent ESB studies demonstrate the effectiveness of chemical management of legacy PFAS, polybrominated diphenylethers, chloroparaffins and plasticizers. Moreover, temporal trends reveal the rise of substitutes such as short-chain perfluoroalkyl substances, non-phthalate plasticizers, and long-chain chlorinated paraffins. Non-Target Screening proves to be a powerful method to complement target analysis and characterise the spatial and historical trends of chemical mixtures in the ESB samples and to identify chemicals of emerging concern that were previously unknown or overlooked, e.g. fluorinated pharmaceuticals. Similarly, new genetic methods are applied to ESB samples to fill knowledge gaps about biodiversity changes in recent decades: Data on shifts in species communities are now becoming available through eDNA metabarcoding and metagenomics, while population genomic analyses within species are applied to detect microevolutionary changes in genomes. The genetic data pave the way for comparisons with data for chemicals and other environmental stressors measured in the same samples. The German ESB samples are available to innovative research ideas in support of environmental management and policies.

6.10.T-05 Towards a Zero Pollution Strategy for Contaminants of Emerging Concern in The Urban Water Cycle

Lian Lundy[1], *Jan Hofman*[2], *Leonard Oste*[3], *Luis David*[4], *Isabel Oller*[5], *Andreas Matzinger*[6] *and Andrea Rubini*[7], *(1)Lulea Technical University, Sweden, (2)University of Bath, United Kingdom, (3)Deltares, Netherlands, (4)Urban Water Unit, Laboratório Nacional de Engenharia Civil, Portugal, (5)CIEMAT, Spain, (6)Kompetenzzentrum Wasser, Germany, (7)Water Europe, Belgium*

A central component of the European Green Deal is the EU Action Plan 'Towards Zero Pollution for Air, Water and Soil' which sets out an ambitious strategy to achieve a Europe where pollution is reduced to concentration levels that are not harmful to human health and ecosystems by 2050. From a water perspective, particular concerns relate to contaminants of emerging concern (CECs), defined here as chemical and biological substances that are not regulated under existing EU water quality regulations but that have been identified as having a potential negative impact on human health and/or environmental endpoints. The development of comprehensive measures to address CECs requires a detailed understanding of their sources, pathways and fate within water environments. As a contribution to achieving this aim and supporting delivery of the zero pollution action plan, the

Water Europe Working Group on Zero Pollution has drawn together international expertise from research and practice to co-produce a series of recommendations for evidence-based policy development and co-identify knowledge gaps that currently hinder achievement of a zero pollution water environment. Use of a source-pathway-receptor approach led to identification of eight key topics which between them encompass a range of environmental, technical and social aspects including point and diffuse sources and pathways, treatment technologies, analytical techniques and governance. Each topic sets out a concise overview of the state-of-art which is used to address a key question from policy support and research needs perspectives. As an example, in relation to principal pathways and their quantification, policy recommendations relate to the development of regulations for all discharge streams (including urban runoff, combined sewer overflows and unplanned discharges), and knowledge gaps associated with stormwater pollution concentrations and volumes and use of online sensors are identified. Through adoption of a cross-sectoral collaborative approach, this opinion piece provides an integrated research and industry perspective on opportunities to enhance regulation. It is further anticipated that implementation of these policy recommendations can significantly contribute to achieving the EU's zero pollution objectives and UN Sustainable Development Goals (e.g. SDG 6 water and SDG 11 Healthy cities), with knowledge gaps forming the basis of a cross-sectoral CEC-mitigation research agenda.

6.10.P Regulation of Contaminants of Emerging Concern: Are We Missing Something?

6.10.P-Mo398 Post-Brexit UK Chemical Regulation and Policy - Does the Future Look Green?
***Lowenna Jones**, Politics and International Relations, University of Sheffield, United Kingdom*
On the 1st of January 2021, the United Kingdom (UK) formally exited the European Union (EU) and ceased to be subject to EU chemical regulation requirements. Prior to the UK's departure from the EU (i.e., Brexit), UK environmental policy and chemical regulation was largely controlled by a series of laws and commitments (i.e., regulation and directives) set out by the EU. The EU is often considered a leading regulatory state, however there is growing concern and scepticism amongst members of civil society, academia, and industry that current regulatory efforts are no longer fit for purpose. Brexit provides the UK government a unique opportunity to reflect on its regulatory policy, and reform its domestic legislation to ensure it is fit for the future. In its departure from the EU, the UK chose to abandon participation with EU regulatory regimes and institutions, instead opting for a narrative of deregulation and divergence. There are concerns that the UK is increasingly vulnerable to poor chemical regulation, and weak implementation, and enforcement. Not least due to the UK's historic reputation as the 'Dirty Man of Europe'. Through the review of relevant UK and EU documents related to the issue of chemical regulation and policy (published June 2016 - October 2022), this research attempts to understand the impact of Brexit on UK chemical regulation and policy. Evaluating whether the future of UK chemical regulation aligns with ambitions set by the EU, whilst highlighting areas where UK and EU chemical regulatory regimes have already begun to diverge. Standards and restrictions (in the UK) are already falling behind those of the EU. The comparative lack of regulatory capacity and resources to assess risk in the UK since its departure from the EU has resulted in the UK considering far fewer protective controls, hazardous substances, or restrictions than that of the EU. As the EU successfully develops and rolls out its own Chemical Strategy in line with the commitments made in its 'Green Deal for Europe' – the UK must decide if it wishes to align with the priorities and targets set by the EU or pave its own path. With divergence an inevitable consequence of two different legal regulatory regimes, the overwhelming concern is that the UK may become a dumping ground for chemicals that can no longer be produced or sold within the EU, whilst restricting trade and access to the European single market.

6.10.P-Mo399 Data Collection and Meta-Analysis on Plant Protection Products Occurrence in Soil at Worldwide Scale
***Shiva Sabzevari**[1] and Jakub Hofman[2], (1)Recetox, RECETOX, Masaryk University, Czech Republic, (2)RECETOX, Masaryk University, Czech Republic*
The usage of chemicals including Plant Protection Products (PPPs) as crop yield booster has been recognized as the most efficient way for decades. According to food and agriculture organization (FAO), average use of pesticides on croplands has been increasing in the world since 1990. As a result, it is essential to monitor and investigate the occurrence of PPPs in different environment compartments. Although soil is generally under severe influence by PPPs applied on the croplands, monitoring the PPPs' residues has been underestimated in this compartment. With focus on currently used pesticides, in this study the situation of PPPs occurrence in agricultural soil in the world was investigated. The data of soil monitoring and surveys of 72 studies published for 50 years (1971 to 2020) from 34 countries in Europe, Asia, Americas, and Africa was collected and unified into one data set. Result of the meta-analysis on 376 individual active substances (281 parental compounds and 106 transformation products) involved in the prepared data set showed that organophosphate pesticides were the main matter of investigation in the majority of the studies in comparison to other chemical groups such as triazines, pyrethroids, and triazoles. The highest number of compounds (56 compounds) addressed in majority of studies (58 studies) were fitting in organophosphate chemical class. Organophosphates also had the highest overall maximum residue concentration (273.8 $\mu g.kg^{-1}$). However, the overall detection frequency was higher for pyrethroids, equal to 37.4 %. Meta analysis at the active ingredient level revealed that mevinphos, diuron-desmonomethyl, esfenvalerate, and cyfluthrin were compounds with higher overall detection frequencies equal to 71, 69.9, 65.3, 62.7 % respectively. The results out of this meta-analysis are hoped to help clarification of the gaps in available data and actions needed toward regulations and official decisions on monitoring and screening PPPs in the soil around the world.

6.10.P-Mo400 What We Need to Know About Microplastics in the Environment
***Joris T.K. Quik**, Melvin Faber, Jeanine Ridder and Susanne Waaijers-van der Loop, National Institute for Public Health and the Environment (RIVM), Netherlands*
Microplastics are small plastic particles measuring less than 5 millimetres. They are found almost everywhere in the environment.

Laboratory experiments have shown that microplastics can have harmful effects on plants and animals, but it is not yet known whether these effects actually occur in the environment as well. This is partly due to wide variations in the shape, size and composition of the material. What is certain is that increasing amounts of microplastics end up in the environment. Solutions are needed to limit this and prevent harmful effects. More research into microplastics is crucial in this regard.
Many studies have already been done on microplastics, but there is no good overview of the findings. As a result, it is unclear what knowledge is lacking to come up with effective solutions. RIVM has therefore created an overview of the knowledge that is still needed in order to determine whether microplastics are harmful to the environment. This overview allows policymakers and other parties to make targeted choices regarding which research should be conducted first, for example to gain more insight into harmful effects. The results can then be used to better determine which measures are most effective.
RIVM spoke with university professors and experts for this study. They believe it is difficult to say which knowledge is needed first, because so much is still unknown. However, it is clear that the knowledge must be assessed in a cohesive manner in order to determine the harmful effects on the environment and develop effective solutions.
Information that is currently lacking for a proper environmental risk assessment includes how quickly microplastics break down in soil and water, and the differences per source in this regard. There is also insufficient data regarding the particle size and quantity at which microplastics are harmful. In addition to policy-based measures, attention must be paid to how behavioural change and innovation can reduce the amount of microplastics that end up in the environment.
In 2020, ZonMw drew up a knowledge agenda to gain a better understanding of the risks that microplastics pose to human health. Together with the present knowledge agenda, this highlights the areas where we need more knowledge about microplastics.

6.11 Risk Communication for Decision-Making: The Role of Community-Contact, Nature-Positive Outcomes, and Risk-Perception

6.11.P-Tu417 Indigenous Practices That Influence Waste Management: Case Studies of Bushbuckridge Local Municipality
***Siyabonga Madonsela**, Cape Peninsula University of Technology, South Africa*
The African continent, just like other developing continents, such as Latin America and Asia, are struggling to manage solid waste. This transpires amidst municipal limited budgets, lack of proper equipment as well as the poor infrastructure especially within marginalized indigenous rural communities. It is for this reason that amongst other reasons local authority grapples with waste management in rural communities of developing countries. However, in addition to these challenges the problem with many local governments of developing continents if not all is to solely focus on indigenized conventional waste management strategies as the panacea of all waste management solutions. This in the process, relegates the waste management knowledge system of the indigenous communities into the background. To this end, the current study sought to investigate the indigenous practices that influence waste management within Bushbuckridge Local Municipality, Mpumalanga Province, South Africa. Seven cases that would capture the spatial cultural diversity of indigenous communities across Bushbuckridge Local Municipality were selected for sampling. From the selected cases of indigenous communities, purposive non-probability sampling techniques were used to sample the groups of interest. Data was collected using the digital voice recording device. Data analysis was carried out using the thematic analysis approach. Whilst Microsoft Excel 2019 was used for data capturing and deriving simple descriptive statistics such as mean, statistically significant, and frequencies. Subsequently, charts, tables, and figures were derived and presented from Microsoft Excel 2019. Deductive and inductive logics were used in the interpretation of the study results. The results of the current study indicate that indigenous communities of Bushbuckridge Local municipality in the absence of formal waste management services from the local authority resort into Indigenous Knowledge system to manage solid waste stream. Taboos (71%), waste combustion (100%), animal feed (86%) and recycling (14%) are amongst some of the indigenous waste management practices espoused by BLM communities. The study argues that the sustainability accounting aspect of these BLM indigenous waste management practices is of paramount importance. Especially if these practices are to be merged into the sustainable integrated waste management strategies that informs the integrated development plans of the municipalities.

6.11.P-Tu418 From Microscopic Biodiversity and Micropollution workshop to Inclusive Citizen Science in the Basque Country
***Belen Gonzalez-Gaya**[1], Olatz Ortega-Vidales[2], Eider Bilbao[3], Oihane Diaz de cerio[3], Aitor Laza[2], Beñat Zaldibar[3], Mireia Irazola-Duñabeitia[3], Harkaitz Eguiraun[3], Jose Amigo[4] and Miren Bego Urrutia-Barandika[2], (1)ESTACI"N MARINA DE PLENTZIA. UPV/EHU, Spain, (2)Estacion Marina de Plentzia UPV/EHU, (3)University of the Basque Country (UPV/EHU), Spain, (4)University of Basque Country (UPV/EHU), Spain*
The Plentzia Marine Station of the University of the Basque Country presents a local citizen science and STEAM project entitled "**Attention! Don't step on me!**" which pursues two main objectives: i) to get people close to the beach and increase their knowledge about the microorganisms inhabiting it; and ii) to raise awareness about the need of caring about marine environment. For this last, it is expected that the participants will experimentally address visible pollution, mainly macro and microplastics. Targeted audience ranges from youngsters students to any potential beach user, particularly pointing to groups not frequent in citizen science or public consultancy activities regarding environmental issues (i.e. functional diversity groups, women, and underrepresented cultural minorities). The plan is to sample water and sand at their closest beach for analyzing **microplastics, meiofauna and plankton** using scientific based methodologies. Although rocky shores host rich macroscopic fauna and flora assemblages, making them appealing sites for marine biodiversity dissemination, their complex topography and slippery substrates makes them risky and hampers access. On the contrary, sandy shores provide friendly environments for most potential

audience, yet, they have been poorly explored for dissemination as their biodiversity is mainly microscopic. Specific workshops will be directed to the leaders of the participating groups (i.e. outdoor activities staff, group coordinators, volunteers, educators) and the sampling will be adapted for collectives with special requirements. In this way, we maximize the extent of the project focusing on the person in charge of the guidance of the group.
The main result will be the activation, motivation and approach of the participants to do science and especially those people who live in unfavorable conditions or belong to minority groups. Moreover, the outcome information (data and images) obtained will be organized on a database that will contribute to expand the knowledge about species inhabiting the ecosystems under study, as well as, the abundance of microplastics. This information will be available following the Open Access policy so it could be used in the future for decision-making policies in the Basque Country.

6.11.P-Tu419 The Future of Ocean Plastics: Designing Diverse Collaboration Frameworks
*Refilwe P Mofokeng[1], **Andrea Faltynkova**[2], Maria Bélén Alfonso[3], Inès Boujmil[4], Isabela de Carvalho[5], Kevin Lunzalu[6], Norlaila mohd Zanuri[7], Ebenezer S Nyadjro[8], Peter S Puskic[9], Dhugal Lindsay[10], Kathryn Willis[11], Tanveer Adyel[12], Catarina Serra-Gonçalves[13], Artur P Zolich[14], Thor Sandberg Eriksen[15], Henri-Count Evans[16], Daniela Gabriel[17], Sara Hajbane[18], Giuseppe Suaria[19] and Delphine Lobelle[20,21], (1)University of KwaZulu-Natal, South Africa, (2)Biology, Norwegian University of Science & Technology (NTNU), Norway, (3)Center for Ocean Plastic Studies, Kyushu University, Japan, (4)National Institute of Marine Sciences & Technologies, Tunisia, (5)University of São Paulo, Institute of Environment and Energy, Brazil, (6)University of California, (7)University Sains Malaysia, Centre for Marine and Coastal Studies (CEMACS), Malaysia, (8)Mississippi State University, (9)Institute for Marine and Antarctic Studies & Centre for Marine Socioecology, Australia, (10)Institute for Extra-cutting-edge Science and Technology Avant-garde Research (X-star), Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan, (11)Center for Marine Socioecology, University of Tasmania, Australia, (12)Monash University, Australia, (13)University of Tasmania, Institute for Marine and Antarctic Studies, The Centre for Marine Socioecology, Australia, (14)Norwegian University of Science & Technology (NTNU), Norway, (15)South African Institute for Aquatic Biodiversity, South Africa, (16)Department of Journalism and mass communication. University of Eswatini, Swaziland, (17)Research Center in Biodiversity and Genetic Resources (CIBIO), University of the Azores, Portugal, (18)University of Western Australia, Indian Ocean Marine Research Centre, Australia, (19)Institute of Marine Sciences - National Research Council, Italy, (20)Fugro, Leidschendam, Netherlands, (21)Utrecht University, Institute for Marine and Atmospheric Research, Netherlands*
Experts and workshop participants discussed their experiences in the collaborative development and implementation of ocean plastic pollution projects held worldwide, guided by three main questions: (i) What is the role of scientists in a multi-stakeholder project?; (ii) How should scientists communicate with other stakeholders?; and (iii) Which stakeholders are missing in collaborative projects and why are they missing? This multidisciplinary, co-learning approach highlights the value of stakeholder engagement for ocean plastic projects with an end goal to identify and implement ocean plastic solutions via innovative technologies, informing policy,
community engagement, or a combination of all three approaches. The target outcomes of the workshop described in this paper include the identification of transdisciplinary (academic-stakeholder) engagement frameworks and specific suggestions that can serve as guidelines for the development of future plastic pollution projects.

6.11.T-01 Holistic LCA of Impact and Benefit Assessment
***Mathilde Vlieg**[1], Delwyn Gloria Jones[2] and Rochelle Florence Bright[3], (1)Malaika LCT, Spain, (2)The Evah Institute, Ecquate, Australia, (3)University of New England, Australia*
Life Cycle Impact Assessment (LCIA) now only measures negative damages. Other sustainability methods that are gaining momentum are however also focused on bringing positive news about the sustainability benefits of products, services or buildings assessed. We have seen Cradle to Cradle, Blue Economy, and now Circular Economy and Nature Positive gaining momentum. Life Cycle Assessment (LCA) has half a century of experience in scientific calculation of sustainability impacts. It has been developed and standardized to a mature and scientific robust method that is been successfully used worldwide. Emerging positive sustainability assessment methods could benefit from the robust scientific background of LCA, and conversely LCA could incorporate assessing benefits into its methods.
Through illustration the authors compare various cohorts of benefit versus damage assessment methods. It then discusses case studies where both LCIA and Life Cycle Benefit Assessment (LCBA) results are used to assess the damages and benefits of project outcomes. The work demonstrates net damages as well as net benefits considering progress in development that is unstainable, sustainable and regenerative.
The paper shows that design preferences could differ when benefits are included versus when they are excluded. It also shows how benefits can be communicated in a transparent way alongside of damages, without the risk of double counting or greenwashing.

6.11.T-02 How to Manage and Confront with The Public Perception in Italian Sites in Contaminated by Per-and PolyFluoroalkyl Substances (PFAS)
***Stefano Polesello**, Water Research Institute - Italian National Research Council IRSA-CNR, Italy*
An environmental scientist can not avoid to face up with the real world, investigating and finding problems and communicate them to all the stakeholders, both authorities and citizens. The role of scientist in risk assessment and communication is central and can have a weight on the risk perception of the stakeholders. A realist approach, which takes into account uncertainty in risk assessment, can be appreciated by authorities leading to minimisation of the problems (with less expenses as a consequence) and even in the worst cases to negationism. On the other hand, a precautionary approach could be forced to an alarmist and even a

catastrophist view. As a practical example I would like to present the history of the drinking water pollution by Miteni Company, in Veneto Region which was discovered in 2013 by our research group during a survey of the PFAS levels in the main river basins in Italy. Overall, the contamination extended over an area of 930 km^2 located inside the Brenta-Bacchiglione river basin and involving three different Provinces (Vicenza, Padova and Verona).
As main scientific actors in the problem at the beginning we chose to act as a scientific consultant for local and national governments, minimising public communication in order to not interfere with the official communication. Since 2018, we intensified contacts and exchanges with stakeholders, environmental association and citizens and we realised that official communication/information toward citizens was very poor and the relationship with authorities and their consultants was seen mainly in a logic of contrast and opposition. How to go beyond this logic? We would like to show some examples from real problems risen in the contaminated areas which regards *a)* the risk connected with the food consumption in the contaminated area; *b)* the derivation of Emission Limit Values for PFAS in industrial and wastewater discharges; *c)* the emissions from plant for thermal reactivation or incineration of GAC used in drinking water and in negative hydraulic barriers.

6.11.T-03 Stakeholder Dialogue as Risk Management on a National Scale
***Katharina Halbach**, Janek Kubelt, Sue-Martina Starke, Ingo Warnke, Ines Flügel and Adolf Eisenträger, German Centre for Micropollutants, German Environment Agency, Germany*
A multi-year dialogue with stakeholders from industry, government, NGOs, water management and research has identified several tools to reduce the entry of micropollutants into water bodies in Germany. This process is currently further developed at the German Centre for Micropollutants which was established at the German Environment Agency (UBA). The main objective is to protect our inland water bodies and the raw water for drinking water production in cooperation with all concerned stakeholders. We will present two of our main tasks and evaluate their impact critically. 1. One main task is the assessment of the toxicological and ecotoxicological relevance of micropollutants. For the risk assessment, we apply the precautionary principle, i.e. we can classify micropollutants as “relevant” by concerning properties such as persistence, mobility or (eco)toxicity. We assess the micropollutants independent from the chemical`s registration. 2. Another main task is the engagement of communication between stakeholders affected by the relevant chemicals. The stakeholders are brought together in so-called "round tables", where all measures to reduce environmental pollution are "put on the table" and discussed with focus on an extended producer responsibility.
Round tables discussing reducing measures for X-ray contrast agents, diclofenac and benzotriazole are finished. Several projects and awareness campaigns resulted from these. As an example, projects implementing the use of urinary collecting systems in Germany coupled with monitoring studies have started to reduce the inputs of X-ray contrast agents to water bodies.
Which criteria are useful to implement a round table for a micropollutant and which measures are realistically put on the table by the stakeholders? We will present the evaluation of the tool and how we are going to use it in the future.
We present a national effort to further reduce the entry of micropollutants in the water bodies and enhance the quality of drinking and surface waters. As it is, so far, a national process, it is important that information is available on the entry pathways in order to evaluate whether national efforts are promising. Our national process is a component between German, European legislation and future European strategies, e.g. Zero Pollution Action Plan, One Substance One Assessment. When being successful tools such as the round table may also be used at a European level.

6.11.T-04 NaturePositive+ Ecolabelling & Transparency Reporting
*David Baggs[1] and **Delwyn Gloria Jones**[2], (1)CEO, Global GreenTag International, Australia, (2)The Evah Institute, Australia*
The needs to pull back from the brink of climate and biodiversity climate tipping points that society, the planet, and nature kingdoms face today are too terrible to fully countenance. The Global GreenTag International (GGTI) Certification Scheme under an ISO 19001 Certified Quality Management System has developed and launched a NaturePositive$^+$ Declaration (NP$^+$D) ecolabelling and transparency reporting program. The authors hope stakeholders find this work useful as manufacturers may apply each of the intrinsic NP$^+$D assessments and metrics individually as a progressive rung on the ‘ladder of progress’ or achieving them together to move to and past net-zero carbon toward holistic Nature Positive outcomes.
GGTI has Certification Mark approvals in US, Canada, NZ and South Africa and via Australian Competition and Consumer Commission approval and registration in Australia. It is an externally verified ISO 14024 compliant 3rd Party Type 1 Ecolabel certification scheme, ISO 14025 Type III Environmental Product Declaration Program Operator and is an externally verified ISO 17065 compliant Conformance Assessment Body. GGTI programs are recognised by major rating tools in 172+ countries.
The new NP$^+$D product certifications and transparency declarations go beyond current thinking on circular economy, risk mitigation, ethical supply chain transparency, ingredient and product hazards and life cycle analysis (LCA). They report climate and biodiversity outcomes of restoring, regenerating, conserving and protecting ‘Natural and Technical Nutrient Cycles’ [10] and identify a pathway to nature positive product outcomes. GGTI has identified shortcomings in current approaches to these issues and developed NP$^+$Ds as a solution for industry uptake. No other single certification yet provides the ease, scope, accuracy and depth of transparency also focused on changing real world outcomes towards Nature Positive.
The NP$^+$D aims to provide markets with concepts and a solution to quantify both natural and technical cycles’ full scope and benefits as no certification has before as depicted in Figure 1. It adapts and integrates available metrics to provide one NP$^+$D score for products, individual measures per issue with transparent reporting on: a. Human Health & Environmental Toxicity; b. Circular Resource Flows; c. Life cycle impacts and benefits; d. Ethical Supply Chains & Modern Slavery.

6.11.P Risk Communication for Decision-Making: The Role of Community-Contact, Nature-Positive Outcomes, and Risk-Perception

6.11.P-Tu420 Communicating Evidence of Positive Outcomes

Delwyn Gloria Jones[1] *and Mathilde Vlieg*[2]*, (1)The Evah Institute, Australia, (2)Malaika LCT, Spain*

The UN Nature Positive Program provides a global impetus for regeneration. Scientific messages and media about accelerating anthropogenic climate change and biodiversity loss have had wide responses. Prevailing reactions, however include bad news, greenwash, disinformation and community indecision. Reports indicate the populace tuning out in confusion and inaction. Apparently, environmental science lacks the communication skills to support sufficient popular regenerative actions globally at grass-roots levels. If so, nature-positive policy and planning needs extended sightlines beyond zero damage to integrated benefits and net-gains.

The aim is to clarify qualitative concepts and challenges then review quantitative methods and case studies illustrating core scientific nature-positive numeracy and literacy to quantify security and viability. Life Cycle Benefit Assessment (LCBA) to model climate security, community wellness and supply viability gains is used alongside Life Cycle Impact Assessment (LCIA) modelling damage and loss

Results are shown of one biomass feedstock diverter case study's results cradle to grave. This commercial kitchen undersink grease diverter system separates and removes fat, oil and grease used to make biodiesel. Compared to no diverter there was one overall net gain and five benefits from reducing damages.

It is one example of how LCA can be more balanced by supplementing LCIA with LCBA to model security in climate, wellness, biodiversity and supply. The paper reviews other climate and biodiversity studies to illustrate net-positive recycled and renewable systems for products buildings, infrastructure and cities.

Whilst conventional environmental science and LCA has a negative bias it disempowers more effective communications and created barriers for nature-positive initiatives. LCBA offers community, government and business a new environmental science tool to measure gains in accelerating restoration and climate security.

Reaching to show gains well beyond zero loss enables a good news focus and truer market assessments. This reach offers hope to inspire wider public action knowing that only huge gains can restore planetary controls.

The authors recommend other environmental sciences extend the reach of allied concepts, tools and numeracy to yield positive messages. Capacity to report positive metrics can also reduce greenwashing prevalent bad news.

6.11.P-Tu421 Environmental Communication: Different Channels Different Level of Pro-environmental Behaviours?

Renata Dagiliute and ***Diana Miškelytė****, Vytautas Magnus University, Lithuania*

The role of final consumers for reaching different environmental policy targets is crucial. Therefore, awareness rising and fostering pro-environmental behaviours is of importance. However, there is a variety of communication channels for environmental information, which can influence the activities undertaken. The study aims to analyse the influence of different environmental communication channels on pro-environmental behaviours indicated by EU citizens. Analysis is based on Eurobarometer survey conducted in 2020 and covering all EU member states of that time. Results reveal that television news remain the dominant source of environmental information (69.3%), followed by internet sources (36.7%) and newspapers (29.1%). Social networks are the source of information for some 18% EU citizens. Only 1.9% of respondents indicated museums, national or regional parks to be a source of environmental information. On the average respondents perform 4.2 of 14 analysed pro-environmental behaviours. Though scientific literature is the source of environmental information only for some 6.8% EU citizens, regression analysis indicate that books or scientific papers contribute to the number of actions performed most significantly. Second most significant source of information contributing to more pro-environmental action taken is internet sources (websites, blogs, forums), followed by newspapers and films and documentaries on television. Those who indicated books and scientific literature as a source of environmental information on average performed 5.9 activities, to compare to 4.8 activities of those receiving information from internet and 4.7 activities then information is received from the newspapers. Hence, preliminary results suggest that despite all sources might be of importance for environmental information provision, less employed ones should be promoted and used to raise awareness on environmental issues and corresponding behaviours.

6.11.P-Tu422 Conveying Impact and Benefits of Recycled Sand

Direshni Naiker[1]*,* ***Delwyn Gloria Jones***[2] *and Mathilde Vlieg*[3]*, (1)Gaia Conscious Consulting, South Africa, (2)The Evah Institute, Ecquate, Australia, (3)Malaika LCT, Spain*

This case study compares uncontrolled quarried river sand versus post-consumer recycled sand near Johannesburg. Results show net damages and benefits considering development in a biodiversity-rich nation. The aim is to show how environmental net-damage and net-benefit can be measured and communicated.

Uncontrolled quarrying gouges riverbanks, erodes soil, silts rivers, oil-pollutes water, disturbs aquatic habitat and downstream ecosystems and heavy vehicles crush vegetation. To produce re-usable fine sand uncontaminated building rubble comprising broken bricks and excavated soil is crushed on site. The functional unit is 60 years use building sand/m^3 filler cradle to grave for e g. bricks, concrete or asphalt.

Methods include Life Cycle Impact Assessment (LCIA) of damage and loss and Life Cycle Benefit Assessment (LCBA) of benefit and gain. LCIA models loss of human health, ecosystems and resource accessibility due to pollution, climate change and land use change that deplete biodiversity, freshwater, minerals and fossil fuels. LCBA models security of human wellness, climate, ecosystems and resource supply, and land regeneration that repletes biodiversity, freshwater, mineral and fossil feedstock.

Table 1 shows biodiversity and climate damages and benefits of use of post-consumer recycled (PCR) sand compared to avoided quarried sand to 100-year horizons.

PCR product has benefits and losses. Its most significant biodiversity and climate security benefits outweigh other losses avoidable by reliance on renewable fuels. Other urban space, social and safety benefits arise.
A case study of damages and benefits of PCR sand use was demonstrated using the LCBA alongside LCIA. Comparing damage versus benefit can reveal net-losses and net-gains. The work demonstrates measurement and messaging essential to move from unstainable to regenerative and sustainable development.

6.11.P-Tu423 North Breton Island Reconstruction: An Example of a Successful Coastal Engineering and Natural Resource Restoration Project
***Lawrence Malizzi**, Ramboll*
North Breton Island is being restored under a contract to the U.S. Fish & Wildlife Service (USFWS) as part of the Deepwater Horizon Oil Spill Natural Resource Damage Assessment and Restoration (NRDAR) process. The project scope included permitting, investigation, construction design, planning, and construction implementation.   is project is within the Breton National Wildlife Refuge (BNWR). Th design restored beach, dune, and back-barrier marsh habitats within the island platform's footprint to support breeding birds, including brown pelicans, terns, skimmers, and gulls. The oject team collected, compiled, analyzed, and managed topographic, bathymetric, sub-bottom, and magnetometer data of the island and the target borrow area and associated conveyance corridors, access channels, and project fill areas, as well as, sediment transport/velocity studies and impacts from recent hurricanes. The te also completed geotechnical, environmental, and cultural resource investigations in the target borrow area and within the project fill area and developing strategies to resolve potential conflicts with land rights, oyster leases, and oil and gas infrastructure. North Br on Island construction design included; approximately 76.2 acres (16,000 linear feet) of beach, 138.7 acres of dune, 137.3 acres of back barrier marsh habitat, a total island width of 1,100 feet, bounded by sloped foreshore and back barrier marsh platforms, an elevated dune platform of 8 to 10 ft. above sea level (optimum elevation to be determined through engineering and design) by 400 ft. wide at the base and 100 ft. wide at the top, a gulf-side beach 3 feet above sea level by 200 ft. wide, a landward back barrier marsh platform approximately 3 ft. above sea level and 500 ft. wide, and a targeted borrow area of approximately 677 acres. The construction of North Breton Island was completed in the beginning of 2022. Despite setbacks due to very active 2020/21 hurricane seasons. The General Macarthur dredge, owned by Callan Marine, pumped over 2.5 million CY of sand onto the Island. On a typical day, a crew of 40 to 50 people kept the dredge pumping around the clock and spread sand around the island using heavy earth moving equipment. In April 2021, Brown Pelicans began to nest in the Northern portion of the Island and are now nesting across the entire island. Communicating the success of the project is important to build consensus for similar projects in the future.

6.11.P-Tu424 The Urgent Need for Nature-Positive Words, Ways and Weights
***Rochelle Florence Bright**, University of New England, Australia*
The ability of environmental scientists to engage, educate and inspire the general public will determine whether the world reaches the United Nations' goal of nature-positive by 2030. SETAC's advisory group on Science and Risk Communication (SCIRIC) alludes to an absence of public trust in environmental communications, and the media's focus on "disasters". They ask "Is it possible to to tell positive stories and still show the relevance of our topics?"
This paper argues that it is difficult to tell positive stories when environmental measures and outcomes continue to be framed in negative language. Studies in communication across numerous fields highlight that while talk of disaster, or loss-framed messaging, might immediately get an audience's attention, it is positive communication of real benefits and gains that leads to action. Positive framing of potential and delivered benefits highlights what is possible, promotes autonomy, and fosters sustained engagement, all of which are fundamental to successful behaviour change.
A nature-positive goal therefore requires a nature-positive language, spoken by those who walk their talk. To claim their position as key climate change influencers, scientists, policy makers, and corporations must stop focusing on damages and improvement expressed as less worse outcomes, exemplified in Life Cycle Inventory Analysis (LCIA) vocabulary. Nature-positive language grounded in Life Cycle Benefit Analysis (LCBA) offers a way to translate scientific research, government policy, and corporate climate action into genuine, measurable gains for the planet and people.

6.11.P-Tu425 Behaviour Test With Earthworms as an Additional Tool in Environmental Education About Soil Pollution Impacts For High School and University Students
*Ondina Ribeiro[1], Mateus Machanguana[2], Cláudia Rubio[2], **Cláudia Ribeiro**[3] and João Soares Carola[4], (1)UTAD, Portugal, (2)School of Life Sciences and Environment, University of Trás-os-Montes and Alto Douro (UTAD), Portugal, (3)Rua central de Gandra, Portugal, (4)CITAB, Portugal*
Environmental pollution caused by human activities can affected the soil and its physical and chemical properties disturbing soil biodiversity and ecosystem functionsThus, the issue of soil pollution must be integrated as part of environmental education in high school but also in university students using hand on approach to increase interaction with students and engagement. Environmental education becomes important for students' reflection on environmental issues. Thus, this work aimed to involve students in environmental issues by giving basic theorical concepts and practical component conducting a simple behavioural test with earthworms (*Eisenia fetida*) in lead-contaminated soil as an opportunity to real experience, improving kinesthetics learning. The students carry out the behaviour test, selecting 10 adult earthworms to place in a test container with two sections, one with a control soil and the other with a contaminated soil with different concentrations of lead (5, 50 and 500 mg/kg) with 3 replicates. After 48 hours, the students counted the number of in each section of container and the avoidance behaviour was determined. With this behavioural test, students were able to contact in a more direct way to soil pollution and its effects on terrestrial organisms, and also about lead concern for wildlife and Humans, namely kids and food webs. After 48 hours of exposure, an

avoidance behaviour of earthworms was observed for the highest concentration of lead (500 mg/kg). Almost all the organisms (9 in 10) were in the control soil with an avoidance percentage of 90%.
In conclusion, students learn theoretical concept related to soil pollution and hand on approach to assess lead effects. Students feedback show that the increase knowledge about soil conservation importance in food webs, ecosystem services, superficial water and groundwater quality. At the end they show better understanding about the direct and indirect impacts of soil pollution in wildlife and on human health. More work will be implemented to used questionaries' to assess better the knowledge improvement before and after the task, including in future same task for younger students.

6.11.P-Tu426 Pesticides and Their Metabolites in European Surface and Groundwater: Understanding Interacting Regulations and Approaches to Environmental Monitoring

*Gregory Hughes[1], **Mahmood Al Ramahi**[2], Simon Mayer[3] and Adrian Simon Terry[4], (1)GeoSpatial Analytics, United Kingdom, (2)Crop Science Division, Bayer AG - Crop Science Division, Germany, (3)Bayer AG - Crop Science Division, Germany, (4)Cambridge Environmental Assessments, United Kingdom*

Regulation designed to protect the environment and consumers is constantly evolving. This is driven by the need to consider new scientific knowledge as well as the desire for increased harmonization between different regulations. While the latter has the potential to simplify some aspects of regulatory requirements it also potentially leads to additional complexity, data requirements, and issues of interpretation.
One such area is environmental quality assessment utilizing environmental monitoring data. Interpretation of such data should be based on scientifically robust environmental quality standards to avoid incorrect conclusions and sub-optimal risk management decisions. However, defining substance specific quality standards or water treatment removal efficiencies requires additional effort as does ensuring they are applied in the correct situation, like only at drinking water abstraction locations which requires knowledge of where these are. This may lead to simplifying assumptions being made by regulatory agencies seeking to follow the guidance. While overly precautionary assessments based on simplification may be expedient and ultimately protective of the environment, they may have additional consequences like the withdrawal of economically important products with favorable risk-benefit profiles or the costs of continued monitoring for low risk substances.
This poster seeks to produce a synthesis of these interacting EU Directives assessing environmental monitoring data and the quality standards or regulatory thresholds they require to do so. In addition, the data required and guidance available to define these endpoints, the monitoring data and summaries to which they should be applied, and their intended use will be considered. Gaps in available data and guidance to ensure consistent compliance assessment under these regulations will be highlighted. Recent developments like the proposed harmonized monitoring guidelines (SANTE 2020/12830) as well as revision of the Drinking Water Directive which, amongst other objectives, refocuses considerations of compliance to raw water alongside that of the tap of the consumer requiring the collection of data that identifies abstraction points as well as their source catchments will be factored in. It will also consider upcoming developments such as the proposed revision of the Water Framework, Groundwater and Environmental Quality Standards Directives.

6.11.P-Tu427 Risk Management of Plant Protection Products: The Role of Farmers as Decision Makers on Site

***Jonas Schartner**[1], Balthasar Smith[1], Zvonimir Perić[2], Jörn Strassemeyer[2] and Burkhard Golla[2], (1)Federal Office of Consumer Protection and Food Safety, Germany, (2)Julius Kühn-Institute Federal Research Centre for Cultivated Plants (JKI), Germany*

Data-based decision-making processes are not only crucial in the context of risk assessment of plant protection products, but also offer enormous potential in the context of risk management. When deciding on the authorisation of a plant protection product, it must be ensured that the conditions imposed with the authorisation for the protection of the environment can be complied with a high degree of certainty and in a controllable manner. Improved data bases on local conditions that are available across the board can make the risk management mentioned much more efficient and target-oriented. At present, farmers have few options when it comes to implementing risk reduction measures. Ideally, the farmer on site should be enabled to make flexible and appropriate decisions on the use of risk reduction measures with the help of suitable support systems.
This poster presentation examines the common existing risk mitigation measures and the variables they contain that are based on factors in the field. Georeferenced data will be used to model the best possible representation of real field conditions. Emphasis will be placed on processing LiDAR data containing high resolution 3D information. The goal is to capture both the location and shape metrics of non-target areas of Plant Protection Products (PPP) applications (such as hedges, field margins and edges of embankment). In addition to the method, results for specific regions with data availability are presented. The derived information is provided at the end to best assist the farmer via online tools and web services. In a second part, the possibilities for further development are investigated, as it can be assumed that certain data will be available on national level in the near future. This concerns the protection of aquatic organisms, groundwater and the protection of insects or plants that are not the target of the crop protection measure. Various web services and tools, which are currently under development, will be examined and sample solutions already developed will be presented.

6.11.P-Tu428 Toward a Greener Pharmacy: How to involve Doctors and Pharmacists in The Environmentally Conscious Prescription of Medicines

*Francesca Cappelli[1], Vitalia Murgia[2], **Stefano Polesello**[3], Grazia Ferrara[4], Luisa Mattoli[5] and Massimo Mercati[5], (1)University of Antwerp, Belgium, (2)Associazione Italiana Medici per l'ambiente ISDE Italia, Italy, (3)Water Research Institute - Italian National Research Council IRSA-CNR, Italy, (4)Apoteca Natura SpA, Italy, (5)Aboca SpA, Italy*

In recent decades, the combination of "pharmaceuticals" and "personal care products" (PPCPs) has been recognized as contaminants of emerging concern because their widespread and universal use leads to pseudo-persistence in aquatic

environments with ecological impacts on aquatic organisms, thus also posing a risk of selective pressure which can lead to a reduction in biodiversity, as well as the occurrence of antibiotic and viral resistance.
Doctors and pharmacists are the direct interlocutors of patients regarding the correct use of medicines and should give their contribution, each in their own field of action, in promoting the use of more environmentally friendly medicines. The present work presents an Italian pilot project for the information of doctors and pharmacists on the environmental risks of selected pharmaceuticals, through the production of a web-based collection of synthetic fact sheets on active pharmaceutical ingredients (APIs).
The first part of the project was devoted to the collection of occurrence data of APIs in the Italian water compartments, cross-referenced with sales data to generate a first list of about 80 APIs, for different therapeutical classes. For these prioritised compounds, the main physico-chemical and ecotoxicological data were collected to produce a synthetic Risk Score presented in substance-specific fact sheets which, in the phase of therapeutic prescription, can guide doctors and pharmacists in choosing more eco-sustainable medicines with equal therapeutic efficacy.
A similar approach could then be extended in a full-scale project to other compounds present in medicines such as excipients, personal care products and cosmetics, or to additives and colorants widely used in the food to raise awareness among both production and distribution technicians and consumers. The aim is to encourage proactive action to limit the use and when available, replace with products with a lower environmental impact to protect ecosystems and, consequently, human health.

6.11.P-Tu429 Should What Is Joined Together by Chemistry Be Separated by Chemists? Studying Chloroalkanes in Particular and UVCB Substances in General
Chris Howick[1]*, Andrew Jaques*[2] *and Richard Mariner*[3]*, (1)INOVYN Chlorvinyls, United Kingdom, (2)Chlorinated Paraffins Industry Association, (3)Euro Chlor, Belgium*
Since 2020 there have been significant regulatory developments for medium- and long-chain chloroalkanes (medium chain chlorinated paraffins and long chain chlorinated paraffins). Many of these developments are due to the different, global, approaches to understanding the environmental properties of this group of substances as they exhibit differences in their key variables, principally the length of the carbon skeleton and the level of chlorination. The challenge of describing environmental properties of substances such as these with complex compositions (some with over 100,000 components) is made apparent by the fact that both industry and regulators disagree on how to approach the challenge but, also, that different regulatory processes take different approaches as well. Such variations in approach to the categorisation of chloroalkanes are also seen in scientific literature, which has burgeoned in the past five years, but add to the confusion.
This work gives a summary on how substances with complex compositions have been evaluated by environmental testing on individual components as part of the EU REACH registration dossier and REACH substance evaluation programme. Such assessments show a general inverse relationship between the biodegradation rate and average chlorination level and yield results on specific commercial products. However some may use these same data to ascertain biodegradation properties of individual congeners and then use these to predict the properties of other products that may or may not contain such congeners.
We provide an overview on not only how the different approaches between industry and regulators results in different conclusions but also how distinct approaches from different regulators leads to diverse substance identities in different regulations. It also shows how a substance, shown to be inherently biodegradable in one test, can receive a persistent conclusion when assessed via a congener approach. The resulting regulatory decisions have practical consequences but also demonstrate that, in the coming years, product testing requirements are likely to accelerate.

6.11.P-Tu430 Risk Should Not Be Made Complicated When the Hazards and Exposure Are Clear
Hans Peter Arp*, Norwegian Geotechnical Institute (NGI), Norway*
Different stakeholders will approach scientific uncertainty differently. Scientists are often driven to reduce uncertainty; regulators are driven to act on uncertainty (e.g. by invoking the precautionary principle), and those that are responsible for causing the environmental stress often seek to use scientific uncertainty as basis for inaction or deniability. To cut through these different viewpoints, the tool developed by William of Ockham (1287-1347), referred to as Ockham's razor, can be useful for governance. Ockham's razor states that "Entities are not to be multiplied without necessity", meaning in practice for this context that if adding new variables/complexities does not lower the overall uncertainty or picture of a sustainability assessment, then they should not be added, as they will only make governance more complex, and less transparent. When it preventing harmful chemicals from entering the environment, this has an impact on the role of risk perception and communication. In many cases, the hazards and risk of exposure are clear enough, from the perspective of some stakeholders, to prevent a substance from allowing a harmful chemical to be produced for a certain use. However, those who can profit from such substances, either as a producer or a consumer, may be drawn into the discussion of uncertainty to keep questioning the risk models, as a strategy to keep allowing the harmful substances in the environment.

6.11.P-Tu431 Is Discharge of Chemicals from Oil Extraction Offshore Harmful to the Environment?
Kirit Wadhia*, Environmental, NOV, United Kingdom*
The discharge of produced water is of concern in view of potential environmental impact. Approach involving mere chemical analysis is no longer considered sufficient.   holistic approach entailing whole effluent toxicity (WET) assessment from an ecotoxicological perspective has been increasingly advocated. Mo over, there is a need to employ a risk-based approach/assessment (RBA).
RBA has been instigated under OSPAR initiative and member countries have put in place appropriate implementation programmes. This presentation provides a comprehensive perspective of the UK RBA process.   insight into the development of

the initial trial to the formulation of the current stepwise programme process involving chemical analysis, ecotoxicity testing, modelling and reporting.
Key considerations of the produced water risk management elements are discussed. The aspect of intrinsic toxicity contribution from production chemicals and naturally occurring substances is examined. sential considerations of the key regulatory criteria and drivers are analysed.
The implication of the findings of the initial phase of the UK risk-based approach (RBA) programme are highlighted and how these impact future sustainable developments.
A definitive evaluation of the global RBA panorama is presented to rationalise top-down and bottom-up strategies conveying the global disparity that exists in the regulatory approach and existing infrastructure to consolidate the way forward.
The predictions are that major oil companies not only will continue with current level of production but will expand their operations that extract and refine fossil fuels.
The realisation is becoming all too apparent that in order to have a stable and safe planet reaching net zero emission is imperative. Whilst renewables are viewed favourable in terms of significant growth area, indubitably the issues and considerations pertaining to safe discharge of produced water remain at the forefront.
The intrinsic elements of importance for evaluation including production chemicals and naturally occurring substances play a key part. Methodology for assessment and inference from a global regulatory perspective lacks definitive approach and the disparity that exists inevitably compounds issues and instils lack of confidence.
Scope for pragmatic and prudent solutions to address pertinent issues will be highlighted.

6.11.P-Tu432 Drinking Water Relevant Substances in the Meuse
Tineke Slootweg[1]*, Gerdien van Genderen Genderen - de Kloe*[2]*, Bert Rousseau*[3]*, Thomas Oomen*[4] *and André Bannink*[4]*, (1)Het Waterlaboratorium, Netherlands, (2)Aqualab Zuid, (3)Water-link, (4)RIWA-Meuse*
The river Meuse is used as a drinking water source for 7 million people in Belgium and the Netherlands. RIWA-Meuse, the Association of river water works along the Meuse, aims for clean water in the river Meuse to guarantee the sustainable supply of impeccable drinking water. In 2007 RIWA-Meuse began to focus on specific substances which are relevant for the production of drinking water to advocate improvement of the water quality.
The goal of this study was to evaluate and update the current list of drinking water relevant substances (List 1) and identify candidate drinking water relevant substances from results of screening analyses and literature (List 2). The evaluation was performed based on measurement data from the monitoring stations and intake points along the Meuse in the period 2016-2020. Substances are considered as relevant if they fulfil a fixed set of criteria concerning i.e. their detection frequency, occurrence in concentrations above the target value set in the European River Memorandum, removal by water treatment, toxicity, odour/taste threshold and exceedance of the legal drinking water standards. To check if a substance fulfils the criteria monitoring data has to be available. Substances that are expected to be present in the Meuse, but are not monitored yet, are marked as candidate relevant substances and are recommended to be monitored by either a target analysis or screening.
This evaluation resulted in well-founded lists including 32 relevant substances and 33 candidate substances. The lists contain substances with a broad range of applications. Using the prioritization methodology substances that can be ranked according to their relevance for the drinking water production. All associated drinking water companies are committed to monitor the selected substances. The strong point of these joint lists is that it can be used for communication to stress the importance of the Meuse as a source for drinking water. Also it can used to initiate targeted actions to reduce the emission of a substance in the Meuse.

6.12.P SciComm Stars – The Science Awakens

6.12.P-Th404 Daphnia Detectives- The Case of the Pillowcase, Pegs and Pink Particles
Katie Reilly[1]*, Hollie Marshall*[2] *and Iseult Lynch*[1]*, (1)University of Birmingham, United Kingdom, (2)University of Leicester, United Kingdom*
Science communication and public engagement are increasingly being recognised as an important element of research and the scientific process. Involving different audiences at various stages of the research process can increase their understanding of and engagement with the work undertaken, and enrich the overall research process. Through this, we can encourage behavioural changes which are beneficial for a range of topics, including environmental issues. Plastic pollution and microplastics (MP) have rapidly become a hot topic over the past few years, generating a lot of scientific and societal interest on the potential environmental and human health impacts of MP. Following from our research on the potential ways that MP can impact the environmental indicator species *Daphnia*, a suite of public engagement activities and events were undertaken. This has developed into the *Daphnia Detectives* project, which is a bank of open access online resources that cover the topic of MPs and *Daphnia,* from experimental design stages through to example results and data sets that can be used to explore data analysis themes. Although the online content is designed to tie into the UK school curriculum as a way to bring real world and current examples of "research in action" into the classroom, it has the potential to be of interest to wider audiences. More recently, the project has also expanded into several in person events including science fairs and art installations.
A pillowcase, pegs and pink particles form an integral element of the *Daphnia detectives* activities, and are a good example of how everyday and specialist items can be blended to fit scicomm needs! '*Daphnia Detectives*- Science Festival edition', is the focus of this case study, which follows the project from event proposal, assembly of a team of keen researchers, grant application for event consumables and resources, trial and error for the interactive table-top practicals, through to highlights from the event itself and key feedback from the public. This includes our personal highlights (table top DNA escape room and learning line) through to the challenges ("please can someone turn the power on for this part of the building…?") and everything in-between!

6.12.P-Th405 Why Micropollutants in Drinking Water Have So Much to Do With Trust
Thomas-Benjamin Seiler, *Directorate, Hygiene-Institut des Ruhrgebiets, Germany*
In 2021 I got invited by a water supplier to participate in a documentary on micropollutants in drinking water. They were looking for expert opinions on different aspects of this topic, from chemical analytical challenges over biological effects to options for treatment. Being no expert on drinking water in general, let alone any of these specific items, I offered them to talk about the science and in particular risk communication side - which they happily agreed to.
For preparation I received a list of questions I am going to be asked. I made my mind up about what I will say in response to these and used that opportunity to dig deep into 10 years of focusing on science and risk communication in environmental research. I found that what we have come up with in our work within the SETAC Interest Group on Science and Risk Communication (SCIRIC) since its foundation in 2015 is very helpful as a solid base to tackle challenges such as communication about micropollutants in drinking water.
I touched upon trust building, deficit models, confirmation bias and cognitive dissonance, ivory towers, emotional vs. fact-based opinion building and communication, uncertainty in science, risk vs. hazard and a lot more.
For me, as untrained but quite experienced science and risk communicator, this was a wonderful opportunity, the essence of which I would like to share with the wider environmental science community.

6.12.P-Th407 The Right Tool for the Job: Why and How to Adapt Your Science Communication for In-person and Virtual Events
Matteo Piumatti[1] *and Francois Busquet*[2]*, (1)Altertox Academy, Belgium, (2)Altertox, Belgium*
More than ever, the challenges science communicators face nowadays remain daunting: they need to reach out to a variety of audiences with different interests, simplify the message without losing accuracy and engage beyond their community.
To overcome these hurdles, communicators need to be able to work with different tools since each one of them is best suited for specific situations. For example, a podcast might be very effective in describing the latest scientific discovery but does not allow the audience to interact directly and engage with the content. Similarly, depending on the communication objectives, in-person events could work better than virtual ones, even if they add a whole new layer of complexity.
Unfortunately, there is no secret recipe to master all the different actions within science communication. A great deal of trial and error is often required to learn which one is best for each situation and in which you feel more comfortable. Discussing with other science communication practitioners and sharing our stories is the best starting point to improve.
In this proposed talk, I will describe some of the formats encountered and practised since the beginning of my journey in science communication, as well as the recent experience with two innovative tools for science communication in toxicology: the live streaming show TOXstreams and the card game TATAbox.
I will pay particular attention to the differences between in-person and virtual events, drawing from my direct experience. For example, my activities with the science outreach organisation pint of science Belgium and my participation in the “I love science festival” in Brussels during my professional work.
At the same time, I will describe my experience with podcasts and videos. More specifically, with my live streaming show TOXstreams, which merges elements from live talk shows, journalistic emissions and stand-up comedy.
As science communicators, we need to understand that each person we try to engage with is different, and we need to be comfortable with various tools to reach our audience. Sometimes it might not work perfectly, but only practising with new activities will help us and our community to grow.

Track 7: Moving Beyond – Cross Cutting Themes, Emerging and Transdisciplinary Topics

7.01 Agriculture in the 21st Century: Balancing Food Security with Environmental and Public Health

7.01.P-We424 Regulatory Drivers and Testing Standardisation
Kirit Wadhia*, Environmental, NOV Inc, Stromness, United Kingdom*
Impacting different sectors, regulations constitute key aspect of policy making. It is imperative for adequate protection of the environment to address key criteria underpinning the fundamental objectives. rmulating the core policy and monitoring mechanism, evaluation protocols employed for assessment and inference play a vital role.
Standardisation Organisations (ISO, OECD, ASTM) are at the forefront of practices adopted worldwide, advancing the frontiers of innovative methodologies utilised for assessment, inference and policing.
Use of standards significantly contribute in ensuring services (and products) fulfil criteria of reliability, safety and quality. This allows for implementation of robust and fit-for-purpose standards and are instrumental in facilitating international trade and developments. ecifications are vital for business as strategic tools to increase productivity and enhance efficiency. Th allow for effective implementation of statutory measures.
The work of organisations such as ISO and OECD assist in establishing international norms. These Bodies contribute to the identification of prominent issues and the formulation of evidence-based solutions facing environmental and economic challenges of varying magnitude. iority issues on the global agenda are tackled with international co-operation by member countries. International organisations play an important role as standard setting bodies in supporting regulatory co-operation.
The conveyance is aimed to provide insight into the function and modus operandi of global organisations at the forefront in developing, maintaining and innovating international standards. Furthermore, exemplifying the application of standardised protocols implemented in different sectors and in regulatory frameworks.

7.01.P-We425 Biostimulants: a complex ecotoxicological challenge

Nadine S Taylor[1]*, Callum Burgess*[1]*, Peter Godfrey*[1] *and Sarah Clarke*[2]*, (1)Cambridge Environmental Assessments (CEA), United Kingdom, (2)RSK ADAS, United Kingdom*

There is evidence that biostimulant products can benefit arable and field grown horticultural crops, however, there are large knowledge gaps regarding the environmental safety and ecotoxicology of these products. Few studies look at the potential ecotoxicological effects of biostimulants, and those that do tend to focus on the individual component(s) of these products. Whilst acute exposure data, to individual biostimulant components, are generally above the Environmental Hazard Classification threshold of 1 mg/L, there is evidence of sub-lethal, long-term chronic effects. There are instances of toxicity at high and sustained application levels, which is of concern when there are no product usage regulations in place. Several biostimulant categories have exhibited indirect toxicity effects, e.g., increased bioavailability of metals and other bound toxins. Many biostimulants also have pesticidal properties, useful with regards to the dual action of plant growth promotion and crop protection, yet a concern that the non-selectivity of any pesticidal effects could be detrimental to non-target species. Similarly, the use of products that contain growth promoting bacteria will arguably influence the existing natural community composition, structure and function.

Here we discuss the challenges involved in assessing the risk of biostimulant products to the environment. Where environmental risk assessments for products, such as plant protection products (PPPs), can base their decision-making process on a single active ingredient, biostimulant products are made up of various components, in highly variable compositions, with additional interactive effects, that all need to be considered to accurately assess any adverse impact they may have on the environment.

Standard risk assessment approaches, on a product-by-product basis, would provide a clear measure of the ecotoxicologal impacts of a given biostimulant product, and if they are greater or less than the given application rates or predicted exposure concentrations following application. However, indirect toxicity, such as additive or synergistic effects of other contaminants present in the system, and the use of other products that are likely to be applied alongside biostimulants in real-world scenarios, also need consideration.

7.01.P-We426 Overview of Recent Biological Pesticide Evaluations in the EU: Fate and Ecotoxicological Data

Claudia Vaj[1]*, Anne Alix*[2]*, Sian Ellis*[2]*, Elizabeth Collison*[3] *and Sara Lamperti*[1]*, (1)Corteva Agriscience, Cremona, Italy, (2)Corteva Agriscience, Abingdon, United Kingdom, (3)Corteva Agriscience, Cambridge, Cambridgeshire, United Kingdom*

The aim of this poster is to provide a summary of biological pesticides which have been evaluated at EU level since the introduction of the data requirements according to Regulation No. 283/2013. The review will assess the key findings of the EFSA conclusions to highlight data gaps and areas of uncertainty to identify potential recurring trends related to the environmental risk assessment of biological pesticides. The review will include note of any specific approaches such as exposure based waivers or novel study design which have been successfully accepted. The presentation will also relate the identified data gaps to i) the current status of the testing methods specific for biologicals, and ii) the new Commission Regulations (EU) 2022/1438 – 1441 (applicable for microorganisms from November 2022), to determine where further work is required to appropriately address these gaps. We hope this work stimulates continued discussion with regards to the development of scientifically relevant testing strategies and risk assessment schemes for biological plant protection products, facilitating the availability of alternative solutions for farmers in the EU market.

7.01.T-01 A random forest machine learning model for prediction of NMs root uptake and translocation in plants based: application of nanoinformatics in sustainable and precision agriculture

Georgia Melagraki[1]*, Dimitra-Danai Varsou*[2]*, Panagiotis D. Kolokathis*[3]*,* ***Iseult Lynch***[4] *and Antreas Afantitis*[5]*, (1)Entelos Institute, Larnaca, Cyprus, (2)NovaMechanics MIKE, Greece, (3)Department of ChemoInformatics, NovaMechanics MIKE, Greece, (4)University of Birmingham, United Kingdom, (5)NovaMechanics Ltd., Cyprus*

Engineered nanomaterials (NMs) have unique physicochemical features whose potential is being explored in precision and sustainable agriculture for instance, as nano-fertilizers to improve crop yield and nutritional quality, as nano-pesticides which can target pests more effectively with fewer pesticides, minimizing effects on soil health and biodiversity while increasing soil function and nutrient cycling by boosting soil microbiota, or to increase plant resilience to extreme conditions by giving plants improved functionalities that help them cope with environmental stress from climate change. Computational modelling or nanoinformatics can provide critical insights for optimisation of agricultural productivity. Key to all nanoinformatics approaches is the need for a deep understanding of the fundamental mechanisms of interactions of the NMs with the plant-soil and plant-animal systems, and how these interactions change as a function of the NMs properties, the environmental conditions (e.g., soil properties, climate and weather conditions) and the nature of the crops or livestock systems under consideration. The combination of experimental data on soil conditions, plant species, climate conditions, and NMs physicochemical properties, and application of Machine Learning approaches, may be able to predict both the impacts of NMs on the agricultural system (on plants and soil) and the effects of the agricultural system to the NMs (transformations, distribution, and bioavailability). This will contribute to the development of nano-agrochemicals that combine both optimized safety and enhanced functionalities. Here, we present a machine learning model to predict the uptake and transport fate of NMs in soil and hydroponic systems utilising a panel of metal and metal oxide-cored NMs: Ag, CeO_2, CuO, Se, Si, TiO_2, ZnO, exploring the drivers of plant uptake expressed as the root concentration factor (RCF) and translocation factor (TF). The literature dataset was enriched with a computational descriptors calculated using only knowledge of the NMs structure and composition. A Random Forest machine learning model was developed using Enalos+ functionalities via the Isalos Platform, and its accuracy in external validation (R^2=0.81) was the reliability of predictions ensured through a clear d3efinition of the domain of applicability. Application of this model will support the development of NMs for agricultural applications that are safer and more sustainable by design.

7.01.T-02 Ensuring Sustainability of Nanotechnology in Agriculture through Practices of Responsible Innovation

Khara Grieger, *North Carolina State University*

Researchers, industry, regulators, and other stakeholders are interested in harnessing the potential of nanotechnology and engineered nanomaterials to develop more sustainable food and agriculture systems. For instance, nano-fertilizers and nano-pesticides may offer more efficient delivery of agrochemicals while reducing environmental run-off, and nano-encapsulated veterinary medicines may provide more animal friendly vaccine delivery for livestock. At the same time, we know from previous experiences that food and agriculture sectors are known to be among the most sensitive to public scrutiny, particularly related to the use of new and novel technologies, and require consumer acceptance to be deemed truly sustainable. For these reasons, various organizations have developed initiatives to support the responsible development of nanotechnology, including applications in agriculture systems, with most research efforts related to understanding potential environmental, health, and safety (EHS) risks along with efforts to evaluate ethical, legal, and societal implications (ELSI).

Our research integrates findings from EHS and ELSI studies on nanotechnology in food and agriculture (nano-agrifoods) and taps into a growing body of literature focused on responsible innovation of new technologies. Broadly, responsible innovation is a governance approach to innovating new technologies in a way that incorporates social and ethical concerns, stakeholder involvement, and issues of trust and transparency along with practices of inclusion, responsiveness, anticipation, and reflexivity. Through funding provided by USDA/NIFA, our research identifies i) barriers to conducting responsible innovation in nano-agrifood sectors, and ii) actions to address stakeholder concerns related to nano-agrifoods. Outcomes from this work are then coupled with insights from the broader literature on responsible innovation to iii) identify best practices for responsible nano-agrifood innovation that are also relevant for other emerging food and agriculture technologies. This presentation reports on key results related to these research areas and also discusses future directions to support sustainability of nanotechnology in agriculture sectors. Overall, these findings may be relevant for researchers, scientists, industry, and policy-makers to help pursue responsible innovation and ensure sustainability of emerging food and agriculture technologies more generally.

7.01.T-03 Nanobiotechnology-based Strategies for Enhanced Crop Stress Resilience

Jason C. White[1], *Lijuan Zhao*[2], *Jorge Gardea-Torresdey*[3] *and Arturo Keller*[4], *(1)Connecticut Agricultural Experiment Station, (2)Nanjing University, China, (3)Chemistry and Biochemiistry, University of Texas El Paso, El Paso, TX, (4)University of California, Santa Barbara*

Low use and delivery efficiency of conventional agrichemicals is a significant impediment to maintaining global food security, particularly given that a 60-70% increase in food production is needed by 2050 to support the projected population. Further confounding these efforts is a changing climate, which may force increased cultivation of crops under more marginal and stress-inducing conditions. Thus, novel and sustainable strategies for enhancing food production are needed all along the “farm-to-fork” continuum. Nanobiotechnology approaches to engineer crops with enhanced stress tolerance may be a safe and sustainable strategy to increase crop yield. Under stress conditions, cellular redox homeostasis is disturbed, resulting in the over-accumulation of reactive oxygen species (ROS) that damage biomolecules (lipids, proteins, and DNA) and inhibition of crop growth and yield. However, delivering ROS-scavenging nanomaterials (NMs) at the appropriate time and place can alleviate abiotic stress. Importantly, ROS-production in living cells carries both costs and benefits. When present below a threshold level, ROS can mediate redox signaling and defense pathways that foster plant acclimatization against stress. We find that many NMs are ROS-triggering, such as nanoscale Cu, Fe, S, and CuS, but these materials have the potential to be judiciously applied to crop species to stimulate defense systems, prime stress responses, and subsequently increase the biotic and abiotic stress resistance of crops. This knowledge can be used to engineer climate-resilient crops. It is also clear that the ability to effectively tune nanoscale material structure and composition will be critical to maximizing positive impacts, including significantly reduced amounts of agrichemical use while simultaneously enhancing yield.

7.01.T-04 What are the Roadblocks for the Commercialization of Nanoagrochemicals today?

Fabienne Schwab, *University of Fribourg, Adolphe Merkle Institute, Switzerland*

Nanoagrochemicals are an emerging solution to solve environmental issues due to poorly targeted agrochemical application and their toxicity to non-target organisms. As with every emerging technology, nanoagrochemicals have pros and cons. Here, an overview will be given on the opportunities and limitations of nanoagrochemicals based on the most recent research on the efficiency, mode of action, and delivery of active ingredients. In addition, an analysis of nanoagrochemical definitions and their regulatory significance, and the challenge to compare them with conventional products will be presented. Finally, based on these findings, the commercialization potential of different nanoagrochemicals will be discussed, including their hazard potential and scale-up cost. Overall, the most significant challenges for nanoagrochemicals today are to optimize them for field application, produce them at a competitive cost, and overcome the regulatory obstacles to register products containing nanomaterials.

7.01.P Agriculture in the 21st Century: Balancing Food Security with Environmental and Public Health

7.01.P-We427 Nematicidal Effect of Ultrasound-Extracted Cyanotoxin

Emily Yi Wai Chiang, *School of Engineering, University of Guelph, Canada*

Root-knot nematodes are one of the plant-damaging plant-parasitic nematodes in agriculture reducing crop yield food quality. The conventional solutions to control these plant-parasitic nematodes involve inherent negative impact on the environment as well as inefficacy after year after year of continued use, so biological control is among the most promising sustainable alternatives. The present study examines the nematicidal potential of two microalgal species: *Trichormus variabilis* and *Nostoc punctiforme* against a root knot nematode *Meloidogyne hapla*. *T. variabilis* is known to produce a neurotoxin, anatoxin-a, and *N. punctiforme* is known to produce a hepatotoxin, microcystin. The main objective of this study is to investigate the effect of ultrasonication on the extraction of secondary metabolites from these two microalgae, and the secondary objective of this study was to check for their soil nematode suppressing potential. Ultrasound results in cell wall disruption of the microalgal species, thus resulting in enhanced release of secondary metabolites. Microalgal biomass was treated with an ultrasound probe at 50 % amplitude, 20 kHz frequency, using water as the extraction medium, for 5–30 min. The extraction efficiency was determined in terms of the total chlorophyll content of the extract. Microscopic images of the treated cells were also investigated to gain insight into the effect of the ultrasonication time on the cell morphology. The nematized control soil contained 80 nematodes per kg soil, and upon addition of *T. variabilis* extracts (TV), 100 % nematodes are reduced. With *N. punctiforme* extract (NP) addition, 66 % nematode inhibition is observed. For a combination of the two microalgal extracts (TV + NP), 91 % nematode inhibition is observed. Paired t-test indicated that the number of nematodes in microalgal extract treated soil are significantly different ($p < 0.05$), thus implying that the microalgal treatment could result in nematode suppression. The higher inhibition for TV treatment can be attributed to the concentration of the cyanotoxin present in the extract. Also, the predominant toxin produced by TV is anatoxin-a and by NP is microcystin, hence the ratio of these metabolites in the extract dominates the nematode suppressing strength.

7.01.P-We428 Effect of Plant Biopesticide-spiked Soils on Earthworms and Soil Enzymatic Activity, With Biochar as an Ameliorant

*Hein Smith[1], Oladayo Amed Idris[1], Owen Rhode[2] and **Mark Maboeta**[1], (1)North-West University, South Africa, (2)Agricultural Research Council-Grain Crops, Spain*

Plant biopesticides are not only effective at managing agricultural pests, but they are also culturally acceptable and do not significantly damage the ecological system or exacerbate environmental pollution. *Bidens pilosa* L. and *Tagetes minuta* L. are examples of plant biopesticides used for crop protection. This study aimed to investigate the potential effects of the biopesticides on earthworms and soil enzymatic activity with reference to the conventional pesticide, fenamiphos, and the efficacy of biochar in the amelioration of plant biopesticide-spiked soil. A sublethal endpoint was considered using *Eisenia andrei* as a bioindicator. The avoidance behaviour, relative growth rate (RGR), and reproduction success were evaluated following OECD standard guidelines. Genotoxicity was evaluated using a comet assay and soil enzymatic activity spectrophotometric methods. The RGR and fecundity of *E. andrei* in fenamiphos-treated soil were significantly lower than in soil treated with plant biopesticides (*B. pilosa* and *T. minuta*). Surprisingly, treatments with biochar had a lower earthworm RGR compared to treatments without biochar. However, biochar does not have a significant impact on the reproduction of *E. andrei.* On the contrary, biochar supplemented treatments showed no DNA damage, suggesting biochar prevents genotoxicity. There were no significant differences in the alkaline phosphatase and urease activities in all treatments, including soils supplemented with biochar. But β-glucosidase activity increases in soil treated with 25 and 100 mg/kg Fenamiphos and 250 mg/kg of *T. minuta*. According to the findings of this study, fenamiphos has a greater negative impact on soil organisms than plant biopesticides. Further, biochar is not an efficient ameliorant for the studied plant biopesticides and pesticide.

7.01.P-We429 Challenges in the Registration of Natural Substance Pesticides From An Ecotox Point Of View

***Jutta Müther**[1] and Aleksandra Zakryś Zalewska[2], (1)Ecotoxicology, GAB Consulting, Germany, (2)GAB Consulting, Germany*

Under the Farm to Fork and Biodiversity strategy, the use and related risk of chemical pesticides as well as the use of the more hazardous pesticides should be reduced by 50% by 2030. Pesticides consisting of natural substances, like plant extracts, fatty acids, and oils are one tool to achieve this ambitious goal.

The lack of adequate testing procedures and of updated evaluation guidance (as recently published for Microbials) leads to risk assessors' conclusions which put natural substances like fatty acids, plant extracts or oils at a disadvantage.

This abstract highlights challenges related to the ecotoxicological risk assessment, common to most natural substances, which were faced meeting the data requirements of Reg (EC) No 283/2013 and No 284/2013. Recommendations for improvements to facilitate a reasoned evaluation and registration of natural compounds are presented.

The data requirements for Reg (EC) No 1107/2009 are targeted primarily at discrete, single-compound, chemical pesticides. The properties of natural substances are significantly more complex and difficult to fit into this schema. The evaluations for the broad variety of natural compounds are commonly handled on a case-by-case basis. Our experience is that this leaves both regulators and notifiers uncertain of how to provide and evaluate the requirements specified in EU regulations.

From the ecotoxicological point of view the most important challenges are: 1) The physical-chemical properties of natural substances and the resulting need to adapt existing testing methods. 2) The performance of accompanying analytical work for dose verification. 3) Interpretation of achieved endpoints and risk assessment calculations.

In this context, different aspects like lead component approach for multi-component plant extracts, biological degradation of active ingredients in test systems or extremely high application rates for fatty acids and oils are addressed.

Repeated testing, with modified testing methods trying to overcome the above-mentioned difficulties lead to inhomogeneous data packages. The interpretation and evaluation of this data is not possible in a consistent, straightforward way. In most cases it is not possible to prove safe use of a natural substance pesticide by standard risk assessment calculations and a weight of evidence approach needs to be applied. For both regulators and notifiers, the question remains how much uncertainty and deviation from the usual evaluation process is acceptable.

7.01.P-We430 Practical Challenges of Data Generation to Address Regulatory Requirements for Microbial Organisms

Anne Alix[1], *Sian Ellis*[1], *Claudia Vaj*[2] *and Sara Lamperti*[2], *(1)Corteva Agriscience, United Kingdom, (2)Corteva Agriscience, Italy*

The data requirements present a range of practical challenges when generating data for microorganism biopesticides. Without available standardized test guidelines specifically for microbials and due to the varied nature of their activity, assessment will often need to be made using specifically tailored studies. Toxicity and effects endpoints may therefore differ between studies and study design should be adapted to the nature of the mode of action and to establishing conditions in which the micro-organisms may produce toxic effect. For agrochemicals the assessment relies on established standardized guidelines and methodologies, which are not sufficient to cover all the data needed for micro-organisms and so a more adaptable review process is required. To ensure an appropriate evaluation of the exposure and toxicity, there needs to be a balance between addressing deviations from the data requirements while ensuring the studies are necessary and fit for purpose to cover the action and behaviour of the microbial. Weight of evidence assessments using different sources of information may prove to be more appropriate than studies alone.
The focus of this poster presentation is to identify some issues for consideration when developing appropriate testing strategies for microorganisms in their use as biological pesticides.

7.01.P-We431 Regulatory Challenges in the EU to Providing Biological Solutions to Deliver the Green Deal

Martin Tilbrook, *Andy Chadwick and Clare Lane, ERM Regulatory Services, United Kingdom*

Despite the European Commission's/Parliament's stated aim of replacing conventional chemical pesticides with biological pesticides, there are a number of regulatory barriers to overcome in registering biological pesticides in the EU. ERM has recently been involved with preparing a number of biological pesticides for submission to EU regulatory authorities, including botanical, biochemical and microbial products.
Current guidance under Regulation 1107/2009 requires that microbial pesticides are also additionally subject to 'Part A' data requirements (i.e. as applied to conventional chemical pesticides) due to their production of secondary metabolites that occur naturally in the environment.
European Commission guidance on botanical active substances states:
Estimated exposures of the (components of the) botanical active substance should be compared to the natural exposure situations in different relevant environmental compartments (water, soil, air). The risk can be considered acceptable when estimated exposures are lower or similar to the natural exposure situations and no unacceptable effects occur on relevant non-target organisms.
However, as well as natural background level comparisons, regulatory authorities have required comprehensive exposure assessments for soil, groundwater and surface water designed for conventional chemical pesticides for botanical pesticides.
The exposure assessments showed an acceptable risk to groundwater and to soil and surface water-dwelling organisms. ERM has received positive feedback on the approach from the authority responsible for the evaluation of the first of these biopesticides as it progresses through the EU's regulatory system.
Due to potentially high application rates required for some biological pesticides for efficacy, groundwater modelling can predict levels above the EU hazard cut-off of 0.1 µg/L. Since this cut-off is not based on risk, it is considered that it should not apply for natural substances with existing background levels of exposure.
Due to the above obstacles, cost and extended timeframes, registration of biological pesticides lags behind the US, despite the objectives of the SUR/Green Deal, echoed by the EU Parliament recently during a seminar on the Sustainable Use Regulation (13 October 2022).

7.01.P-We432 Long-term Exposure of Bumblebees (*Bombus terrestris*) in Semi-Field Studies

Markus Persigehl[1], *Mareike Beinert*[1], *Florian Ballhaus*[1], *Guido Sterk*[2], *Paraskevi Kolokytha*[2] *and Janna Hanegraaf*[2], *(1)Tier3 Solutions, Germany, (2)IPM Impact, Belgium*

Biological plant protection products (Biopesticides) play an increasingly important role for sustainable crop production following the farm-to-fork strategy set in 2020 in the EU. Biologicals (bacteria, fungi, viruses etc.), like all other active substances used in plant protection products (PPP) have to fulfil the approval criteria laid down in (EC)1107/2009 concerning the placing of PPP on the market. However, due to their different modes of action, test designs have to be adapted in order to better serve the profile of the biological.
One essential adaptation in study designs is the duration of the exposure period. In pollinator semi-field effect studies (e.g. OECD75/EPPO170 for honey bees or icppr ring-tested study designs for mason and bumblebees) the exposure period in the tunnel is set to 7-10 days. This is in most cases not sufficient for testing biologicals as they continue growing and thus exposure increases with time.
For testing biologicals on the large earth bumble bee (*Bombus terrestris*) we developed a semi-field design with an exposure period of up to 30 days. Additionally, modified R&D hives were used to ensure a maximum synchronized development of bumble bee colonies. Further adaptations of the hives reduce disturbance during colony assessments. Details of the test design will be presented.

7.01.P-We433 Toxicity Data of a New Generation Biopesticide Based on the Activity of a Peptide Regulating The Expression of a Digestive Enzyme in Insects

Libânia Queirós[1], *Matilde Moreira dos Santos*[2], *Artur Sarmento*[2], *Sandra Afonso*[2], *Mari Gigauri*[2], *Mykola Rasko*[2], *Camila Campello*[2], *Rui Ribeiro*[2], *José Paulo Sousa*[2], *Estevão Mano*[3], *João Transmontano*[3] *and Tiago Luz*[4], *(1)CWT - TURISTRADER, Portugal, (2)University of Coimbra, Centre for Functional Ecology, Portugal, (3)Neovictus, Campus Politecnico, (4)Department*

Life Sciences, University of Coimbra, Centre for Functional Ecology, Portugal
Some peptides have the potential to regulate the expression of essential enzymes for the digestion process in insects, which may constitute a mode of action to control insect expansion. Biopesticides based on this mode of action may represent a paradigm change in pest management as they are biodegradable and might have high specificity for the target organism, not affecting other species that are beneficial for crop systems. Based on this principle, the BIOSTARV project foresees the search and identification of peptides with the potential to inhibit the expression of trypsin in the intestine of target agricultural pests in southern Europe. A decapeptide produced in the females' ovarian follicle of the *Aedes aegypti* mosquito blocks the trypsin biosynthesis, an enzyme essential for the digestion in the *A. aegypti* larva, and has been used as biocide in several Asian Countries (AC) in a commercial formulation. The application of this decapeptide (TMOF- trypsin modulating oostatic factor) in the larvae leads to the inhibition of their growth, preventing the larvae from reaching the adult state by starvation. The same decapeptide had a similar effect in the larvae of insects of the genera *Anopheles* and *Culex*, which suggests that TMOF has the potential to successfully control insect pests in crop areas. Aiming to evaluate the potential of a biopesticide based on the activity of a decapeptide similar to TMOF to be used in agricultural scenarios, the toxicity of TMOF and the biocide commercialized in AC was evaluated for non-target organisms following the list of assays included in the data requirements of the European Union for the registration of active ingredients and Plant Protection Products. Detailed results of laboratory acute and chronic ecotoxicological tests with aquatic organisms (e.g. *Daphnia magna*, *Chironomus riparius*, *Pseudokirchneriella subcapitata*), honey bees (adult acute - oral and contact – and chronic oral exposure and larval repeated exposure tests), non-target arthropods other than bees (*Aphidius rhopalosiphi* and *Typhlodromus pyri*) and soil organisms (*Eisenia andrei*, *Folsomia candida* and *Hypoaspis aculeifer*) will be presented. Overall, lethal and chronic toxicity data for aquatic organisms have shown that test substances are more toxic to *C. riparius* than to *R. subcapitata* and *D. magna,* while for honey bees, toxicity has been found only in adults chronic exposure and larvae toxicity tests.

7.01.P-We434 The Newly Implemented Regulations for Microbial Active Substances and Products – An Ecotoxicological Perspective
Cozmina Link-Vrabie, Anne Steenbergh, Emily McVey, Mascha Rubach, ***Devdutt Pratap Kulkarni****, Ingrid Bremmer, Renske van Eekelen and Jacoba Wassenberg, Board for the Authorisation of Plant Protection Products and Biocides, Netherlands*
The regulatory framework for plant protection product (PPP) containing micro-organisms is set by the Plant Protection Product Regulation (PPPR; Regulation (EC) No 1107/2009). This regulation states that a PPP can only be authorized when the active substance has been approved, the product is sufficiently effective, and use of the product does not have harmful effects on human health and have no unacceptable effects on the environment. These conditions should be met for all PPPs independent of the type of active substance (microbial or chemical). The data requirements for the active substance and the PPP are set in separately implemented regulations. The approval criteria for the active substance are given in an Annex to the PPPR itself (i.e., Annex II to Regulation (EC) No 1107/2009). The decision and evaluation criteria are provided in an implementing Regulation commonly referred to as the 'Uniform Principles' (see Article 29, paragraph 6 of the PPPR).
In August 2022, newly implemented regulations, which provide updated requirements and criteria for microbial PPP, were adopted. The requirements and criteria were updated to reflect the development of scientific insight and experience gained from the evaluation of PPP containing micro-organisms. These amended regulations with the relevant requirements and criteria for microbial PPP already apply from the 21st of November 2022.
This poster aims to provide further explanations on these newly implemented regulations, focusing on effects on non-target organisms. Based on our experience as a Regulatory Authority, we will provide information relevant for the different stages of dossier preparation and the assessment of effects on non-target organisms.

7.01.P-We435 Systemic Acquire Resistance (SAR) Inducers as an Alternative to Conventional Pesticides – Environmental Hazard Assessment
Marta Markiewicz[1]*, Marcin Smiglak*[2] *and Stefan Stolte*[1]*, (1)Institute of Water Chemistry, Technical University Dresden, Germany, (2)Poznan Science and Technology Park, Adam Mickiewicz University Foundation, Poland*
Systemic acquired resistance (SAR) is a natural long-lasting defence mechanism of plants. SAR can be induced by natural signalling molecules (e.g. salicylic or jasmonic acid) or by synthetic analogues e.g. benzo[1,2,3]thiadiazole-7-carbothioic acid S-methyl ester (BTH). Such induction of natural defence mechanisms can be elicited in broad variety of crops and acts against a wide range of pathogens (bacteria, fungi, viruses). The induction of resistance is also associated with the stimulation of plant metabolism that provides long-lasting beneficial effects like increased yield. Unlike classical pesticides, SAR inducers do not act directly on pathogens but rather stimulate the plant to defend itself. SAR inducers are therefore an alternative to plant protection agents, which might reduce the use of pesticides or even substitute them. BTH - a known SAR inducer - is poorly water soluble and therefore difficult to apply on the fields by spraying. It is however, much more soluble in water in the form of ionic derivatives.
We prepared eleven ionic BTH-derivatives ($BTHCOO^-$) and tested their environmental impacts: ready biodegradability, cytotoxicity and aquatic toxicity (against luminescent bacterium *Aliivibrio fischeri* and water flea *Daphnia magna*). None of the tested compounds proved to be readily biodegradable which is largely due to the fact that BTH itself is not biodegradable, yet five derivatives showed appreciable levels of degradation. The tested SAR inducers were characterized by a wide range of IC_{50}/EC_{50} values in cytotoxicity and (eco)toxicity indicating a highly diverse toxicity. However, a carboxylic acid derivative coupled with a cholinium cation showed a better environmental hazard profile than the parent compound due to lower toxicity and higher, but probably only partial, biodegradability. This compound was also shown to be one of the most effective SAR inducers in tobacco

plants infected with Tobacco Mosaic Virus where the protective actions against virus lasted for over a month after application of this novel SAR inducer.
The development of new SAR-inducers offers a possibility to actively include environmental impacts as one of design criteria using so called 'benign by design' approach. Some BTH-derivatives offer an improvement both in terms of functionality and environmental hazard, while others are significantly more hazardous. The type of counterion accompanying the $BTHCOO^-$ played a pivotal role in defining environmental hazard.

7.01.P-We436 Impact of Copper Oxide Nanoparticles Combined With Indole-3-acetic Acid in *Pisum sativum* Plants and Seeds
***Loren Ochoa*[1] *and Jorge Gardea-Torresdey*[2]*, (1)Environmental Science and Engineering, University of Texas at El Paso, (2)Chemistry and Biochemiistry, University of Texas El Paso* Nanotechnology in agriculture has evolved and helped in seeking solutions to increase food production at a global scale. Copper oxide NPs (nCuO) a potential nano-pesticide in the agricultural sector. It's interaction with phytohormones such as indole-3-acetic acid (IAA) in plants remains to be completely understood. This study aims to evaluate the interaction of nCuO and IAA in green pea (*Pisum sativum*) plants within both plant and the nutritional components in its fruit. Green pea plants were grown to full maturity in soil amended with nCuO, bulk CuO (bCuO), and cupric chloride ($CuCl_2$) at 50 and 100 mg/kg of soil and IAA at 0, 10 and 100 µM. Results from the whole plant indicated that treatments with 10 and 100 µM of IAA in conjunction with all the copper treatments reduced the growth of plants by 23% and 34% accordingly. IAA at 100 µM with Cu treatments changed the nutrient accumulation in tissues. The green pea pods compared to the control showed an increase in the content of Fe (258%) and Ni (325%) in treatments of nCuO at 50 mg/kg. Treatment of bCuO 100 mg/kg increased Ni content by 275%. Cu content increased in stems by 84% and 78% in treatments with IAA at 10 µM with nCuO at 100 mg/kg and bCuO 50 mg/kg, respectively. A reduction of Ca of 32% and 37% was shown in treatments with IAA at 100 µM with nCuO and IAA at 100 µM with bCuO, respectively. The nutritional evaluation of the green pea seeds showed that IAA at both concentrations increments the sugar content by 20%. While IAA at 10 µM does increased protein content by 33%. Fe content in seeds was observed to increase by 41% in 50mg/kg of bCuO treatment, and by 42% in 100 mg/kg nCuO treatments both in the presence of 100 µM of IAA. A reduction of B by 80% was shown in treatments with IAA at 100 µM with nCuO at 50 mg/kg. The combination of IAA and Cu-based compounds can impact the production of green pea plants by reducing the plant number and biomass, though the nutritional quality and production is not affected. To further expand the knowledge of what is already been discovered in the interaction of exogenous phytohormone IAA and nCuO in pea plants, a comparison with the previously mentioned findings will be conducted with a chitosan-based fertilizer intended as supplement for nCuO. This slow-release fertilizer will be evaluated in conjunction with different amounts of IAA to evaluate if the rate of release affects the aforementioned variables within the whole plant and fruit components.

7.01.P-We437 Tunable Release of dsRNA Molecules into Plants from Sustainable Nanocarriers
***Washington da Silva*[1]*, Raja Muthuramalingam*[2]*, Karol Barroso*[3] *and Juliana Milagres*[4]*, (1)Virology, The Connecticut Agricultural Experiment Station, (2)Plant Pathology, The Connecticut Agricultural Experiment Station, (3)Plant Pathology, CAES, (4)CAES*
Virus resistance has been induced in plants by the application of exogenous double-stranded RNA (dsRNA). However, the effectiveness of applying naked dsRNA on leaves is short-lived - dsRNA is quickly assimilated by plant defense mechanisms and is also degraded by environmental factors. are investigating the potential of using nanoparticles to sustain an effective and prolonged delivery of dsRNA into plants with the long-term goal of developing innovative technologies to control plant virus infections. We erformed small RNA profiling analysis in tobacco plants infected with potato virus Y (PVY) and synthesized dsRNAs from PVY genomic regions with a high abundance of virus-derived small interfering RNAs. The plication of the synthesized dsRNAs resulted in 100% protection against PVY on tobacco plants for up to five days. Curren y, we are synthesizing and characterizing different nanocarriers to protect dsRNAs from degradation to prolong the "vaccine effect" of those molecules on plants for pathogen protection.

7.02 Better Safe than Sorry: Safe, Sustainable and Circular Chemicals, Materials and Products along their Lifecycle

7.02.T-01 The Role of Life Cycle Assessment in the Safe and Sustainable by Design: Lessons Learnt From a Case Study
Davide Tosches[1]*,* ***Carla Caldeira***[1]*, Debora Fino*[2] *and Serenella Sala*[1]*, (1)European Commission Joint Research Centre, Italy, (2)Department of Applied Science and Technology, Politecnico di Torino, Italy*
The action plan of the Chemicals Strategy for Sustainability foresees the development of criteria for safe and sustainable by design of chemicals and materials, which integrates aspects from the domain of safety, circularity and functionality of the chemicals or materials considering them throughout the entire life cycle. To support the development of such criteria a framework was developed integrating different dimensions of the sustainability: safety, environmental, social and economic. In particular, environmental sustainability is addressed using Life Cycle Assessment (LCA).
However, the ambition of the SSbD poses some relevant challenges to the LCA community in order to operationalize the assessment towards supporting the sustainability transition of the chemical sector. These challenges are explored in a case study. This study aims to present and show possible ways to address the identified key challenges.
The case study refers to the application of the LCA part of the SSbD framework to a set of non-phthalate plasticisers used in food contact material selected considering the most common ones allowed for food contact according to European regulation. A phthalate plasticiser (DEHP) is also included to be used as a possible reference material. The plasticisers are considered for the use in a specific packaging application: the manufacturing of PVC based gaskets for metal lids.

The LCA was performed applying the Product Environmental Footprint (PEF) method. The scope of the study is a cradle to grave analysis of the plasticisers, which function is to provide the proper softness to manufacture a polyvinylchloride gasket. The modelling of the life cycle is performed using literature data complemented by the use of a process design software and primary data from companies.
During the development of the case study several challenges were so far identified, such as: the need to define application specific criteria, the availability of primary data in the chemical industry.
The identification of challenges in the use of LCA supporting the SSbD framework is crucial to develop the latter into a decision-making tool. This case study was pivotal to illustrate that challenges in the use of LCA are related to all steps, from goal and scope to life cycle impact assessment. Overarching issues are related to data availability and quality, and the definition of a proper application-specific benchmark as a basis to set criteria and requirements.

7.02.T-02 Safe and More Sustainable Alternatives in the Innovation Funnel; A Case Study on Biobased Materials in Cosmetics
Nina Melander[1]*, Anna-Karin Hellström*[2] *and Lisa Skedung*[1]*, (1)RISE Research Institute of Sweden, Sweden, (2)Environemntal Chemistry, RISE Research Institute of Sweden, Sweden*
The Safe and Sustainable-by-design (SSbD) concept can be used to guide the early design phase in the innovation stage-gate process of chemicals and materials to minimize hazardous effects on human health and the environment along the life cycle while considering a specific function. Here we aim at identifying a screening methodology for the SSbD-steps from existing and newly developed tools to be applied early in the innovation stage-gate process. To define the methodology and explore suitable tools we use a case study on nanocellulose in cosmetics, a biobased material with high dermal exposure for consumers. This adds complexity to the assessment like identifying and managing trade-offs relevant to the transition to a bio-economy.
Nanocellulose is a renewable material derived from the most abundant biopolymer in nature and can have a wide variety of potential applications due to its interesting properties. The choice of starting material, pre-treatment, and process affect safety and environmental impacts from raw material extraction, production, use phase, and end-of-life. A cross-disciplinary team of professionals from chemistry, formulation chemistry, toxicology, life cycle assessment, and techno-economy has been formed to explore the four assessment steps in SSbD-criteria. Questions that will be addressed are for example: when and what (bio)material and chemicals should be prioritized for analysis, to what extent is a sustainability analysis required early in the design phase, how can *in silico* predictions be used for complex biomolecules and what *in vitro* assays should be prioritized for chosen endpoints and risk assessments. To answer these questions a combination of *in silico, in vitro*, literature and experimental data will be used. For the screening methodology, we suggest both new and existing tools from several disciplines including alternative assessment.

7.02.T-03 Chemicals in Textiles: Can We Ensure a Safe Circular Economy in the Textile Sector?
Agathe Bour[1]*, Thomas Christensen*[1]*, Agnieszka Hunka*[2]*, Annemette Palmqvist*[3]*, Else Skjold*[4] *and Kristian Syberg*[1]*, (1)Roskilde University, Denmark, (2)Sustainable Business Unit, RISE Research Institute of Sweden, Sweden, (3)Dept. of Science and Environment, Roskilde University, Denmark, (4)Institute of Architecture and Design, Royal Danish Academy, Denmark*
The textile industry has grown extensively in the past decades and is now one of the largest industries in the world, generating more than 92 million tons of waste every year. This tremendous production goes along with severe environmental impacts, including greenhouse gases emissions, use of freshwater supply and arable land, and generation of severe chemical pollution. Thousands of tons of pesticides and fertilizers are used every year, additionally to a myriad of chemicals used throughout the production chain, such as lubricants, solvents, bleaches, dyes, processing aides, and water and stain repellents. The textile industry is currently unsustainable, and systemic changes must be made. One lever to tackle this issue is the transition to a circular textile economy, which must ensure users' safety and the absence of hazardous substances in recycled textiles. Concern has been raised on the (in)ability of current regulations to provide sufficient protection regarding recirculating materials. The aim of this presentation is to discuss potential regulatory loopholes and suggest solutions to ensure better safety of circular textiles. First, we present the toxicity profile of 711 substances that may be found in textiles. For selected examples, we also present how chemicals have been regulated over time. Based on this analysis, we identify regulatory gaps that could lead to hazardous chemical exposure, then present potential solutions to ensure a safe transition to a circular textile economy. Among the studied chemicals, we identified carcinogenic-mutagenic-reprotoxic (CMR) substances, endocrine disruptors, skin and/or respiratory sensitizers/allergens, and chemicals completely or partially lacking hazard data. Based on the case studies of PFOS and dicofol, we identify issues for safe textile recirculation and show they stem from the fact that regulations are based on chemical risk assessments that do not consider chemicals' specific hazardous properties and/or are not adapted for circularity. To address these issues, we argue that an improved risk assessment of chemicals should consider both chemicals hazardous properties (*e.g.* endocrine disruption, carcinogenicity) and product's multiple life cycles, instead of being limited to the product's end-of-life stage. In this perspective, we also discuss the recent ecodesign Regulation, how it could improve the circularity of the textile sector, and which key point should be included in the future delegated acts.

7.02.T-04 Application of Life Cycle Assessment (LCA) Methodology to Drive Environmental Sustainability Improvements in the Manufacture and Delivery of Pharmaceuticals
Andy Whiting *and Alexander Mullen, Astrazeneca UK, United Kingdom*
Across the product value chain, there is increased stakeholder interest for holistic information on the environmental impact of medicines, and the regulatory environment is shifting towards zero pollution, low carbon sustainable products. To make strategic decisions about how to best reduce the environmental impact of products, many pharmaceutical companies are making increased use of life cycle assessment (LCA).

LCA is an internationally recognised method of quantifying environmental impacts across the entire value chain of a product (ISO 14040 and 14044). It identifies hotspots within a product's life cycle where the impacts are greatest. Thus these areas can be prioritised and targeted, and potential solutions can be tested through scenario analysis.
However, there remain challenges to overcome with the LCA approach. The development and manufacture of a new medicine is a complex endeavour and it can be difficult to assess sustainability in early development when data availability is limited. There is a lack of standardisation within the pharmaceutical sector, leading to LCA results not being shared more widely due to fear of unfair comparison. Common rules, tools and scoring systems need to be developed for the sector. Additionally, despite considering many environmental impacts, there are issues associated with the complexity and uncertainty of LCA's ecotoxicity impact category and its relationship with existing environmental risk assessment approaches.

7.02.T-05 Assessing the Growth of The Field of Alternatives Assessment Over The Last 10 Years
*Monika A. Roy[1], Aude Bechu[2], **Joel Tickner**[2] and Molly Jacobs LeFevre[2], (1)UMass Lowell, Lowell, MA, (2)University of Massachusetts, Lowell*
Alternatives Assessment is a tool for the informed substitution of identified chemical hazards in consumer products and industries, with the intent of avoiding "regrettable substitution". The field of Alternatives Assessment has grown steadily over the last few decades and became particularly established with the publishing of the 2013 Royal Society of Chemistry's "Chemical Alternatives Assessments" book and the subsequent publishing of the 2014 U.S. National Research Council's "Framework to Guide the Selection of Chemical Alternatives". Since then, Alternatives Assessment methodologies, frameworks, tools, case studies, and a community of practice have developed. In 2018, Tickner et al. published the article "Advancing Alternatives Assessment for Safer Chemical Substitution: A Research and Practice Agenda" (https://doi.org/10.1002/ieam.4094), in which they amassed input from 40 experts to outline specific needs for the field in five critical areas: hazard assessment, comparative exposure assessment, lifecycle considerations, decision-making, and professional practice. Here, we assessed how the Alternatives Assessment field has grown in these five areas since 2013.
Alternatives Assessment literature covering frameworks, methods, tools, policy analyses, reviews, and case studies from 2013 through 2022 were collected for review using specific search terms in PubMed and GoogleScholar. Results were categorized by critical area and sub-area, literature type, and literature form. Over 200 sources were identified, including ~100 peer-reviewed journal articles. Identified sources also included government reports, white papers, non-peer-reviewed commentaries, books, theses, conference papers, and seminars. Together, these sources provide insights on advancements in the field for each of the five critical areas, as well as other aspects of the alternatives assessment process that are important and still evolving. This presentation will highlight these advancements, as well as the needs that still remain to be addressed in the field going forward.

7.02.P Better Safe than Sorry: Safe, Sustainable and Circular Chemicals, Materials and Products along their Lifecycle

7.02.P-Mo401 Safe And Sustainable by Design Chemicals and Materials: A Framework For Criteria Definition
***Carla Caldeira**[1], Lucian Farcal[2], Irantzu Garmendia Aguirre[1], Davide Tosches[2], Lucia Mancini[2], Antonio Amelio[1], Kirsten Rasmussen[2], Hubert Rauscher[2], Juan Riego Sintes[2] and Serenella Sala[2], (1)EC JRC, Italy, (2)European Commission Joint Research Centre, Italy*
The EU Chemicals Strategy for Sustainability (CSS) aims at contributing to the safeguard of human health and the environment as part of an ambitious approach to move towards a zero-pollution and toxic-free environment. A key action defined in the CSS is the development of criteria for safe and sustainable by design (SSbdD) chemicals. SSbD aims at facilitating the industrial transition towards a safe, zero pollution, climate-neutral, and resource-efficient production and consumption, addressing adverse effects on humans, ecosystems and biodiversity from a lifecycle perspective. To fulfil these ambitions, there is the need to develop a framework for the definition of criteria for SSbD chemicals and materials to steer innovation towards the green industrial transition, foster substitution or minimisation of the production and use of substances of concern, and minimize impact on human health, climate, and the environment. This study presents a SSbD framework developed in line with these objectives to support the design and development of safe and sustainable chemicals and materials within the research and innovation phase. The framework is composed of two components: a (re)design phase in which design guiding principles and indicators are proposed to support the design of chemicals and materials, and a safety and sustainability assessment comprising 5 steps that can be carried out sequentially or in parallel, depending on the specific purpose of the exercise. The steps include: hazard assessment of the chemical/material (Step 1), human health and safety aspects in the chemical/material production and processing phase (Step 2), human health and environmental aspects in the final application phase (Step 3), environmental sustainability assessment along the entire chemical/ material life cycle (Step 4), and social and economic sustainability assessment, providing (Step 5). The framework will be tested with case studies to identify and collect bottlenecks, and measures to address them will be explored. Insights gained from the testing phase will support the refinement of the framework and criteria.

7.02.P-Mo402 Challenges and Opportunities for Safe and Sustainable by Design Assessment of Chemicals and Materials
***Elisabetta Abbate**[1], Ad M. J. Ragas[2], Carla Caldeira[3], Mark Huijbregts[4], Leo Posthuma[5] and Serenella Sala[6], (1)Radboud University, Nijmegen & European Commission - Joint Research Centre, Netherlands, (2)Radboud University Nijmegen, Netherlands, (3)EC JRC, Italy, (4)Radboud University, Netherlands, (5)National Institute for Public Health and the Environment (RIVM), Netherlands, (6)European Commission Joint Research Centre, Italy*
The importance of chemical products for modern society is undeniable since they deliver essential sevices throughout many sectors. However, along their life cycle, chemicals are responsible for water, air, and soil pollution and the related impacts, e.g. on climate change, biodiversity loss, and human health. Hence, there is a clear need for a new approach that guarantees the safe and

sustainable design, production, use, and waste management of chemicals. In this direction, the European Commission published the Chemicals Strategy for Sustainability (CSS) aiming to address those issues. Within the CSS action plan, the Safe and Sustainable by Design (SSbD) concept is introduced as a principle for the substitution and development of new chemicals, materials and products. Safety assessment and environmental, social, and economic sustainability assessments should be combined with design principles to evaluate whether a chemical is safe and sustainable, already in an early stage of its development.
Several studies already identified challenges for SSbD assessment, for example, data availability and quality, methods for data scale-up, modelling aspects of chemical functionality. To move towards an operational framework, those challenges need to be addressed by the scientific community, supporting implementation into businness and policy. The goal of this study is to support the development of an SSbD assessment framework by answering the following research question: *What are the most important challenges and opportunities to create an operational SSbD assessment procedure for chemicals that can be implemented by the chemical industry?* For each step of the SSbD assessment framework, we identified potential challenges, both scientific and operational, that need to be further addressed and we provided recommendation toward the operationalization of the SSbD framework.
Among all the challenges, the introduction of a "Step 0" is crucial as an entry point to further guide the SSbD assessment. To do so, the development of archetypes with specific guidelines could contribute on providing support the operationalization of the SSbD framework. Further recommendations on other challenges provided through this study might guide further improvement toward the operationalization of the SSbD framework.

7.02.P-Mo403 Interdisciplinarity as the Backbone for Sustainable Transitions: A Housing Crisis Case Study
Elizabeth Migoni Alejandre[1]*, Alexander Wandl*[2] *and Arjan van Timmeren*[2]*, (1)Urbanism-ETD, Leiden University, Netherlands, (2)Technical University Delft, Netherlands*
The Netherlands, among many other countries in Europe, is facing a housing crisis, with an estimated amount of over 900,000 houses needed by the end of 2030 to satisfy short-term and increased urbanization demands. Governmental efforts are requiring input from universities, housing associations and other relevant stakeholders that can help guide the transition towards sustainable cities. These strategies are being developed, considering advances on construction processes and biomaterials that present positive opportunities for carbon and energy neutral buildings. However, in the middle of this transition towards environmentally sustainable cities, several questions remain on the underlying conditions that seem to be at the root of some of the problems we are trying to solve. The limited availability of trained human resources on the construction sector is presenting complications for the realization of projects, with a similar problem found on the material supply side, where communities that own extensively managed forest plantations are running out of people to work in them. Several factors are playing a role, among them, generational interests driven by consumerism and separation from the natural world by technocratic views surface as some of the most challenging to address. Furthermore, the high demand for housing is emerging not solely out of an increased global population and refugee crisis due to global political instability, but also due to high immigration to cities from rural areas. This increased urbanization seems to be influenced by both, a perceived lack of opportunities in rural regions, and as a direct result of the degradation of natural resources and landscapes, such as pollution, erosion, desertification, among many other impacts. Therefore, when addressing sustainable strategies, the question remains: are we asking the right questions? Interdisciplinarity thus, becomes essential for a robust assessment of the environmental implications of new design and service systems, challenging the current status with input from multiple stakeholders willing to redefine baselines. For researchers working on the development of global population scenarios and the quantification of environmental impacts, the challenge is to consider impact drivers that arise, for example, from socioeconomic differences and unsustainable societal trends, and work in collaboration with multiple disciplines for the development of integrative solutions.

7.02.P-Mo404 Machine Learning Analysis of Regional Sustainable Development
Chen I-Chun[1]*, Kui-Hao Chang*[2]*, Ming-Chin Kao*[2]*, Yen-Fu Liu*[2] *and Yang Chen*[2]*, (1)Department of Land Resources, Chinese Culture University, Taiwan, (2)National Cheng Kung University*
Based on the responsibility of sustainable development, the Taiwan government announced the Sustainable Development Goals (SDGs) in 2018, including 18 core goals and 143 sub-indicators to adopt the localization. The establishment pathway was only considered through a significant definition but the causal relationship between each indicator has been ignored. In addition, the changes in the sustainability of the regional governance need objective analysis. In view of this, we obtain the Taiwan open data, containing high information granularity at township levels, such as SDG1: no poverty; SDG2: zero huger, SDG3: health; SDG4: education; SDG6: environment protection; SDG7: affordable energy; SDG8: economy; SDG11: sustainable city; SDG15 life below the land. To assess the cluster correlations and geographical characteristics of sustainability of the regional governance, we use the unsupervised machine learning methods to predict the spatiotemporal changes. Hopefully, the preliminary study's findings in the Kaohsiung city can apply the adaptation strategy for the sustainability of regional governance.

7.02.P-Mo405 Using iSafeRat® Desktop as a Quick and Efficient Tool as Part of a Process to Develop New Safe and Sustainable by Design Substances
Gaspard Levet*, Franklin Bauer, Floriane Larras, Etienne Bourgart and Paul Thomas, KREATiS, France*
In accordance with the EU Commission's desire to move to Safe & Sustainable by Design (SSbD) products, it is essential to develop new molecules that are both functional and as non-hazardous as possible. To help reach this goal, KREATiS proposes an innovative approach based on new molecule design optimization for use in chemistry, pharmaceuticals, cosmetics or agrochemicals. Using the Mechanism of Toxic Action (MechoA) of the molecules (predicted by MechoA+ profiler in the OECD

QSAR Toolbox or MechoA Premium model in iSafeRat® Desktop), we propose a tool that can aid R&D development, as part of the SSbD process, to help limit (eco)toxicological concern from early stages of product development, prior to performing regulatory studies and dossier submission. A workflow developed by KREATiS, has been successfully applied for several compounds in the fragrances, general chemicals and agrochemical industries. It can identify critical endpoints (e.g. unexpected MechoA, high toxicity to a given species) for the investigated molecules. Then, based on expert judgment, it is possible to provide clues on how to adjust the structure to avoid these, while trying to preserve the intended properties of the chemical (e.g. herbicidal action). The broad range of models included in iSafeRat® Desktop allows the identification of unwanted mechanisms of toxic action as well as the quantification of potential toxic effects before and during the development of new lead compounds. This workflow is a holistic approach, it uses a combination of different in-house models based on MechoAs, such as high-accuracy QSAR models predicting acute and chronic aquatic toxicity, an autoxidation profiler, sensitisation profiler, skin and eye irritation/corrosion models. Using predictive tools to estimate the relative toxicity of a large batch of promising compounds in early-stage research can save time and help focus on the most appropriate compounds. It is cheaper than experimental tests and respects the 3Rs paradigm. It also reduces the risk of problems later in the regulatory process. Combining *in silico* with key experimental tests can further increase confidence in the approach.

7.02.P-Mo406 Including Criteria for GREENER Active Pharmaceutical Ingredients in the R&D Process: Opportunities and Need for Tools and Assays
Caroline Moermond[1], *Neele Puhlmann*[2], *Andrew Ross Brown*[3], *Stewart Owen*[4], *Jim Ryan*[5], *Jason Snape*[4], *Bastiaan Venhuis*[1] *and Klaus Kümmerer*[2], *(1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Institut für Nachhaltige Chemie und Umweltchemie, Leuphana University Lüneburg, Germany, (3)Exeter University, United Kingdom, (4)Astrazeneca UK, United Kingdom, (5)Environment, Health and Safety, GSK, United Kingdom*
Recently, we published criteria for GREENER active pharmaceutical ingredients. Application of this GREENER approach to drug discovery and development will help to reduce impact of medicinal residues on the environment. The criteria include effect reduction by avoiding non-target effects or undesirable moieties, exposure reduction via lower emissions or environmental (bio)degradability, no PBT (persistent, bioaccumulative, as well as toxic) substances, and, in those cases where it was not possible to apply these criteria, risk mitigation. With all these criteria however, patient health is of primary importance as medicines are required to be safe and efficacious in treating the disease. Before the criteria can be applied, tools and assays need to be developed in alignment with Drug Discovery and development principles. We will discuss which characteristics of these tools and assays are important and how current ecotoxicological tools may be adapted.

7.02.P-Mo407 Environmental Impact of Pharmaceutical Products – A Systematic Review of Life Cycle Assessment Methods and Outcomes
Lowik Pieters[1], ***Martijn van Bodegraven***[2] *and Rosalie van Zelm*[2,3], *(1)Centre for Sustainability, Environment and Health, National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Centre for Sustainability, Environment and Health, Dutch National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Department of Environmental Science, Radboud Institute of Biological and Environmental Science, Radboud University, Netherlands*
During the life cycle stages of healthcare processes and products, many emissions and resource extractions occur that can have negative health and environmental effects. If one person is cured today, at the expense of making other people sick tomorrow, healthcare becomes counter-productive. Safe and sustainable pharmaceuticals can contribute to a healthy healthcare system. To understand the environmental consequences of pharmaceuticals, Life Cycle Assessments (LCAs) can provide valuable input. However, there is currently no agreement on the application and usability of pharmaceutical LCAs in footprint studies for the healthcare sector.
This literature review on all available scientifically published LCAs of pharmaceutical products until May 2022 aims to A) present the current state of the science of life cycle inventories (LCIs) and LCAs of pharmaceutical products whereby methodological choices, knowledge gaps and challenges are identified and B) present how to address these challenges in further research in the field.
LCAs of 63 pharmaceutical products with a known active pharmaceutical ingredient (API) and 6 with an unknown API have been retrieved during literature screening. The review also includes production processes such as solvent use (25 products), nuclei for API synthesis (2) and drug packaging (5).
Preliminary results show that common inconsistencies in performing LCAs for pharmaceutical products are missing life cycle stages, unspecified inventories, a limited life cycle impact assessment and missing interpretation steps. During the presentation, perspectives will be presented on how to address these challenges.

7.02.P-Mo408 Recombinant Production of Peptide Antibiotics – An Interdisciplinary Approach to Develop Sustainable Antibiotic Alternatives
Lisa Michel[1], *Jörg Andrä*[2], *Stephan Noll*[2] *and Gesine Cornelissen*[2], *(1)Biotechnology, Hamburg University of Applied Sciences (HAW), Germany, (2)Hamburg University of Applied Sciences (HAW), Germany*
The ubiquitous contamination of the aquatic environment with antibiotic residuals accelerates the worldwide spread of antibiotic-resistance genes. Still, it is not predictable, how great the long-term impact of antibiotic-polluted surface and drinking water on human health will be. To face this global challenge, new effective, and rapidly and completely degradable antibiotics are urgently needed. An alternative to conventional antibiotics are natural structure-based antimicrobial peptides (AMPs).

The clinical application of AMPs requires an economic large-scale production process. The recombinant expression overcomes several drawbacks of chemical synthesis, but toxic side effects of the AMP on the host system request innovative approaches. A possible strategy is the expression and secretion of an inactive AMP-fusion protein.
For the biotechnological production, a modified sequence of the membrane active region of porcine NK-lysin is chosen. Recombinant *Pichia pastoris* cells are cultivated in a highly instrumented bioreactor using an automated feeding strategy to reach high cell densities for maximum product yield. During purification, the fusion protein is captured by affinity chromatography, further, the final product is separated from its fusion partner. In the end, the activity of the *P. pastoris*-derived AMP is tested. Analysis of the cultivation supernatant demonstrated that the fusion protein is secreted into the cultivation media, indicating that the expression system is not affected by its product. Activity tests showed that the purified AMP has a certain antimicrobial activity. In summary, the first results suggest that the applied strategy could be a promising approach to establish an efficient production process.
The success of heterologous large-scale production of AMPs will have a great impact on the reduction of the emission of antibiotics to the aquatic environment and the future availability of potent antimicrobial pharmaceuticals.

7.02.P-Mo409 Sustainable by Design: An Aquatic Ecosystem Friendlier Alternative for Ciprofloxacin
Qiyun Zhang *and Karel De Schamphelaere, Ghent University - GhEnToxLab, Belgium*
The wide application of antibiotics has brought threats to freshwater ecosystems. Besides direct adverse effects on non-target aquatic organisms, the residues of persistent antibiotics in surface water enhances the selection pressure of antibiotic resistance (ABR) genes, too. The Safe and Sustainable by Design (SSbD) concept promotes sustainable pharmaceuticals that have lower potential hazardous impact on the environment throughout their life cycle: production, emission, degradation, and mitigation. An alternative compound derived from ciprofloxacin (CIP), CIP-Hemi, was developed based on the SSbD concept. Being higher in degradability than CIP, the chemical is likely to be less persistent in the environment. This study compared the ecotoxicity of CIP-Hemi and CIP using a cyanobacteria growth inhibition test. A species sensitive to CIP, *Microcystis aeruginosa* PCC 7806 was employed. As both CIP and CIP-Hemi are ionizable compounds, the test was performed at pH 8.0, at which the highest ecotoxicity of CIP is expected. Test results show that the observed ecotoxicity of CIP-Hemi, described by the 50% effect concentration (EC50), is at least 1 magnitude lower than that of CIP. Hence, CIP-Hemi is a promising compound that might result in reduced ecological risk to aquatic ecosystem.

7.02.P-Mo410 Circular-Economy Challenge – The Power Of Rapid Screening of Chemicals in Plastics is Limited
Helene Wiesinger[1]*, Zhanyun Wang*[2]*, Verena Christen*[3]*, Miriam Langer*[3]*, Roxane Pasquettaz*[4]*, Christophe Bleuler*[4]*, Philippe Favreau*[4] *and Stefanie Hellweg*[1]*, (1)ETH Zürich, Switzerland, (2)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (3)University of Applied Sciences and Arts Northwestern Switzerland - FHNW, Switzerland, (4)Service de l'air, du bruit et des rayonnements non ionisants - SABRA, Switzerland*
Plastic recycling is urgently needed to mitigate climate change and other environmental impacts associated with the production of virgin plastics. However, plastics can contain various chemical substances, including residual monomers, additives, processing aids and non-intentionally added substances (NIAS). These chemical substances can pose various challenges to the transition to a circular economy: by polluting secondary materials, interfering with the recycling process, or having negative health impacts on consumers and workers. Currently, manufacturers provide little information up-front on which substances are present in a specific product, rendering rapid screening of chemicals as a necessary alternative to provide this information. In this study, we aimed to find a suitable, simple and fast screening method to determine which plastic products may contain chemicals posing a high risk to consumers or the transition to a circular economy. We employed complementary techniques to rapidly screen polyvinyl chloride (PVC) building materials for specific chemicals and in-vitro biological effects. Specifically, we used XRF for elemental analysis, solvent extraction and gas chromatography–mass spectrometry (GC-MS) for suspect screening, and solvent extraction and four bioassays (i.e., MTT, Reactive Oxygen Species (ROS), Yeast Estrogen/Androgen Screen (YES/YAS), AMES) for biological screening. We found that many of the building-material samples contained toxic metals (mainly lead), restricted phthalates (mainly DEHP), alternative phthalates (mainly DiNP and DiDP), and alternative plasticizers (mainly DEHT and DEHA), whereas a few samples contained phosphor flame retardants. Some samples showed activity in the employed bioassays. None of the employed methods could predict the presence of problematic substances nor the biological activity of samples on its own. This suggests that a host of methods is needed to get a full picture of the chemical content in a product, and thus, its fitness for recycling. Owing to the immense workload associated with such comprehensive screening campaigns, even the most ambitious efforts will not be sufficient to ensure, in a timely and cost-effective manner, that all hazardous chemicals are eliminated from our material cycles before recycling. Therefore, concerted action is urgently needed to ensure up-front transparency of chemicals in plastics.

7.02.P-Mo411 Safe, Sustainable and Circular by Design Organophosphate Flame Retardants
Hannah Flerlage[1]*, Bianca Stadelmann*[1,2]*, Michiel Kraak*[3]*, Antonia Praetorius*[3] *and Chris Slootweg*[1]*, (1)Van 't Hoff Institute for Molecular Sciences, University of Amsterdam, Netherlands, (2)University of Amsterdam, Netherlands, (3)University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Netherlands*
Safe and Sustainable by Design has gained traction in research and policy spheres as a key tool to achieve a non-toxic environment. However, there are limited examples of the practical application of this concept. In this work we present a case study of redesigning the flame retardants tris(2-chloroethyl)phosphate (TCEP), listed as substance of very high concern under REACH due to its toxic effects on reproduction, and its analogue tris(3-chloropropyl)phosphate (TCPP), for which less data is

available. Both chemicals are frequently found in environmental monitoring studies. The central aim of our redesign is to change the molecular structure to reduce hazard.
We build on a computer-aided approach using *in silico* generation of chemical structures similar to the original chemical and available, established, and applicable QSAR models to predict PBMT related properties. Multicriteria analysis ranked generated structures according to predictions and inspection of the top-scoring compounds identified promising structural features to inform our design. Elements of sustainable production were also considered. Retrosynthetic fragments with a high potential to be sourced sustainably in the future are chosen. Regarding the phosphate core of the molecule, research is underway in our labs to synthesize circular organophosphates from phosphates recovered from wastewater.
We propose two alternative chemicals for TCEP and TCPP, respectively. With a straight-forward design choice we strive to give a clear-cut example of the feasibility of tuning environmental properties by molecular design. The poster will present the redesign process including results of a suite of experimental tests comparing the environmental safety of the original compounds TCEP and TCPP, with that of the newly designed compounds. Experiments are primarily focused on the aquatic environment as the expected most affected compartment exposed via wastewaters. Two experiments are run to study biodegradability, (1) assessing mineralization via CO_2 evolution in different media (sewage sludge, freshwater) using a respicond system, and (2) studying primary degradation and transformation products using LC-MS/MS. Acute and chronic ecotoxic effects on algae, daphnia, and chironomids are determined. Furthermore, we will test the function of the alternatives in flame retardancy tests. This extensive series of experiments will likely make a solid case demonstrating the feasibility of Safe and Sustainable by Design.

7.02.P-Mo412 A 2-Phase Methodology to Assess the Environmental Implications of Agricultural Systems to Inform Sustainability Improvements: Conservation Agriculture as Example

Laura Green[1], Elise Webb[1], Elizabeth Johnson[1], Sarah Wynn[1], Gregor Morgan[1] and ***Christian Bogen[2]****, (1)ADAS, United Kingdom, (2)EMEA Public Affairs, Science & Sustainability, Bayer AG - Crop Science Division, Germany*

To improve sustainability of farming it is important to understand the environmental costs and the benefits of the various tools and methods that are applied within diverse cropping systems.
Based on the available peer-reviewed scientific literature, we initially developed a methodology that used the environmental categories that are usually adressed within environmental risk assessment processes for plant protection products as starting point, and applied it to various other, non-chemical tools that are commonly part of agriculture. Finally, a range of abiotic and biotic impact categories were considered, featuring 12 assessed categories for soil, water, climate and biodiversity.
In a second phase of the work, we explored the scientific literature about the environmental implications of the production systems where those tools and methods are applied. We took the example of conservation agriculture with a focus on wheat production in temperate climates (e.g. comparable to Central Europe) to explore the environmental benefits and limitations of that specific system.
The results of phase 1 show a nuanced picture of the environmental implications related to direct impacts, indirect impacts, their selectivity and potential data gaps when it comes to the different tools and impact categories. Concerning phase 2, for conservation agriculture a multitude of environmental benefits were found, although in temperate climates the system may also present several limitations.
The two-phase assessment of the different tools and environmental impacts of the systems was able to create a broad and nuanced perspective to identify opportunities and trade-offs. This combined approach can therefore help to build a better and more holistic understanding of the agronomic and environmental implications of different management options. The farmer then has the potential to use this information to improve the overall sustainability of their production system, placing emphasis on the environmental impacts that are most important in their particular location and within their agricultural system.
In addition, this approach can support policy-makers to facilitate decision-making by taking into account the available scientific evidence and its conclusiveness, thereby also increasing transparency towards the public and various other stakeholders.

7.03.P Bioelectrochemical Systems Technology for a Better Environment

7.03.P-Mo413 Microbial Electrochemical Systems to Remove Bioactive Pollutants From Water: Finding the Nexus Between Composition of Anodic Microbial Communities, Removal Efficiency and Electrochemical Performance

Claudio Avignone Rossa*, Razieh Rafieenia, Mira Sulonen and Daniel Farkas, Department of Microbial Sciences, University of Surrey, United Kingdom*

The release of pollutants to the environment, caused by human activity, contaminate soils and water bodies with a diverse collection of biologically active compounds, including antibiotics, endocrine disruptors, pharmaceutical and personal care products, pesticides, and other types of potentially toxic molecules, such as chlorinated compounds, polycyclic aromatic hydrocarbons, etc. Some of those compounds are very difficult to remove from water using conventional methods, and remain at concentrations hazardous for humans, animals and plants.
In recent years, developments in microbial electrochemical systems (MES) have prompted their application in wastewater treatment systems. In devices called microbial fuel cells (MFC), electroactive microorganisms colonize the anode, using it as the terminal acceptor of electrons released in the catabolism of substrates present in the feedstock. The circulation of those electrons through an external circuit towards a cathode generates an electrical current. If electroactive microorganisms (single species or microbial communities) are able to degrade those pollutants, they can be inoculated in the MFC, and the combination of their metabolic capabilities with their capacity for extracellular electron transfer may result in efficient removal of recalcitrant pollutants.

In this talk, I will discuss advances in the design of MFCs to overcome the limitations of the process, and how the microbial communities can be studied and analysed to steer their metabolic and electrical performance towards higher process efficiencies. I will present examples of recent work for removal of pesticides, antibiotics, hydrocarbons, and heavy metals from polluted water of diverse origins, and show how the composition of the microbial communities involved can be manipulated to improve their activities.

7.03.P-Mo414 Studying the Extracellular Electron Transfer Mechanisms of Desulfuromonas Acetoxidans to Develop Sustainable Energy Production and Water Desalination

***Ricardo Morgado Soares**[1], Alexandra Alves[2], Catarina Paquete[2] and Ricardo Louro[2], (1)Institute of Chemical and Biological Technology Antonio Xavier (ITQB NOVA), Portugal, (2)ITQB-NOVA, Portugal*

One of the major sustainability challenges of our time is to provide fresh water for human consumption and activities in a scenario of increasing demand from a rapidly growing human population. Since 97% of the planets water supply is in the oceans, water desalination technologies have been emerging as a solution to tackle this major problem. Microbial Desalination Cells (MDC) have the advantageous particularity of producing potable water in a combined process of producing electricity from wastewater treatment. In MDC, electroactive bacteria act as catalysts by supplying this bioelectrochemical system with electrons from the oxidation of organic matter that can be found in wastewaters. Since most characterized electroactive bacteria are not tolerant to high salt concentrations, MDC are inherently prone to be energy inefficient and not suitable for saltwater desalination. In order to improve and optimise MDC technology, we focused our attention on the marine and electroactive bacterium *Desulfuromonas acetoxidans* that has been shown to be prevalent in bioanodes operating in conditions of high salinity. Our work aims to evaluate *Desulfuromonas acetoxidans* DSM 684 electroactivy using *in vivo* and *in vitro* studies. The capacity of *Desulfuromonas acetoxidans* to tolerate salt and produce current in a bioelectrochemical system was assessed, revealing that the optimal growth of *D. acetoxidans* is at 2% NaCl, while current production did not show significant difference between 1, 2 and 3%. In order to understand the key molecular players in the current production, a putative electron transfer pathway composed by multiheme cytochromes was identified in *D. acetoxidans* compared with other related electroactive organisms and characterized using *in vitro* studies. Altogether this study constitute the template for the better understanding of the pathways of *D. acetoxidans* that are key for its application in MDC towards sustainable energy production and water desalination.

7.03.P-Mo415 Bioelectrochemical Treatment Wetlands for Safeguarding Wastewater-borne Antibiotic Emissions

*Vaidotas Kisielius[1], René Kilian[2], Jens C Pors[2], Carlos Alberto Arias[3] and **Pedro N Carvalho**[1], (1)Environmental Science, Aarhus University, Denmark, (2)Kilian Water ApS, Denmark, (3)Aarhus University, Denmark*

Concerns on the occurrence of aquatic pollutants, specifically, antibiotics, antimicrobial resistant microorganisms and microbial pathogens in the environment is increasing. This in turn increases the attention on the performance of wastewater treatment technology for these types of pollutants.

Wastewater is considered a major source of emerging contaminations emission to the environment, mostly because traditional technology and existing treatment plants are not designed to address these pollutants. As a result, efforts to mainstream nature-based solutions to manage wastewater need to carefully assess their performance in relation to antibiotics, antimicrobial resistant microorganisms and microbial pathogens.

The current work, being developed under the umbrella of Project Nature, aims at assessing the performance of a novel hybrid technology that merges a bioelectrochemical system with a treatment wetland. More specifically, this novel technology is being benchmarked against current state-of-the-art treatment wetland technology (vertical flow and intensified with aeration) for secondary wastewater treatment.

Three full-scale systems (30 - 200 PE) implemented in Denmark treating domestic wastewater are being monitored since May 2022 for 1-year period. Influents and effluents are being sampled monthly and analysed for target model antimicrobial compounds and respective transformation products, and DNA-based techniques to characterize pathogens and antimicrobial resistance, together with classical water quality parameters. The selected list of target compounds includes 14 antibiotics (e.g., azithromycin, erythromycin, sulfadiazine); 5 antimicrobials (e.g., quaternary ammonium chlorides), 3 antifungal agents (e.g., miconazole), and over 30 other domestic wastewater-relevant micropollutants.

The first results indicate that several antibiotics are measured in the influent of the study sites. However, it can be seen that the decentralized wastewater systems (< 200 PE) show different antibiotic occurrence patterns and concentrations than in large urban wastewater treatment plants. Removals above 63% (of e.g. trimethoprim) have been observed.

At SETAC Europe we will present the first monitoring results of the bioelectrochemical treatment wetland, a unique system in Scandinavia, with a large potential for replication. The potential of these nature-based solutions to control antimicrobial emissions will be very important for their future application.

7.03.P-Mo416 Electrostatic Separation of Nanoplastics from Wastewater

***Amna Abdeljaoued**[1,2], Beatriz López Ruiz[1,3], Yikalo Eyob Tecle[1], Patrik Stenner[1] and Nicolas Vogel[3], (1)Particle Processing, Process Technology & Engineering, Evonik Operations, Germany, (2)Institute of Particle Technology, Evonik Operations, Germany, (3)Institute of Particle Technology, Friedrich Alexander Universität, Erlangen–Nürnberg, Germany*

Microplastics, generated by the degradation of plastic waste, have been found in almost all ecosystems across the globe and remained catching attention as an emergent pollutant. Such micron-sized particles, however, may only be the tip of the iceberg. Nanoplastics, represent the nanoscale size of these tiny particles. With sizes much smaller than 1µm, they can be even more environmentally problematic as such particles may be taken up and interfere with individual cells of organisms. Still, their very small size makes identification and removal much more challenging compared to conventional microplastics. Thus, the research field of Nano plastics is still in its infancy. In our present work, we aim to remove Nanoplastic materials from wastewater through the use of their unique properties. We apply a combination of electrochemical and colloidal processes to remove such tiny particles from an aqueous phase. A model system has been chosen as a starting point to have a control over all the influencing parameters and to prove a basic understanding of the separation mechanism. These findings are consequently transferred to industrial wastewater as a real environmental system. Both systems have been efficiently treated and cleaned from nanoparticles. The recovery percentage reached 98% and 95% from the model system and the industrial wastewater systems respectively. To take the process further, a scale up of the technique in a continuous mode is currently being performed.

7.03.P-Mo417 Bioelectricity Production by Terrestrial Microbial Fuel Cells using a PAH Contaminated River Sediment

*Snezana Maletic[1], Domenico Borello[2], Gabriele Gagliardi[2], Carlotta Cosentini[2], Valeria Ancona[3], Anna Barra Caracciolo[4], Gian Luigi Garbini[5], Alessandra Narciso[6], Andrea Visca[5], Natalia Leone[3], Claudio Scardamaglio[5], Ludovica Rolando[5], Srdjan Roncevic[7], Mrijana Kragulj Isakovski[7] and **Paola Grenni**[5], (1)University of Novi Sad, Serbia, (2)La Sapienza University of Rome, Italy, (3)CNR-IRSA Bari, Italy, (4)Water Research Institute - Italian National Research Council IRSA-CNR, Italy, (5)CNR-IRSA Rome, Italy, (6)Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (7)University of Novi Sad, Faculty of Sciences, Serbia*

Dredged river sediments can be contaminated by Polycyclic Aromatic Hydrocarbons (PAHs) due to their accumulation in sediments.

Terrestrial Microbial fuel cells (TMFCs) are bioelectrochemical system with soil or sediment as the electrolyte. TMFCs have been investigating for their ability to harvest electricity from microbial activity and, at the same time, biodegrading persistent contaminants.

In this framework, a TMFC experiment in open and closed-circuit conditions was set up with a river sediment collected from a navigable channel (Bega) located between Romania and Serbia. It contained PAHs (920±153 µg/kg), total petroleum hydrocarbons (1799±286 mg/kg) and heavy metals (Cr, Cu, Pb and Zn). Some TMFCs were also set up with sediment plus compost (3% w/w) for testing if an additional carbon source could enhance microbial activity. Control sediment (without cathode and anode) were also set up. TMFC polarization curves were performed daily by a measurement station. The circuit was closed applying several resistances.

TMFC activation time was relatively low, probably due to the microbial community adaptation to contaminant presence. Compost addition had a beneficial effect on the power output (maximum average power density: 173 mW/m^2 in compost presence; 53 mW/m^2 in compost absence). These values were highlighted by the internal resistance behavior. In fact, TMFCs with compost recorded an initial lower external resistance (300 Ω) if compared to sediment without compost (1000 Ω). The resistance reduction was due to the conductivity increase, probably for microorganism proliferation. At the end of the experiment (4 months), anode, bulk and cathode samples were collected for microbiological, ecotoxicological and chemical analyses. Total microbial number and activity were analyzed and the Allivibrio fischeri and Heterocypris incongruens ecotoxicological tests were performed for all conditions. Moreover, PAH (EPA 8000b), TPH (ISO16703:2004) and heavy metals (EPA7010) were analysed. Finally, a spectroscopic characterization of sediments was performed by an ASD FieldSpec portable spectroradiometer. Microbiological analyses showed the presence of more active bacterial populations in compost presence, with the highest values at anode. The ecotoxicological tests showed some positive effects on the organisms tested presumably due to the non-complete PAH degradation, with the formation of toxic transformation products.

7.03.P-Mo418 Bioelectrochemical Systems as a Platform for Biodegradation and Biosynthesis of Surfactants

***Grzegorz Pasternak**[1], Natalia Tyszkiewicz[2], Bartosz Widera[2], Aleksander de Rosset[2], Piotr Młynarz[2] and Piotr Rutkowski[2], (1)Faculty of Chemistry, Wroclaw University of Science and Technology, Poland, (2)Wroclaw University of Science and Technology, Poland*

Microbial fuel cells (MFCs) have been recognized as systems that are capable of degrading multiple types of pollutants, including problematic hydrophobic compounds. In recent years, significant efforts have been made toward MFC-based degradation. Such an approach may become a solution for both in-situ and ex-situ methods of biodegradation. MFCs and other types of bioelectrochemical systems (BESs) give the unique opportunity to control the bacterial metabolism through electrical cuircuts, as well as to extract energy from degraded organic matter.

In this work, petroleum and waste cooking oil degraders and biosurfactant producers were acquired from several types of environments. These communities were sampled over Europe and Asia, including: pristine environments, moderately contaminated nature areas, urban environments, and heavily contaminated sites. Small scale MFC and BES designs, were used to adept and develop communities capable of degrading hydrophobic waste products. These communities were further investigated towards biosynthesis of surfactants. The waste cooking oil as fuel revealed higher surface activity, reaching 37 mN/m, while the occurrence of surface activity for petroleum was recorded only after several months of adaptation and reached 47 mN/m. In both cases, the occurrence of biosurfactants was correlated with the electrochemical activity, suggesting a direct contribution of biosurfactants in metabolism in MFC-supported biodegradation.

The analytical studies revealed the presence of rhamnolipids based on both types of substrates as well as microbial species producing other types of biosurfactants. Therefore, we have shown that biosurfactants can be produced within BES systems to combat the environmental pollution.

7.04 Environmental Toxicology and Chemistry in Africa: Tackling Legacy and Emerging Pollutants

7.04.P-Mo420 Evaluating the Potential Human Health Effects and Impact of Gold Mine Activities on River Osun, Osun State Nigeria

Gbadebo Clement Adeyinka[1], *Babatunde Femi Bakare*[1] *and Fatai Afolabi*[2], *(1)Chemical Engineering, Mangosuthu University of Technology, South Africa, (2)Applied Sciences Department, Osun State Polytechnic, Nigeria*

The quest for safe potable water is increasingly required by the day most especially in developing countries globally. Surface water is one of the main sources of water supply and this has contributed significantly to the larger population groups for both domestic, agricultural, and in some cases industrial use. Osun River is a major river within its catchment area that flows southwards through central Yorubaland in southwestern Nigeria into the Lagos Lagoon and the Atlantic Gulf of Guinea. It is sacred and reserved along its course within the Osogbo groove. Human activities such as mining practices by illegal and unregulated licensed gold mining activities at the upper course along the Ilesha axes have caused a sudden change in the colour of the river thereby influenced negatively, compromising the quality of the Osun River. Therefore, there is a need for urgent attention to know the current state of this river for the health and safety of people that depend on it. In this study, the impact of mining activities with the probable health risk associated with precious metals such as gold and silver as well as other selected heavy metals were collected at six (6) strategic points along the course of this river. A 250 mL water sample was collected in sterilized screw-capped amber plastic bottles at a depth of 10-15 cm from the flowing river at each point following a standard method (Harmel et al. 2010). Water samples were acidified using nitric acid. The samples were filtered using 0.45 µm Acrodisc syringe filters, prior to analysis. The selected heavy metals were analyzed by inductively coupled plasma optical emission spectrometer (ICP-OES, PerkinElmer, Waltham, Massachusetts, United States) at a selected wavelength. The result indicated that the metals investigated were found to be present in the samples along the river course. The concentrations of the metals ranged from 33.40 – 137.0 µg/L (Au), 33.30 – 434.0 µg/L (Ag), 231.80 – 405.20 µg/L (As), ND (Cd), 58.80 – 71.20 µg/L (Co), 78.80 – 168.20 µg/L (Cu), 1330 – 3880 µg/L (Fe), 85.80 – 246.30 µg/L (Mn), 58.0 – 96.10 µg/L (Ni), 35.40 – 97.10 µg/L (Pb) and 120.70 – 428.00 µg/L (Zn). All the heavy metals were present except Cd which was below the detection limit. Most of the heavy metals investigated could likely pose adverse health effects to the aquatic life and the humans that get exposed to this river.

7.04.T-01 Utilizing a Geographic Information System-based Knowledge Hub for Contaminants of Emerging Concern in South African Water Resources developed using Open-Source Software

Tarryn Lee Botha, *Water Research Group, North-West University, South Africa*

Protecting surface freshwater sources is now a top priority in water resource management due to population increase and diminishing resources. In the past, society has responded to issues based on the availability of financing, the gravity of the threat, and the level of public outrage. The ability to identify the causes of contaminated water supplies is crucial for achieving this. These elements are continually shifting as new contaminants are released into sources of surface water. The interest in contaminants of emergent concern (CEC) is growing as we go deeper into the digital age. Unrestrained pollutants are contaminants of emerging significance because they are now being found in our water bodies. These can include nanomaterials, flame-retardants, microplastics, agricultural waste, pharmaceuticals and personal care products, which may cause ecological or human health impacts. The continued unregulated use of these products could lead to further ecological risks. Although studies are being done to determine which contaminants are present in South African water sources, the results of these studies and the information that is currently available are not compiled and presented to the scientific community and stakeholders in readily accessible formats and platforms. To create environmental regulations, authorities must be informed of recent study findings. With the aid of technology from the fourth industrial revolution, we were able to compile data from the literature and present it to both regulatory authorities and researchers in an accessible geographic online format. In order to enable visualization on an interactive map that can be continuously updated, a standard Excel spreadsheet was created, uploaded to a PostgreSQL database running a PostGIS extension, and then processed in the GeoServer. The ability to access information in near-real time will lessen the likelihood of redundant research efforts, foster interdisciplinary cooperation, and serve as a CEC early warning system for South African water resources. This technology can be expanded upon to include several other geographical regions.

7.04.T-02 Toxic Informal Solar Lead-Acid Battery Recycling in Malawi

Christopher Kinally[1], *Fernando Antonanzas-Torres*[2], *Alejandro Gallego-Schmid*[1] *and Frank Podd*[1], *(1)University of Manchester, United Kingdom, (2)University of La Rioja, Spain*

In Malawi, electricity deprivation is recognised as a risk to the country's development and future stability. With the inadequacy of the national electricity grid, Malawi's national electrification strategy depends on the private off-grid solar market, aiming to import and deploy millions of household scale off-grid solar (OGS) products by 2030, currently in absence of a waste management strategy. Malawi's OGS market is predominately unregulated; solar home systems are distributed by unmonitored and uncertified suppliers and rely on lead-acid batteries with short expected lifetimes (< 4 years). This study investigates the informal recycling of lead-acid batteries in Malawi, which is known to be one of the world's most toxic industries but has not been reported in Malawi before and has not been considered in relation to electrification strategies across sub-Saharan Africa. Data was collected by observing two informal recyclers in peri-urban villages near the capital city of Lilongwe carrying out the informal recycling process for lead-acid batteries used in off-grid solar home systems. The data was collected as part of a series of studies addressing off-grid solar waste in Malawi, including a mass flow analysis of the informal lead-acid battery recycling process. The rudimentary methods of fabricating improvised lead battery cells are described, slightly differing between the recyclers but following the same principles.

Between 3.4-4.2 kg of lead was lost to the environment during the informal recycling of a single battery (0.27-0.29 kg lead lost per kg of battery), representing 108-133 times the oral lethal dose of lead for a 70 kg adult. Either 0.67 or 3.66 kg of dilute sulphuric acid was split to the floor (0.05 of 0.25 kg sulphuric acid lost per kg of battery), depending on if the acid was collected

and reused in the recycled battery or discarded on the street. There is a paucity of research on the lead exposure and absorption pathways from informal lead-acid battery recycling in low- and middle-income countries, although, the observed battery recycling processes took place on busy streets within peri-urban villages, exposing densely populated communities to life-threatening quantities of lead pollution. These severe environmental and human health burdens risk being exacerbated by Malawi's national OGS electrification strategy. Further studies are urgently needed to investigate the health impacts of OGS waste across sub-Saharan Africa.

7.04.T-03 Examining the Impact of Pyrethroid Leaching From Insecticide Treated Net Fishing on Mortality and Oxidative Stress Biomarkers in Aquatic Organisms

***Deirdre Honoria Doyle Love*[1]**, *Francisco Paneques[2], Melissa Filgueiras[2], Jessica Donaldson[2], David Larsen[3] and Joseph H Bisesi[1], (1)Environmental and Global Health, University of Florida, (2)University of Florida, (3)Syracuse University*

The distribution of insecticide treated mosquito nets (ITNs) is a great public health success story, with studies suggesting these nets reduced the global burden of Malaria by approximately 40%. ITNs are typically treated with pyrethroids, which are known to have a low toxicity to mammals and high toxicity to aquatic organisms. Recent studies have shown that ITNs are being used for alternative practices, including fishing. In a study from a waterside community located on Lake Tanganyika, 87.2% of people utilized their mosquito net for fishing as opposed to malaria protection. Coinciding with reports of off label fishing, there are reports of a decrease in fish quality and quantity. Quantitative data is missing to support these claims, so we designed experiments in both vertebrates, P. promelas, and invertebrates, D. magna to investigate the toxicity of ITNs. Organisms were exposed to varying sizes of nets, 1cm2, 5cm2, 10cm2, 20cm2, and non-treated 20cm2 sized nets. Two pyrethroid treated nets were tested alpha-cypermethrin treated nets and deltamethrin treated nets. We tested six exposure scenarios for 7 days and mortality was recorded. To test for sub-lethal effects, we focused on oxidative stress endpoints that have been linked to pyrethroid exposure. Following sublethal exposures, we measured SOD1,2,Catalase, P53, PXR, and CYP3A4 expression using qPCR in the P. promelas larvae to expand our understanding of oxidative stress and sublethal impacts. Results from our mortality experiments showed that both ITNs used in our experiments are highly toxic to invertebrates. The use of new Alpha-cypermethrin treated net led to 100% mortality in all treatment groups in under 48 hours. When organisms were exposed for 30 minutes we observed 100% mortality in the 5cm2,10cm2, and 20cm2 sized nets and a slight reduction in toxicity for the 1cm2 net. For our Deltamethrin experiments, using a net new all treatments reach 100% mortality by 72 hours. When we reused the nets throughout the experiment, all treatment groups except for 1cm2 reach 100% mortality by 168 hours. When the organisms were exposed for 30 minutes, all treatments reached 100% mortality, except for the 1cm2 sized net which reached 40% mortality.Results from our sub-lethal exposures include significant results for all of our genes when compared to our housekeeping gene. Results from these studies indicated that ITNs are highly toxic to invertebrates and can lead to sub-lethal changes following exposure.

7.04.T-04 Air pollution in Dakar (Senegal): A Case Study on Outdoor and Indoor Exposure

***Anthony Verdin*[1]**, *Awa Ndong BA[2], Jeremy Thomas[3], Fabrice Cazier[4], Mathilde Cabral[5], Anne Garat[3], Delphine Allorge[3], Guillaume Garcon[3], Jean-Marc Loguidice[3], Amadou Diouf[5], Mamadou Fall[5], Maurizio Gualtieri[6] and Dominique Courcot[7], (1)UCEIV, University of the Littoral Opal Coast, France, (2)Uceiv, Université du Littoral Côte d'Opale, France, (3)University of Lille, France, (4)CCM, Université du Littoral Côte d'Opale, France, (5)Université Cheikh Anta Diop, Dakar, Senegal, (6)University of Milano-Bicocca, Italy, (7)Unité de Chimie Environnementale et Interactions sur le Vivant, UCEIV UR4492, FR CNRS 3417, University of Littoral Côte d'Opale (ULCO), France*

The harmful effects of indoor and outdoor air pollution on human health are of great concern nowadays in several regions of the world. Dakar, the capital and biggest city of Senegal, is characterized by a vehicle fleet characterized by poorly efficient combustion technologies that largely contributes to the deterioration of air quality. In this study, we firstly evaluated indoor and outdoor air pollution levels (CO, CO2, NO, NO2, PM10) at an urban site in Dakar city center and at a rural site. Then, the individual exposure levels to selected pollutants and the variations in the levels of biomarkers of exposure were investigated in different groups of persons (bus drivers, traders working along the main roads and housemaids).

BTEX analysis revealed that toluene was the volatile pollutant with higher concentrations, ranging from 800 to 1950 µg/m^3. Benzene and xylenes concentrations were from 150 to 650 µg/m^3 while ethylbenzene was always around about 50 µg/m^3. Benzene concentration was significantly higher for the housewives group than for professionals. The high concentrations found for housewives is probably due to the cooking habits (coal used in kitchens as combustible), local practices (important incense burning) and use of cleaning products that are important emitters of volatile organic compounds. Different urinary metabolites were selected to assess human exposure. t-t-MA was not detected (below the detection limit) in urine samples, while S-PMA values were higher for housewives when compared to professionals. The level of 1-HOP, used to assess a pyrene exposure, was slightly higher in drivers (compared to traders, city housewives and district semirural housewives). Statistical analysis revealed that urinary 1-HOP levels were significantly higher for urban site housewives compared to those at the semirural district. Moreover, urinary levels of DNA oxidative stress damage (8-OHdG) and inflammatory (interleukin-6 and -8) biomarkers were higher in urban subjects in comparison to rural ones. The air quality measurement campaign showed that the bus interior was more polluted with PM10, CO, CO2 and NO than the market and urban or rural households. However, the interior of households showed higher concentration of VOCs than outdoor sites confirming previous observations of higher indoor individual exposure level to specific classes of pollutants.

7.04.P Environmental Toxicology and Chemistry in Africa: Tackling Legacy and Emerging Pollutants

7.04.P-Mo421 Catalytic Ozonation of 4-chlorophenol using Beta-iron oxy hydroxide (β-FeOOH) Nanoparticles: Efficiency and Toxicity Studies

Beatrice Opeolu[1]*, Michael Akharame*[2]*, Omoniyi Kolawole Pereao*[1] *and Olalekan Fatoki*[3]*, (1)Cape Peninsula University of Technology, South Africa, (2)Department of Environmental Management and Toxicology, University of Benin, Nigeria, (3)KolaDaisi University, Nigeria*

Nano-based water treatment applications and processes are currently receiving much attention due to their perceived ability to resolve numerous challenges encountered during conventional water treatment operations. They provide innovative and progressive approaches to solve water scarcity, and contamination issues around the world. Despite their huge potential, the use of nanomaterials for water treatment purposes is raising concerns about the safety and health implications of our environment and biota therein.

The utilization of polymer matrices as support materials for the immobilization of nanomaterials can offer some measure of safety by preventing their release into the environment during process application, and also brings about ease of recovery and regeneration for reuse. This study focused on the "safe application" of the beta-iron oxy hydroxide (β-FeOOH) nanoparticles, in continuation of previous work that established its capability as an effective catalyst when applied in catalytic ozonation processes. The β-FeOOH nanoparticles were synthesized using the hydrothermal synthesis method and incorporated into polyamide matrix via the *in-situ* method to fabricate magnetic nanocomposites. The FTIR, TEM, SEM, EDS, PXRD and nitrogen adsorption-desorption characterization were carried out for the materials. Catalytic properties of the β-FeOOH/polyamide nanocomposite (1.25 wt%) was evaluated by assessing its ability to degrade 4-chlorophenol (4CP) in aqueous solutions through catalytic ozonation processes; samples were collected at different time intervals and analysed by LC-MS-TOF. The effect of pH on degradation efficiency of the 4CP was also evaluated. Results showed a 98.0 % degradation of 4CP within 40 min relative to 64.01 % for ozonation alone. The efficiencies of the nanocomposite for 4CP degradation were 85.36 %, 86.54 % and 95.05 % obtained for pH 3, pH 7 and pH 10 respectively at 30 min, with corresponding rate constants of 0.0645, 0.0665 and 0.1123. The composite exhibited excellent reuse potential with minimal decrease of its degradation ability over six cycles. No leaching of iron was observed when applied in acidic, neutral and alkaline conditions. Additionally, the COD and TOC values for real wastewater was effectively reduced by 51.28 % and 89.22 % after 60 min by the polymeric nanocatalyst. The *Daphnia* acute toxicity test results affirmed the need for ecological and human health risk assessment of remediated wastewater.

7.04.P-Mo423 Comprehensive Monitoring of Surface Water in the QwaQwa Area (South Africa) Combining Chemical and Biological In-Vitro Tests

Dirk Jungmann[1]*, Hilmar Börnick*[2]*, Stephanie Graumnitz*[2]*, Ngitheni Nyoka*[1]*, Beatrice Opeolu*[3]*, Patricks V. Otomo*[1] *and Marinda Avenant*[1]*, (1)University of The Free State, South Africa, (2)University of Applied Sciences Dresden, Germany, (3)Cape Peninsula University of Technology, South Africa*

QwaQwa, a former homeland area in South Africa, is part of the Free State province. Recently the area has been plagued by regular interruptions in water service delivery, mainly due to water scarcity, poor and aging infrastructure, poor water governance and corruption. The situation is exacerbated by poor surface water quality, putting local communities using the water for drinking and irrigation at high risk compromising. Despite this, information on the water quality and ecological condition of the local rivers as the main water resources, is very limited. A once-off sampling campaign was carried out in March 2022 to record the potential pollution of the surface waters. The results of this study will enable the local authorities to identify sources of pollution and to develop targeted measures. Towards this purpose, biological and chemical monitoring was carried out in this area at 4 rivers and with a total of 9 sampling sites. Our hypothesis that the contamination corresponds to countries with established wastewater treatment could not be confirmed. Beside monitoring physico-chemical parameters, effect monitoring with a total of 9 in-vitro tests together with extensive chemical analysis was carried out with the water samples. The results show a high pollution of water bodies in urban areas and a lower pollution of rural areas. For the effect monitoring the yeast estrogenic screen (YES) showed at two sampling sites in urban areas response and the yeast dioxin-like screen (YDS) responded at all sampling sites except the two sites closed to the minor populated source of the rivers. Similar pattern was found by chemical analyses. However, pharmaceuticals as micropollutants show a clear difference to developed regions, such as Europe, which correlates with age distribution as well as with occurring diseases. For example, HIV drugs were found in considerable concentrations as a special feature. Iron, zinc and aluminium were detected above the environmental quality standards, however the proof of origin was unclear. The detetected pollutants corresponds to a general expected patterns for these areas, but in detail very specific evidences were also found, for example in the analyses of pharmaceuticals. For this area a decentralised management of water purification is proposed to solve water pollution issues.

7.04.P-Mo424 Oxidative Stress Biomarkers of Metal Pollution in the Non-Native Macrophyte, *Ceratophyllum demersum*, Cape Town, South Africa

Reinette G Snyman[1]*, James P. Odendaal*[2]*, Judith L. Arnolds*[3]*, Deborah V. Erasmus*[4] *and Jeanine L. Von Metzinger*[5]*, (1)Conservation and Marine Sciences, Cape Peninsula University of Technology, South Africa, (2)Environmental and Occupational Studies, Cape Peninsula University of Technology, South Africa, (3)South African National Biodiversity Institute, South Africa, (4)Horticultural Sciences, Cape Peninsula University of Technology, South Africa, (5)Microbial and Health Biotechnology Institute, Cape Peninsula University of Technology, South Africa*

Our research has shown that Cape Town's urban rivers are generally heavily polluted with metals, particularly Zn, Fe, Al and Cu. The Diep River, Milnerton, has been of particular interest to us, as it is one of the largest and most important freshwater systems in Cape Town, surrounded by numerous pollutant sources. The macrophyte *Ceratophyllum demersum* is known to be a hyperaccumulator of metals and used for phytoremediation. It grows prolifically in the Diep River. Our study investigated metal toxicity in *C. demersum*, by determining chlorophyll content and antioxidant responses in plants collected from a heavily polluted river site and compared them with specimens growing in an unpolluted pond (reference plants), to determine whether these responses can be used as biomarkers of oxidative stress. Concentrations of Zn, Fe, Al and Cu were determined with an ICP-MS, whilst chrorophyll *a*, *b* and total chl were determined by spectrophotometry. A suite of antioxidant responses was investigated. River plants generally showed significantly ($p<0.05$) higher metal bioaccumulation. AsA, CAT, SOD and TBARS were all significantly higher in river plants, whilst TP, FRAP, ORAC and GSHt were all significantly lower ($p<0.05$). CD's did not differ. Results showed that, although reference plants experienced some stress, river plants experienced far greater pollutant-induced oxidative stress. Despite this, the river plants did not show significantly lower chlorophyll content, demonstrating the species' ability to tolerate oxidative stress. When reference plants were transplanted into the polluted river in baskets and exposed for 12 weeks, they bioaccumulated metals to significantly higher concentrations ($p<0.05$) than the naturally occurring river plants and chlorophyll production was significantly promoted ($p<0.05$) during the 12 weeks, probably due to the additional nutrients in the polluted water. Our study showed that antioxidant responses in *C. demersum* seem to be reliable biomarkers of oxidative stress due to metal and pollutant-"cocktail" exposure in the field. However, chlorophyll content as field biomarker requires further investigation. We propose *C. demersum* as possible model in South African aquatic biomarker studies, due to its hyperaccumulation abilities, generally sensitive responses to chemical changes, high tolerance and abundance.

7.04.P-Mo426 Speciation of Heavy Metals and Health Risk Analysis In Some Selected Agricultural Zones In Taraba State Nigeria

Olawale Otitoju[1], *Bilyaminu Habibu*[2] *and Grace Otitoju*[1], *(1)Federal University Wukari, Nigeria, (2)Biochemistry, Federal University Wukari, Nigeria*

The soil environment is a reservoir of nutrients and pollutants to Plants and Animals. Several of these pollutants have been implicated in causing several health issues in both humans and wildlife species. Agricultural soil plays major role in food safety and security. Most of our food items are laden with lots of pollutants and the consumption of contaminated foods has serious implication on health. Heavy metals are potential environmental pollutants, they have the ability to bio-accumulate in plants and eventually get to humans through food. This study evaluated the presence of heavy metals (HM) and health risk assessment in soil on arable farmlands in selected agricultural zone of Taraba State, Nigeria. Different soil samples were collected and processed, HM (Pb, Cd, Cr, Hg, and As) concentrations were analyzed using Atomic Absorption Spectrophotometry (AAS). The results showed that Chromium concentration was generally high in all the studied areas with values ranging from 1.71 to 2.29mg/kg. However, Cadmium and Arsenic followed moderately with values ranging from 0.05 to 0.07mg/kg while Lead and Mercury had the lowest concentration of less than 0.03mg/kg across the studied areas. Ecological Risk Assessments parameters: Target Cancer risk, Hazard index (HI) and estimated daily intake (EDI) was determined to assess the non-carcinogenic health risk. Bali LGA recorded the highest levels of HM having the highest health risk, while Yorro and Zing LGAs had low hazard risk index. This Study shows that although heavy metals were present in the selected soil samples, the risk of exposure is low and may not pose any health challenge to humans based on the concentration detected.

7.04.P-Mo428 Origin and Chemical Characterization of Atmospheric Pollution (PM2.5) in Dakar (Senegal)

Salimata Thiam[1], *Fabrice Cazier*[2], ***Anthony Verdin***[3], *Mouhamadou Lamine Daffe*[4], *Mamadou Fall*[4] *and Dominique Courcot*[5], *(1)Uceiv, Université du Littoral Côte d'Opale, France, (2)CCM, Université du Littoral Côte d'Opale, France, (3)UCEIV, University of the Littoral Opal Coast, France, (4)Université Cheikh Anta Diop, Dakar, Senegal, (5)Unité de Chimie Environnementale et Interactions sur le Vivant, UCEIV UR4492, FR CNRS 3417, University of Littoral Côte d'Opale (ULCO), France*

9 million of deaths are attributable to air pollution, mostly particulate (i.e. PM), which refers to a complex mixture of airborne chemicals (Lelieveld et al. 2020). The objective of this study was to chemically characterize fine particles ($PM_{2.5}$) sampled at Medina, a locality strongly influenced by road traffic, and to determine their natural and/or anthropogenic origin. To do so, 74 samples of $PM_{2.5}$ were collected (5 days a week and 10 h/day) using a high-speed cascade impactor (Staplex, model TFIA, New York, USA). These particles were subject to an organic chemical characterization (PAHs and paraffins) by gas phase chromatography coupled to mass spectrometry (GC-MS) and an inorganic analysis (elemental and ionic composition) by spectrometry of inductively coupled emission (ICP-OES) and ion chromatography (IC). On average, the annual emission of $PM_{2.5}$ at Medina is estimated at 152.7 $\mu g.m^3$. 15 polycyclic aromatic hydrocarbons (PAHs), 22 metallic trace elements (ETM), 6 ions in addition to paraffins were identified on the collected $PM_{2.5}$. The total PAHs, paraffins and ETM were respectively 4.88, 1062 and 10686 $ng.m^3$. Identification sources indicate that anthropogenic activities, including road traffic and the burning of biomass such as charcoal, are the major contributors.

7.04.P-Mo429 Chemical Characterization And In Vitro Toxicological Effects of Atmospheric Pollution (PM2.5) Collected in Cotonou, Benin

Boris Fresnel Cachon[1], ***Anthony Verdin***[2], *Stéphane Firmin*[3], *Lucie Ayi Fanou*[4], *Faustin Aissi*[1], *Ambaliou Sanni*[4], *Dominique Courcot*[5] *and Fabrice Cazier*[6], *(1)Uceiv, Université du Littoral Côte d'Opale, France, (2)UCEIV, University of the Littoral Opal Coast, France, (3)Institut Polytechnique LaSalle Beauvais, France, (4)Université d'Abomey-Calavi, Benin, (5)Unité de Chimie Environnementale et Interactions sur le Vivant, UCEIV UR4492, FR CNRS 3417, University of Littoral Côte d'Opale (ULCO), France, (6)CCM, Université du Littoral Côte d'Opale, France*

Airborne particulate matter (PM), a major component of outdoor air pollution was also classified as carcinogenic. Moreover, the International Agency for Research on Cancer showed an increasing risk of lung cancer with increasing levels of exposure to PM. Hence, it is somewhat critical to have a better knowledge on the air pollution PM in Africa. After particulate matter (PM)

sampling in Cotonou (Benin), a complete physicochemical characterization of $PM_{2.5}$ and $PM_{>2.5}$ was led. Average concentrations of air particulate matter were 180.9 µg/m^3 and 94.5 µg/m^3 in $PM_{2.5}$ and $PM_{>2.5}$, respectively. Total PM number with aerodynamic diameter ≤ 2.5 µm was 97.5 % in both PM. The most abundant water-soluble ions concentrations recorded were Ca^{2+}, SO_4^{2-}, NO_3^-, Na^+ and Cl^- for both PM. Moreover, chemicals concentrations were almost two fold higher in $PM_{2.5}$ than in $PM_{>2.5}$ with total metals of 10.78 µg/m^3 found in $PM_{2.5}$ versus 5.68 µg/m^3 in $PM_{>2.5}$. Identification tools of major pollution source as inorganic elements, paraffins, fatty acids ratios and PAHs ratios indicated that PM under study were originated from traffic exhaust.
Then, their adverse health effects were evaluated by using *in vitro* culture of human lung cells. BEAS-2B cells (bronchial epithelial cells) were intoxicated during short-term exposure at increasing PM concentrations (1.5 to 96 mg/cm^2) to determine global cytotoxicity. Hence, cells were exposed to 3 and 12 mg/cm^2 to investigate the potential biological imbalance generated by PM toxicity. Our findings showed the ability of both PM to induce oxidative stress and to cause inflammatory cytokines/chemokines gene expression and secretion. Furthermore, PM was able to induce gene expression of enzymes involved in the xenobiotic metabolism pathway. Strong correlations between gene expression of metabolizing enzymes, proinflammatory responses and cell cycle alteration were found, as well as between proinflammatory responses and cell viability. Stress oxidant parameters were highly correlated with expression and protein secretion of inflammatory mediators.

7.05 Multi-Purpose Use of Wastewater Based Epidemiology for Assessing and Evaluating Public Health Status: Challenges and Opportunities on a Global Scale

7.05.P-Tu433 Wastewater-Based Epidemiology As A High-Throughput Method To Investigate Human Exposure To Bisphenols. Method Development, Pilot Application and Contrast to Urinalysis

Andrea Estévez Danta[1]*, Rosa Montes*[2]*, José Benito Quintana*[1] *and Rosario Rodil*[1]*, (1)Universidade de Santiago de Compostela, Spain, (2)University of Santiago de Compostela, Spain*

Bisphenols are widely used in plastic production and as additives. Thus, bisphenol A (BPA) and its most prominent substitutes, bisphenol F (BPF) and bisphenol S (BPS) have been detected in many environmental samples. Human exposure to bisphenols can be estimated by measuring the concentration of precursor and metabolites in urine. Alternatively, wastewater-based epidemiology (WBE) is a very promising methodology that can complement human biomonitoring.
In this context, the aim of this study was to develop an analytical methodology for the determination of 4 metabolites from BPA: monosulfate (BPA-S), disulfate (BPA-DS), β-D-glucuronide (BPA-G) and bis-(β-D-glucuronide) (BPA-DG), 2 metabolites from BPS: monosulfate (BPS-S) and β-D-glucuronide (BPS-G) and 2 metabolites from BPF: monosulfate (BPF-S) and β-D-glucuronide (BPF-G) in wastewater and to assess their usability as biomarkers for WBE. The method was applied to the analysis of wastewater samples from 4 Spanish cities (A-D) and 1 Portuguese city (E). Exposure to bisphenols at city C was also investigated by urinalysis as a pilot assay. The methods, based on solid-phase extraction (SPE) followed by liquid chromatography-tandem mass spectrometry (LC-MS/MS), showed quantification limits below 35 ng/L for metabolites in wastewater, and 2.2 ng/mL for bisphenols in urine
BPA-S, BPS-S and BPF-S were positively detected in wastewater samples. None of the compounds was detected in city B. The highest exposure levels were determined for BPA in City A and D (mean: 86-1231 µg/(day/1000inh.)) and for BPF in City A (206 µg/(day/1000inh.)). Human exposure to BPS in wastewater was also detected but at lower levels (41-100 µg/(day/1000inh)). WBE-derived exposure was referred to average-body weight and compared with the tolerable daily intake (TDI) level for BPA, exceeding this threshold in Cities A and D. BPA, BPF and BPS were positively detected in the urine samples from City C. BPF was detected at the highest concentration and frequency, in 91% of the urine samples (median: 14.9 ng/mL), followed by BPA at a lower frequency (16%, median <1.1 ng/mL). BPS was also detected with high frequency but in general low concentration levels (82%, median: 0.90 ng/mL).

7.05.P-Tu434 Turning Wastewater Treatment Plants into Sentinels of Public Health: The case study of Larnaca

Popi Karaolia[1]*, Annalisa Quattrocchi*[2]*, Iakovos Iakovides*[3]*, Panayiota Loutsiou*[3]*, Georgios Nikolopoulos*[1] *and Despo Fatta-Kassinos*[1]*, (1)University of Cyprus, Cyprus, (2)Department of Primary Care and Population Health, University of Nicosia Medical School, Cyprus, (3)Nireas-International Water Research Center, University of Cyprus, Cyprus*

The COVID-19 pandemic has brought about globally concerted efforts in wastewater-based epidemiology (WBE), which have successfully focused on the detection of SARS-CoV-2 virus RNA in sewage wastewater, in order to better understand the dynamics and spatiotemporal trends of the pandemic.
An integrated, multi-disciplinary sewage-based surveillance system was implemented in Cyprus to track SARS-CoV-2 trends through various SARS-CoV-2 genetic marker concentration normalization approaches based on wastewater physicochemical characteristics, accompanied by epidemiological analyses. This system monitors all seven (7) urban areas and wastewater treatment plants (UWTPs) of Cyprus, in a national country-wide surveillance campaign for SARS-CoV-2 genetic markers during the pandemic. Herein, the case study of Larnaca is shown, whose influent urban wastewater was surveilled for a continuous period of 18 months (March 2021-September 2022).
Weekly SARS-CoV-2 genetic marker concentrations were normalized according to different physicochemical parameters (COD, TN, TP and NH_4-N). The PE at any given time of sampling, were assessed for the best approximation to the UWTP-served population of 76000 PE, as provided by the Sewerage Board of Larnaca.
The most suitable physicochemical parameters for PE estimation were COD and TP. These gave the closest approximation to the UWTP-served population of 76000 PE. The highest N2 concentrations were observed in July 2021 and in March 2022, using all four physicochemical parameters for concentration normalization. These were in agreement with the numbers of diagnosed COVID-19 cases.

The log_{10} wastewater concentrations of N2 and E genetic markers showed a trend that followed that of the 7-day and 14-day log_{10} cumulative number of cases. This fact shows the ability of the wastewater-based system to reflect the trends of COVID-19 cases in the UWTP-served community of Larnaca.
According to the findings of this study, COD and TP were shown to be suitable parameters for SARS-CoV-2 genetic marker concentration normalization in urban wastewater. This work also includes the wastewater-based surveillance of all 7 urban areas and UWTPs of Cyprus. Wastewater SARS-CoV-2 genetic marker concentrations agreed, and reliably tracked the number of diagnosed COVID-19 cases and pandemic dynamics in Larnaca. Through this wastewater-based surveillance system, the value of urban wastewater as a sentinel of public health was proven.

7.05.P-Tu435 Evaluation of Wastewater-based Epidemiology of COVID-19 Approaches in Singapore's 'Closed-system' Scenario: A Long-term Country-wide Assessment
***Caixia Li**[1], Mauricius Marques dos Santos[2] and Shane Allen Snyder[3], (1)Nanyang Environmental & Water Research Institute, NTU, Singapore, (2)Nanyang Environment & Water Research Institute (NEWRI), Nanyang Technological University, NEWRI, Singapore, (3)Nanyang Environmental & Water Research Institute, Singapore*
With the COVID-19 pandemic the use of WBE to track diseases spread has rapidly evolved into a widely applied strategy worldwide. However, many of the current studies lack the necessary systematic approach and supporting quality of epidemiological data to fully evaluate the effectiveness and usefulness of such methods. Use of WBE in a very low disease prevalence setting and for long-term monitoring has yet to be validated and it is critical for its intended use as an early warning system. In this study, two monitoring scenarios were used: (i) city wide monitoring (population 5,700,000) and (ii) community/localized monitoring (population 24,000 to 240,000). Additional epidemiological data gathered include the number of active cases detected and the geospatial distribution of public places visited by the infected individuals while contagious. Prediction of active cases by WBE using multiple linear regression shows that a multiplexed qPCR approach with three gene targets has a significant advantage over single-gene monitoring approaches, with $R^2 = 0.832$ (RMSE 0.053) for an analysis using N, ORF1ab and S genes ($R^2 = 0.677$ to 0.793 for single gene strategies). A predicted disease prevalence of 0.001% (1 in 100,000) for a city-wide monitoring was estimated by the multiplexed RT-qPCR approach and was corroborated by epidemiological data evidence in three 'waves'. Localized monitoring setting shows an estimated detectable disease prevalence of ~0.002% (1 in 56,000) and is supported by the geospatial distribution of active cases and local population dynamics data. Data analysis also shows that this approach has an limitation in sensitivity, or hit rate, of 62.5 % and an associated high miss rate (false negative rate) of 37.5 % when compared to available epidemiological data. Nevertheless, our study shows that, with enough sampling resolution, WBE at a community level can achieve high precision and accuracies for case detection (96 % and 95 %, respectively) with low false omission rate (4.5 %).

7.05.T-01 Use of a Freshwater Bivalve to Assess the Viral Risk of Water Bodies
***Julie Do Nascimento**[1], Alain Geffard[2], Melissa Palos Ladeiro[2], Christelle Lopes[3], Nicolas Boudaud[4] and Christophe Gantzer[5], (1)University of Reims Champagne-Ardenne (URCA), France, (2)Umr-I 02 Sebio, University of Reims Champagne-Ardenne (URCA), France, (3)Umr Cnrs 5558, University of Lyon, France, (4)ACTALIA, (5)University of Lorraine, France*
Faecal contamination of freshwater is a source of diffuse pollution, which could carry pathogenic microorganisms. Among them, enteric viruses could be responsible of waterborne outbreaks. Their direct detection in water is too expensive and difficult to set up on routine analyses. So, indicators of faecal pollution usually used, such as the bacteria Escherichia coli. Nevertheless such bacteria indicator is not enough reliable to estimate the viral hazard. Thus, many studies also suggest that F specific RNA bacteriophages could be used as indicators of enteric viruses in food and in water environments. F specific RNA bacteriophages (FRNAPH) display similar morphology than enteric viruses such as noroviruses and these infectious particles can be easily quantified in simple and complex matrices using standard or published methods. However, the detection of infectious FRNAPH in water has also several limits including the low loads in some situations, requiring the filtration of a large quantity of water, and the variability of the results due to the dynamic character of the matrix (rivers).
To improve viral detection in freshwater environments, we propose to use a sentinel species (the freshwater bivalve mollusc *Dreissena polymorpha*) as a biosensor, due to its bioaccumulation capacities. This bivalve mollusc is already used as model in ecotoxicological studies to detect chemical such as persistent organic pollutants and microorganisms (i.e. bacteria, protozoan parasites). In this study, we aim to answer 3 questions: i) Do *D. polymorpha* accumulate FRNAPH in a dose-dependent manner? ii) Do FRNAPH concentrations in *D. polymorpha* remain in equilibrium with their environment contamination level during exposure? and iii) Do *D. polymorpha* keep the FRNAPH signal even after the exposure (depuration kinetics)?
The results show that *D. polymorpha* is able to accumulate infectious FRNAPH in laboratory conditions as demonstrated in a previously study, that is of a great interest for in situ application. Infectious FRNAPH concentrations in mussels reflect the exposure load in only 24 hours. The depuration phase seems to be exponential. The kinetics of accumulation and depuration of viral particles in mussels will be formalize through a toxico-kinetic model to describe the relationship between FRNAPH load in the mussels and the level of contamination of the water for monitoring purposes. *In situ* experiments will be performed by active transplantation to promote this outcome.

7.05.T-02 Assessing the Exposure of Italian Population to Food Contaminants Through Wastewater-Based Epidemiology
***Noelia Salgueiro-Gonzalez**, Carlotta Gennaro and Sara Castiglioni, Environmental Health Sciences, Istituto di Ricerche Farmacologiche Mario Negri, Italy*
Food safety is an issue of concern for public health, as foodborne illnesses are an important cause of morbidity and mortality worldwide, with a considerable impact also on socioeconomic development. Foodborne diseases are mainly caused by bacteria,

viruses and parasites, or by chemical substances entering the body through contaminated food and/or water. Food consumption is one of the most important routes of human exposure to contaminants, including natural (e.g. mycotoxins), process (e.g. acrylamide) or environmental pollutants (e.g. pesticides). Different indicators are normally combined to evaluate population exposure to food contaminants, such as human biomonitoring studies (HBM) and intake estimations. These approaches face several limitations and therefore, novel tools are needed to monitor rapidly and objectively human exposure to contaminants and support public health authorities.
This study aimed to (i) assess the capability of wastewater-based epidemiology (WBE) to evaluate community-wide exposure to food contaminants, especially mycotoxins, (ii) apply WBE approach in the first nationwide monitoring performed in Italy and (iii) evaluate spatial and temporal patterns of exposure. Urban wastewater samples were collected from 14 Italian cities during a 3-years period (2020-2022). Quantitative analysis of selected biomarkers was carried out by solid-phase extraction followed by liquid chromatography-tandem mass spectrometry to achieve the low levels of these contaminants expected in wastewater. For mycotoxins, fumonisins and deoxynivalenol (DON) were found in almost all cities during the investigated period, being DON the most frequently detected in accordance with HBM studies. Mass loads were back-calculated and statistically compared, evidencing spatial and temporal patterns of exposure. Mass loads were also used for calculating daily intake and WBE results for mycotoxins were normally lower than the safety values proposed by different food organizations, demonstrating no risk for human health. WBE is a reliable complementary tool for evaluating community-wide exposure to food contaminants, able to enhance the information currently provided by HBM studies and intake estimations. Thus, WBE can be an additional indicator for public authorities to drive prevention strategies concerning food safety.

7.05.T-03 Application of Wastewater-Based Epidemiology as a Tool to Assess Public Health – A Case Study in the UK during SARS-CoV-2 Pandemic

Nicola Ceolotto[1]*, Kishore Kumar Jagadeesan*[2]*, Ruth Barden*[3]*, Richard Standerwick*[3] *and Barbara Kasprzyk-Hordern*[2]*, (1)Chemistry, University of Bath, United Kingdom, (2)Department of Chemistry, University of Bath, United Kingdom, (3)Wessex Water, United Kingdom*

Non-communicable diseases (NCDs), also known as chronic diseases, are responsible of 41 million deaths/year, corresponding to the 74% of all yearly deaths. They are characterized by long duration, slow progression, non-transmissibility, and reduced quality of life. Current approaches to assess public health involve surveys, morbidity, deaths, prescriptions, and sales data. These tools are not feasible to obtain reliable pictures of health status as they contain many uncertainties (e.g. bias from self-report, incomplete treatment plan, different report formats). For this reason, a comprehensive approach is needed to provide accurate data to monitor health status of communities and reduce risks factors related to NCDs. Wastewater-based epidemiology (WBE) enables a systematic approach to estimate trends in consumption of pharmaceuticals and evaluate health status of population with high resolution. Human markers (e.g. pharmaceuticals) are excreted by individuals into urban sewer networks; as such, influent wastewater (IWW) can be considered as an invaluable source of information related to population's health; through the quantification of target compounds, it is possible to obtain information about pharmaceutical consumptions and lifestyle for a given wastewater catchment area. In this study, WBE was applied to assess public health status of communities in Southwest of England during Covid19 pandemic estimating pharmaceuticals consumption. Two 24h-composite IWW samples/week were collected for two years (Mar20-Mar22), processed using solid-phase-extraction and analysed via UPLC-MSMS. Daily loads (DLs) were calculated, considering concentrations, wastewater flows, and metabolism correction factors. Normalization of DLs using population served per catchment allowed comparisons among different-sized communities and results were overlayed with Covid19 cases. Using this approach, it was possible to identify trends in pharmaceuticals consumption at different stages of the pandemic. Data triangulation highlighted changes in the consumption during periods of high Covid19 cases and lockdowns; moreover, this study shows that WBE can be used as near real-time monitoring tool for selected pharmaceuticals as proxy for population's health.

7.05.T-04 Estimation of Alcohol Consumption in the Spanish Population through the Analysis of Ethyl Sulfate in Wastewater

Rocío Inés Inés Bonansea[1]*, Valeria Bobrisev*[2]*, Cristina Postigo*[3]*, José Benito Quintana*[4]*, Rosa Montes*[5]*, Iria González-Mariño*[6]*, María Rosa Marcé*[7]*, Lubertus Bijlsma*[8]*, Yolanda Pico*[9]*, Rosario Rodil*[4]*, Andrea Estévez Danta*[4]*, Elisa Garcia*[8]*, Claudia Simarro*[8]*, Andreu Rico*[10]*, Rodrigo Alvarez-Ruiz*[11]*, Daniele Sadutto*[12]*, Yolanda Soriano Juan*[11]*, Yolanda Valcarcel Rivera*[13]*, Sara Rodriguez-Mozaz*[14]*, Lluis Corominas*[15]*, Manuel Miró*[16]*, Gorka Orive*[17]*, Manuel Isorna*[18]*, Unax Lertxundi*[19]*, Ester López-García*[2]*, Pablo Lara*[20]*, Eva Pocurull*[21]*, Xiana González-Gómez*[22]*, Ailette Prieto*[23]*, Núria Fontanals*[21]*, Nestor Etxebarria*[23]*, Vicente Andreu Andreu*[24]*, Felix hernandez Hernandez*[8]*, Noelia Domínguez*[25]*, Eduardo González*[20]*, Marina Pintado*[20]*, Miren López de Alda*[2] *and Sergio Santana*[26]*, (1)Water, Environmental and Food Chemistry (ENFOCHEM), IDAEA-CSIC, Spain, (2)Spanish Research Council (CSIC), Institute of Environmental Assessment and Water Research (IDAEA), Spain, (3)IDAEA, CID-CSIC, Spain, (4)Universidade de Santiago de Compostela, Spain, (5)University of Santiago de Compostela, Spain, (6)Universidad de Salamanca, (7)Universidad Rovira i Virgili, (8)University Jaume I, Spain, (9)Centro de Investigaciones sobre Desertificación, Universidad de Valencia, Moncada, Spain, (10)IMDEA Water Institute, Spain, (11)University of Valencia, Spain, (12)Environmental and Food Safety Research Group of the University of Valencia (SAMA-UV), Spain, (13)Department of Medical Specialties and Public Health, Rey Juan Carlos University, Spain, (14)Catalan Institute for Water Research (ICRA), Spain, (15)Instituto Catalán de Investigación del Agua (ICRA), (16)Grupo de Investigación FI-Trace de la Universidad de las Islas Baleares, Spain, (17)NanoBioCel Group, Laboratory of Pharmaceutics, School of Pharmacy, University of the Basque Country UPV/EHU, Spain, (18)Universidad de Vigo, (19)Araba Psychiat Hosp, Spain, (20)Universidad de Cadiz, (21)Universitat Rovira i Virgili, Spain, (22)Universidad de Santiago de Compostela, (23)University of the Basque Country (UPV/EHU), Spain,*

(24)CIDE (CSIC UV GV), Spain, (25)Universidad Rey Juan Carlos, (26)Universidad de Cádiz
Alcohol is one of the most consumed psychoactive substances throughout the world and it is very socially accepted and integrated into everyday life. According to the Global status report on alcohol and health, pure alcohol consumption per person aged 15 or older in Spain was 10.7 liters per year (WHO, 2019). In this study, an alternative and complementary method to those approaches currently used to estimate alcohol consumption by the population is described. This method, wastewater-based epidemiology (WBE), allows back-calculating the alcohol consumption rate in each population from the concentrations of a selected biomarker measured in sewage waters.
A total of 28 wastewater treatment plants (WWTPs) were sampled in 22 Spanish cities that belong to 10 autonomous communities. Time-average 24h composite raw wastewater samples were collected from the studied WWTPs on consecutive days along 1 week in the spring and autumn seasons of 2021 and 2022. The EtS was analyzed using an analytical method based on ion-pair liquid chromatography-tandem mass spectrometry (LC-MS/MS).
The alcohol consumption estimated from levels of EtS in the analyzed samples ranged from 4.5 and 46 mL/day/inhabitant, with significant differences between cities from different regions and between regions. Also, it is observed that consumption on weekends is higher than on weekdays, with average consumption rates more than 2.2 times higher from Friday to Sunday than from Monday to Thursday. The alcohol consumption investigated in 2021 and 2022 in comparison with previously reported data (in the Spring of 2018) shows the highest consumption values in 2018, the lowest in 2021 (when the COVID-19 pandemic restrictions were still important), and a recovery to intermediate values in 2022. WBE-derived estimates of alcohol consumption were comparable to previous studies and the values reported by the Spanish Ministry of Health, Consumption and Social Welfare in collaboration with the National Institute of Statistic (INE).
In conclusion, the study finds that the WBE approach is a very useful tool, complementary to traditional methods, to estimate the consumption of alcohol in a population.
Acknowledgements: This research was funded by Spanish Plan Nacional Sobre Drogas (ref. 2020I009) and Generalitat de Catalunya (SA-2022-430). We are thankful to local authorities and WWTP operators for their help in sample and data collection.

7.05.P Multi-Purpose Use of Wastewater Based Epidemiology for Assessing and Evaluating Public Health Status: Challenges and Opportunities on a Global Scale

7.05.P-Tu436 Profiling of PAHs Biomarkers in Wastewater in the Aspect of Public Health Risk Assessment of Hazardous Chemicals Exposure at Urban Areas

Katarzyna Styszko[1], *Justyna Durak*[2], *Elżbieta Sochacka-Tatara*[3] *and Agnieszka Pac*[3], *(1)AGH University of Science and Technology, Poland, (2)Cracow University of Technology, Poland, (3)Jagiellonian University, Poland*
There is strong evidence of health risks from human exposure to organic air contaminants such as PAHs (polycyclic aromatic hydrocarbons) from combustion processes (solid fuels, coal and biomass), as well as communication. Most of the high-molecular-weight PAHs are only slowly degraded and hence represent a long-term potential health hazard to living beings. There is a lack of knowledge and understanding of community-wide exposure to organic air pollutants, especially in highly urbanized areas in Eastern Europe.
PAHs entering the body in an some part are removed in unchanged form but mostly undergo few step process of biotransformation and detoxification process and then are excreted via urine and feces as their hydroxy metabolites.
The aim of the study was the determination of the hydroxyl PAH metabolites profile in wastewater. The stability of three OH-PAHs in wastewater was confirmed in the first step of our studies and was presented in J. Durak et al. (J. Durak et al. 2021).
The 24 composite samples of wastewater influent were collected at the "Plaszow" wastewater treatment plant (WWTP) in Krakow, in winter and summer. This plant is the biggest one in the city and the third in the country, treating over a 70% of Krakow wastewater from over 480 thousands of inhabitants in the central part of the city, with an average capacity of 165.000 m^3/day.
Studies were carried out using SPE-GC-MS/MS method for the determination of selected OH-PAH (1-hydroxy and 2-hydroxynaphthalene (1-OH-NAP, 2-OH-NAP), 2-hydroxy and 9-hydroxyfluorene (2-OH-FLU, 9-OH-FLU), 9-hydroxyphenathrene (9-OH-PHEN), 1-hydroxypyrene (1-OH-PYR), 3-hydroxybenzo(a)pyrene (3-OH-BaP)) in samples collected in WWTP. Analysis was carried out by means of a Thermo Scientific GC TRACE 1300 (GC-(IT)MS/MS) and a TriPlus RSH Autosampler.
The average concentrations of compounds ranged from 5 ng/L to more than 400 ng/L. The highest concentrations of OH-PAH were detected in the influents, for 2-OH-NAP and 9-OH-FLU in winter and summer. However, their concentrations were twice lower in summer. A similar trend was observed for other compounds. 1-OH-PYR was observed for influent and effluent samples only in winter at average concentrations of 8 ng/L and 5 ng/L, respectively.

7.05.P-Tu437 A Novel Analytical Tool Using HRMS (Orbitrap) for the Estimation of Drugs of Abuse Consumption through Wastewater-based Epidemiology: Development & Application in Real Samples from Valencia, Spain

Vasiliki Soursou[1], *Julian Campo*[2], *Vicente Andreu Andreu*[2] *and Yolanda Pico*[1], *(1)Centro de Investigaciones sobre Desertificación, Universidad de Valencia, Moncada, Spain, (2)CIDE (CSIC UV GV), Spain*
Wastewater-based epidemiology (WBE) estimates the consumption of drugs of abuse in any given population. Developing methods for the rapid screening and confirmation of drugs of abuse and their metabolites is still a priority. A method to quantify six illicit substances indicators using solid-phase extraction (SPE) and UHPLC-HRMS/MS (Orbitrap Exploris 120) was developed, validated and applied to the analysis of these wastewater samples. As far as the HRMS/MS system is concerned, the correct tuning of instrumental parameters was crucial to achieve selectivity, sensitivity and reproducibility for the analytes.

Different acquisition modes are available while using a Q-Orbitrap platform and the optimized protocol focused on targeted analysis. The best results were obtained by applying a full scan (FS) and, then, a target MS^2 ($ddMS^2$) using an inclusion list that contains the most important drugs and a filter for dynamic exclusion. Amphetamine, benzoylecgonine, cocaine, methamphetamine and ecstasy were detected in positive mode, while 11-Nor-9-carboxi-delta-9-tetrahidrocannabinol, the main secondary metabolite of cannabis formed in the human body after consumption, was detected in negative mode. Intra- day precision (% RSD, n = 3) ranged from 0.03 to 18.7 %, while linearity (R^2) values were higher than 0.9970 and the lowest method detection limit was 0.01 µg/ ml. The method was applied for the estimation of drug consumption in wastewater samples taken from the two main wastewater treatment plants of Valencia city during a whole week in November. Cannabis and cocaine estimated consumptions remain the highest in Valencia during the last 10 years, with calculated amounts up to 66 g/day/1000inh and 9 g/day/1000inh, respectively. Higher consumption during weekends was observed, mainly for recreational reasons.

7.05.P-Tu438 Wastewater-Based Epidemiology for Monitoring the Evolution of SARS-CoV-2 in Different Spanish Municipalities

Felix hernandez Hernandez[1], *Alberto Celma*[2], *Lubertus Bijlsma*[3], *Maria Barbera*[3], *Manuela Barneo*[3], *Juan Bellido*[4], *Rosa de Llanos*[3], *Rafael Goterris*[3], *Ferran Martínez*[3], *Marisa Rebagliato*[3], *Ernesto Santateresa*[5] *and Nuria Zamorano*[5], *(1)University Jaume I, Spain, (2)Swedish University of Agricultural Sciences (SLU), Sweden, (3)University Jaume I, Spain, (4)Epidemiology Dpt, Public Health Center of Castellón, Spain, (5)FACSA*

Analysis of urban wastewater has shown great potential for monitoring the evolution of COVID-19 pandemic within communities. It is a fast and cost-effective tool that enables tracing of both symptomatic and asymptomatic transmission of SARS-CoV-2. Measuring the SARS-CoV-2 RNA in wastewater has been of help to evaluate the evolution of the pandemic and to take appropriate measures to face this problem. However, some critical issues related to the type of samples collected, the stability of the RNA material, and back calculation aspects including estimation of the number of inhabitants and mobility of the population, have been less studied.

In this work, we have applied the general WBE strategy to a wide study performed in several municipalities from the Castellon province, Spain. The above-mentioned critical issues are discussed, together with the stability of samples under different storage conditions. Special attention is drawn to the comparison of 4h or 24h-composite samples to better monitor SARS-CoV-2 in wastewater. The evolution of the pandemic in the first steps of 2020 is illustrated with data collected from RTq-PCR analysis, and data provided by wastewater analysis are interpreted and compared with a wide set of epidemiological indicators (the day of onset of symptoms, date of diagnosis, date of declaration, date of admission to hospital care) for validation of the approach used. This is a comprehensive study in which a combined analysis of epidemiological data as well as WBE-driven data at the same municipalities are compared and discussed. may help other researchers to standardise or improve their sampling and storage protocols for SARS-CoV-2 detection and quantification in wastewater to gain confidence in the interpretation of the results.

7.05.P-Tu439 Wastewater, Useless but Valuable – A Scientific Perspective

Femi Oloye[1], *Paul Jones*[2], ***Oluwabunmi Femi-Oloye***[3] *and John Giesy*[2], *(1)Toxicology Center, University of Saskatchewan, Canada, (2)University of Saskatchewan, Canada, (3)Toxicology Center, Canada*

Wastewater is a reservoir for measuring infection levels, illicit drugs or chemicals in a given community. The importance of wastewater became more popular recently because of the SARS-COV-2 surveillance. Future pandemic surveillance can be done if the knowledge gained from SARS-CoV-2 RNA monitoring in wastewater can be preserved and improved. This work will focus on the advantage of monitoring SARS-CoV-2 RNA from wastewater, the lesson learned during the COVID-19 pandemic, and the problem to avoid in the future. Wastewater surveillance data from Saskatchewan, Canada, was a critical tool for decision-making during the Omicron wave when clinical data became unavailable. One of the advantages of wastewater data is that it can be made public without compromising anyone's right to privacy. Wastewater surveillance gave an early warning for the next wave for all waves since 2021, which, if capitalized on, could help with proper planning. New variants of concern (VOC) were also detected in wastewater before evidence in clinical samples. Most importantly, all circulating variants can be captured through wastewater whole genome sequencing, which might not be possible in clinical samples. Effective reproduction number has also been developed from wastewater data, which is helping to understand the surveillance data. Other models which are helping to predict the communal cases and hospitalization data have been generated from wastewater surveillance. The recent surveillance work has shown the importance of collaboration between health authorities, government agencies and researchers. The unavailability of clinical data limited the extent to which models can be developed to aid future research work in most cities.

7.05.P-Tu440 Drug Consumption in German Cities and Municipalities During the COVID-19 Lockdown: A Wastewater Analysis

Reinhard Oertel[1], *Sara Schubert*[2], *Björn Helm*[3], *Robin Mayer*[3], *Roger Dumke*[4], *Ali El-Armouche*[5] *and Bertold Renner*[2], *(1)Institute of Clinical Pharmacology, GWT-TU Dresden, Germany, (2)Institute of Clinical Pharmacology, Technical University Dresden, Germany, (3)Institute of Urban and Industrial Water Management, Technical University Dresden, Germany, (4)Institute of Medical Microbiology and Virology, Technical University Dresden, Germany, (5)Institute of Pharmacology and Toxicology, Technical University Dresden, Germany*

Analysis of illicit drugs, medicines and pathogens in wastewater is a powerful tool for epidemiological studies to monitor public health trends. Since the spread of the coronavirus disease (COVID-19) worldwide, wastewater-based epidemiology (WBE) has become an additional tool to monitor the prevalence of SARS-CoV-2 infections at local or even national level. The samples collected for this purpose can also be used for numerous other epidemiological studies.

The aims of this study were to (i) assess spatial and temporal trends of population-normalized mass loads of illicit drugs and nicotine in raw wastewater in the time of regulations against SARS-CoV-2 infections (2020–21); (ii) find substances that are feasible markers for characterizing the occurrence of selected drugs in wastewater.
Raw sewage 24-hour composite samples were collected in catchment areas of 15 wastewater treatment plants (WWTPs) in urban, small-town and rural areas in Germany during different lockdown phases from April 2020 to December 2021. Parent substances (amphetamine, methamphetamine, MDMA, carbamazepine, gabapentin and metoprolol) and the metabolites of cocaine (benzoylecgonine) and nicotine (cotinine) were measured.
The daily discharge of WWTP influents were used to calculate the daily load (mg/day) normalized by population equivalents (PE) in drained catchment areas (in mg/1,000 persons/day). An influence of the regulations to reduce SARS-CoV-2 infections such as contact bans and border closures on drug consumption has been proven in some cases and refuted in several. In addition, metoprolol and cotinine were found to be suitable as marker substances for the characterization of wastewater. A change in drug use was visible at the beginning of the Corona crisis. There after from mid-2020, no obvious effect was detected with regard to the regulations against SARS-CoV-2 infections on concentration of drugs in wastewater. Wastewater-based epidemiology is suitable for showing changes in drug use during the COVID-19 lockdown.

7.05.P-Tu441 Neurodegenerative Disease Prevalence Rates and Sewage Sludge Heavy Metals in the United States (2017-2022)
Melanie Engstrom Newell[1]*, Ayesha Babbrah*[1]*, Raj Rathnam*[1]*, Erin M Driver*[2]*, Anumitha Aravindan*[3]*, Devin A Bowes*[1]*, Katherine B Henke*[2] *and Rolf Halden*[1]*, (1)Arizona State University, (2)Center for Environmental Health Engineering, Arizona State University, (3)Biodesign Center for Environmental Health Engineering, Arizona State University*
Neurodegenerative diseases (NDDs) such as Alzheimer's Disease (AD), Parkinson's Disease (PD), and amyotrophic lateral sclerosis (ALS) require extensive testing over months or years before a diagnosis is established and treatment can begin to improve survivorship and quality of life. Studies indicate strong associations between environmental exposure to heavy metals (e.g., cadmium, arsenic, manganese, and mercury) and NDDs. Varied regional NDD prevalence rates throughout the United States suggest that certain environmental conditions (e.g., contamination from industrial runoff) could increase exposure to heavy metals in certain populations, thereby increasing the risk of NDD development. Municipal sewage sludge reports of heavy metal concentrations regulated by the Environmental Protection Agency could serve as viable data sources to assess the relationship between environmental exposure and NDD prevalence rates. This study aimed to determine whether heavy metal concentrations correlate with NDD prevalence rates. We hypothesize that heavy metal concentrations in sewage sludge positively correlate with regional NDD prevalence rates (95% CI). Sewage sludge reports from wastewater treatment plants in the Human Health Observatory network were analyzed for the maximum and monthly average concentrations of arsenic (75 and 41 mg/kg, respectively), cadmium (85 and 39 mg/kg), and mercury (57 and 17 mg/kg). The low observable adverse effect level (LOAEL) was used as the benchmark to distinguish between high and low concentrations for arsenic and mercury, whereas the no observable adverse effect level (NOAEL) was used for cadmium due to limited human data. Furthermore, average individual exposure was calculated using census population density estimates. Expected results are that sites with cadmium concentrations above the NOAEL (0.005 mg/kg/day), arsenic concentrations above the LOAEL (0.014 mg/kg/day), or mercury concentrations above the LOAEL (0.003 mg/kg/day) will also report prevalence rates (per 100,000 people) above the mean for AD (184.0), PD (245.7), and ALS (4.9). Identifying NDD-susceptible populations prior to symptom onset has the potential to reduce diagnostic delays and extend or improve quality of life. Importantly, if this research finds a positive correlation between heavy metal concentration and NDD prevalence, it has the potential to raise awareness of this risk factor and encourage screenings for NDDs earlier in life for susceptible populations.

7.05.P-Tu443 Wastewater bAsed Surveillance: More Than a One Trick Pony
Laura M Langan[1]*, Abigail Henke*[2]*, Fallon Bain*[3]*, Aubree Miller*[3]*, Christine Snow*[3]*, Robert Sean Norman*[4] *and Bryan W. Brooks*[1]*, (1)Environmental Science, Baylor University, (2)Biology, Baylor University, (3)Center for Reservoir and Aquatic Systems Research, Baylor University, (4)Environmental Health Sciences, Arnold School of Public Health*
Following the identification and spread of SARS-CoV-2, scientists worldwide and especially the international water community rapidly developed methods to quantify the viral genetic signal in untreated water. Wastewater based epidemiology (WBE), and methods associated with this field now act as complementary tools to clinical testing for SARS-CoV-2, or as a replacement to clinical testing whereby individual testing has become less common over time. To date, wastewater-based surveillance has been primarily used to evaluate SARS-CoV-2 spread but has recently begun to expand its domain of usage to include infection trends of gastrointestinal diseases, but also respiratory diseases sch as respiratory syncytial virus (RSV). Here we report that monkeypox virus can be detected in wastewater composite supernatant-solid in two wastewater facilities, but also at various institutions including correctional, assisted living and university dormitories. Unsurprisingly, certain locations demonstrated higher viral loads then others. In general, monkeypox testing is limited in these locations, making it difficult to determine the strength of the association between viral quantification in water and positivity rates at the community level, with wastewater testing the only means to monitor community spread currently. As such, WBE represents an important tool to augment monkey pox and other virus surveillance and public health response efforts.

7.05.P-Tu444 Variation in Locational Response to Omicron, The Emergence of Cryptic Lineages?
Laura M Langan[1]*, Abigail Henke*[2]*, Mia Ryon*[3]*, Fallon Bain*[4]*, Aubree Miller*[4]*, Christine Snow*[4]*, Robert Sean Norman*[5]*, Heidi K Bojes*[6] *and Bryan W. Brooks*[1]*, (1)Environmental Science, Baylor University, (2)Biology, Baylor University, (3)Baylor University, (4)Center for Reservoir and Aquatic Systems Research, Baylor University, (5)Environmental Health Sciences, Arnold School of*

Public Health, (6)Environmental Epidemiology and Disease Registries, Texas Department of State Health Services
In late 2021, the variant named Omicron was identified due to an S gene drop out during regular sample checking in South Africa. This variant spread extraordinary rapidly with the initial wave of BA.1 from December to February 2022, followed by the emergence of another subvariant named BA.2. Regular monitoring of wastewater treatment plants under an ongoing wastewater-based surveillance study with the state of Texas identified Omicron two weeks prior in Denton before its detection in Waco. hereafter, it was detected in numerous other facilities. Sampling consisted of (a) once weekly sampling and analysis of wildtype (N1, N2) and omicron specific indicator (P13L), (2) normalization to fecal indicator (PMMoV) and (c) comparison with active cases/hospitalizations. The time profiles of SARS-CoV-2 in wastewater broadly matched the waves of active cases, but with two notable differences between assisted living facilities (n = 5) and correctional facilities (n=6). For these two locations, differences were detected in the frequency of positive detects for targets, with assisted living facilities having less then 50 % agreement between targets compared to > 90 % agreement between targets for the correctional facilities (> 100 % agreement up to April). Samples have been sent for sequencing to determine if the assisted living facilities represent a potential source for the emergence of mutations/cryptic lineages given the suggested frequency of drop offs in nucleotides suggested by the results, the results of which will assist in improving our understanding of the spread and mutations associated with this ongoing infectious disease.

7.06 Next Generation of Risk Assessment and Management of Chemicals to Address Nature Preservation and Ecosystem Services

7.06.T-01 Conflicting Priorities in the Environmental Risk Management of Plant Protection Pproducts (PPP)

***Gertje Czub**, Jonas Schartner and Achim Gathmann, Federal Office of Consumer Protection and Food Safety (BVL), Germany*

In the European Union, a variety of European and national programs as well as strategies have been established in recent years with the aim to minimise the environmental exposure to chemical substances. As chemical formulations being directly emitted into the environment, plant protection products (PPP) are addressed in several of these strategies. One prominent example is the European Green Deal with its Farm-to-Fork strategy for a fair, healthy and environmentally-friendly food system. In this strategy, targets have been defined for an union-wide extensive reduction of chemical PPP use and a substitution by less hazardous substances, an increasing use of non-chemical alternatives, an enforcement of integrated pest management, an increase in organic farming and reduction or ban of chemical PPP in sensitive areas, among others.

For a sustainable design of plant protection, a multi-dimensional analysis of the environmental and socioeconomic impacts of each measure is required. For instance, the effects of herbicides on non-target organisms need to be assessed in comparison with the impact of ploughing on the natural soil habitat, enhanced erosion and an increase in the CO_2-footprint due to longer driving times. Another example is how the progressive use of digitalisation in farming on the one hand side contributes to a reduced and more precise PPP use. On the other hand, it stimulates the (re-)establishment of large-scale agricultural landscapes, counteracting the need for small-scale landscapes for preservation of ecotones. These analyses prevail the challenges of balancing different ecosystem services, in particular food security and biodiversity.

In addition to these measures, a paradigm shift in the PPP authorisation itself might be required. Today, an authorisation is in general granted on a national scale in conjunction with risk mitigation measures to be applied independent on the regional conditions. An authorisation (or rejection) of PPP for use in specific regional areas instead of an authorisation on an entire national scale might allow for a more precise risk management and at the same time pest control and resistance management. Challenges of such an approach are, among others, technical prerequisites, the communication of measures and restrictions to the end user and the possibility to control these specific mitigation instruments, for instance by robust monitoring programmes.

7.06.T-02 Availability and Applicability of Biodiversity Field Data to Enable Assessment of Biodiversity Loss Caused by Organic Pollution on a European Scale

***Iris Pit**[1], Annemarie van Wezel[1] and Anna Sobek[2], (1)University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Netherlands, (2)Environmental Science, Stockholm University, Sweden*

The biodiversity of freshwater ecosystems is declining faster than that of any other ecosystem. The water resources are affected by multiple stressors as a result from drivers including urban and agricultural land use, hydropower generation and climate change. Actions to secure freshwater biodiversity have been inadequate and no global framework exists to guide policy responses with the urgency needed. A major challenge here is to develop methods for diagnosing the relative importance of organic pollution among other stressors present in freshwater ecosystems. In order to asses such broad-scale questions about freshwater biodiversity dynamics, it is urgent to assess freshwater diversity with proper biodiversity indicators. This may be hampered by data confidentiality, usage restrictions or limited accessibility, or data integration and quality issues despite universal acceptance of the FAIR (Findable, Accessible, Interoperable, Reuseable) data principles. The goal of this study is to establish the availability and applicability of biodiversity field data of European rivers and whether this data is suitable to enable assessment of biodiversity loss caused by pollution on a European scale. We will present available abundance data of geographical Europe. Presented data will be compiled, alligned and harmonized in terms of sampling protocols and taxonomical level. Biodiversity indicators will include species richness and species abundance. Discussion will be on the quality and the quantity of the biodiversity indicators to estimate the applicability of an eco-epidemiology study on European scale.

7.06.T-03 Calibrating Predicted Ecotoxicity Effects to Observed Species Loss By Using Ecological Models

***Susan A Oginah**[1], Leo Posthuma[2,3], Jaap Slootweg[2], Michael Z. Hauschild[4] and Peter Fantke[4], (1)Environmental and Resource Engineering, Technical University of Denmark (DTU), Quantitative Sustainability Assessment, Denmark, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Department of Environmental Science, Radboud University,*

Netherlands, (4)Technical University of Denmark (DTU), Quantitative Sustainability Assessment, Denmark
Linking ecotoxicity impacts to species loss is relevant for translating model-predicted species-level effects to damage on functional diversity and further to damage to ecosystem services. There are ~12,000 chemicals with available measured in vivo effect test data, enabling quantification of predicted impact of chemicals and mixtures. However, we still lack a refined calibration between predicted and observed impacts in terms of species loss. To address this gap, we introduce a systematic approach that consists of a stepwise procedure to plot raw data from all sampling sites, derive quantitative insights into toxic pressure as a limiting factor for species and biodiversity, and apply refined methods, such as Generalized Linear- and Generalized Additive Models and TITAN (Threshold Indicator Taxa Analysis), to finally yield insights about species loss. Our approach is used to derive data-driven extrapolation factors for linking the potentially affected fraction of species (PAF) for a given chemical to the potentially disappeared fraction of species (PDF) for use in life cycle impact assessment (LCIA) and chemical risk assessment. We start from the Netherlands big (bio-) monitoring data set; we first grouped the data into sub-regions with similar background characteristics, calculated mixture toxicity pressure (msPAF) at the level of chronic EC10 equivalents (msPAF-EC10eq), mapped macrofauna data and mixture toxicity pressure information based on spatial information and modeled the species abundance changes as functions of changes in the mixture toxicity pressure. In our results, we found taxa responding sensitively to low mixture exposures (i.e., showing abundance decline), while we also found some more tolerant taxa with abundance increasing up to moderate mixture exposures. Abundance and biodiversity generally decline upon exceedance of protective standards, and the data allow to calibrate PAF to PDF relationships. Ecological models, such as TITAN, can thus be used to determine consistent extrapolation factors to derive the effect-to-damage relationships required in different decision-support tools.

7.06.T-04 iTrackDNA: Breaking Down Barriers for Confident Environmental DNA Adoption in Environmental Surveys and Decision-Making

Caren C. Helbing[1], *Louis Bernatchez*[2], *Jerome Dupras*[3] *and Valerie S Langlois*[4], *(1)University of Victoria, Canada, (2)Universite Laval, Canada, (3)University of Quebec, Canada, (4)Ete, Institut national de la recherche scientifique (INRS), Canada*

The analysis of environmental DNA (eDNA) - genetic material shed from organisms into their environment - promises to provide rapid, non-destructive, accurate and cost-effective biodiversity information. However, inconsistent practices and poor quality eDNA detection tools threaten End-User (regulators, industry, Indigenous Peoples, NGOs) uptake because of unacceptably high false negatives and false positives that can compromise effective management decision-making.

iTrackDNA is a multi-year, large scale applied research project that is addressing these concerns with researchers and End-Users across Canada and sectors. It is building End-User capacity through innovative, accessible, socially responsible genomics-based analytical eDNA tools for effective decision-making by: 1) supporting the creation of a targeted eDNA detection national standard; 2) building eDNA kits to detect 100 priority invertebrates, fish, amphibians, birds, reptiles, and mammals in Canadian coastal and inland ecosystems; 3) applying 10 eRNA kits for determining animal biosurveillance, biosanitation, and bioremediation effectiveness; 4) generating decision support software for modeling regional biodiversity changes integrating Indigenous Ecological Knowledge; 5) developing an eDNA training, certification, and inter-lab validation framework for consultants, researchers, regulators, and managers; and 6) producing a guidance document on eDNA-based methods integration into management, policy & regulations.

Recent progress will be presented to highlight activities to build and augment the eDNA community of practice through national eDNA standards adoption and transformative testing to confidently enable eDNA applications in coastal and inland ecological surveys and biosurveillance for mining, forestry, energy, and infrastructure projects.

7.06.T-05 Simulating The Effects of Chemical Stressors on a Recreational Fishery: An Ecosystem Services Approachtoo Risk Assessment

Susanna Mölkänen, *Lorraine Maltby and Philip Warren, University of Sheffield, United Kingdom*

Recreational fisheries are a cultural ecosystem service providing recreation for millions of anglers globally. In freshwaters, such fisheries are under increasing pressure from chemical stressors and provide a good example of an environment where the ecosystem service approach can be applied to chemical risk assessment. By modifying the ecological model InSTREAM v7.3, an individual-based model (IBM) on salmonids, we can simulate the effects of chemical stress on a recreational fishery to determine the response of the angling stock. InSTREAM v7.3 was modified to include the effects of chemical stressors on chemical effect endpoints in trout individuals, including growth, reproduction, and survival as well as on an indirect endpoint, prey density. These endpoints were tested under varying exposure scenarios with and without recovery to determine the changes in the trout populations in a river reach. This was achieved by simulating varying levels of endpoint inhibition from no effect to full endpoint inhibition. The changes in the trout population were then equated to angling stock (trout older than 1 year and larger than 20 cm in length). The angling stock in the recreational fishery is then equated to ecosystem service delivery through angler satisfaction. For the chemical effect endpoint of growth rate, the angling stock stabilises in continuous exposure scenarios, however, it decreases by up to 83% of the baseline angling stock until thirty percent of growth rate where the angling stock is fully depleted. When the trout population is simulated with a recovery period following five years of chemical exposure, the angling stock recovers to baseline conditions in all levels of growth rate. The results vary for the different endpoints and will be discussed further. This study demonstrates the use of an IBM approach for linking chemical exposure effects on individual organisms to ecosystem service outcomes. Moving forward the combined chemical effects will be investigated as well as identifying the influence of spatial scale on the ability of recreational fisheries to tolerate chemical stress. This shows how adapting an ecological model can be used to address ecosystem service delivery in chemical risk assessment for a recreational fishery.

7.06.P Next Generation of Risk Assessment and Management of Chemicals to Address Nature Preservation and Ecosystem Services

7.06.P-Tu445 Risk Assessment to Support and Promote Efficient Overall Protection of Biodiversity – An Activity Within the Horizon Europe Partnership for the Assessment of Risk from Chemicals

Johan Axelman[1]*, Annette Aldrich*[2]*, Gustaf Boström*[3]*, Yann Devos*[4]*, Sabine Duquesne*[5]*, Mikaela Gönczi*[6]*, Matthias Liess*[7]*, Vanessa Mazerolles*[8]*, Silvia Pieper*[5]*, Ralf Bernhard Schaefer*[9]*, Jose Tarazone*[10] *and Lina Wendt-Rasch*[1]*, (1)Swedish Chemicals Agency, Sweden, (2)Federal Office for the Environment, Switzerland, (3)Swedish University of Agricultural Sciences (SLU), Sweden, (4)European Food Safety Authority, Italy, (5)German Environment Agency, Germany, (6)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (7)Department of System Ecotoxicology, Helmholtz Centre for Environmental Research (UFZ), Germany, (8)French Agency for Food, Environment and Occupational Health & Safety (ANSES), France, (9)iES - Institute for Environmental Sciences, University of Kaiserslautern-Landau (RPTU), Germany, (10)Instituto de Salud Carlos III, Spain*

As a response to the EU Green deal initiatives Farm to fork, Biodiversity, Soil and Chemicals strategies an activity has been set up within the 7-year Horizon Europe Partnership for the Assessment of Risk from Chemicals (PARC) to improve the environmental risk assessment (ERA) of plant protection products (PPP).
This activity will explore a holistic scientific reframing of the regulatory ERA to more realistically assess ecosystem impact of plant protection products (PPPs) and to overcome the shortcomings of the current substance-by-substance assessment paradigm. The activity will investigate possibilities to simplify and focus the methods used for the ERA of PPPs.
The activity involves 20 European research partners covering compentences in ecotoxicology, chemistry, ecology, environmental monitoring, systems science, environmental modelling and computer science. The works is divided into four main projects, Exposure, Effects, Benchmark and Landscape ERA. Projects Exposure and Effects aim to consolidate and update prospective ERA models by strengthening the feed-back loop from environmental monitoring and by doing so investigate possibilities to reduce complexity in the assessments. Monitoring data on exposure and effects of PPPs from different regions in Europe are assembled. Prospective ERA methods of varying degree of detail will also be tested in parallell. The results from comparisons of prospective ERA methods versus monitoring data will feed into other projects Benchmark and Landscape ERA aiming to 1. improve comparability between assessments for different PPPs, and 2. develop holistic approaches to assess effects of multiple PPP use and ecosystems stressors at the landscape level.
A key objective of the PARC research is to warrant regulatory feasibility and implementation of new concepts and tools. To this end a managing subtask engaging regulators and other stakeholders has been set up to ensure regulatory relevance and feasible time perspectives for regulatory implementation. The PARC activity aims at facilitating the transition towards a next generation, systems-based ERA.

7.06.P-Tu446 Science-Based Recommendations to Address Chemical Pollution as a Threat to Biodiversity

Gabriel Sigmund[1]*, Leonie Mueller*[2]*,* ***Ksenia J Groh***[3]*, Marlene Ågerstrand*[4]*, Thomas Backhaus*[5]*, Miriam L. Diamond*[6]*, Walter R. Erdelen*[7]*, David Evers*[8]*, Martin Scheringer*[9]*, Zhanyun Wang*[10] *and Andreas Schäffer*[11]*, (1)University of Vienna, Austria, (2)RWTH Aachen University, Germany, (3)Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (4)Stockholm University, Sweden, (5)University of Gothenburg, Sweden, (6)Department of Earth Sciences, University of Toronto, Canada, (7)Ostrhauderfehn, Germany, (8)Biodiversity Research Institute, (9)Institute of Biogeochemistry and Pollutant Dynamics, Switzerland, (10)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (11)Institute for Environmental Research, RWTH Aachen University, Germany*

Chemical pollution is a threat to biodiversity worldwide. This has been recognized in the Post-2020 Biodiversity Framework, which proposes to regulate the release of chemicals into the environment and identifies specific indicators focusing on pesticides, nutrients and plastic waste (Target 7). We support the inclusion of these substances but believe that other groups of pollutants that may contribute to biodiversity loss should also be considered and included in biodiversity-related targets for the reduction of chemical pollution. Specifically, we propose to include per- and polyfluoroalkyl substances (PFAS), endocrine-disrupting chemicals (EDCs), non-agricultural biocides, and toxic metal(loid)s. In addition, data on emerging pollutants (e.g., industrial chemicals, liquid crystal monomers, pharmaceuticals, and personal care products) need to be regularly reviewed and added to Target 7 of the Post-2020 Biodiversity Framework in case of threats to biodiversity.
To protect ecosystems and biodiversity from those pollutant groups, various strategies exist to reduce emissions of hazardous chemicals through simplifying and grouping chemicals, reducing the production of chemicals that are not strictly needed and innovative synthesis strategies ("benign by design"). In this context, the entire life cycle of chemicals, i.e. production, use phase and end-of-life, must be considered and insights from different expert communities need to be bridged and translated to enable true interdisciplinary biodiversity-related risk assessments and consequential measures. As a crucial step in this regard, we propose to establish data inventories that provide transparent information on the production, transport and emissions of chemicals in cooperation with industry. These to date often hardly accessible data could serve as the basis for indicators to monitor the effectiveness of the pollution-related targets set post-2020 biodiversity framework and related activities.

7.06.P-Tu447 Building an European Partnership for Next- Generation Systems-based Environmental Risk Assessment (PERA) – A Project Developing a Roadmap For action

José Paulo Sousa[1]*, Annette Aldrich*[2]*, Johan Axelman*[3]*, Thomas Backhaus*[4]*, Stephan Brendel*[5]*,* ***Sabine Duquesne***[5]*, Saskia Knillmann*[5]*, Silvia Pieper*[5]*, Maria Schmied-Tobies*[5]*, Andreas Focks*[6]*, Sheila Holz*[7]*, Emilia Silva*[7]*, Chris Topping*[8]*, James H. Williams*[8] *and Louise Wipfler*[9]*, (1)University of Coimbra, Centre for Functional Ecology, Portugal, (2)Federal Office for the*

Environment, Switzerland, (3)Swedish Chemicals Agency, Sweden, (4)University of Gothenburg, Sweden, (5)German Environment Agency, Germany, (6)Institute of Mathematics, University of Osnabrueck, Germany, (7)University of Coimbra, Portugal, (8)Aarhus University, Denmark, (9)Environmental Risk Assessment, Wageningen Environmental Research (WUR), Netherlands

The European Partnership for next generation, systems-based Environmental Risk Assessment (PERA) is a strategic initiative launched by the European Food Safety Authority (EFSA) in response to the recognition that the current ERA paradigm has "fallen out of step with scientific knowledge and progress" and the new policy and societal ambitions e.g. the EU Green Deal strategy to better safeguard the environment. EFSA commissioned the development of a roadmap to facilitate a transition to an integrated environmental risk assessment (ERA) approach. The PERA systems-based approach aims to connect relevant partners from various sectors across regulatory silos, promotes and facilitates the sharing of data and expertise, and improves efficiency and transparency of the risk assessment process. The PERA roadmap comprises a problem description (current state), a vision (future state) and a series of steps to move towards the vision (transition process). It was developed after extensive desk research and multiple stakeholder interviews, that were used to identify partners, areas needing further development, challenges, blockers and collaboration opportunities. We designed a vision for next generation ERAs, initially focused on pesticides, based on the ideas of stakeholders discussed during workshops and accounting for the identified strengths and weaknesses of the current ERA system. The PERA vision is a framework for systems-based ERA, with a concentric circle model. Its core circle builds upon and strengthens current ERA processes by focusing on pesticide specific aspects useful for comparability and decreasing the assessment complexity of pesticides. The inner core circle is surrounded by a supportive circle of landscape scale ERA, that addresses ecosystems properties of generic relevance for all pesticides. These two ERA circles are in turn connected to surrounding circles representing the agricultural, ecological and production systems as well as the political, economic and social systems. To fully optimize the process these circles need to be interconnected with information feed-back loops. The vision and roadmap were designed to incorporate the strengths, knowledge and expertise of the current state into a new holistically framed systems-based ERA. Strategies for transition, as well as concrete projects to spark the transition process are proposed and include concrete and tangible steps in a holistic direction within the current regulatory framework.

7.06.P-Tu448 Predicting Pesticide Effects on Aquatic Community Endpoints in Rice Fields of Southern Europe – A Bayesian Network Approach

Sophie Mentzel[1], Claudia Martínez[2], Andreu Rico[3], Merete Grung[1], Knut Erik Tollefsen[1], Paul van den Brink[4] and ***Jannicke Moe***[1]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)IMDEA Water Institute, Spain, (3)Cavanilles Institute of Biodiversity and Evolutionary Biology, University of Valencia, Spain, (4)Wageningen Environmental Research (WUR), Netherlands*

Bayesian network (BN) can aid some of the shortcomings of traditionally deterministic environmental risk assessment by better accounting and communicating uncertainty and variability. In our approach, they are used as a meta-model to predicting potential effect on different biological levels in the aquatic ecosystem. To achieve this, we incorporate inputs and outputs of a process-based exposure model (e.g., RICE Water Quality model - RICEWQ) and a probabilistic case-based effect model (e.g., Predicts the Ecological Risks of PESTicides - PERPEST) into BN models. The RICEWQ model was run with various scenario combinations based on meteorological, hydrological conditions, and agricultural scenarios. The PERPEST model predicts the effect on different biological endpoints using case-based reasoning applied to a database of microcosm and mesocosm experiments. In this study, we focused on the pesticide exposure in rice fields surrounding a Spanish Natural Park considering three selected pesticides: acetamiprid, MCPA, and azoxystrobin. The BN enabled the communication of uncertainties transparently connected to the predicted direct effect on exposure in the rice field and indirect effect on different biological endpoints, endpoint groups and community level for the aquatic environment. Also, with the developed model we can compare the different scenarios and pesticide types thereby aiding better informed decision-making.

7.06.P-Tu449 Assessing In-field Effects of Pesticides in the Frame of the European Regulation and Implications for the Protection Of Biodiversity

Stephan Brendel[1]*, Magali Solé[1], Jeremias Martin Becker[2], Klaus Swarowsky[1], Henrike Madrenes[1], Steffen Matezki[1], Silvia Pieper[1] and Jörn Wogram[1], (1)German Environment Agency, Germany, (2)IV 1.3, German Environment Agency, Germany*

The use of plant protection products (PPPs) plays a major role in the loss of overall biodiversity in agroecosystems [1,2]. The current legal framework stipulates that PPP "*shall have no unacceptable effects on the environment*…", which is further specified by the consideration of the "*impact on non-target species"* and the "*impact on biodiversity and the ecosystem*" (Regulation (EU) 1107/2009). According to Reg. (EU) 283/2013 this includes also "*potential indirect effects via alteration of the food web*". Nevertheless it is evident that PPPs have persistent negative effects on biodiversity [1].

In typical agricultural landscapes, a high percentage of the total area is covered by agricultural fields ("in-field areas"). Agricultural fields provide important habitats for non-target terrestrial plants (NTTPs) and arthropods (NTAs) that are highly dependent on in-field areas. These species are an integral part of the terrestrial biodiversity, and declining in-field populations can also affect the off-field area through altered meta-population dynamics. Nevertheless, in-field effects are not assessed at all for NTTPs and are likely severely underestimated for NTAs. Additionally, NTTPs and NTAs form the basis of the food webs, and population declines both in- and off-field can affect consumer species including farmland birds and mammals. The current environmental risk assessment of PPP largely ignores indirect effects via alteration of food webs [2]. Although these gaps are likely a major reason for the decline in biodiversity caused by PPPs, the protection requirements of Regulation 1107/2009 laid out above have still not been implemented 13 years after its entry into force.

To protect biodiversity and to satisfy legal protection requirements, the coming revision of the risk assessment guidance for NTTPs and NTAs must include an appropriate assessment of in-field effects and indirect effects via alteration of the food webs. In our contribution we highlight current gaps and present a simple assessment scheme to broadly consider the outlined deficiencies in risk assessment until the respective guidance documents have been revised.

7.06.P-Tu450 Towards an Ecosystem-based Approach to Environmental Risk Assessment for Freshwater Ecosystems
Claudia Rivetti[1] *and Andrea Gredelj*[2]*, (1)Unilever - Safety and Environmental Assurance Centre, United Kingdom, (2)Unilever, United Kingdom*
Ecological Risk Assessment (ERA) has been traditionally used in the environmental management of freshwater bodies to help evaluate the risk of anthropogenic pressures on the structure and function of ecosystems, including for data-poor scenarios. Conventional approaches to ERA predominantly evaluate the dose-response relationship of individual stressors attested on a limited range of taxa, which are used as proxies for predicting potential impacts on the freshwater ecosystem. ERA also addresses the associated uncertainty to account for the inter- and intra-species extrapolations, with the application of assessment factors, whose magnitude depends only on the availability and number of data points and test species. As a result, it does not directly consider all potential impacts of chemicals and their mixtures on the complex processes and interspecies interactions occurring in ecosystems. Yet, varying responses of different species to chemical exposure, and cascading ecological effects make outcomes difficult to predict at the community and ecosystem levels. Ecosystem-based management requires consideration of the whole suite of anthropogenic pressures affecting the entire freshwater ecosystem(s), rather than focusing on individual chemical and biological components. Recent advancements include understanding indirect effects, measuring functional compensation, assessing trade-offs, and including links to ecosystem services delivery, which are yet to be fully explored under an ERA context. Here, we review approaches currently available supporting ecosystem-based considerations and present a conceptual framework towards their integrated implementation, highlighting their role in operationalizing an ecosystem-based ERA for freshwater ecosystems. This framework builds on the existing methodologies for evaluating the cumulative impacts of multiple pressures on multiple ecosystem components and will propose a strategy towards making ecological risk assessment more representative of ecosystem-level responses.

7.06.P-Tu451 Significant Improvement in Freshwater Invertebrate Biodiversity in English River Over The Past 30 Years
Yueming Qu[1]*, Virginie Keller*[1]*, Nuria Bachiller Jareno*[2]*, Michael Eastman Dr*[1]*, Francois Edwards*[3]*, Monika D Juergens*[1]*, John Sumpter*[4] *and Andrew C Johnson*[1]*, (1)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (2)University of Portsmouth, United Kingdom, (3)APEM, United Kingdom, (4)Brunel University, United Kingdom*
There remains a persistent concern that freshwater biodiversity is in decline and being threatened by chemical exposure. As the UK, and particularly England, is a densely populated nation with rivers of modest dilution capacity, this location is very suitable to examine how freshwater biodiversity has fared over the past 30 years. The biodiversity changing trends based on long-term dataset of 240,916 freshwater macroinvertebrates records from 1989 to 2018 for England was retrieved and examined from Mutiple characteristics (latitude, altitude, slope gradient and water flow). A sub-set of approximately 200 sites per English Region (1515 sites in total with 62514 samples), with the longest and most consistent records were matched with waste water exposure (predicted from the LF2000WQX model), upstream land cover (Land Cover Map 2015). understand changes in aquatic macroinvertebrates diversity and sensitivity with respect to these parameters, the biotic indices of (i) overall community's family richness, (ii) Ephemeroptera, Plecoptera, Trichoptera (EPT) family richness, and (iii) the score used for reporting for the National River Authority (UK) and for the Water Framework Directive (EU) known as the Biological Monitoring Working Party (BMWP) were selected. It was found that for all altitude, latitude, slope gradient, river size, waste water exposure levels, and differing proportions of upstream woodland, semi-natural, arable and urban land cover, all biodiversity or sensitivity indicies examined improved over this period, although this has slowed in some cases post 2003. On a rage, the response of family richness against the tested multiple stressors has gone from 15 to 25 family groups, a 66% improvement over 30 years. The improvement in average EPT family richness (3 to 10 families, a more than three times gain), which are considered to be particularly sensitive to pollution, imply macroinvertebrates biodiversity is still benefiting from a national improvement in water quality. Separately, we found that whilst urban area in the catchment was a strong suppressor of biodiversity, those urban areas which contained a higher woodland percentage had a lower harmful effect. This provides support for Nature-based Solutions for the urban area.

7.06.P-Tu452 Can Biofilm Functional Endpoints Reflect the Ecological Status of Rivers?
Nuria Isabel Rubio Morales[1]*, Natalia Sánchez Cosijn*[2]*, Anna Romani*[2] *and Helena G Guasch*[1]*, (1)Centro de Estudios Avanzados de Blanes, Spain, (2)University of Girona, Spain*
Rivers are one of the most impacted ecosystems worldwide, yet we need them to deliver a wide range of services for human populations. Within rivers, fluvial biofilms are especially connected to the capacity of the river to provide supporting environmental services, particularly nutrient and carbon cycling, but is it possible that those functional indicators reflect the ecological status of the river? To answer this question, we sampled epilithic and epipsammic (sediment) biofilms from 20 rivers along Catalonia (NE Spain): 7 classified as deficient/very deficient, 4 identified as mediocre and 9 classified as good/excellent ecological status by the Catalan Water Agency (ACA). We measured 3 functional aspects of biofilms: primary production, respiration and functional diversity by Community-Level Physiological Profiles using Biolog Ecoplates®. We hypothesise that good ecological status rivers will have higher functional diversity and a slightly positive net primary productivity (NPP), yet we seek to define these thresholds empirically.

Ecosystem functions are the basis of ecosystem services; therefore, the aim of this work is to characterise functional endpoints in fluvial biofilms, find patterns that help us distinguish between deficient and good status rivers and evaluate if they can be used in Ecological Risk Assessment (ERA) and as early warning signs of ecosystem service loss.

7.06.P-Tu453 A Toolbox of Strategies to Allow Successful Reduction in Copper PPP Applications Aligned with the European Green Deal

***Adrian Simon Terry**[1], Robert Morris[2], Ann Orth[2] and David Brown[1], (1)Cambridge Environmental Assessments, United Kingdom, (2)Albaugh*

Currently copper is approved as a fungicidal active substance for more than 50 different diseases in viticulture, horticulture, hops, market garden and arable crops. It is used, for example, in vineyards to control downy mildew (*Plasmopara viticola*), on arable crops to protect potato against late blight (*Phytophtora infestans*), in apple orchards to prevent the spread of scab (*Venturia inaequalis*), but also in many other crops. Although copper formulations have been used for more than 100 years, there are no reported resistances which makes it a very important tool in pest management systems for conventional farming and, particularly, for organic farming. In recent years regulatory restrictions on its use (a maximum number of doses per hectare and per year) have been implemented. Furthermore, the European Green Deal aims to reduce the use of chemical pesticides in agriculture by half by 2030 whilst also targeting an increase in organic production to 25% of agricultural land. These increased restrictions on the number of authorised applications of copper, and the ongoing threat of a total ban, present a challenge for growers, and particularly for organic growers, who are prohibited from using synthetic fungicides.

This study presents a critical review and summary of available scientific and technical information relating to reducing copper use whilst limiting plant health risk. A range of possible technical solutions were identified that include improved pesticide product formulation and application technology (including precision farming); better disease prediction tools and optimisation of application timing; and improved crop management processes to reduce disease. These potential solutions were assessed for their potential effectiveness in reducing pesticide input, cost and sustainability, and pathway to deployment, including how to incorporate these solutions into existing production/pest management systems and barriers to and conditions necessary for the adoption in the field. This toolbox aims to overcome producers' aversion to perceived risks (increased occurrence of disease) and provide them with a credible range of tools to reduce copper use while maintaining plant health and disease control. This will be essential to achieve the goals of the European Green Deal, and allow the sustainable use of copper pesticides to continue.

7.06.P-Tu454 Testing a High Throughput Assay for DNA-based Monitoring and Assessment of Lake Quality in England

***Niamh Eastwood**[1], Jiarui Zhou[2], Kerry Walsh[3], Jo-Anne Pitt[3], Arron Watson[1], Jonathan Warren[3] and Luisa Orsini[1], (1)University of Birmingham, United Kingdom, (2)School of Biosciences, University of Birmingham, United Kingdom, (3)Environment Agency*

DNA analysis of biological samples for environmental assessment is undergoing rapid development and potentially offers a more cost-effective and efficient means of acquiring species data for ecological assessment, analogous to and broader than, that currently gathered by more established methods. Current statutory biomonitoring approaches are low throughput and focus on single taxonomic groups which can fail to capture wider community-level changes leading to shifts in ecological status. DNA based approaches can target multiple taxonomic groups, be analysed with a standardised pipeline to reduce bias inherent in visual identification of species and processed with high-throughput methods to increase data generation.

Here, we carry out a proof of concept study to test a DNA based assessment of 50 lakes across England. We use two sample types (water and biofilm) from lakes with a range of ecological quality scores, previously measured with standard methods. We use multi-marker metabarcoding to measure biodiversity from across the whole lake community in a high throughput manner.

We integrate community level biodiversity data and environmental data (water chemistry, climate data) using multi-view learning to identify signatures of lake quality and find the environmental factors driving changes in biodiversity in lakes of different qualities.

7.06.P-Tu455 Assessing Risk of Offshore Windfarms Towards Ecosystem Services

***Dries Fredericus Elisa Louis Lorré**[1], Sara Vandamme[1], Ulrike Braeckman[1], Katrien Van der Biest[2], Colin Janssen[3] and Jana Asselman[4], (1)Ghent University, Belgium, (2)University of Antwerp, Belgium, (3)Laboratory for Environmental Toxicology (GhEnToxLab), Ghent University, Belgium, (4)Blue Growth Research Lab, Ghent University, Belgium*

Offshore wind energy is widely regarded as one of the most credible sources for increasing renewable energy production. Currently, the Belgian offshore wind farms (OWFs) accommodate a total capacity of 2.26 GW and the installation of another 3.5 GW is proposed in the latest marine spatial plan. Although physical and biological impact of OWFs are frequently studied and become more and more understood, a comprehensive tool to evaluate changes in ecosystem services is lacking. Yet, all stakeholders could benefit from such a tool, as it enables intuitive evaluation of both environmental burdens and opportunities by monetizing the ecosystem services into "ecoservice capital". To this end, we propose a novel approach to assess the risks of OWFs on marine ecosystems. A set of ecosystem services were selected in collaboration with multiple key stakeholders. Ecosystem services were quantified using science-based models equations and driving parameters were selected. Environmental risk assessment (ERA) procedures were used to quantify the impact of OWFs on the ecosystem parameters, and subsequently coupled to the ecosystem services. This resulted in an evaluation of the impact and risk of changing ecoservice capital. As a first case study, waste remediation (as sedimentary nitrate reduction) was selected as ecosystem service. Total organic matter (TOM) and fine sediment fraction quantities were found to be good proxies within this model. As the Belgian part of the North Sea is one of the best studied and monitored marine areas in the world and OWFs are intensively monitored within this area, extensive data regarding these parameters is available and was used to construct predictive ERA models. Confirming previous results, no significant change in TOM was observed. However, the fine sediment fraction adjacent to turbines showed an increase of almost

5%. Based on these findings the impact is assumed to induce only low risk towards changing waste remediation potential of the environment, as the impacted area represents only 1.2% of the entire OWF area. This proof of principal study demonstrated the use of ecosystem service evaluations in past and present ecological risk assessment procedures. However, a more complete view and evaluation using other ecosystem services needs to be conducted to provide a more holistic view of sustainable design and developments of future offshore advancements.

7.06.V Next Generation of Risk Assessment and Management of Chemicals to Address Nature Preservation and Ecosystem Services

7.06.V-01 Artificially Mimicking Fluvial Ecosystems to Study the Influence of Biofilms on Toxicity Potential of Chemical Using Bioenergetics Traits of Fish (*Gambusia affinis*)

Amina Khalid[1]*, Berta Bonet*[2]*, Helena Guasch Padro*[3]*, Nuria Isabel Rubio Morales*[4] *and Anna Vila Gispert*[5]*, (1)Institute of Aquatic Ecology, Universitat de Girona, Spain, (2)Centro de Estudios avanzados de Blanes (CEAB), Spain, (3)Centre d'Estudis Avançats de Blanes, CSIC, Spain, (4)Centro de Estudios Avanzados de Blanes, Spain, (5)GRECO, Institute of Aquatic Ecology, Universitat de Girona, Spain*

Biofilms (BF) modulate the toxicity of chemicals by providing sites for biotransformation and/or chemical transfer to other organisms in fluvial ecosystems. Moreover, environmental variables influence the regulatory services of BF assemblages such as their capacity to oxygenate water and uptake the excess of dissolved nutrients. The effect on water quality due to reduced expression of these regulatory services can gravely affect the population fitness of higher trophic levels. An exposure study of 200µg/L of 1H-Benzotriazole (BTR) was simulated in the laboratory for 21 days by employing 12 microcosms (recirculating channels) with two functional groups: BF grown in artificial channels, fish kept in 90L aquaria and sediment in each aquaria to increase environmental realism. Four treatments used, with three replicates each, were: fish control (C), biofilm control with fish (BC), fish with BTR (FT) and biofilm, BTR and fish (BT). In the setup, water quality construed the BF functional performance. The study examined direct effects, without BF and indirect effects in the presence of BF, of BTR on bioenergetics traits of fish (standard metabolic rates SMR, maximum metabolic rates MMR and absolute aerobic scope AAS) as a proxy of population fitness. Interestingly, the fish controls (C) exhibited lower MMR (P= 0.01) and AAS (P= 0.05) than BF controls which demonstrates that there is an apparent sticky link between these two functional groups. BTR in presence of BF (BT) raised the maintenance cost (SMR) significantly ($P=0.02$) compared to its control (BC) but the difference between C and FT; FT and BT; and BC and C remained insignificant ($P=0.19$; *0.66* and *0.12,* respectively), demonstrating indirect effects. Similarly, the MMR, which determine the ability of fish to carry energetically expensive activities, was lower in the BT treatment compared to its control, BC (P= 0.005). The endpoint AAS carries functional value because it represents the energy available to carry simultaneous activities including growth and reproduction. We also found that BF influenced the toxicity by reducing AAS in BT treatments significantly (P= 0.01) relative to its control (BC). BF plays a significant role in defining the energy limits of fish and provides realism in the assessment of direct and indirect effects of chemicals on population fitness in fluvial ecosystems.

7.06.V-02 Effects of Palm Kernel Oil, Olive Oil, Crude Oil and Honey on Renal Function of Male Albino Rats

Chinedu Imo[1] *and Nelson Wilson*[2]*, (1)Federal University Wukari, Nigeria, (2)Biochemistry, Federal University Wukari, Nigeria*

This study investigated the effects of palm kernel oil, olive oil, crude oil and honey on renal function of male albino rats. These chemical substances are used in traditional medicine for various purposes, including as antidote for poisons. **Methods**: Thirty healthy male albino rats were purchased and used in this research study. The animals were randomly placed into five groups (n=6). The animals were administered the corresponding chemical substances for a period of three weeks. They were later sacrificed and their blood samples and kidneys collected for biochemical and histological analysis respectively. **Results**: Urea increased in all the groups administered the different chemical substances compared to the control. The increase is statistically significant ($p<0.05$) in groups 4 and 5, and non-significant ($p>0.05$) in groups 2 and 3 when compared to the control (group 1). Creatinine increased non-significantly ($p>0.05$) in all the test groups compared to the control. Sodium decreased non-significantly ($p>0.05$) in group 2, but increased non-significantly ($p>0.05$) in groups 3, 4 and 5 compared to the control. Potassium increased non-significantly ($p>0.05$) in group 2, but increased significantly ($p<0.05$) in groups 3, 4 and 5, while chloride increased significantly ($p<0.05$) in groups 2, 3 and 5 and non-significantly ($p>0.05$) in group 4 compared to the control. Photomicrographs of histoarchitectural state of the renal tissues showed some forms of alterations in some parts of the tissues of the test animals when compared with the control. **Conclusion:** This study showed that long term administration of palm kernel oil, olive oil, crude oil and honey, as used in this study could cause certain alteration to renal functions. The order of renal intoxication caused by the administration of the chemical substances is crude oil > honey > olive oil > palm kernel oil.

7.07 One Health: Ecotoxicology at the Human-Animal-Ecosystem Interface

7.07.T-01 One Health Approach for Evaluating Presence and Effect of Pharmaceuticals Discharged via a Wastewater Treatment Plant in the Marine Environment

Daniela Maria Pampanin[1]*, Jason Tyler Magnuson*[1]*, Gorm Kipperberg*[1]*, Magne O. Sydnes*[1] *and Daniel Schlenk*[2]*, (1)University of Stavanger, Norway, (2)Environmental Sciences, University of California, Riverside*

Marine sewage outfalls are major contributors of complex mixtures of pharmaceuticals, personal care products, other emerging contaminants and legacy contaminants, which together represent important ecological challenges in aquatic environments. Most traditional wastewater treatment plants are not designed to remove pharmaceuticals, which are increasingly used, especially after the pandemic. To face such challenge the One Health approach has been chose in order to combine the impact of discharged

pharmaceuticals on human, organisms, and environmental health, by focussing on the interaction between disciplines and effects on the total environment. The case scenario of the wastewater discharge of Stavanger, the 4th largest city in Norway, is presented as an example of evaluation of the presence and effects of pharmaceuticals in the marine environment, combining disciplines like chemistry, biology, modelling, environmental economics and social science.
The modelling of the wastewater treatment plant (WWTP) discharge was carried out using DREAM (Dose related Risk and Effect Assessment Model). Water from the WWTP (as composite samples) of the inlet and outlet, seawater and sediment from the discharge point, as well as biota samples were collected and analysed for their chemical content in terms of pharmaceutical compounds. In parallel, laboratory exposures were carried out to better understand the potential transfer of pharmaceuticals from water and sediment to biota.
Chemical and biological analyses were conducted to quantify the risk. The collaboration with economists with expertise in environmental valuation and bioeconomic modelling helped to produce an auxiliary economic analysis relevant for stakeholders, public resource managers, and policymakers. Database of relevant environmental benefit-transfer values were compiled.
Wastewater treatment plant discharges pose a risk to the ecosystem and the organisms living in, which can become a threat to human. The One Health approach allowed a holistic vision of the environmental challenge and was accurate in identified the environmental challenge in all its aspects, which is the first important step toward effective solutions when it comes to anthropogenic impacts.

7.07.T-02 A Complex Problem: Hydraulic Fracturing Wastewaters on Freshwater Organisms and Human Perspectives
Tamzin A Blewett[1]*, Erik Folkerts*[2]*, Connor B. Stewart*[1]*, Ivy Luu*[3]*, Aaron Boyd*[1]*, Daniel Alessi*[3]*, Greg Goss*[3] *and Richard Glen Uhrig*[3]*, (1)Biological Sciences, University of Alberta, Canada, (2)University of Miami, (3)University of Alberta, Canada*
Hydraulic fracturing is a technique used globally to recover oil and gas from impermeable sources (e.g., shale, coal beds). During this process chemical additives are injected into the ground at high pressures to "fracture" rock formations yielding oil and gas. Over time mixtures of the injected chemicals (e.g., biocides, PEG), minerals associated with the fracture (e.g., metals and salts) and hydrocarbon products (e.g., polycyclic aromatic hydrocarbons (PAHs)) will flow back to the surface as a complex solution termed flowback and produced water (FPW). Spills or intentional applications (e.g., as a dust and ice suppressant) of hydraulic FPW can be devastating to freshwater environments and communities. Overall, previous work has shown decreases in reproduction, survival, and growth of many species (e.g., *D. magna*, Rainbow trout, zebrafish) but has focused largely on survival without understanding the possible implications of climate change and how this will alter toxicity. In our study, *Daphnia* were exposed to two concentrations of FPW (0.25% and 0.75%) for 48 hours, and allowed to grow in clean media for 19 days following exposure. Growth, survival, reproduction, as well as oxygen consumption, and systems level quantitative proteomic analysis showed extensive perturbation of metabolism and protein transport in *D.magna* at exposures of 0.25% and 0.75% of whole FPW effluent. In acute rainbow trout exposures, bioaccumulation of the PAH phenanthrene was altered under different temperatures (4, 13, 17°C) and when present in combination with FPW exposure. Overall, these data will help to understand real-world exposure scenarios, and the possible biological and ecological impacts on human and ecosystem health.

7.07.T-03 Effects of the Plasticizer Diethyl Hexyl Phthalate on Physical Fitness: A One Health Case Study of Contaminants at the Human-animal-ecosystem Interface
Joseph H Bisesi[1]*, Amanda Buerger*[2]*, Caitlyn Parente*[2]*, Jason Harris*[2]*, Emily Watts*[2] *and Alexis Wormington*[2]*, (1)Environmental and Global Health, University of Florida, (2)University of Florida*
Environmental contamination with plastics has become a global issue impacting both high density urban and low density remote/rural environments. As a result, exposure to plastics and their component plasticizers has become a ubiquitous issue across the human-animal-ecosystem interface. These exposures can come directly from leaching of plasticizers into food and water sources, or indirectly through leaching from micro/nano plastic materials in the diet. While plasticizers have been implicated as obesogens in humans, they may also pose a threat to aquatic animals who may experience exposure through water and food sources. For example, phthalate plasticizers are suspected to influence obesity through dysregulation of the peroxisome proliferator activated receptors (PPAR), which are nuclear receptors involved in the synthesis, metabolism, and storage of lipids in the gastrointestinal system and other organ systems throughout the body. However, little research has examined whether these same pathways may be impacted in aquatic organisms and whether disrupted molecular pathways result in phenotypic responses. Recently our team has examined long term exposures to the plasticizer diethyl hexyl phthalate (DEHP), one of the most commonly found plasticizers in food and water around the world. We found that is causes distinct changes in gastrointestinal function at the molecular level, which are exacerbated by poor diet. Further, we have demonstrated for the first time that exposure to the plasticizer DEHP impacts lipid mobilization during exercise, which limits the ability to perform prolonged exercise, which can impede weight loss in humans and ecological fitness in fish. Results from these studies indicate that plasticizers have the potential to impact both humans and aquatic animals, necessitating a one health approach for dealing with this complex and global problem.

7.07.T-04 Contaminated Sites and Indigenous Peoples in Canada and the USA - A One Health Investigation
Nil Basu *and Katie Chong, McGill University, Canada*
Indigenous communities in Canada and the USA are disproportionately exposed to contaminated sites, often due to industrial activities adjacent to Indigenous lands. Contaminated sites pose unique challenges to many Indigenous peoples who consider the land as an integral part of food systems, language, culture, and spirituality. Federal management of contaminated sites near 'fence-line' Indigenous communities is challenged by epistemological differences, regulatory barriers, and a lack of scientific research to support community-specific exposure assessment. While pollution in general has been well-studied in the context of

Indigenous peoples, there is limited information available on the unique issue of federal contaminated sites, and a lack of coordination between industries, governments, scientists, and Indigenous communities. Most studies are focused on a local scale, which are important, but evidence synthesis is also needed to inform decision-making. Thus, we conducted a scoping review to identify and map available information on contaminated sites and Indigenous peoples in Canada and the USA, utilizing three streams of data retrieved from January-March 2022: a systematic literature search (key word groups: *Indigenous people* and *contaminated sites*); a grey literature search; and an analysis of federal contaminated site data (Canada's Federal Contaminated Sites Inventory (FCSI) and US EPA's Superfund Database). Our search yielded 49 peer-reviewed articles, 17 grey literatures, and 8114 federal site records (1236 Superfund, 6878 FCSI), allowing us to summarize the state-of-the-science on the exposure of 'fence-line' Indigenous communities to contaminated sites, management strategies, and the inclusion of Indigenous peoples in site processes. The results spanned many disciplines, revealing the contamination of the lands of 815 distinct Indigenous tribes and nations and the presence of 440 different contaminants or contaminant groups found at 4976 contaminated sites. By integrating three diverse data streams we discovered a disparate body of information, pointing to the need to prioritize holism, efficiency, and Indigenous leadership in site assessment, management, and research. This should include re-thinking community-specific risk assessments to better understand Indigenous conceptualizations of human and ecological health, and greater collaboration between the scientific community, Indigenous leadership, and federal governments.

7.07.T-05 Chemical Hazard in Edible Insects – Accumulation and Elimination of Contaminants from the Substrate
Diogo Filipe Nunes Cardoso[1]*, Ana Rita R. Silva*[1]*, Regina Duarte*[2]*, Beatriz Chico*[2]*, Pedro Serrano*[2]*, Pedro Brandão*[2]*, Marija Prodana*[1]*, Ana Góis*[1]*, Amid Mostafaie*[1] *and Susana Loureiro*[1]*, (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)CESAM & Department of Chemistry, University of Aveiro, Portugal*
Considering the global food crisis, there is a need to find innovative, safe and sustainable solutions for the current food demand. At the same time, waste generation is a severe problem incompatible with the planet's carrying capacity. Insects are presented as one of the most sustainable alternative solutions as protein sources for food and feed. Due to their efficient bioconversion capacity, insects can be used as waste control, with the advantage of reusing non-valuable products and being a valuable protein source. However, while we aim for sustainable food production, safety assessments are mandatory, such as understanding how safe the use of insects is for food/feed when reared in different substrates. This study aims to go beyond the current state of the art by comprehensively evaluating how and to which extent insects uptake and eliminate contaminants over time, rather than simply measuring contaminants after exposure to a contaminated substrate. With complete two-phase bioaccumulation studies with an uptake (contaminated sediment) followed by an elimination (clean sediment) phase, data was used in toxicokinetic modelling. Identifying the key gaps in the literature, this work aims to evaluate the bioaccumulation capacity of mercury (Hg) - already reported to bioaccumulate in insects, yet without information on the elimination - and benzo[a]pyrene (B[a]P) – still not addressed as a chemical hazard in edible insects - understanding how it is uptaken and eliminated in *Tenebrio molitor* (YMW) when exposed to a maximum allowed concentration of each one of these compounds in feedstuff.
This study demonstrated that when insects are exposed to Hg and BaP at the maximum allowed levels by European Union regulation for feed, they accumulate contaminant levels that make them unsuitable for feeding other animals. However, after a depuration period, it was demonstrated that insects could reduce their contaminant to concentrations that comply with the legislation in force. In the case of Hg, 4 to 5 days should be enough for a safer consumption of these insects – a longer period is required for B[a]P. This is especially pertinent when insects are used as converters of waste, where some concerns are raised regarding all the contaminants that can be present. In those cases, this study supports the option of a depuration period in a clean substrate after exposure to the waste. This period will vary depending on the insect species and the classes of contaminants.

7.07.P One Health: Ecotoxicology at the Human-Animal-Ecosystem Interface

7.07.P-Th408 Mercury Exposure to Humans from the Consumption of Small Cetaceans in St. Vincent & the Grenadines, West Indies
Jessica Dutton[1]*, Meaghan McCormack*[1] *and Russell Fielding*[2]*, (1)Biology, Texas State University, (2)HTC Honors College, Coastal Carolina University*
St. Vincent & the Grenadines (SVG) has a small whaling operation, taking on average over 400 odontocetes (toothed whales and dolphins) each year for human consumption. Muscle and blubber are sold through commercial vendors, whereas liver and kidney are distributed through informal networks. Odontocetes have high tissue mercury (Hg) concentrations due to their long life spans and high trophic positions, yet little is known about Hg concentrations in Caribbean odontocetes taken for human consumption and the frequency at which they are consumed. This study 1) investigated the total Hg (THg) concentration in muscle, blubber, kidney, and liver of killer whales (*Orcinus orca*), false killer whales (*Pseudorca crassidens*), short-finned pilot whales (*Globicephala macrorhynchus*), Risso's dolphins (*Grampus griseus*), and dolphins from the *Stenella* genus taken for human consumption using a Direct Mercury Analyzer, and 2) determined the role of odontocete-based food products in the diet of the Vincentian population as a proxy for Hg exposure using interview surveys. For all species combined, mean THg concentrations (µg/g dry weight) were greatest in liver (730; n = 17), followed by kidney (274; n = 10), muscle (76.4; n = 59), and blubber (4.57; n = 36). All liver samples and most kidney, muscle, and blubber samples exceeded the FAO/WHO human consumption advisory level of 1 µg/g wet weight. Interview surveys (n = 921) determined that odontocete-based food products are consumed by 66% of respondents in SVG with meat being the most popular food product. Over a quarter (27.7%) of respondents consumed odontocetes more than once per month and 2.9% more than once per week. Based on the FAO/WHO provisional weekly tolerable weekly intake (PTWI) guidelines for methylmercury (MeHg) exposure, assuming only one of these tissues is consumed and there is no other source of MeHg exposure, blubber can be consumed the most each week (1331 g), followed by kidney (364 g), liver

(104 g), and muscle (52 g). The consumption of odontocete-based food products may present a public health risk in SVG due to the frequency at which it's eaten. It is recommended that the SVG government issue a Hg advisory regarding the consumption of odontocete-based food products and implement species-specific whaling quotas to reduce the likelihood of the most Hg contaminated species (killer whale and short-finned pilot whale) being consumed.

7.07.P-Th409 Implications of Climate Change for Dietary Contaminant Exposure in Alaskan Subsistence Communities

***Kristin Nielsen**, University of Texas at Austin*

Remote coastal communities in high latitude regions are especially vulnerable to adverse impacts of climate change on community health and resilience. This is particularly evident in Alaskan subsistence communities, where changes in the timing, abundance, availability, and quality of subsistence resources are contributing to a range of concerning public health inequities and cultural erosion. Rural Alaskans have some of the highest fish consumption rates in North America; however, subsistence consumption of fish has declined by 31% since the mid-1980's. Community surveys indicate that these trends are driven by a few primary factors - notably, climate change and pollution, which are inextricably linked by chemicals with global biogeochemical cycles that are tightly coupled to climate (including some contaminants). Changes in various climate-driven factors (e.g., melting permafrost, diminishing sea ice, glacial retreat) may necessitate changes to traditional food storage and preservation methods and meaningfully alter the composition of subsistence diets via several direct and indirect mechanisms, both of which have implications for dietary contaminant exposures. This presentation will discuss climate-driven factors that may contribute to food safety and security issues in rural and Alaska Native subsistence communities, as well as the relative risks to public health that are attributed to increasingly westernized diets in high-latitude subsistence communities in Alaska.

7.07.P-Th411 Microplastics in a Local Population of Dolphins (*Tursiops truncatus*): A One Health Approach to Coastal Monitoring

***Bonnie M. Ertel**[1], Austin D. Gray[2] and Wayne E. McFee[3], (1)Key Species and Bioinformatics Branch, CSS, on contract to NOAA NCCOS, (2)Biological sciences, Virginia Tech, (3)Coastal Marine Mammals Assessment Program, NOAA National Centers for Coastal Ocean Science*

Within the tidal creeks of Charleston, South Carolina (USA) resides a population of bottlenose dolphins (*Tursiops truncatus)* that represent sentinel species for monitoring the health of coastal ecosystems. Microplastics (particles less than 5mm) are anthropogenic contaminants of emerging concern that are ubiquitous in the environment and have been documented within marine biota, including in piscivorous predators such as dolphins. However, no long-term studies have assessed microplastics in a local population of dolphins. This research aims to quantify and identify microplastic particles in the gastrointestinal tracts of bottlenose dolphins stranded around the Charleston estuary dating back to 2016. We examined dolphin stomach and intestinal contents for microplastics by rinsing contents into stainless-steel sieves to retain particles ≥125µm, digesting biological remains with a 10% KOH solution, and using Raman spectroscopy to identify polymer types. Preliminary results from seven stranded dolphins indicate high levels of contamination, ranging from 76-2249 total microplastics per animal (1175±288, mean±SE). The most common plastic polymer identified was polypropylene (35%), which is commonly used in fishing gear. This ongoing research will continue to assess archived dolphin samples and also investigate levels of microplastics in local fish to elucidate the potential for trophic transfer of these contaminants into the diets of mammals, including humans. This study can help inform coastal managers by taking a One Health approach to assess the health of our coastal ecosystem, animals, and also humans.

7.07.P-Th412 A One Health Solution to Control Residual Malaria Transmission: The Not-So-Hidden Added Value of Ecotoxicology and Environmental Chemistry

***Andre Patrick Heinrich**[1], Hermann Sié Pooda[2], Christophe Roberge[3], Rolf-Alexander During[4] and Karine Mouline[5], (1)Institute of Soil Science and Soil Conservation, Justus Liebig University Giessen, Germany, (2)Centre International de Recherche-Développement sur l'Elevage en zone Subhumide (CIRDES), Burkina Faso, (3)MedinCell, France, (4)Justus Liebig University Giessen, Germany, (5)Institut de Recherche pour le Développement (IRD), France*

Sixty years ago, Rachel Carson's Silent Spring shaped environmentalism and exposed hidden ecological costs of the first modern insecticide DDT which revolutionized malaria control. Despite major environmental and health risks, DDT is still used as last resort to fight malaria vectors (mosquitoes). The burden of the disease plateaued in recent years, and it became clear that human health is closely linked to animal and environmental health, ultimately resulting in the holistic strategy called One Health.

In the combat against malaria, the success of control tools like insecticide-treated nets and indoor residual spraying is often undermined by new behaviour of mosquitoes to escape exposure. Zoophagy is one of them, with mosquitoes being diverted by control tools to alternative blood sources than humans, which are mostly domesticated animals. In Burkina Faso, the ANIVERMATE project investigates treating cattle with ivermectin as a new vector control tool. The idea: *Anopheles* mosquitoes receive ivermectin via blood meal and die. However, since excreted veterinary drugs can enter the environment and harm ecosystems, ecological consequences of residues are considered upfront. Combining human, animal and environmental health creates a true One Health approach. Showcasing the expertise and added value that ecotoxicology and environmental chemistry bring to the table of human health concepts was the main motivation of this One Health project.

Our 3-arms design study used local cattle and *An. coluzzii* mosquitoes from Burkina Faso. We compared a classical, injectable ivermectin veterinary formulation (IVOMEC-D®) and a new long-acting depot formulation designed to provide vector control for at least six months. First, we characterized the pharmacokinetics in cattle plasma and dung. Efficacy was evaluated relatively to ivermectin plasma concentration by following mosquito mortality after direct skin feeding assays on treated cattle hosts at different delays after application. Modelling approaches were used to determine efficacy in the field setting.

To assess environmental risks, we monitored ivermectin dissipation in dung over a 90-day period. Sorption studies complemented this environmental fate review. The predicted environmental concentrations and behavior were related to published ecotoxicological observations on dung fauna. Kinetics in dung and plasma and the preparatory environmental risk assessment are presented together with proposed risk mitigation measures.

7.07.P-Th413 Distinctive Gastric Structural Responses of Wistar Rats Exposed to Environmental Concentrations of Tributyltin (TBT)

Kainã Rocha Cabrera Fagundes[1]*, Felipe Santana*[2]*, Renata Mari*[1]*, Lucas Correia*[3] *and Regina Silva*[3]*, (1)UNESP- Campus do Litoral Paulista, Brazil, (2)Biological and Environmental Sciences, UNESP- Campus do Litoral Paulista, Brazil, (3)UNIFESP - Instituto De Saúde E Sociedade*

For decades, the application of antifouling (AF) such as tributyltin (TBT) has been used not only for its antifouling feature but also in other industrial processes. In consequence, tons of this compound are still available in aquatic environments. As water treatment systems are still very deficient in eliminating persistent and highly toxic compounds, their presence in nature affects not only organisms in general, but also human health. Therefore, this study aimed to evaluate the histopathological effects of the gastric structures of Wistar rats exposed to environmental concentrations of TBT. For that purpose, 36 male Wistar rats were used. The experiment was carried out in 60 days (photoperiod of 12HL/12HD, 23ºC±1ºC), the rats were divided into 3 experimental groups with 4 animals per group: group (CG), the control group, by gavaging only with corn oil; group 1 (G1), gavaged with 20ng.g^{-1} of TBT diluted in corn oil; and group 2 (G2), gavaged with 600ng.g^{-1} of TBT diluted in corn oil. Then, the organisms were euthanized by the decapitation. The stomach of each group was fixed in formalin solution 10%, then the materials were proceeded under histological routine. Cuts of 5µm were stained with Hematoxilin-Eosin; Picrossirus Red; Masson Trichrome; Periodic Acid Schiff and Alcian Blue pH 1.0. The histological morphometric parameters and analyzed by Tukey's One-Way ANOVA. The G1 presented the stomach with several structural and composition damages. The nonglandular stomach presented thick layer of keratin. The hyperkeratosis can be related to direct contact with TBT, leading to inflammation, ulcer and cancer. The mucus secretion was poorly seen, resulting in malformation of bolus. Muscular layer atrophy was severe in this treatment. In the G2, the nonglandular stomach had hyperkeratosis as seen in G1. The glandular stomach mucosa was poorly in mucus secretion. In all strata, there were hemorrhagic centers infiltrated lymphocytes mainly in the submucosa, indicating inflammatory process. In the long-term, the gastric function can be damaged and disabled. We conclude that the ingestion of TBT even at environmental concentration has significative changes in the gastric morphophysiological composition. The TBT can affect mainly the aquatic organisms, due to accumulating and affecting the trophic chain, so using a rat as a human parallel organism, we can measure the morphophysiological damages of environmental levels of TBT in our food and water.

7.07.P-Th414 Can I Eat This Fish? - Dietary Recommendations to Reduce the Mercury Risk Exposure in Portugal

Maria Donas-Bôtto Bordalo[1]*, Andreia Rodrigues*[1]*, Sónia D. Coelho*[1]*, Diana Campos*[1]*,* ***Sizenando Nogueira Abreu***[2]*, Fernando Morgado*[1] *and Hugo C. Vieira*[1]*, (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)CESAM & Department of Biology, University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal*

Fish consumption is undoubtedly an important component of the human diet, with recognized nutritional value. Unfortunately, fish consumption is also a major pathway of human exposure to mercury (Hg).

In recognition of the risks associated with exposure to Hg through diet, the Joint Expert Committee on Food Additives (JECFA) have determined a maximum limit to Hg intake called provisional tolerable weekly intake (PTWI) of 1.3 µg kg body weight (bw)$^{-1}$ week^{-1}. Furthermore, JECFA also established the maximum permitted Hg level of 0.5 µg g^{-1} (ww) in fish muscle and 1 µg g^{-1} (ww) in the muscle of some predatory fish. Despite that, JEFCA concluded that determining reference levels for Hg in fish may not be the best way to reduce Hg exposure in the general population. On the contrary, it recommends advising risk groups on the risk and benefits of fish consumption in order to effectively reduce the number of individuals with higher exposures than PTWI. Fish consumption in Portugal increased 9% from 2015 to 2018, reaching 60.9 kg in 2018 (36.6 kg higher than EU-28 average). Portugal is thus one of the countries with the highest fish consumption per capita in the EU and the world. Interestingly, other countries with lower fish consumption per capita (e.g. USA, Canada, Ireland, Australia and New Zealand) have already established specific guidelines considering the risk-benefit of fish consumption, whereas, in Portugal, such guidelines are lacking. Despite some scientific publications focusing on Hg exposure through fish seafood consumption, the results of these studies have not yet been applied in the development of specific recommendations. A knowledge transfer between the academia and the society would empower the population with tools to a responsible selection of the fish species and amount of fish to eat considering the risk-benefit of fish consumption.

So, in order to bridge this gap, CAN I EAT THIS FISH? project aims to: 1) provide the largest and more complete assessment of Hg levels in fish in Portugal considering different ecological and geographical aspects (with a special focus on the Estarreja Region, due to the scenario of historical contamination by Hg). 2) evaluate the exposure of the Portuguese population to the Hg through diet. 3) develop tools with simple and precise language that allow mitigating exposure to Hg. An overview of the project's main aims and tools to achieve the proposed objectives will be discussed in detail.

7.08 Precision Application – A Way to Reduce Environmental Risk?

7.08.T-01 Digitalization - Chances and Risks of New Technologies in Plant Protection for the Environment and Sustainability

Michael Hess[1]*, Maria Lippl*[2]*, Cécile Périllon*[3]*, Anne-Katrin Mahlein*[4] *and Christina Pickl*[3]*, (1)German Environment Agency (UBA), Germany, (2)GreenSurvey – Institut für Marktforschung Prof. Dr. Menrad, Germany, (3)German Environment Agency,*

Germany, (4)Ifz, Institut für Zuckerrübenforschung an der Universität Göttingen, Germany
The aim of the presented study was to describe the landscape of developments in new plant protection technologies and strategies, and identify their potential for reducing the environmental impact of plant protection in practice. Not only the opportunities and risks of new technologies need to be evaluated, also their maturity for implementation into agricultural practice must be estimated.
Current developments were identified by means of literature research and qualitative interviews and selected for their potential impact. A stakeholder workshop was organized to present the outcomes of the survey and discuss the results.
The highest level of maturity of some spray application systems was confirmed during the stakeholder workshop. Most participants voted for spot spraying, followed by band spraying, weeding robots and decision-making support. A high potential to reduce the impact of plant protection on the environment was seen for robot technologies.
The results indicate, that particularly technics related to patch treatments show a high potential to decrease the impact on the environment, especially when connected to an alternative to pesticide application. The stakeholder workshop made clear, that further development is needed for sensor-based strategies respecting in-field biodiversity.
Cited obstacles for the implementation of the technologies were unknown rentability, deficits in infrastructure and complexity of data exchange interfaces. The demand for data to measure the progress in sustainability confronts with the fear of control and sanctioning. As stated in the workshop, it is very much the personal motivation of the farmer that decides on the implementation into practice and the potential impact on the environment.
For the implementation of any development into practice the stakeholder workshop recommended comprehensive and independent advice and effective financial support at the farm level, financing the application and achievement of environmental goals, not just the financing of a new device.
As the digital transformation concerns all crop management areas, it is reasonable to regard risks and opportunities on the farm level and look out for synergistic effects, especially for the investment and environment. Since the farmer plays a key role in the adaptation of the new technologies, measurement and evaluation of the environmental effects should be possible on the farm level as feedback and incentive, not only in research and regulation.

7.08.T-02 Exploring Groundwater Leaching Concentrations From Partial-Area Applications: A Two-Dimensional Modelling Exercise
*Francis P. Donaldson and **Bernhard Jene**, BASF SE, Germany*
Agrochemical leaching in the EU is assessed for regulatory purposes with one-dimensional transport models which exclusively consider vertical transport to underlying groundwater. Such an approach is reasonable for homogenous broadcast field applications, as lateral dispersion and transport are mostly only minor effects as they are only relevant at the boundaries of the sprayed area (*i.e.*, the field boundaries). However, such transport processes may become more important in the case of targeted and precision partial area application techniques (such as banded and spot application) as most of the applied area would become influenced by a boundary between sprayed and unsprayed areas.
Two-dimensional modelling work using HYDRUS-2D has been previously presented which demonstrated the concentration reduction in groundwater when considering a banded application. The present work further expands on this effort, comparing one-dimensional (vertical transport) modelling with more realistic two-dimensional modelling approaches. The impact of input parameters (including nonlinear sorption) is considered, and comparisons across all FOCUS groundwater scenarios are made to demonstrate that the groundwater concentrations will be affected (and scale) with the fraction of the treated area.

7.08.T-03 Precision Application and Soil Organisms – Matter of Scatter or Just Chatter?
***Jörg Hanisch**[1], Gunnar Henkes[1], Michael Faupel[2], Jan-Dieter Ludwigs[2] and Daniel Ruf[2], (1)Rifcon, Germany, (2)RIFCON, Germany*
Technological innovations such as precision spraying makes it possible to treat agricultural fields partially or individual plants only. This leads to heterogeneous pesticide spraying patterns compared to conventional full-area application. In turn, soil organisms are exposed to a correspondingly heterogeneous load regarding the field perspective. However, how such 'precise application' of pesticides affects soil organisms on the field level is very limited. In the context of precision application pattern, it is not the absolute amount of agent applied per field what is considered crucial, but the actual spatial distribution of compound and soil organisms across an agricultural field. It is assumed, that the pattern itself has a strong influence on how individual species, functional groups and the community are affected. For this reason, a study was designed to investigate the effects of a precise spray application on the earthworm community within a field scale. Carbendazim was applied at an application rate of 8 kg a.s./ha on 50% of the treatment area in 3 different checkerboard application patterns with different scaling. In addition, a fully applied positive and a negative control were carried out. The earthworm community was observed over a period of one year. In addition to total earthworm abundance, different ecological groups were analyzed separately. Our results show that primarily the scale of the application pattern has a clear influence on total earthworm abundance with different ecological groups showing different responses. The results of the study contribute to a better understanding of the possible effects of precision application on different ecological groups of soil organisms and will be presented and discussed.

7.08.T-04 Modelling Spray Drift in Precision Applications
***Henk Jan Holterman**, Koen Van Boheemen and Jan Huijsmans, Agrosystems Research, Wageningen University & Research, Netherlands*
Precision application of plant protection products (PPPs) results in a reduction in the amount applied and could also result in a lower exposure of different off-field areas and non-target organisms to PPPs. Precision applications for crop protection could play

a role in the exposure assessment of PPPs in the authorisation process. Typically, variable-rate and spot-spraying applications can be distinguished. In a variable-rate application the whole field is treated while the dose is varied to meet the conditions in each location. In a spot-spraying application for each location the decision is made whether or not a (full dose) spray application is required. Finally, a hybrid form exists where variable-rate and spot-spraying are combined. This study focusses on the exposure reducing effects of variable-rate and spot-spraying applications in arable crops, particularly regarding the downwind off-field deposits due to spray drift. For this purpose a new spray drift model was developed which takes into account the non-uniform dose rates at the crop field. In the model, field sections receiving a certain PPP dose rate are identified as polygons. This approach is similar for both variable-rate and spot-spraying applications. Implicitly, each polygon is treated as a (very) small crop field. As such, each polygon contributes to downwind spray drift, depending on its area and on the applied dose rate. The sum of all these contributions is the total spray drift that occurs. In the current set-up, adjacent watercourses are the non-target areas to protect. Watercourses are imaginarily divided into segments of about 10 m length. Spray drift deposits are computed on each watercourse segment. Spray drift deposits on a watercourse segment depend on its location with respect to the treated field sections and on wind direction. Only downwind segments can receive spray drift deposits. Variable-rate and spot-spraying applications lead to drift reduction, partly due to the reduced amount of PPP used. Example computations indicate that drift reductions can be higher or lower than the reduction from reduced amount of PPP. This depends on the distribution and location of field sections with reduced dose rates. In this study, a few test cases are investigated for different wind directions. The results indicate that drift reductions seem to be rather insensitive to wind direction. Further research is needed to verify this remarkable finding.

7.08.T-05 DriftRadar by Bayer: Integrated Drift Management During Spray Operation to Prevent Drift

Andrew C. Chapple[1]*, Josy Bravidor*[2]*, Frank Dietz*[3]*, Yves Jaschinski*[3]*, Susanne Lauck-Birkel*[3]*, Catherine Legue*[4]*, Walter Mayer*[3]*, Daniela Portz*[3]*, Robert Puhl*[3]*, Katarzyna Maria Ubysz*[5] *and Anna Zdunek*[5]*, (1)Environmental Safety, Bayer AG - Crop Science Division, Germany, (2)Bayer AG - Crop Science Division, Eritrea, (3)Bayer AG - Crop Science Division, Germany, (4)Bayer S.A.S., France, (5)Bayer Sp.z.o.o., Poland*

DriftRadar, an ongoing project at Bayer AG, is a stepping-stone towards a vision of a fully integrated digital label with digitalized, *in situ* or field-localized risk assessment and customized risk mitigation in real-time. It demonstrates a solution to increasing label comprehension (*c.f.*, French national, department, and local drift requirements), sustainability, and regulatory compliance by implementing the right label recommendations for selected products applied to a crop using automated spray application. DriftRadar helps to manage the complexity of dealing with multiple risk assessment compartments for vulnerable off-target areas (*e.g.*, a residential area downwind or a stream next to a cropped field) and can consider the conditions in the field – the wind direction. Label requirements are loaded from a regulatory compliant database (the example used here is Bayer's LabelHub) and automatically applied downwind to the adjacent areas in a customized way during spray operation. Off-crop (NTA/NTTP, water, residential areas and adjacent fields) are mapped into the software. A GPS sensor captures the exact position of the sprayer in the field and a wind sensor measures wind direction every 10th of a second. These parameters are used to close nozzles or change to drift-reducing nozzles while spraying and the required no-spray buffer-zones (*e.g.*, towards residential areas) are automatically applied during operation to prevent drift (*e.g.*, to bystanders). Software records all activities including the *in situ* wind direction at the scale of the decision making and finally stores this data as part of the normal record-keeping activity on the farm in compliance with regulations. Two proofs of concept for this approach have been successfully completed at the ARVALIS research station at Boigneville, France and at Inhort, Skierniewice, Poland, and have been shown to the French and Polish regulatory authorities. Improvements to the system as suggested by the research institutes are being implemented. Through the work described, we have demonstrated the possibility that, eventually, all aspects of the regulatory oversight of pesticide spray application can follow a digitalized, *in situ* or field-localized risk assessment. It also opens up the possibilities of integrating customized risk mitigation in real-time for local field conditions. [A 360° preview of the system can be seen at https://go.bayer.com/driftradar.]

7.08.P Precision Application – A Way to Reduce Environmental Risk?

7.08.P-We438 How Do We Develop Environmental Risk Assessments for the Precision Application of Herbicides ?

Joanna Davies*, Syngenta, United Kingdom*

Regulatory guidance updates continue to restrict the use of herbicides in the EU while the EU Green Deal has set the target of reducing pesticide volume and risk by 50% by 2030. Specifically, proposed changes to risk assessment scheme for non-target terrestrial plants may prohibit the broadcast use of some products completely. Work conducted on behalf of CropLife Europe has demonstrated that in the absence of herbicides, growers may adopt alternative weed control practices, notably mechanical weed control. Mechanical weed control has unintended adverse consequences on several economic and environmental factors, including food production costs, machinery and fuel usage, soil health, surface water quality (via increased nutrient run-off) and, ultimately, climate change. These adverse effects run contrary to the principles of regenerative agriculture, which promotes retention of carbon within soil and aims to limit the contribution of agriculture to climate change.

Precision application (PA) technologies for herbicides provide a means of reducing total volumes applied per unit area, whilst avoiding the need for mechanical weed control. However, current EU risk assessment approaches assume application at a maximum broadcast application rate to 100% of field area. In cases where treatment of entire fields is not necessary for weed control, new risk assessment approaches are needed to take account of the reduction in treated area. The consequences of these reductions for risk assessment will vary for each environmental compartment, (i.e. soil, ground water and surface water) and non-target organism (NTO) class (i.e. birds, mammals, aquatic organism, bees, non-target arthropods, soil organisms and non-target plants). Faupel et al suggest that some aspects of risk assessment, notably groundwater, drainage-driven exposure and mobile

NTOs, can be adapted by assuming that a reduction in treated area is equivalent to a corresponding reduction in broadcast rate. However, for risk assessments that are driven by drift estimates or less mobile NTOs, new approaches are needed that take account of the spatial and temporal distribution of the application across a field.
To inform the development of environmental risk assessments for the PA of herbicides, the following factors are considered in this presentation: (1) PA systems and capabilities; (2) spatial and temporal distribution of weeds (3) relevance of PA system and weed distribution to environmental assessment.

7.08.P-We439 How to Consider the Benefits of Precision Application in Regulatory Risk Assessment
Rena Jutta Irene Isemer[1]*, Joachim Dressel*[2]*, Francis P. Donaldson*[3]*, Thomas-Georg Hofmann*[3]*, Anne Alix*[4]*, Laurent Oger*[5]*, Sophie Hane-Weijman*[6]*, Martin Herchenbach*[7]*, Neil Morgan*[8] *and Bernhard Gottesbueren*[3]*, (1)Crop Science, Bayer AG - Crop Science Division, Germany, (2)Syngent Crop Protection AG, Switzerland, (3)BASF SE, Germany, (4)Corteva Agriscience, United Kingdom, (5)CropLife Europe, Belgium, (6)FMC Corporation, Switzerland, (7)Digitalisation, Industrieverband Agrar e.V., Germany, (8)Syngenta, United Kingdom*
In the European Union, Plant Protection Products (PPP) are subject to thorough risk assessments prior to registration. These risk assessments require that exposure estimates reflect “worst-case” scenarios built on conservative assumptions in order to cover all conditions of cultivation for a particular crop across Europe. Consequently, the risk assessment almost never represents the circumstances under which crop protection products are actually applied. The development of digital and precision tools as well as targeted application equipment, enabling that the most appropriate use rate is applied only where needed, is underway. These will become the way to use products in the next decade, as per the Green Deal objectives. Combining existing spatial information with the additional data generated by these innovative technologies, site-and-time specific risk assessments will become possible. It therefore becomes necessary to reconcile risk assessments with the application practices in use in the field.
Regulators at national and EU level as well as industry experts are working to address how digital and precision application (PA) can be taken into account in risk assessments. In order to facilitate and enable the activities necessary to integrate the required changes into the regulatory risk assessment, CropLife Europe formed the Digital Ag in Regulatory (DARe) team in 2021. A roadmap has been developed, demonstrating how the EU approval procedure for PPPs should be adapted over time: 1) Adaptation of existing assessments for PA uses with new data and concepts, as well as with risk mitigation measures reflecting capabilities of PA tools. 2) Introduction of new risk assessments for PA uses into guidance documents. 3) Development of the regulatory paradigm towards execution of risk assessments and risk mitigation for PA uses based on actual field data at the time and location of application, depending on data availability and capabilities of the technology, supported by electronic documentation.
The team has initiated a mapping of relevant activities across EU institutions, Member States, and industry associations, which will be presented. A proposal will be made on how precision application could be included in the current regulatory framework for specific areas. Working objectives for the scientific/regulatory community to foster the inclusion of precision applications and its many benefits in the risk assessment will be proposed.

7.08.P-We440 Spotted: Heterogenetic Pesticide Exposure and its Effect on Springtails
Melanie Hagen-Kissling[1]*, Elias de Bree*[2]*, Rik Delhem*[2]*, Livia De Felici*[2]*, Micha d'Oliveira*[2]*, Julia Friman*[2]*, André Grove*[2]*, Silvio Knaebe*[3]*, Koen Verhoogt*[2] *and Bogdan Dehelean*[2]*, (1)Eurofins MITOX B.V., Netherlands, (2)Eurofins-MITOX B.V., Netherlands, (3)Eurofins Ecotox, Germany*
Precision farming, i.e., applying pesticides precisely to field areas of pest infestation only, is a promising method to decrease the negative effect of agricultural production on the environment, without decreasing crop quality at the same time. So far, it is not known what the effect of such heterogenic pesticide exposure on the dynamics of soil arthropods, especially those with small home ranges would be. Here, we focus on springtails (Collembola), which are among the most abundant groups of soil decomposers, inhabiting various organic substrates. Furthermore, they are a food source for a wide range of specialist and generalist predators, making them a key group for the functioning of ecological networks.
Here we ask: How does a patchy application of insecticides translate into effects on springtail populations and communities? Is the time until recovery after a pesticide application in springtails correlated/depending to/on (1) direct overspray, (2) the proportion of treated surroundings, (3) the distance to treated surroundings?
To answer these questions, we conducted a field experiment to assess the effects of patchy pesticide spraying on springtail populations and communities. The study was performed in a winter wheat field, using a checkerboard design. This design consisted of control plots and treatment plots sprayed with an increasing proportion of pesticide (20%-100%). Springtails were monitored using suction sampling technique. Data analysis was performed both at the level of the arthropod community and at the level of the individual populations.
The knowledge about the effect of patchily sprayed fields on the dynamics of springtail populations is crucial to compare effects of patchy versus continuous application of a pesticide on springtails. Furthermore, the gained information could be used to populate spatially explicit population models, which can help to explore effects of heterogenic pesticide exposure on arthropod populations on larger spatial scales.

7.08.P-We441 Precision Agriculture – Implications for a Bird and Mammal Risk Assessment Under Regulation 1107/2009
Joerg Hahne[1]*, Markus Ebeling*[1]*, Manousos Foudoulakis*[2]*, Steven Kragten*[3]*, Alex Blakey*[4]*, Joachim Nopper*[5]*, Thomas Bean*[6]*, Dennis Sprenger*[7]*, Sonja Haaf*[8] *and Alex Mauss*[1]*, (1)Environmental Safety, Bayer AG - Crop Science Division, Germany, (2)Corteva Agriscience, Greece, (3)Syngenta Agro, Germany, (4)Environmental Safety, Syngenta, United Kingdom, (5)BASF SE, Germany, (6)FMC Corporation, (7)Corteva Agriscience, Germany, (8)Environmental Safety, ADAMA Deutschland, Germany*
Since the adoption of the current Sustainable Use Directive (SUD) in 2009, technological advancement led to a significant

number of new digital and precision agricultural solutions, including precision application of pesticides. Using plant protection products to a level of agronomic need is in line with the objectives of the 'European Green Deal' to reduce pesticide use by 50% by 2030. Although the existing regulatory framework already provides a high level of protection against possible detrimental effects on the environment, the use of precision agriculture can further reduce exposure and consequently risk. Precision agriculture is defined as "doing exactly what a plant or animal needs within the limits of time and space and according to economic and social boundaries with respect for environmental aspects". Practical examples indicate that, e.g., variable applications can currently reduce the applied plant protection product by between ~10 and ~40%. To reflect precision agriculture also in the regulatory decision making on plant protection products, an understanding of which practices qualify as precision agriculture and lead to reduced environmental exposure is needed. Guidance is currently lacking on how to account for these practices in the risk assessment for birds and mammals, where precision agriculture techniques might help reduce exposure, particularly for long-term risk assessments.
We will highlight four different precision application techniques for pesticides (precision drilling, shielded band spray, drip irrigation and spot application) that can reduce field exposure to birds and mammals. We identify for each of these techniques open points in the current bird and mammal risk assessment scheme and propose possible solutions on how these could be addressed. To develop specific bird and mammal risk assessment schemes for precision application and to discuss how to address open questions a dedicated workshop involving relevant stakeholders might be needed.

7.08.P-We442 Spatially Explicit Population Models Support Impact Assessment of Precision Application – A Common Vole Example

Oliver Jakoby*, Torben Wittwer, Felix von Blanckenhagen, Tina Grimm, Lara Ibrahim, Martin Vallon and Michael Faupel, RIFCON, Germany*

Precision farming has the potential to reduce the impact of pesticides on the environment. Particularly, a more precise use of pesticides can result not only in a reduced pesticide load, but also in a spatially heterogeneous application pattern on the field scale. Accordingly, the effect of the pesticide on populations of non-target species might change. Spatially explicit effect modelling is a valuable tool for environmental risk assessments (ERA) of pesticides, which can also be applied when considering precision applications. Models allow a practical and costeffective investigation of a multitude of application and exposure patterns leading to the understanding of their effects on non-target in-field species populations, the quantification of uncertainties and accordingly, they have the potential to optimize precision application patterns even further.
RIFCON´s individual-based and spatially explicit population model *eVole* is frequently used in ERA for small mammals to understand the risks of pesticide applications on a field to landscape scale. In this hypothetical case study, we use *eVole* to investigate the impact of spatially heterogeneous pesticide applications in agricultural fields on common vole (*Microtus arvalis*) populations. Specifically, different schematic pesticide application patterns, including band applications as well as spot and patch treatments, are tested and compared to a standard full field application of the pesticide.
Differences in the magnitude and duration of potential effects on vole populations are quantified and the impact of differently fragmented precision applications are discussed. In addition, the proportion of food taken from treated habitat per individual are extracted and the differences in the distribution over the whole population are examined.
Our case study demonstrates the potential of spatially explicit effect models in investigating, understanding and optimising precision applications. The results provide cost-effective information that can improve the overall understanding of the underlying mechanisms to support risk assessment and management, as well as complement field study approaches.

7.08.P-We443 Modelling the Reduction Effect of Spot Applications on Pesticide Runoff Losses from Fields with a PRZM-VFSMOD Coupling

***Stefan Reichenberger**[1], Robin Sur[2], Klaus Hammel[2], Jorge Olivares-Rivas[3] and Rafael Muñoz-Carpena[4], (1)knoell France SAS, France, (2)Bayer AG - Crop Science Division, Germany, (3)knoell Germany, Germany, (4)University of Florida*

Increasingly, crop protection products are not applied homogeneously over the whole field, but rather as so-called spot application to selected field areas. For treated spots not located directly at the downslope edge of the field it may happen that a part of the pesticide lost with surface runoff from the treated spots may be removed from the surface runoff via infiltration or sedimentation before reaching the field outlet. The objective of this study was to test the hypothesis that the untreated area between the field edge and the treated spots can reduce the loss of pesticides via surface runoff and erosion from the target area to receiving surface water bodies.
A large number of simulations with a coupled modelling system (PRZM, VFSMOD and a TOXSWA metamodel) were performed in order to quantify the effect of untreated field areas on the retention of pesticide-laden water and sediment as a function of the distance between treated spots and field edges. The spot application was modelled using a geometrically simplified approach (dimension reduction), that is, aggregating the treated spots to a band with a defined width and distance from the downslope field edge. The upslope untreated area and the treated band were simulated with PRZM (FOCUS R1 scenario for winter cereals; spring application of 8 different dummy compounds with different sorption and degradation properties). The surface runoff and eroded sediment generated by the upslope part of the field were transformed into a runoff hydrograph as input for VFSMOD, which was used to model the downslope part of the field. The parameterization of VFSMOD was adapted to reflect an annual arable crop as opposed to a permanently grassed buffer strip. For each event in the simulation period, Predicted Environmental Concentrations in surface water (PECsw) were calculated with a TOXSWA metamodel. A large number of different widths and positions on the slope of the treated band were tested and the pesticide losses and PECsw evaluated.

Since VFSMOD models only sediment deposition, but not erosion, the downslope part of the field is treated as a sink area for eroded sediment, while in reality it could also be a source area. Consequently, the range of applicability of this assumption (no erosion from the downslope part) was also investigated.

7.08.P-We444 Digital Label Compliance as an Enabler for Bringing Realism to Risk Assessments: A Croplife Europe Initiative

***Anne Alix**[1], Dominic Widmer[2], Krisztian Szegedi[3], Martyn Griffiths[4], Raj Unnithan[5] and Michal Kicinski[6], (1)Corteva Agriscience, United Kingdom, (2)Syngent Crop Protection AG, Switzerland, (3)BASF SE, Germany, (4)Bayer AG - Crop Science Division, France, (5)CropLife Europe, United Kingdom, (6)CropLife Europe, Belgium*

Plant Protection Products (PPPs) in agriculture are regulated through EC Regulation No. 1107/2009. The evaluation process imposes preliminary risk assessments and the precise setting of directions of use for the active substance at the EU level. This is followed by the PPP authorisation at the member state level with implementing risk mitigation measures before placing them on the market (EC, 2009). The risk assessments rely on hundreds of guideline-compliant studies and are performed to reflect worst-case use and exposure scenarios (EC, 2013a and 2013b). Label instructions are established based on the outcome of these worst-case scenarios used for the risk assessments. Therefore, they cannot reflect the high potential of adaptive application scenarios depending on the conditions under which products are used in the field. The diversity European farmers face, agro-environmental conditions and pest pressures faced by European farmers are also not reflected. Furthermore, modern technologies and stewardship measures are rarely considered in risk assessments even though they are essential to meet increasingly stringent compliance requirements and represent a central piece of developing a more sustainable food production model as outlined by the EC's Communication on the EU Green Deal and specifically in the F2F and the Biodiversity strategies which aim to reflect consumer, policymaker and societal expectations.
This presentation will introduce the Digital Label Compliance (DLC) project being developed by CropLife Europe, working with various stakeholders. The DLC aims to increase label comprehension and compliance via digital labels offering easy access and readability of the typically highly complex label directions, and so contribute to reducing risk during all relevant operations, including handling and application of Plant Protection Products by growers. The digital label not only enables the future automated application of Plant Protection Products according to the registered directions for use, including all precautions but also allows consideration of the geolocation and actual conditions of a grower's field. This, combined with the subsequent recording of spray operations provides a robust basis for the collection of data reflecting real conditions of use, which can feed into realistic field-specific risk assessment scenarios.

7.08.P-We445 Digital Labels Enabling Field Specific Risk Assessment and Tailored Risk Mitigation

***Karandeep Singh**[1], Susanne Lauck-Birkel[1], Andrew C. Chapple[2], Katja Timm[1] and Sarah Lewandowski[3], (1)Bayer AG - Crop Science Division, Germany, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany, (3)Bayer AG - Digital Transformation and IT Crop Science*

A typical agricultural product comes with a physical label providing important information about the safety, quality and specific information identifying the product in the container. However, there is limited space to share enriched, detailed, customized information for a given product that is useful for farmers to make data-driven decisions that support precision and enhanced sustainability. For our Plant Protection Products (PPPs), directions for use and all precautions to be taken at all stages must be indicated on the label, thus making labels increasingly more complex to read. Label instructions are established based on the outcome of the worst-case scenarios considered for the risk assessments and thus rarely reflect the actual conditions under which products are used in the field. This could include a diversity of application machinery, agro-environmental conditions, and pest/weed/fungal pressures faced by the farmers. The rapidly changing needs of farming towards digitalization and integration of all inputs and outputs into planning software to drive decisions and document them require a smooth and efficient label data transfer. Access to the relevant label data is the backbone of any such solution. We show how two ongoing initiatives at Bayer AG, "DriftRadar" enabled by the "Digital Label"- demonstrate a complete end-to-end solution to increasing label comprehension and regulatory compliance by implementing the right label recommendations on *e.g.*, buffer zones for selected products applied to a crop using automated spray application. In order to achieve an efficient front-end application like DriftRadar, we require high quality and up-to-date relevant label data in a structured machine-readable and -actionable format. We have developed LabelHub, a new central data platform, and a central access point for a fast and flexible data provision. It collects, harmonizes and transforms data from Bayer internal and external sources. It opens up the opportunity to include additional data like regulatory endpoints required for *in situ* risk assessments and tailored risk mitigation specific to the actual field, will allow to adapt to changing risk assessment needs with new data and concepts, and will allow to execute- these assessments and risk mitigation in future based on actual field data at time and location of application, depending on data availability and capabilities of the technology.

7.08.P-We446 Targeted Spray Application in Onions Using a Crop-Adapted Pulse Width Modulation Sprayer

*Gerrit Van Steenbergen and **Henk Jan Holterman**, Agrosystems Research, Wageningen University & Research, Netherlands*

Onions are a difficult to spray crop since its canopy is open and the leaves are pointing upwards. The major part of the sprayed liquid is sprayed onto the ground between the plants on the onion bed and on the path between the beds. A field experiment was performed to measure spray deposition on the onion leaves and on the ground of a reference sprayer, a crop-adapted pulse width modulation (PWM) sprayer and a crop-adapted PWM sprayer with a lowered sprayer boom in combination with nozzles above the paths directed towards the beds. The goal was to measure if the crop-adapted PWM sprayers are able to retain spray deposition on the crops while lowering the total sprayed volume on the field. Lowering the total sprayed volume on the field will decrease the emission of plant protection products to air, ground and surface water. Spray deposition was measured in three crop stages when the plants had a height of around 15 cm (BBCH 13/14), 35 cm (BBCH 42) and 55 cm (BBCH 44). Before spraying, the Normalized Difference Vegetation Index (NDVI) was measured using a HandySpec handheld crop sensor. The dose rate was adjusted based on the NDVI from 0.2 to 0.7 to a rate of 90 to 300 l/ha, respectively, by changing the PWM duty cycle. Spray deposition on the leaves and on ground collectors was analysed using a spectrophotometer. The relative deposition on the onion leaves using the crop-adapted PWM sprayer was equal or significantly lower than with the reference sprayer in all crop stages. The relative deposition on the onion leaves using the PWM sprayer with lowered sprayer boom and nozzles directed towards the crop was equal in crop stage 1 and significantly higher in crop stage 2 and 3 compared to the reference sprayer. Spray deposition on the paths between the onion beds for this sprayer was 30% lower compared to the reference. A low sprayer boom and directing the nozzle above the path towards the onion beds increases relative spray deposition on the leaves in later growth stages. No increase was found for this sprayer in the first crop stage and for the conventional crop-adapted PWM sprayer compared to the reference sprayer in all crop stages.

7.08.P-We447 Environment Risk Assessment: How UAV Technology Could Contribute and Be Beneficial
Gaëlle Der Hagopian[1]*, Rena Jutta Irene Isemer*[2]*, Sarah Hovinga*[3]*, Walter Mayer*[4]*, Martyn Griffiths*[5]*, Matthias Tempel*[4]*, Josef Exler*[4] *and Robin Sur*[6]*, (1)EMEA Regulatory Science, Bayer AG - Crop Science Division, France, (2)Crop Science, Bayer AG - Crop Science Division, Germany, (3)Bayer AG - Crop Science Division, (4)Bayer AG - Crop Science Division, Germany, (5)Bayer AG - Crop Science Division, France, (6)Environmental Safety, Bayer AG - Crop Science Division, Germany*
In the European Union, the sustainable use of pesticides is a major component of the agricultural framework. The future Sustainable Use Regulation considers precision farming and precision application as enablers of sustainable agriculture, helping to apply the right amount of the right product, at the right time, in the right place. Accordingly, precision application is an important approach helping to meet the goals of the European Commission's Green deal to reduce the risk and impact of pesticide use.
Which farming device(s) could then contribute here? Emerging technologies such as satellite imagery, data analytics, sensors, drones/UAVs (unmanned aerial vehicles), robotics, and artificial intelligence are key players in this context. For weed management (post-emergence application of herbicides) remotely gathered data by UAVs can be used by ground sprayer being equipped with a dedicated patch spraying setup or can be paired with a targeted UAV application. Both could be an opportunity for volume reduction of pesticides, by replacing a broadcast application with a precision application. With that, this helps to reduce environmental exposure (less drift and groundwater entry). Furthermore, this targeted application by UAV allowance provided, could also bring additional value, such as reducing soil compaction, fuel consumption, as well as the volume of water used.
The data resulting from precision application by UAV could then contribute to feed a realistic environmental risk assessment, using field-specific conditions. However, clarifications would be necessary on how this will concretely contribute to be part of the modelling and standardization of the environmental risk assessment. Data availability will be an important parameter to consider, particularly data ownership.
The scientific community is interested in having appropriate data available on drone technology, more precisely on broadcast application, as it represents the worst-case scenario regarding environmental impacts. To dive deeper into this, initiatives have begun around the world with industry participation (OECD, CLI, AEPLA), to obtain, among others, environmental data (drift data). We will present to which extent the UAV technology can provide precise data and share our proposal on how to best consider those data in the environmental risk assessment.

Track 8: Special Sessions

8.01 Establishment of a Science-Policy Panel to Contribute Further to the Sound Management of Chemicals and Waste and Prevent Pollution

8.01.T-01 Background and Next Steps for the Open Ended Working Group and Establishment of the Intergovernmental Science-Policy Panel
Kevin Helps*, UNEP Principal Scientific Officer, and Secretariat Science Policy Panel for the Continued Sound Management of Chemicals, Waste and Pollution Prevention, Kenya*
Background, steps already taken and what's next for the OEWG, and the process towards creating an Intergovernmental Science-Policy Panel for the Continued Sound Management of Chemicals, Waste and Pollution Prevention.

8.01.T-02 Lessons Learnt From the IPCC and IPBES That Will Inform the Design and Operation of the New Science-Policy Panel - What Can We Expect to See Moving Forward
Robert Watson*, Co-Chair Geo 7 and Chair of Technical Advisory Group to UNEP, United Kingdom*
Lessons learnt from the IPCC and IPBES that will inform the design and operation of the new science-policy panel, and what we can expect to see moving forward.

8.01.T-03 What Questions Should Be Posed to the Global Academic Community, How Does the Community Go About Answering These Questions, and Is Consensus Important?
Hanna Andrea Rother*, University of Cape Town, South Africa*

What questions should be posed to the global academic community, how does the community go about answering these questions, and is consensus important?

8.01.T-04 Reflections on the Process of the Open Ended Working Group - Recommendations for Governments
Jason Weeks*, IEH Consulting, United Kingdom*
As a science expert to the UK delegation for the 1.2 OEWG, what are your reflections on the process so far, and what recommendations do you anticipate for governments?

8.01.T-05 How can the LCA Community Contribute to the Process?
Carla Caldeira*, EC JRC, Italy*
How can the LCA Community Contribute to the Process?

8.01.T-06 What Role Can Scientists Working in the Business Sector Play in This Process, and Why Is This Important?
Stewart Owen*, Astrazeneca UK, United Kingdom*
What Role Can Scientists Working in the Business Sector Play in This Process, and Why Is This Important?

8.01.T-07 The Importance of Including Early Career Scientists in the Process, and What They Can Contribute
Joanke van Dijk*, Utrecht University, Copernicus Institute of Sustainable Development, Netherlands*
The importance of including early career scientists in the process, and what they can contribute.

8.01.T-08 The Role That Professional Societies Can Play in the Process, and the Challenges and Benefits of This Type of Engagement
Camilla Alexander-White*, Royal Society of Chemistry, United Kingdom*
The role that professional societies can play in the process, and the challenges and benefits of this type of engagement.

8.02.A Generating Experimental Data to Inform Effect Modelling: Challenges, Opportunities and Lessons Learned

8.02.A.T-01 Variability in Experimental Data: Mortality and Sublethal Endpoints
Anja Coors*, ECT Oekotoxikologie, Germany*
The calibration and validation of effect models requires experimental data of high quality, i.e., data that are reproducible, among other criteria. Yet, natural biological and technical variability set limits to exact reproducibility of toxicity estimate values and to the prediction of biological parameters such as survival and reproduction. The design of calibration and validation experiments that support effect models should take into account the natural background variation in order to not generate datasets that only seemingly indicate low uncertainty or, in the contrary, appear to invalidate well-calibrated models. Another aspect in this context is that background variation, and thereby inherent uncertainty, varies among species and investigated endpoints, which renders it difficult to establish one default standard design for model calibration and/or validation. This talk will present examples for background variation and discuss underlying reasons and consequences in order to support a discussion of what can and what cannot be expected from experimental data when used in effect modelling.

8.02.A.T-02 Perceptions of Goodness of GUTS Fits – Virtual Ringtest
Barbara Bauer[1], Alexander Singer[2], Oliver Jakoby[2], Torben Wittwer[2], Thomas G Preuss[3], Johannes Witt[3] and ***Andre Gergs****[3], (1)Rifcon, Germany, (2)RIFCON, Germany, (3)Bayer AG - Crop Science Division, Germany*
Before a toxicokinetic-toxicodynamic model can be used for risk assessment, the quality of the model fit to the calibration data and its predictive performance on independent validation data should be evaluated. The evaluation should be based on both qualitative criteria (visual assessment) and quantitative Goodness-of-Fit (GoF) metrics. Cut-off values for some, but not for all, metrics are suggested by authorities to decide if model performance is acceptable according to a specific metric.
In this study we compare model evaluations based on either qualitative (visual inspection) or quantitative (GoF) criteria for General Unified Threshold models for Survival (GUTS) models. GUTS can be used to mechanistically model lethal effects of toxicants on non-target aquatic organisms in environmental risk assessment. The aims of this study are to identify whether quantitative criteria coincide with human perception of model performance, and if so, whether cut-off points for GOF metrics can be defined that meaningfully separate suitable from unsuitable models.
For this purpose, we calibrated and validated GUTS models on a large set of survival data from toxicity test. We created an online anonymous survey where >70 calibration and validation model fits were ranked by several dozen participants. Participants were asked to score model fits on a scale of 1 to 6 (i.e. good to poor model performance). The expertise of participants ranged from 'little experience in modelling' to 'modelling experts'. We compared expert evaluations from the survey to quantitative GoF metrics (e.g. NSME, PPC, SPPE and pseudo r^2) and to an average GoF index that comprises information from all the metrics. Visual assessments and the average GoF index generally agreed on model performance, especially for very good and very poor fits. Interpersonal variation was largest among evaluators for intermediate quality fits. We found no systematic effect of affiliation or modelling experience on the visual evaluation score. All metrics showed some correspondence to visual scores. Only one of the metrics had a threshold-like relationship to scores, while others showed linear or exponential relationships. With these findings our study can contribute to the standardisation of methods in evaluating GUTS model performance and increase the understanding of GoF metric values in the GUTS context.

8.02.A.T-03 Ring-Testing Experiments vs. Ring-testing Models: Results from CLE Algae Project

Cecilie Rendal[1], *Johannes Witt*[2], *Thomas G Preuss*[2], *Ian Sims*[1], *Roger Baetscher*[3], *Sibylle Eck*[2], *Monika Ratte*[4], *Emily Scorgie*[5], *Eric Bruns*[6] *and Roman Ashauer*[3], *(1)Syngenta, United Kingdom, (2)Bayer AG - Crop Science Division, Germany, (3)Syngenta Crop Protection, Switzerland, (4)ToxRat Solutions, Germany, (5)Syngenta, Netherlands, (6)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Ring testing of experimental methods for the generation of validation data for TKTD modelling is a significant undertaking that requires collaboration across industry, academia and regulators. The experimental workload is considerable as many laboratories execute complicated experiments in the highly co-ordinated and standardized structure required for a systematic ring test. The complexity of the experiments means that the subsequent evaluation of the data is equally complex. With the ongoing Crop Life Europe ring test for green micro-algae as an example, we here discuss the multifaceted considerations required in answering the simple question: *Does the experimental method generate data that is robust enough for model validation?* To fully answer this question, we highlight the correlation between our confidence in modelling results and our understanding of the characteristics of the underlying experimental data. We explore alternative metrics for quantifying uncertainty in the ring test data, and how each of these metrics relate to modelling results in a risk assessment perspective. Thus, we not only establish how our data relates to EFSA requirements for model validation, but we also explore how the variance in experimental data influences toxicokinetic parameters, and in turn how error in toxicokinetic parameters cascades through the modelling framework. With this exercise we attempt to understand and quantify both model uncertainty and experimental uncertainty within our modelling framework. This will not only help to define validity criteria for future generation of data using the experimental methodology, but also increase our confidence in the modelling approach and facilitate decision making through full transparency of the uncertainty from various sources.

8.02.A.T-04 Developing Experimental "Standards" When Effect Modelling is the Aim

Anna Huang[1], *Annika Mangold-Doring*[2], *Paul van den Brink*[2] *and Jan Baas*[2], *(1)Wageningen Environmental Research (WUR), Netherlands, (2)Wageningen University & Research, Netherlands*

Toxicity experiments play a fundamental role in generating data for the risk assessment of toxic chemicals. Usually, these experiments follow standards with strict lab conditions developed by various organizations, such as the United States Environmental Protection Agency (EPA) or the Organization for Economic Co-operation and Development (OECD). In these experiments the usual endpoint is an LC_{50} (lethal concentration 50%) or a NOEC (No Observed Effect Concentration) which are time dependent, and do not provide any mechanistic information. Therefore the extrapolation potential of the test to real-life circumstances with time-varying concentrations in a dynamic environment, is very limited at best.

To address this issue, ecotoxicological effect models, such as toxicokinetic and toxicodynamic models (TKTD), have become increasingly popular in understanding the mechanisms of chemical toxicity and thereby greatly increasing the extrapolation potential of a laboratory test. Although TKTD models offer advantages in capturing and predicting toxic effects, their applicability is limited by the lack of specific experimental requirements for model calibration and validation.

To bridge this knowledge gap, we have developed a set of specific and feasible criteria for effect model calibration experiments, based on previous recommendations from the EFSA PPR Panel (EFSA PPR Panel (Panel on Plant Protection Products and their Residues) et al. 2018) and our own research. These criteria involve considering the biotransformation of chemicals in the toxicokinetic test, using an exposure concentration range that can produce 0 to 100% toxic effects, selecting effect-dependent observation time points with a minimum of three, and transparently reporting data to reveal inter- and intra-species sensitivity. Standardizing these experiments would enable various organizations, including academic and regulatory agencies, to utilize effect models to improve chemical risk assessment.

8.02.A.T-05 Including Experimental Conditions in Parameter Uncertainty Estimation

Florian Schunck[1] *and Matthias Liess*[2], *(1)Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Department of System Ecotoxicology, Helmholtz Centre for Environmental Research (UFZ), Germany*

Risk assessment increasingly recognizes the need for New Approach Methods (NAMs) to evaluate the effects of toxicants (Côté, Darling, & Brown, 2016). Among these, mechanistic models can be used to predict the effects of unknown compounds because they rely on bio-physical relationships rather than purely statistical relationships. This, however, requires that the parameters describing the model are unbiased and have low unexplained variance.

Parameter uncertainty is reduced by increasing the amount of information presented to the model. Traditionally, this is done by increasing the number of replicates or by pooling of experiments from different laboratories. However, even highly standardized protocols such as the *Daphnia Reproduction Test* (OECD, 2012) leave some room for variability between laboratories, raising the question of whether variables are truly i.i.d. Another source of uncertainty is the loss of information between models and experiments. In the worst case, biased estimates can arise if the model is not an accurate description of the data generating process.

This work presents a simulation framework to assess **bias** and **uncertainty** by explicitly modeling the experimental conditions. Experimental protocols can be provided to the simulator in a spreadsheet-like style. In addition, the observational process can be accurately described, including details of the measurement, which may also be subject to interlaboratory variation. Working in such a framework has three major advantages: 1) The data generating process is more accurately described, reducing the estimate's bias. 2) The same model can be fitted on many more experiments, since the experimental condition is *just* another input variable. 3) The most important metadata of the experiment is stored by default, which improves data quality and reproducibility.

A discretized simplified dynamic energy budget (DEBkiss) (Jager, 2018) model is fitted on a chronic exposure dataset of *Daphnia magna* with and without considering the experimental protocol. The results show that the parameter estimates for resource distribution () and egg-mass significantly depend on the experimental protocol.

8.02.B Generating Experimental Data to Inform Effect Modelling: Challenges, Opportunities and Lessons Learned

8.02.B.T-01 Why Do We Care About Uncertainties When Designing New Experiments and How Should We Account for Them?

Sandrine Charles, *University Claude Bernard Lyon 1, France*

Generating experimental data to inform effect modelling is not a new topics as since it almost goes back to the very beginning of ecotoxicology. What is new is on one hand the models used to characterize the effects of exposure to chemical substances, mechanistically and accounting for both the concentration- and the time-dependency; on the other hand, the enormous amount of information accumulated over time, which is now available, in theory, to plan new experiments. In its early days, ecotoxicology was equipped with experimental protocols dedicated to hypothesis tests, unfortunately erroneously employed to define observed thresholds of toxicity. Although regulations have since evolved, recommending the use of dose-response models, experimental protocols have changed very little, focusing on the number of replicates rather than the number of tested concentrations, while the number of time points is fixed according to lab constraints instead of model needs. Statistical optimal design theory, however, allows the setting of experimental conditions (dose levels, measurement times…) in a way which optimizes the number of required measurements and organisms to obtain the desired precision of the results at constant cost. For example, showed that reliable nominal concentration may be fixed based on prior knowledge and literature research instead of on preliminary experiments. It quickly becomes clear that if experimental protocols are still not optimized for the use of dose-response models, they are even less so for mechanistic effects models. Despite this, we now know that these standard protocols, far from being optimal, may be sufficient for are sufficient to fit toxicokinetic–toxicodynamic models such as the reduced GUTS models. Even if some people identified optimal experimental designs for a toxicokinetic–toxicodynamic model based on a Bayesian method, we are still far from revolutionizing the environmental risk assessment. In this talk, I will illustrate how taking uncertainties into account is a promising alternative in the design of new experiments, without changing habits, neither in the way experimental data are collected, nor in the way they are used to fit models. I will give two examples: one with a dose response model to assess the toxicity of an herbicide on plant growth; a second with a GUTS model to assess cadmium effect on survival over time of gammarids.

8.02.B.T-02 Integrating Heterogeneous Data from Tissue to Population Level to Model Data-poor Species

Peter Vermeiren*, Natural Sciences and Environmental Health, University of South-Eastern Norway, Norway*

The widespread occurrence and enormous diversity of environmental pollutants could affect many non-target wildlife species, far beyond the limited number of ecotoxicological model species that are traditionally investigated. For many wildlife species, however, there are practical and ethical limitations to ecotoxicological data collection both in lab and field, resulting in poor data coverage for these species. Further, given the current push to reduce vertebrate toxicity testing, additional data are unlikely to become available in the near future. This raises real questions for the quantification of potential threats posed by environmental pollution to wildlife.

The formulation and combination of several mechanistic models, supported by databases derived from systematic, quantitative literature meta-analyses, could offer a solution to develop quantitative effect models for relatively data-poor wildlife species. Such effect models build on our understanding of ecological, physiological, and toxicological mechanisms which can be generalized across species, as well as integrate and harmonize best available data regarding observed patterns of exposure, accumulation and effects scattered across the scientific literature.

In this presentation, I will show some approaches employed to collect data and knowledge from scattered sources, and how to homogenise and integrate them into mechanistically based models. Along the way I will highlight opportunities to improve such approaches in the future as well as obstacles remaining. I will outline how meta-analyses and models could work together to allow for simulations and scenario analyses that cross multiple levels of biological organisation. This outline will be supported with examples from ongoing work on reptile species, where ecotoxicological data are particularly poorly available.

8.02.B.T-03 Seeing Variability in Experimental Data: Perks and Disadvantages from a Regulatory Perspective

Alberto Linguadoca *and Alessio Ippolito, European Food Safety Authority, Italy*

Growing calls (Topping et al., 2020) for increased realism in regulatory environmental risk assessment (ERA) frameworks have partially triggered the development of progressively more articulated ERA schemes (e.g., EFSA, in prep). In the area of pesticides, the need to incorporate realism and complexity in ERA may have effectively triggered a paradigm-shift, whereby reductionist approaches will be slowly replaced by more holistic frameworks (EFSA, 2021). Such transition may constitute a tremendous opportunity to boost the confidence and case-specificity in decision making. However, it may also require dealing with increasingly rich, complex and variable datasets, which may contribute to exacerbating the challenges of both risk assessment and management. We may be some time away from such a transition being taken up by EU regulatory frameworks. However, the ongoing trend toward increased complexity in ERA has effectively sparked the need to better contextualise challenges and opportunities related to using variable data in the context of regulatory risk assessment.

ERA relies upon consecutive tiers across which the problem formulation is narrowed down to increasingly specific regulatory questions. This paradigm, whereby realism, complexity and case-specificity of the assessment increase in a stepwise manner, may set the basis to identifying challenges and perks of relying upon variable data.

In my presentation I will give a regulatory perspective on how environmental risk assessors may be interested in constraining or exploiting intrinsically variable data depending on the specific regulatory question under assessment across the tiered system.

8.03 The European Green Deal (Chemicals Strategy for Sustainability)

8.03.T-01 Key question 1: Science-based decision-making (I)
Sabine Elisabeth Apitz, *Integrated Environmental Assessment and Management, United Kingdom*
How do we avoid misuse of the phrase 'science-based', what does it mean, is all data useful data, and what level of information is sufficient to make informed decisions?

8.03.T-02 Key question 1: Science-based decision-making (II)
Anna Lennquist*, ChemSec, Sweden*
How do we avoid misuse of the phrase 'science-based', what does it mean, is all data useful data, and what level of information is sufficient to make informed decisions?

8.03.T-03 Key question 2: Multidisciplinary and transdisciplinary solutions (I)
Joel Tickner*, University of Massachusetts, Lowell*
Multidisciplinary and transdisciplinary solutions are called for, but how do we (as SETAC members and stakeholders) facilitate and achieve truly effective collaborations between different disciplines involved in the design, production, and assessment of chemicals, on what topics, and to what end?

8.03.T-04 Key question 2: Multidisciplinary and transdisciplinary solutions (II)
Leo Posthuma*, National Institute for Public Health and the Environment (RIVM), Netherlands*
Multidisciplinary and transdisciplinary solutions are called for, but how do we (as SETAC members and stakeholders) facilitate and achieve truly effective collaborations between different disciplines involved in the design, production, and assessment of chemicals, on what topics, and to what end?

8.03.T-05 Key question 3: Modernised chemicals risk and alternatives assessment processes appropriate for the CSS (I)
Maurice Whelan*, European Commission Joint Research Centre, Italy*
Which elements should be included in a modernised chemicals risk and alternatives assessment processes appropriate for the CSS's stated goals? How to prioritise the investment of efforts between high-throughput hazard screening using 'simplified' NAMs-based approaches, and the more holistic, spatially and temporally resolved analyses needed to assess ecological effects of chemical mixtures in the environment? What are the CSS's key science-data gaps to both inform decisions on chemicals and shape future chemicals that are Safe and Sustainable by Design?

8.03.T-06 Key question 3: Modernised Chemicals Risk and Alternatives Assessment Processes Appropriate for the CSS (II)
Kristin Schirmer*, Environmental Toxicology, Swiss Federal Institute of Aquatic Science and Technology, Switzerland*
Which elements should be included in a modernised chemicals risk and alternatives assessment processes appropriate for the CSS's stated goals? How to prioritise the investment of efforts between high-throughput hazard screening using 'simplified' NAMs-based approaches, and the more holistic, spatially and temporally resolved analyses needed to assess ecological effects of chemical mixtures in the environment? What are the CSS's key science-data gaps to both inform decisions on chemicals and shape future chemicals that are Safe and Sustainable by Design?

8.03.T-07 Key Question 4: Science-data Gaps to Inform Decisions and Shape Future Chemicals that are Safe and Sustainable by Design (I)
Jan Robinson*, International Association for Soaps, Detergents and Maintenance Products (A.I.S.E.), Belgium*
What are the CSS's key science-data gaps to both inform decisions on chemicals and shape future chemicals that are Safe and Sustainable by Design?

8.03.T-08 Key Question 4: Science-data Gaps to Inform Decisions and Shape Future Chemicals That Are Safe and Sustainable by Design (II)
Hans Sanderson*, Aarhus University, Denmark*
What are the CSS's key science-data gaps to both inform decisions on chemicals and shape future chemicals that are Safe and Sustainable by Design?874
