The production of plastics has increased explosively. Although the history of plastics is relatively short, more than 390 million tons of plastics were produced in 2021 and it has been estimated that the production will double during the next 20 years. Almost half of the plastic produced is used in single use products like packages. To save the non-renewable natural resources, it is essential that this material after used is recycled as efficiently as possible. Waste Framework Directive 2008/98/EC and Directive 94/62/EC on packaging and packaging waste, have set the ambitious goal that 50% of plastic packaging should be recycled in 2025. In addition to plastic packages, plastics from other uses with large volume should also be covered by recycling as well. These include plastics from building and construction, automotive, households, agriculture as well as the plastics from electronics and electronical devices.

However, concerns on the chemical safety of the recycled plastics have been raised. The recent report of the United Nations Environment Programme stated that over 13 000 different chemicals have been identified in plastic materials, from which over 3 000 were identified as substances of potential concern. To ensure the chemical safety of the recycled plastic materials, the materials containing hazardous chemicals should be identified and removed from the material cycle.

In this presentation, the subproject “Towards safe circular economy by assessing chemical risks of plastic recycling” of EU LIFE funded project PlastLIFE SIP will be introduced. It aims at safer circular economy of plastics by 1) identification of hazardous chemicals in plastic waste streams, by 2) producing data on the mixture effects of the chemicals in plastics to be utilized in risk assessment, by 3) developing methods for risk assessment of plastics and by 4) creating a framework for assessment of chemical risks of plastic waste fractions. PlastLIFE is an extensive project implementing the national program, Plastics Roadmap for Finland. The PlastLIFE project is co-funded by the European Union (LIFE21-IPE-FI-PlastLIFE). Views expressed in this presentation are however those of the authors only and do not necessarily reflect those of the European Union or CINEA. Neither the European Union nor the granting authority can be held responsible for them.

3.21.PC Polymers and Their Chemicals: Environmental Fate, Hazards, and Risk Assessment

3.22 The Fate and Effects of Micro- And Nano-Plastics in Relation to Ecosystems

3.22.T-01 Systematic comparison of environmental stresses (shear, humidity, UV, pH, temperature, enzymes) on microplastic fragmentation and release of nanoplastics and dissolved organics.

Wendel Wohlleben, Dr.[1], *Katherine Santizo*[1], *Patrizia Pfohl*[1], *Sam Harrison*[2], *Richard Cross, PhD*[2], *Joana Marie Sipe*[3], *Mark Wiesner*[3], *Gbotemi Adediran*[2], *Antonia Praetorius*[4], *Charlotte Catrouillet*[5], *Brandon Lopez*[3] *and Claus Svendsen*[2], *(1)BASF SE, Germany, (2)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (3)Duke University, (4)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands, (5)University of Amsterdam, Netherlands*

In this study, we generated a large experimental dataset to understand the mechanisms for microplastic fragmentation and degradation of their physico-chemical characteristics, as dependent on the resistance to environmental stresses. We selected LDPE, PP, HIPS, TPU, PET, PLA, and PA to cover the diversity of relevant plastics, covering both conventional and degradable plastics. The systematic comparison utilised standardised equipment to apply the stresses that are also combined to represent different ecosystems:

- OECD TG111 (hydrolysis) conditions were applied to test pH, temperature, marine water influence
- ISO 4892 (UV) conditions were applied and varied to test UV, temperature, humidity influence.
- Shear forces varied between the very effective sampling by high-shear sonication (ISO 22293), and lower shear by collision with suspended sand. Additionally, shear forces were applied with measured torque on macroscopic specimen.
- Specific enzymes were applied.

To quantify fragmentation and degradation multiple analytics are utilized. An adaption of the NanoRelease protocol, ISO22293:2020, is used to quantify the smallest fragments, from 0.01 µm, thus allowing to show micro- to nano-plastic fragmentation. Chemical degradation is assessed via ATR-FTIR, DSC and GPC analysis, as well as microcracking via SEM. Dissolved organics (DOC) are quantified after filtration at 0.02µm.

As expected, microplastic degradation depended on the polymer type and specific environmental conditions. DOC are utilized to ensure mass balance by quantifying any dissolved components, and turned out to be a significant mass transfer for irradiated LDPE and HIPS, and even the dominant mass transfer for PA-6 and TPU. In contrast, the PP with UV-stabilizing additives remained stable with no significant releases, as expected. Hydrolytic & enzymatic degradation and fragmentation. Hydrolysis under OECD TG 111 conditions up to 1 year was compared to marine water and enzyme-containing media. The positive control PLA depolymerised at 65°C to DOC, confirmed as lactic acid. All other polymers showed more subtle degradation, e.g. the molar mass of the PA microplastics reduced up to a factor 0.5, releasing also DOC, but few fragments. The combined results on shear forces allow a scaling of the influence of forces on the ablation and abrasion of fragments from aged microplastic. The generated data is also used for the parameterization of the new fragmentation model FRAGMENT-MNP.

3.22.T-02 Impact of Microplastics and Additives in Marine Ecosystems

Thompson[4], Marja Lamoree[6], Kevin Thomas[7], Martin Wagner[5] and Andy Booth, PhD[3], (1)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (2)Norwegian Institute for Water Research (NIVA), Norway, (3)SINTEF Ocean, Norway, (4)Plymouth University, United Kingdom, (5)Norwegian University of Science & Technology (NTNU), Norway, (6)Vrije University Amsterdam, Netherlands, (7)University of Queensland, Australia
Plastic pollution poses a complex threat, not only due to its physical presence but also to the inclusion of chemical additives during production. The increasing amount of microplastics (MP) and their associated chemicals resulting from fragmentation is an intricate yet poorly understood hazard to marine ecosystems. Most toxicity assessments of MP rely on pristine reference materials that inadequately represent environmental particles from everyday consumer products, leading to gaps in understanding their impact. This study aimed to discern the role of MP as a pollutant and a carrier of chemical additives while distinguishing between long-term effects originating from MP versus those from additives in marine species. Fifty plastic products were analyzed, covering various polymers and additive chemical profiles, using non-target chemical screening. Initial baseline toxicity of extracts from each product using Bacterial Luminescence and Algal Growth tests, indicated varied toxicity across products, with higher chemical content correlating with increased toxicity, particularly in elastomer-based products. Comprehensive toxicity testing of leachates from 5 products with high (car tire rubber (CTR), balloons, washing gloves, shoe soles (SS)) or low (PET bottle) baseline toxicity revealed significant impacts on several organisms across trophic levels. Leachate exposures led to impaired fertilization, larval development, and physiological disruptions in copepods, oysters, sea urchins, polychaetes, cod larvae and primary cells from mussels and halibut. Microalgae exposed to leachates from CTR displayed hindered growth and photosynthetic capacity, primarily due to oxidative stress. Juvenile mussels exposed to SS leachates also showed impacted clearance rate and lipid peroxidation. Investigations using cod larvae and adult mussels showed that the additive chemicals in CTR, rather than the particles alone, drove significant adverse effects on survival, hatching success, neurotoxicity and oxidative stress. The complexity of assessing the impact of chemical mixtures associated with plastic consumer products highlights the need to use diverse organisms and endpoints across biological levels to identify key toxicity drivers. This research emphasizes the critical need for mechanistic assessments to discern toxicity drivers between MP leachates and particles and identify key polymer-associated chemicals for potential mitigation strategies to reduce environmental impacts.

3.22.T-03 Microplastics-Induced Multigenerational Gut Microbial Changes in Daphnia magna: A Matter of Plastics or Particles?

*Gloria Fackelmann[1,2], **Christoph Schuer**[3], Carolin Weil[4], Simone Sommer[5], Nicola Segata[1,6] and Martin Wagner[7], (1)Department of Cellular, Computational and Integrative Biology, University of Trento, Italy, (2)Institute of Evolutionary Ecology and Conservation Genomics, University of Ulm, Germany, (3)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (4)Department Aquatic Ecotoxicology, Goethe University Frankfurt, Germany, (5)Institute of Evolutionary Ecology and Conservation Genomics, Ulm University, Germany, (6)Scientific Institute for Research, European Institute of Oncology, Italy, (7)Norwegian University of Science & Technology (NTNU), Norway*
Although originally described in oceans, microplastic (MP) pollution now spans the globe and all kinds of ecosystems. As MPs are being found throughout the food web, interest in their effects on organismal health is growing. One dimension of health that has been neglected in MPs research is the microbiome. These host-associated consortia of microbes and their genes interact with host immune and nervous systems and play a vital role in host metabolism. Thus, alterations to the microbiome have been implicated in various diseases. While emerging research shows links between MPs and microbial disturbance, potential mechanisms and multigenerational impacts have yet to be described. Here, we investigated whole-organism microbial alterations in response to MPs exposure using an experimental design with both pristine as well as wastewater-treated (wwMP) polystyrene (PS) MPs (< 63 mm) in three different particle concentrations (80, 400, 2,000 particles mL-1), plus two different control types (low and high food levels). All this was applied across four generations of *Daphnia magna* individuals, a staple model organism in ecotoxicology. The majority of MP (either pristine or wwMP, we found no significant differences between them) effects on the daphnid microbiome (alpha diversity, beta diversity in terms of composition and heterogeneity) can be explained as particle effects, since the treatment with increasing MP concentrations mirrors the treatment with high food (i.e., high algae concentration) vs low food availability. This coupled with the increase in alpha diversity in higher MP concentration groups lends support to the hypothesis that MPs and other particles act as vectors for microbes to gain access to host-associated microbiomes. We observed a generational effect in that the effects of particles on the microbiome grew over the generations (from F0 to F3). Despite this, there were still MP-specific effects, especially on more rare microbial components of the microbiome. Although daphnid microbiomes treated with higher MP concentrations mirrored those in the presence of only high food levels, the MP-treated daphnids were in no way as healthy, as our previously published work shows lower survival and reproduction rates in higher MP concentration groups. This work shows the importance of choosing a representative control group when investigating MP effects and warns against equating a lack of changes to the microbiome with a lack of negative host health impacts.

3.22.T-04 Swimming in plastics: How nanoplastics disrupt larval fish neurobehavioral and molecular rhythms?

***Xiaoyu Duan**[1], Mohamed Helal[2], Morten Frendø Ebbesen[3], Jonathan Brewer[3], Knut Erik Tollefsen[4], Henrik Holbech[5] and Elvis Genbo Xu[2], (1)Department of Biology, University of Southern Denmark, Denmark, (2)Biology, University of Southern Denmark, Denmark, (3)Department of Biochemistry and Molecular Biology, University of Southern Denmark, Denmark, (4)Norwegian Institute for Water Research (NIVA), Norway, (5)University of Southern Denmark, Denmark*

Nanoplastics (NPs) have attracted global attention due to their potential ecological and health impacts.Previous ecotoxicological studies have reported nanoplastic toxicity in various aquatic organisms but there is still limited understanding of how and why different nanoplastics affect or do not affect embryonic development and early life stage behaviors. Here, we investigated the embryonic and neurobehavioral effects of polystyrene nanoplastics (PS-NPs) with different sizes (0.05 µm to 1 µm) and surface charges (plain PS-NP, amino-modified PS-NP, and carboxyl-modified PS-NP) on early-stage zebrafish. Zebrafish embryos were exposed to PS-NPs at a wide range of concentrations (0.1 to 10 ppm) from 2 to 120 h postfertilization. The dose-responsive toxicological assessment included mortality, hatching, deformities, locomotor activities (distance, rotation, and mobile state), as well as biochemical and global transcriptomic responses. The results showed that nanoplastic exposures did not affect the mortality and hatching rate of zebrafish but caused morphological deformities and significantly disrupted the swimming behavior of larvae. The 3D high-resolution bioimaging confirmed the accumulation of PS-NPs in the larvae. Furthermore, RNA-Seq and bioinformatical analyses predicted and identified the key biological processes and molecular pathways significantly affected by PS-NPs, such as regulation of circadian rhythm, response to light stimulus, photoperiodism, and circadian rhythm. These findings provide new insights into the surface-charge-dependent sublethal neurotoxicity of nanoplastics and highlight the challenge of assessing the ecological risks of nanoplastics due to the high complexity of nanoplastic mixtures in the aquatic environment.

3.22.P The Fate and Effects of Micro- And Nano-Plastics in Relation to Ecosystems

3.22.P-Tu309 Monitoring of microplastics in 132 Iowa Lakes in relation to recreational activities and land use

***Boris Jovanovic*[1]**, *Psalm Amos[1], William Crumpton[1], Grace Wilkinson[2] and Djuradj Miloševic[3], (1)Iowa State University, (2)University of Wisconsin, Madison, (3)Faculty of Sciences and Mathematics, University of Niš, Serbia*

Global annual plastic production rate is approaching 400 million metric tons, with substantial amounts invading aquatic environments yearly. Numerous studies have been conducted monitoring marine environment plastic litter. However, an understanding of the magnitude of plastic litter in freshwater ecosystems is lagging, particularly for microplastics (MP (s) - 100 nm to 5 mm in length/diameter). Their ubiquitous presence and small sizes are potentially concerning, since MP effects remain inadequately understood. Our objective was to document the concentration of MPs in lake surface waters, and investigate how abiotic, biotic, and anthropogenic elements explain the variability of MP concentrations among lakes. We sampled MPs in 132 Iowa lakes, collected throughout the water column with a Wisconsin net (mesh sizes of 63 µm). A fully automated custom-built Bruker LUMOS-II Fourier-transform infrared (FTIR) spectro-microscope was employed to identify MPs. Average MP concentration across lakes was 5.2 particles/L, with dimensions averaging 139 µm in length and 77 µm in width. Predominant MP polymers collected were polyvinyl chloride (46% of all MPs), polyester (30%), and polyethylene (11%). To explore the variables that best described the variability in MP concentration among lakes, two variance partitioning analysis (VPA) models were created: one classical and one based on Louvain Groups. The classical model explained 7.5% of data variability based on: roads; developed medium, and high intensity land cover; sewage plants; and thermocline. The second model explained 8.3% of data variability based on: lake area; max lake depth; zooplankton tow depth; Secchi depth; lake perimeter; lake shoreline development factor; evergreen forest cover; and thermocline. Overall, the presence of roads, developed low, medium, and high intensity cover were positively correlated with MP concentration, alongside household visits standardized to the lake area. Lake area, Secchi depth, lake perimeter, lake shoreline development factor, lake maximum depth, and zooplankton tow depth were negatively correlated with MP concentration. The presence of thermocline was negatively associated with MP concentration. MPs currently do not pose a significant threat to Iowa lakes, based on the modeled hazardous concentration affecting 5% of species, however, continuous monitoring is advised.

3.22.P-Tu310 Understanding the Seasonal Distribution of Microplastics Along Two Major European Rivers: River Elbe (Germany) and River Thames (UK)

***Alice Horton*[1]**, *Katsia Pabortsava[1], Friederike Stock[2], Christopher Feltham[1] and Richard Lampitt[1], (1)National Oceanography Centre, United Kingdom, (2)Referat Biochemie, Ökotoxikologie, Bundesanstalt für Gewässerkunde, Germany*

The ubiquitous presence of microplastics (MPs) in the environment is well-known, with research on freshwater systems growing. However, the spatial and seasonal factors affecting microplastic spread and abundance in rivers is not well-studied, despite an understanding that these are likely significant factors influencing microplastic concentrations. This study analysed surface water samples from two major European rivers, the German part of the River Elbe and the River Thames in the UK. Samples were collected using *in situ* filtration, collecting of particles down to 10 µm from hundreds of litres of river water. Microplastics were extracted using digestion and flotation, and Fourier-Transform infrared imaging spectroscopy (µFTIR) used to analyse particles > 25 µm. Preliminary data suggest that the microplastic concentrations were highly variable between sites and seasons in both the Thames and the Elbe. While the maximum concentrations in both rivers were detected in summer, some sites showed higher concentrations in winter. The microplastic load in the Thames was generally higher than in the Elbe, with the four highest concentrations in the Thames all higher than the maximum concentration detected in the Elbe. The maximum concentration in the Thames (1761 MPs/m^3) was more than two times higher than the maximum in the Elbe (837 MPs/m^3). In contrast to our hypothesis, the highest concentrations of microplastics in the Thames and the Elbe were detected in upstream sites, where urban influence is low. At one of the two estuarine sites in the Elbe very few microplastics were detected in either the summer or winter (6.6 and 1.7 MPs/m^3 respectively), while MP concentrations in the Thames varied at tidal sites depending on the season. Low concentrations in the lower Elbe sites are despite proximity to heavily urbanised locations, highlighting the importance of local hydrography in influencing the microplastic abundance and distribution. These data suggest that microplastic concentrations in rivers are generally higher than estuarine and coastal waters, likely due to the proximity to land-based inputs, with microplastics becoming dispersed and diluted upon reaching the marine environment. Further analysis will be carried out to interpret any observed differences in plastic loads in between the seasons, rivers and sites. Seasonal samples for 2023, plus data on microplastic abundance in fish from these rivers are currently being processed and will also be included.

3.22.P-Tu311 Distribution and characterization of microplastics in the coastal areas of the Mediterranean Sea
Laura Sforzi[1]*, Saul Santini*[2]*, Laura Santi*[1]*, Stefano Nenciarini*[1]*, Alessandro Russo*[1]*, David Chelazzi*[1]*, Tania Martellini*[2]*, Alessandra Cincinelli*[2] *and Duccio Cavalieri*[1]*, (1)University of Florence, Italy, (2)Department of Chemistry "Ugo Schiff", University of Florence, Italy*
The production and consumption of plastic have drastically increased over the years, due to its cost-effective, durable, lightweight, and resistant characteristics. The same characteristics determine its high dispersion in marine waters and, consequently, within marine organisms, affecting the abundance and diversity of their microbiota. The Mediterranean Sea, as is now well known, is one of the environments most affected by Microplastic pollution, and for this reason, it is becoming increasingly necessary to implement capillary and constant control and mitigation strategies. This is the context for the MICROPLASMED project, which studied the relationship between the role of the marine microbiome as an indicator of different levels of microplastic pollution. To this end, surface water samples were collected between April and August 2022 in different coastal areas of the Mediterranean Sea from five different FAO divisions, aiming to map the distribution, concentration, and composition of the microplastics present. At the same time, samples of Mullus Barbatus (red mullet) were collected and their guts were analyzed for comparison with the results obtained from the water samples analysis. The results showed the presence of microplastics in 95 percent of the water samples, where the highest concentrations were found in Ventotene (Italy) and Istanbul (Turkey), confirming a close correlation between the amounts of microplastics and highly populated areas with high rates of tourism, intense ship movement, and industrial, urban and agricultural discharges. Plastic polymers were characterized by micro-FTIR together with a high percentage of cellulose fibers and fragments of polysaccharide origin. The samples' analysis not only allowed us to obtain essential information on the concentration of microplastics along the Mediterranean coasts but also on the importance of a complete characterization through the speciation of the polymers. This aspect is fundamental to understanding their source, estimating the possible impacts on the marine and coastal ecosystem, and assessing their distribution, but above all to distinguishing synthetic from natural and not lead to an overestimation of the final data. The data obtained represent an important contribution not only to the study of the distribution of microplastics but also to the development of common analytical protocols that allow unambiguous methods of analysis and representation of the results obtained.

3.22.P-Tu312 Emission characteristics of microplastic in urban stormwater runoff: rainfall characteristics and land-use patterns
Youna Cho*, Sang Hee Hong, Won Joon Shim, Sung Yong Ha, Gi Myung Han and Mi Jang, Ecological Risk Research Department, Korea Institute of Ocean Science and Technology, Korea, Republic of (South)*
Stormwater runoff is considered a major pathway for land-based microplastic transportation to aquatic environments. We investigated the emission characteristics and loads of microplastics to aquatic environments through urban stormwater runoff during four rainfall events by applying time-weighted stormwater sampling at stormwater outlets from industrial, residential, and commercial catchments and highways. MPs were widely detected in stormwater samples from industrial (1-2,480 n/L), residential (2-1,080n/L), commercial (3-1,810n/L) catchments, and highways (2-2,650 n/L). During the rainfall event, the amount of MP emitted from industrial, residential, commercial catchments and highways was calculated to be $1.54\text{-}46.1 \times 10^8$, $0.63\text{-}28.5 \times 10^8$, $0.63\text{-}6.30 \times 10^8$, and $0.13\text{-}8.73 \times 10^5$ particles, respectively. Polypropylene, polyethylene, and polyester were found as major polymers, accounting for around 70% of total microplastics. The fragment was the dominant shape of microplastics, and the most common size class was 20-100 μm or 100-200 μm. The discharge characteristics of microplastics inter– and intra–event were affected by the land-use type and rainfall characteristics. The microplastics in stormwater were more concentrated when the number of antecedent dry days (ADDs) was higher; the concentration of microplastics generally peaked in the early stage of runoff and varied according to rainfall intensity during a rainfall event. The MP load per drainage area was highest in the industrial catchment. The contamination level and load of microplastics were heavily affected by the total rainfall depth. Most microplastics were transported in the early stage of runoff. The microplastic emission via stormwater runoff was significantly higher (99%) than that through the discharge of wastewater treatment plant effluent (1%) in the same area, implying that stormwater runoff is the dominant pathway for transporting microplastics to aquatic environments.

3.22.P-Tu313 Development and Validation of High-Throughput Methods for the Sampling, Extraction and Analysis of Marine Microplastics
Lars Michael Hildebrandt[1]*, Ole Klein*[2]*, Tristan Zimmermann*[3] *and Daniel Pröfrock*[3]*, (1)Department of Inorganic Environmental Chemistry, Helmholtz-Zentrum Hereon, Germany, (2)Inorganic Environmental Chemistry, Helmholtz Center Hereon, Germany, (3)Inorganic Environmental Chemistry, Helmholtz-Zentrum Hereon, Germany*
To capture the full extent and long-term impacts of global microplastic pollution, reliable and harmonized chemical-analytical protocols (sampling and sample preparation) and detection techniques are mandatory. We have analyzed microplastics in subsurface water or sediment samples from the tropical Indian Ocean, the Northeast Atlantic Ocean, the East Greenland coast, and the Congo Canyon using a completely validated sampling (stainless-steel fractionated filtration unit), sample purification (microwave-assisted enzymatic-oxidative digestion) and automated imaging workflow (laser direct infrared (LDIR) imaging). Additionally, complementary mass spectrometry techniques such as ICP-MS/MS or Py-GC-MS were applied for validation

and method comparison purposes. Finally, only the application of a standardized protocol enables direct comparability of the large datasets which is usually strongly hampered in microplastic research. The complex results enable conclusions about the exposure levels as well as possible entry, fragmentation, and transport pathways. We investigated areas with an a priori high anthropogenic plastic footprint and remote areas. However, the results did not always confirm the assumptions and underpinned that that the distribution patterns of microplastic particles and fibers still pose scientific puzzles.

3.22.P-Tu314 The spatial abundance and distribution of microplastics in the surface sediment of Masan Bay, South Korea

Dayeong Jeong[1]*, Sang Hee Hong*[2]*, Youna Cho*[2]*, Gi Myung Han*[2]*, Sung Yong Ha*[2] *and Won Joon Shim*[2]*, (1)Korea Institute of Ocean Science and Technology (KIOST), Yeongdo-gu, Korea, Republic of, (2)Ecological Risk Research Department, Korea Institute of Ocean Science and Technology, Korea, Republic of (South)*

Microplastic pollution emerged as a growing global environmental issue due to its widespread occurrence and potential ecological repercussions. This study focused on evaluating the presence, characteristics, and potential sources of microplastics in Masan Bay, South Korea. As Masan Bay faces escalating environmental challenges amid industrial and urban development, a thorough analysis of microplastic presence in its sediment became imperative. Masan Bay, one of the special management sea areas in Korea, confronts significant land-based pollution stemming from neighboring international trade ports, industrial complexes, and residential regions. In June 2022, sediment samples from the surface layer up to 3cm depth were collected across 27 stations within Masan Bay using Van Veen grabs. Microplastics were separated from the sediment through density separation employing lithium metatungstate (LMT, 1.6 g/cm^3) and digested with wet peroxide oxidation. These samples were filtered through silicon filter paper (pore size: 10 μm) and were examined using micro-Fourier transform infrared spectroscopy (μFT-IR). The abundance of microplastics in Masan Bay sediment ranged from 3,190 to 77,600 n/kg d.w. (mean: 19,800±17,100 n/kg d.w.). The dominant shape of microplastics was fragments (> 80%), followed by the fibers (19%). The predominance of low-density polymers such as polypropylene (53%), polyethylene vinyl acetate (10%), and polyethylene (7%) was found in the bottom sediments, which might be due to aggregation with biogenic (or inorganic) matters or fecal pelletization process in the water column. This finding indicates the role of marine sediment as a sink for microplastics. Non-fibrous particle sizes dominantly ranged between 20-100 μm or 100-200 μm, while fibrous particles exhibited a broader range (20-5000 μm). The standing stock of microplastics in the sediment layer up to 3cm in Masan Bay was calculated to be approximately 21.3 trillion particles. The microplastic concentration showed an increasing trend from the outer to inner areas of the bay, and the inner side exhibited higher polymer diversity. These findings indicate a possibility of a substantial inflow of microplastics into the inner areas of Masan Bay from nearby residential and industrial zones and ports. Moreover, these insights provide crucial information about the occurrence and influx of microplastics in Masan Bay.

3.22.P-Tu315 Characterization of Plastics Obtained in the OSPAR Monitoring for Marine Litter in 5 Beaches of the Bay of Biscay

Nagore Gonzalez Soto[1,2]*, Edgar Dusacre*[3]*, Idoia Fuertes*[4]*, Maria Ballesteros*[4]*, Clément Moreno*[5]*, Eider Bilbao*[1]*, Amaia Orbea PhD*[6]*, Sophie Lecomte*[3]*, Jérôme Cachot*[7] *and Miren P. Cajaraville PhD, PhD*[6]*, (1)Zoology and Animal Cell Biology, CBET+, PiE, University of the Basque Country UPV/EHU, Spain, (2)EPOC UMR 5805, University of Bordeaux, France, (3)University of Bordeaux, France, (4)Surfrider España, Spain, (5)Surfrider Foundation Europe, France, (6)CBET+ Research Group, Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain, (7)EPOC CNRS, University of Bordeaux, France*

During the last years, the scientific community focused in elucidating the impact of plastic pollution on the marine environment; especially regarding micro and nanoplastics (MNPs). But, in order to achieve this challenging goal, ecotoxicological studies need to move from commercial pristine MNPs to more environmentally relevant ones. In this context, the FIERA project aims to assess the toxicity of a representative mix of environmental plastics collected in the southwest of the Bay of Biscay. As a first step, plastics were collected following the OSPAR guideline for Marine Litter Monitoring (100 m transect) once per season in 5 beaches of the Basque Country: 4 in Spain (Gorrondatxe-Getxo, Alkolea-Mutriku, Orrua-Zumaia and Murgita-Donostia from January to October 2023 and 1 in France (Tarnos-Baiona) from July 2023 to March/April 2024. After each sampling, items per beach and season were divided into 3 categories (foams, fragments and recognizable objects), the colour and weight of each item were annotated and the polymer composition determined by FT-IR. Almost 94% of the items collected in January and July 2023 were plastic polymers. No clear site- or season-dependent trend was observed in the proportions of foams, fragments and recognizable objects. White was the predominant colour followed by transparent in all beaches and seasons, with the only exception of Alkolea. Regarding polymer composition, 9 polymers were found (polypropylene (PP), polystyrene (PS), polyvinyl chloride (PVC), polyethylene terephthalate (PET), polyethylene (PE), polyamide (PA), polyurethane (PUR), ethylene-vinyl acetate (EVA) and polyacrylamide (PAM). PE was the only polymer found in all samplings, while PS and PP were found in all beaches, but not all seasons. Taking into account the number of items, the abundance of polymers was PE > PP > PS > PET > PUR > PVC > PA > EVA = PAM. When the weight of items was considered, abundance was: PE > PVC > PP > PET > PA > PS > PUR > EVA > PAM. Polymer abundances by items or by weight both varied with beaches and seasons. Results highlighted the complexity of characterizing plastic pollution in the Bay of Biscay, due to differences found between different beaches and seasons. *Funded by the Spanish MICIN project FIERA (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and “ERDF A way of making Europe”) and the Basque Government through a grant to the consolidated research group IT1743-22 and a postdoctoral fellowship to NGS.

3.22.P-Tu316 Hemocyte Responses upon Foodborne Exposure to Three Sizes of Polystyrene Nanoplastics on Mussels Mytilus galloprovincialis

Nagore Gonzalez Soto[1,2]*, Tamer Amr Hafez*[2,3]*, Marisa Sarria Pereira de Passos*[4]*, Eider Bilbao*[2]*, Amaia Orbea PhD*[5]*, Douglas Gilliland*[6]*, Miguel-Ángel Serra*[7] *and Miren P. Cajaraville PhD, PhD*[5]*, (1)EPOC UMR 5805, University of Bordeaux, France, (2)Zoology and Animal Cell Biology, CBET+, PiE, University of the Basque Country UPV/EHU, Spain, (3)Department of Biology,, Norwegian University of Science & Technology (NTNU), Norway, (4)European Commission - Joint Research Centre (JRC), Belgium, (5)CBET+ Research Group, Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain, (6)European Commission - Joint Research Centre (JRC), Italy, (7)European Commission - Joint Research Center (JRC), Italy*

The evidence of the harmful effects of microplastics on marine organisms has greatly increased in the last years, but information regarding the impact of nanoplastics (NPs, <1 µm) is still insufficient. Bivalves are widely used sentinel organisms due to their filter-feeding ability, among others. This work aims to elucidate the differential toxicity of 3 sizes of polystyrene (PS) NPs (50, 200 and 1000 nm) on the hemocyte responses and condition index (CI) of mussels *Mytilus galloprovincialis*. Mussels were dietarily exposed for 7 days through microalgae *Isochysis galbana* to a low dose (LD:10^3 NPs/mL) and a high dose (HD: 10^8 NPs/mL for 50 and 200 nm NPs and 10^6 NPs/mL for 1000 nm NPs). Each experiment was performed twice, as follows: E1&E4) 50 nm, E2&E5 200 nm, E3&E6 1000 nm. Despite the 6 experiments were run in less than a month, there were significant differences between the 2 independent experiments of each NP. No differences in CI were found within each experiment, but differences were observed between the 2 independent experiments, possibly due to the spawning events observed during the acclimation period of E3&E4. Similarly, higher reactive oxygen species production was observed in hemocytes of control mussels of E3&E4 compared to E1&E2 and E5&E6, but no differences were seen in NP treatments compared to controls within experiments. Cell viability of control hemocytes decreased in experiments E3&E4 and E5&E6 in comparison to E1&E2. This could have masked the size-dependent response to the NPs, as in E1 hemocytes showed lower viability (LD and HD) and phagocytic activity (HD) than controls, but not in E4. Similarly, hemocytes of mussels exposed to LD in E2 showed lower viability than controls, but the contrary was observed in E5. In conclusion, a trend for size-dependent effects on mussel hemocytes was observed. However, hemocyte responses varied along time, possibly due to the seasonal variations in mussels physiology connected with the gametogenic cycle. Further work is needed to elucidate the impact that MPs and NPs may have in mussels at different periods of their gametogenic cycle to allow their use as sentinel organisms for monitoring MP and NP pollution in the marine environment. *Work funded by the EC CAS NANOPLASTICS project (DG JRC), the Spanish MICINN FIERA project (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and "ERDF A way of making Europe") and the Basque Government grant to consolidated research groups (IT1743-22).

3.22.P-Tu317 Microplastic uptake and trophic transfer in mid-consumer fish species in a heavily contaminated river

Badiozaman Bin Sulaiman[1]*, Holly A. Shiels*[2]*, Jamie Woodward*[3]*, Juan Garcia*[1]*, Hannah Burton*[1] *and Carlos Nery*[4]*, (1)University of Manchester, United Kingdom, (2)Division of Cardiovascular Sciences, Faculty of Biology Medicine and Health, University of Manchester, United Kingdom, (3)Department of Geography, The University of Manchester, United Kingdom, (4)Division of Cardiovascular Sciences, University of Manchester, United Kingdom*

Multiple urban and sub-urban rivers in the UK were identified to be highly contaminated with microplastics. The River Tame, Greater Manchester, was the most contaminated among these rivers and contained multiple riverbed microplastic hotspots. The majority of microplastic in the River Tame comes from wastewater effluent, and the release of untreated wastewater during low flow is the driving mechanism behind riverbed hotspot formation. The high content of beads and fragments indicates frequent discharge of untreated wastewater, and flooding can effectively entrain the complete assemblages of microplastics and flush them downstream. The river community is therefore subjected to a dynamic microplastic exposure risk, of chronic and acute homogeneous or heterogeneous microplastic assemblages depending on the point source input locations and river flow events. This study aims to determine whether the microplastic in a heavily contaminated urban river (i.e., River Tame) is taken up by biota and transferred across trophic levels. We investigated the occurrence, assemblage, uptake and bioaccumulation of microplastic in the gills and gastrointestinal tract of two mid-consumer fish species (common minnow and three-spined stickleback), as well as the microplastic loads in host fine bed sediments and prey items (invertebrates). A total of 93 individual fish (common minnows, n=41; stickleback, n=52) were collected from the Reddish Vale and Dukinfield reach of the River Tame, and the gills and gastrointestinal tract (n=48 per organ; minnow = 21, stickleback = 27) were isolated, chemically digested and filtered onto glass-fibre filter. Microplastics were identified and quantified on a digital microscope at 100x base magnification. A melt-test was performed on all suspected particles, and polymer analyses were conducted using µ-FTIR spectroscopy. We found that the microplastics in the River Tame spread from the environment into the biota (Mean±SEM; Minnow=17.11±3.93 MPg-1 Ind.; Stickleback=12.39±1.36 MPg-1 Ind.). Microplastic levels were higher in the population living near wastewater treatment outflow (P=0.0016), and fragments (51.7%) and fibres (43.0%) are the most abundant forms of microplastic. Microplastic enters through respiratory and gastrointestinal pathways, and intake in relation to body size varies between species. While bioaccumulation was not observed, we show that there are active cycles of microplastic within the trophic component of the River Tame biota.

3.22.P-Tu318 Microplastic accumulation in oysters from Hong Kong's Deep Bay and Yong Shue O.

Zahra H.H. Alfahmi[1,2,3]*, Nur Azeyanti Norhashim*[2,3]*,* ***Raul Martin Hilder Nine***[2]*, Kamila Sarkeeva*[2]*, Carlos Nery*[4]*, Patrick W.S. Joyce*[5]*, Ian Kane*[3,6]*, Cyrill Bussy*[3,7]*, Laura J. Falkenberg*[5,8] *and Holly A. Shiels*[2,3]*, (1)Division of Biology, Faculty of Basi sci, University College Adham, Umm Al-Qura University, Saudi Arabia, (2)Division of Cardiovascular Sciences, Faculty of*

Biology Medicine and Health, University of Manchester, United Kingdom, (3)Manchester Environmental Research Institute, United Kingdom, (4)Division of Cardiovascular Sciences, University of Manchester, United Kingdom, (5)Simon F.S. Li Marine Science Laboratory, School of Life Sciences, Chinese University of Hong Kong, Hong Kong, (6)School of Earth and Environmental Sciences, University of Manchester, United Kingdom, (7)Division of Immunology, Immunity to Infection and Respiratory Medicine, School of Biological Sciences, University of Manchester, United Kingdom, (8)UniSA STEM, University of South Australia, Australia
In 2016, each person in Hong Kong produced an average of 163.45 kg of plastic waste and about 0.05% of this ends up as marine litter in the form of microplastics (MPs); global trends suggest plastic use has only increased. MPs are plastic particles under 5 mm in size. They are pervasive, being found in over 220 marine species and in almost every oceanic layer. Their small size contributes to their ubiquity in marine organisms, especially filter feeders like oysters. However, lab studies considering MP uptake are often based on exposure to unrealistically high MP concentrations. To better understand realistic MP accumulation in the natural environment, we investigated MPs in sediments, waters, and oysters from two Hong Kong locations of different proximity to anthropogenic activity (Yong Shue O, YSO) and oyster aquaculture (Deep Bay, DB), during the wet and dry season. MPs were extracted by standard potassium hydroxide digestion protocols, followed by filtration onto 47 mm glass-fibre filters of 0.7 µm then 0.1 µm pore size. Quantitative visual selection was conducted at 40x to 100x magnification using stereo- and digital- microscopes. Examples of putative MP will be analysed to ascertain chemical identity. For the dry season, we found that all oyster samples were positive for MP with mean (±SD) abundances of 82.76 ± 92.64 (n=46) putative MP g^{-1} of tissue in DB and 137.1 ± 161.8 g^{-1} of tissue (n=64) in YSO. In DB, the digestive gland contained 48% of our counted MP, the gills had another 28%, and the mantle contained the remaining 24%. These distributions were different in YSO, where most MP was found in the mantle. Our biotic samples were largely made up of transparent fibres (74% of MP) and blue fibres (11% of MP). Other colours and shapes (fragments and beads) were minor contributors. Significantly more MP g^{-1} was seen in the YSO than DB location (t-test: p=0.042). This difference was not observed in water samples (2.78 ± 1.69 MP L^{-1}, DB; 1.14 ± 0.39 MP L^{-1}, YSO; mean ± SD, n=3, t-test: p=0.179). We now aim to study associations between abiotic and biotic data. Our analysis of the wet season is ongoing but will provide insight into the role of MP inflow from rivers on MP accumulation in coastal oyster populations. Understanding MP prevalence in bivalves has implications for aquatic health and health of humans consuming oysters and our findings may be used to develop effective policy regarding plastic pollution.

3.22.P-Tu319 Microplastic Pollution In Biological and Environmental Matrices From An Aquaculture In Portugal And Potential Impacts To Human-Beings

Daniela C. C. Silva[1], João C. Marques[1] and ***Ana M. M. Gonçalves**[1,2]*, *(1)Department of Life Sciences, University of Coimbra, MARE - Marine and Environmental Sciences Centre / ARNET – Aquatic Research Network, Portugal, (2)Department of Biology & CESAM, University of Aveiro, Portugal*
Marine bivalves are largely produced in aquacultures for human consumption and can be impacted by several pollutants, including microplastics (MPs), that can cause potential harmful effects. The MP abundance and characterization in surface water, sediments, and bivalve tissues of *Magallana gigas* (diploids and triploids) and *Ruditapes philippinarum* were assessed in an aquaculture at the Ria de Aveiro coastal lagoon (Portugal) and the daily MP intake by humans via bivalve consumption was estimated.

Microplastics in surface water (0.00–5.33 MP particles/L) were mainly transparent fibers (100–2500 µm) with some seasonal variations, while in sediments (15.47–114.55 MP particles/kg) were predominantly blue and red fragments (100–2500 µm) with seasonal and tidal variations. Seasonal and tissue differences were observed in *M. gigas* diploid (0.33–5.00 MP particles/tissues), *M. gigas* triploid (0.00–1.00), and *R. philippinarum* (0.00–3.33). Microplastics, mainly pink and transparent films (1–100 µm), were found essentially in visceral mass, digestive gland, and gills. *M. gigas* diploid and *R. philippinarum* had higher microplastic abundances than *M. gigas* triploid. The main polymers were polypropylene and polyethylene. The daily MP intake via consumption of un-depurated bivalves may pose a threat to human health, particularly to adults, very elderly, and pregnant women.

3.22.P-Tu320 STUDY OF THE MICROPLASTIC ABUNDANCE AND COMPOSITION IN GASTROINTESTINAL TRACT OF SEABIRDS FROM THE CANARY ISLANDS DETERMINED BY OPTICAL MICROSCOPY AND ATR-FTIR

***Gema Paniagua**[1]*, *Pilar Fernández Hernando[2], Gema Paniagua González[2], Rosa Mª Garcinuño Martínez[2], Juan Carlos Bravo Yagüe[2], Begoña Jiménez[3], Airam Rodríguez[4] and Juan Munoz-Arnanz[3], (1)National University of Distance Education (UNED), Spain, (2)Departamento de Ciencias Analíticas, Facultad de Ciencias, Universidad Nacional de Educación a Distancia (UNED), Spain, (3)Institute of Organic Chemistry, Spanish National Research Council (IQOG-CSIC), Spain, (4)Departamento de Ecología Evolutiva, Museo Nacional de Ciencias Naturales CSIC, Spain*
Currently, plastic pollution is a significant environmental problem worldwide, especially in the marine environment, where plastic debris enters in a wide range of sizes, and particularly the nanoplastics (0.001-0.1 µm) and microplastics (in the size range of 0.1–5000 µm) which have a special interest mainly due to their small size, as well as long environmental persistence. In addition, the intake of these micro- and nano-sized plastics by marine animals is the cause of internal injuries, a feeling of satiety and in many cases of death.

The present work is focused on the study of the presence of microplastics in the gastrointestinal tract of Cory's shearwaters (*Collectris borealis*) which are native to the Canary Islands. For this, the dissection of the samples was carried out to isolate the possible plastic particles present in the proventriculus and ventriculus of the birds. The digestion of biogenic organic matter preserving the integrity of synthetic polymer particles is an essential step for the microplastic analyses. Therefore, an appropriate digestion protocol with a base (potassium hydroxide) 70% in combination with an oxidizing agent (hydrogen peroxide) 30% at room temperature during 48 h, were carried out. Different analytical techniques such as optical microscopy and Attenuated Total Reflectance Fourier Transform Infrared spectroscopy (ATR-FTIR) have been used for detection and identification of the microplastics particles that have been found.

The percentage by weight of microplastics with respect to body weight and stomach weight were 2% and between 3-12%, respectively. Microplastics with a size less than 3 mm were found in the ventricle, while in the proventriculus the size was up to 5 mm. Fibers (34%) and pellets (25%) were the most frequently observed morphology, and, based upon ATR-FTIR analysis, polyethylene (56%) was the most common identified polymer, followed by polypropylene (25%) and poly(vinyl chloride) (19%). This study provides insight into the magnitude of microplastics pollution in the coasts of the Canary Islands and describes a methodology to improve future microplastics studies in Cory's shearwaters (*Collectris borealis*).

3.22.P-Tu321 Birds Of Prey and the Threat of Artificial Microparticles

Chloe Wayman[1]*, Miguel González-Pleiter*[2]*, Elisa L. Sorribes*[3]*, Rocio Fernández-Valeriano*[3]*, Fernando Gonzalez*[4]*, Roberto Rosal*[5] *and Irene Lopéz-Marquéz*[3]*, (1)Chemical Engineering, University of Alcala (UAH), Spain, (2)Biology, Autonomous University of Madrid (UAM), Spain, (3)Wildlife Hospital, Group of Rehabilitation of the Autochtonous Fauna and their Habitat (GREFA), Spain, (4)Grupo de Rehabilitación de la Fauna Autóctona y su Hábitat (GREFA), Spain, (5)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain*

Abstract

Inadequately managed plastic waste results in their accumulation within natural ecosystems. Once in the environment, polymers undergo weathering leading to their breakdown into microplastics (MPs). The increase of MPs contamination has become a serious problem, threatening the environment and organisms, including avian species. Predatory birds occupy the top of the trophic web, and therefore play a vital role in ecosystem balance. This study investigated the presence of MPs and artificial-non-plastic particles (ANPP) in digestive and respiratory systems of four predatory birds, within different environments intertwined with human activity. This included species: Common Buzzard *(Buteo buteo)*, Black Kite (*Milvus migrans)*, the Eurasian Sparrowhawk *(Accipiter nisus)* and Northern Goshawk *(Accipiter gentilis)*. Their digestive and respiratory systems were extracted, chemically digested with KOH and the solutions obtained were filtered through a 25µm stainless steel mesh. Detected microparticles were measured, classified according to their shape (fibers or fragments), quantified and identified using micro-FTIR. The results showed the presence of MPs and ANPPs in the four species, with an average of 7.9 MPs and 9.2 ANPPs per specimen. The predominant shape consisted in small-sized fibers (>98%) of polyester, acrylic materials, and synthetic celluloses. It is important to highlight that all the digestive systems contained at least one MP. For the first time, MPs have been detected in the respiratory systems analyzed of predatory birds. When comparing the incidence of the MPs in digestive and respiratory systems obtained from predatory birds collected in urban areas against rural areas, there was a significant higher presence in the urban areas. These findings underscore the need for further research on the impact of the contamination due to plastics and other anthropogenic materials in predatory birds

3.22.P-Tu322 Concentration, Characteristics and Risk Assessment of Microplastics in Echinoderms of the Western Cape, South Africa: a need for Science-Based Solutions to Mitigate Impacts of Microplastics

Conrad Sparks *and Danielle Julius, Cape Peninsula University of Technology, South Africa*

Information and knowledge about microplastics (MPs) in echinoderms inhabiting coastal environments along South Africa is poor. The aim of this study was to determine coastal MP abundance (MPs/I) and concentration (MPs/g) ingested by various echinoderms species. Sampling took place in summer 2020 during low tide at 14 sites, along the coast of the Western Cape, South Africa. MPs were extracted and analysed based on shape, colour, size and polymer type (using an FTIR-ATR). An ecological risk assessment was done to assess the potential risks posed by MPs in echinoderms. MP abundance and concentration was highest in echinoderms sampled from Kalk Bay (59.95 ± 4.68 MPs/I and 2.90 ± 0.38 MPs/g respectively), identifying stormwater outfall pipes and human activities as the main source of MP contamination. Suspension/deposit-feeding sea cucumbers displayed a high MP abundance (17.57 ± 2.34 MPs/I) and predator feeding sea stars and cushion stars had high MP concentrations (2.47 ± 0.23 MPs/g). Suggesting non-selective suspension/deposit-feeding invertebrates ingest more MP particles than other feeding strategies. Filaments were the most dominant MP shape (94.48%) for all echinoderm samples, with black/grey particles being the dominant colour (45.48%). The dominant sizes ingested by echinoderms were 1000 – 2000 µm (31.86%), 2000 – 5000 µm (25.86%) and > 5000 µm (20.24%). Polyethylene (PET) (49.48%) was the dominant polymer type recorded in all echinoderm samples. Based on the risk assessment, MPs recorded at Mouille Point (site 6) poses the greatest ecological risk associated with polymers. MP concentrations reported in this study provides a baseline for future studies along the Western Cape coastline, South Africa. Furthermore, substantive efforts are required to mitigate the impacts of MPs.

3.22.P-Tu323 A Plastic Trap? Factors Influencing Microplastics Trapping in Coastal Vegetated Canopies

Hayley McIlwraith[1,2]*, Penelope Lindeque*[1]*, Trevor Tolhurst*[2] *and Matthew Cole*[1]*, (1)Plymouth Marine Laboratory, United Kingdom, (2)University of East Anglia (UEA), United Kingdom*

Coastal areas are prone to plastic accumulation due to their proximity to land based sources. Coastal vegetated habitats (e.g., seagrasses, saltmarshes, mangroves) provide a myriad of ecosystem functions, such as erosion protection, habitat refuge and nursery grounds, and carbon storage. The biological and physical factors that underlie these functions may provide an additional benefit: trapping of marine microplastics. While microplastics occurrence in coastal vegetated sediments is well documented, there is conflicting evidence on whether the presence of vegetation enhances microplastics trapping relative to bare sites. Moreover, the factors that influence the likelihood of microplastic trapping remain understudied. We aimed to investigate how vegetation structure and diversity as well as microplastic type influences microplastic accumulation in a UK saltmarsh. In September 2022, we sampled sediment from Blakeney National Nature Reserve. Quadrats (N = 20; n = 5) were placed across four levels of species diversity – no vegetation, monospecific grass (*Spartina anglica*), monospecific branched (*Atriplex portucaloides*), and diverse (>3 species). We recorded species presence, percent vegetation cover, and canopy height. In the laboratory, we will isolate, quantify, and characterise microplastics using an overnight organic matter digestion, followed by centrifugal density separation, visual microscopy, and micro-FTIR spectroscopy analysis. We will compare microplastics abundance and characteristics across each level and type of vegetation cover. We predict that (i) sites with high species diversity will have higher microplastic loads than those with low (or no) species diversity; (ii) more structurally complex vegetation will have higher microplastic loads than less structurally complex vegetation; and (iii) different microplastic types will have different depositional patterns. The outcome of this work will enrich our understanding of coastal vegetation as a microplastics sink and inform where hotspots of microplastic accumulation are most likely to occur within a biogenic canopy. By increasing our understanding of microplastics pollution within highly valued coastal habitats, we can aid protection, restoration, and potential clean-up efforts.

3.22.P-Tu324 Unveiling human exposure to microplastics from water sources

Virginia Gálvez Blanca[1]*, Carlos Edo*[2]*, Miguel González-Pleiter*[3]*, Francisca Fernández-Piñas*[3]*, Francisco Leganés*[3] *and Roberto Rosal*[2]*, (1)University of Alcala (UAH), Spain, (2)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain, (3)Biology, Autonomous University of Madrid (UAM), Spain*

This study addresses the growing concern of microplastic (MPs) pollution in water sources through a comparative análisis of MPs presence in tap and bottled water in Spain. The primary goal is to assess and compare MPs concentrations in these crucial drinking water sources. Tap water samples were collected from 24 points across 8 locations, using steel filters with a 25 μm opening size. Simultaneously, bottled water assessments focused on 1.5 L poly(ethylene terephthalate) bottles from mayor Spanish brands. The methodology involved particle collection using 0.8 and 1 μm pore size filters, followed by photographic, spectroscopic, and micro-FTIR identification. In tap water, the avarage concentration of MPs was 12.5 ± 4.9 MPs/m^3, accompanied by anthropogenic particles (APs) at 32.2 ± 12.5 APs/m^3, with polyamide, polyester, and polypropylene identified as the main polymers. In contrast, bottled water showed an average MP concentration of 0.890 ± 0.192 MPs/L, primarily composed of white and transparent polyester particles, accompanied by artificial nonplastic particles (ANPPs) at 1.73 ± 0.32 ANPPs/L primarily composed of cellulose. Daily intake estimates ranged from 12 to 55 ng kg^{-1} day^{-1}, suggesting a low-risk scenario. The results indicate that, although MPs in tap water present minimal health risks, bottled water, while still low-risk, exhibits notably higher concentrations of plastic. This highlights the importance of considering both sources in thorough assessments. The study contributes significantly to our understanding of microplastic exposure, emphasizing the necessity for additional research and the adoption of sustainable water management practices. The relevance of this research lies in advancing our knowledge of microplastic contamination across various water sources, offering insights that can inform the development of public health policies and practices. The comparative approach of the sudy enhances its applicability, providing valuable guidance for future efforts aimed at mitigating the impact of MPs on both human health and the environment.

3.22.P-Tu325 Priorities to Inform Microplastics Management, Monitoring, and Research: A California Case Study

Diana Lin[1]*, Tony Hale*[1]*, Kaitlyn Kalua*[2]*, Kayli Paterson*[1]*, Rebecca Sutton*[1] *and Ezra L Miller, PhD*[1]*, (1)San Francisco Estuary Institute, (2)California Ocean Protection Council*

The state of California, USA, proposes to establish the first statewide microplastics monitoring program designed to inform management decisions to protect aquatic ecosystems from microplastics pollution. However, scientific understanding of microplastics (including tire-wear particles) presence, fate, and impacts lag behind the urgent information needs environmental policy-makers have to manage microplastics pollution. Therefore, it is critically important for microplastic researchers to understand the priority "management questions" policy-makers and water quality managers have to inform near and long-term environmental policy decisions, and prioritize research funding and efforts to address these "management questions" and associated monitoring data needs. We gathered input from federal, state (California), and local government agencies, and local water quality managers to understand the priority management questions and information needs on microplastics. We synthesized diverse input into a comprehensive framework, and articulate clear monitoring goals and objectives for a statewide monitoring program. We also identify priority research needs to address priority management questions, and invite SETAC members to provide input as well through an on-line questionnaire. Input received during SETAC will be incorporated into the developing California statewide microplastics monitoring strategy. Lessons learned from California's approach may be applicable widely to other governments embarking on developing monitoring strategies to inform microplastics management.

3.22.P-Tu326 Incorporation of Micro- and Nanoplastics in Sea Ice During Freezing

Alice Pradel[1]*, Rudolf Hufenus*[2]*, Martin Schneebeli*[3] *and Denise M Mitrano*[4]*, (1)Department of Environmental Systems Science, ETH Zurich, Switzerland, (2)Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)WSL Swiss Federal Institute for Snow and Avalanche Research, Switzerland, (4)Environmental Systems Science, ETH Zurich, Switzerland*

Despite being remote, the Arctic is widely contaminated by microplastics (MPs, 1um to 5mm). In fact, concentrations of MPs >10mm are orders of magnitude higher in sea ice compared to the underlying seawater. This could put the polar food web at high risk of exposure since the porosity of sea ice, generated by brine channels, is an important habitat for photosynthetic organisms. Furthermore, the environmental fate of small MPs (1um to 10mm) and nanoplastics (NPs, <1um) at the seawater/sea ice interface is unknown due to the analytical challenges involved in quantifying them. Therefore, it is crucial to understand how MPs and NPs become enriched in sea ice. To achieve this, we developed a novel laboratory experimental set-up which mimics sea ice growth and allows us to quantify plastics within the ice and brine channels separately. Our hypothesis was that the extent of particle incorporation into sea ice is dictated by their size and density. To this end, we compared the fate of various species: a dissolved molecule (Rose Bengal), NPs, nanosoot, and two MPs of similar size but different densities. Rose Bengal and nanosoot were quantified by absorbance spectroscopy. Model metal-doped NPs and MPs were quantified by inductively coupled plasma mass spectrometry using trace elements as a proxy for plastics. Artificial sea ice was generated with a temperature gradient of 1.0 to -5.1ºC. At the end of the experiment, the ice was centrifugated to remove the brine. The morphology of the ice (assessed by m-computed tomography) and its salinity was similar to that of young natural ice. For all treatments, we quantified all species in brine, ice and the underlying liquid. Salts and Rose Bengal were equally enriched in the brine channels and depleted from the ice. However, MPs followed divergent transport pathways depending on their density. High-density MPs were depleted in both brine and ice whereas low-density MPs were slightly depleted from brine and enriched in ice. While NPs and nanosoot were depleted from ice, their rate of enrichment in brine was intermediate between the one of dissolved species and PET-MPs. This suggests that these nanometric particles follow a distinct transport pathway due to their colloidal properties. In conclusion, we can expect the accumulation of low-density MPs in the solid ice matrix and of NPs in the brine channels. This work therefore elucidates which organisms are at risk, and which type of plastic particle they may be exposed to.

3.22.P-Tu327 Modification of a Nile Red Staining Method for Microplastic Detection in Environmental Media

Fiona Quin Zabel *and Lance T Yonkos, Environmental Science & Technology, University of Maryland*

Numerous methods have been developed for microplastics isolation and quantification in various environmental media, many of which require elaborate/expensive analytical equipment and decontaminated lab space. This study seeks to create a reproducible and economical method for the isolation of microplastics in surface water and sediment samples that is reliant on Nile Red staining. We use a Nile Red pre-staining step prior to sample digestion, density separation, and filtration to mitigate downstream in-lab contamination. To test the method generated, we seasonally collected replicate surface water samples from urban streams in the Chesapeake Bay Watershed, USA for one year and quantified microplastic concentrations via fluorescent microscopy. We investigated spatial and temporal microplastic concentrations with the goal of estimating the impact the University of Maryland College Park campus has on microplastic abundance. This method was also applied to sediment samples from the abyssal plain of the Pacific Ocean to see if the method is amenable to the quantification of samples containing substantial and variable sediment loads. The proposed sampling and quantification method found some success in both surface water and marine sediment samples with specific microplastics (≥20 μm) able to be enumerated.

3.22.P-Tu328 Reproducibility and Environmental Relevance: An Impossible Match for Plastic Particles?

Cátia Venâncio[1] *and* ***Miguel Oliveira***[2]*, (1)University of Aveiro, Portugal, (2)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal*

Increased awareness of the potential impact of nanoplastics (NPLs) on biota stems from their higher surface area-to-volume ratios, which impart greater reactivity and adsorption capacity compared to their larger microsized counterparts. The research in this area has progressed rapidly. Nevertheless, the generated data may possess limited relevance due to the trade-off between achieving reproducibility under controlled laboratory conditions and maintaining environmental significance, creating a potential disconnect.

The nanoplastics used in laboratory settings often lack significant analogies with those present or expected in the natural environment, further widening the disparity between laboratory findings and real-world situations. This work aims to underscore the intricacies and potential misunderstandings frequently encountered in published research concerning the size and shape of NPLs.

Current research on nanoplastics appears guided by commercial particle availability and technological constraints (e.g., characterization possibilities), as well as the goal of assigning specific size and shape effects. Despite the relevance of these findings, particularly for industry, the current state of contamination makes the relevance of this information limited to assess the impact of particles already present in the environment, which include different sizes, shapes, ages and additives/contaminants. Therefore, at an initial stage, these restrictions can be overcome by resorting to more complex studies that involve the combination of different sizes and shapes of plastic polymers that would more effectively replicate the varied nature of nanoplastic pollution in the environment. However, it should be noted that such an approach would increase the complexity of research efforts. An initial strategy, recognizing the variability of size and shape proportions between sites and the current impracticality of on-site characterization, involves employing mixture models for various contaminants. This involves the selection of sensitive species and parameters.

3.22.P-Tu329 PlasticFADE: Introducing a Mechanistic Model for Plastic Fragmentation and Degradation in the Environment

*Yibo Tang and **Anne-Marie Boulay**, CIRAIG - Ecole Polytechnique de Montreal, Canada*

Plastics are generally durable, yet they fragment and degrade under natural conditions, affecting their mass, residence time, and size distribution in the environment. Existing models that address plastic fragmentation and degradation have provided an oversimplified picture. These models often assume constant rates over time, apply identical rates to different polymers and compartments, and consider inadequate shapes and sizes of plastics. To address this challenge, we are developing a model to calculate specific plastic fragmentation and degradation rates by combining a mechanistic understanding of these processes with statistical techniques. The model accounts for the major influencing factors of fragmentation and degradation: properties of the plastics and conditions of their surrounding environment. Although fragmentation and degradation occur simultaneously under various sources of environmental stress, they are modeled separately in this work. Quantitative data from recent plastic weathering studies have been collected, which are used to derive model parameters and validate the modeling results later. These data have been reported in both mass- and number-based formats, for example, loss of the total mass and particles produced per pellet. Accordingly, a unit conversion approach is proposed for the transformation between mass- and number-based rates. Preliminary results highlight the influence of size, shape, and polymer type on the magnitude and variation of fragmentation and degradation rates. The rates computed by the PlasticFADE (Plastic Fragmentation And Degradation in the Environment) model will have a unit of percentage of weight loss per day. These rates can be used in the calibration of existing plastic fate models and the estimation of global plastic mass budget. In addition, these rates will be integrated – in an upcoming study – into the characterization factors for plastic emissions in life cycle impact assessment (LCIA). The life cycle assessment (LCA) community is now working on incorporating plastic impacts into the LCIA framework. The integration of fragmentation and degradation rates will establish the missing link between the impacts of macroplastic emissions and the impacts of secondary micro- and nanoplastics that break down from the macro-sized debris.

3.22.P-Tu330 Relation between Surface Hardness and Elasticity to Carbonyl Indexes of Plastic Products and Environmental Plastic Debris

***Emiko Fujita** and Yutaka Kameda, Chiba Institute of Technology, Japan*

The majority of plastics degrade and break down into macro and microplastics in the marine environment. However, the degradation and fragmentation of plastics in the environment remain insufficiently understood. Particularly, only few studies have reported the physical properties of weathered plastics in the open sea, although properties such as the carbonyl index using infrared spectra have been discussed.

The objective of this study is to uncover the relationship between surface hardness, elasticity and the carbonyl index of micro and macro plastics. Additionally, we aim to investigate the connection between product plastics and environmental plastics. Fifty polypropylene (PP) products were purchased from stores or online shops, and thirty PP films were collected from the open sea in the Pacific and Indian Oceans through collaboration with volunteer commercial ships. Additionally, fifty PP debris items, such as lids from plastic bottles, films, and fragments, were collected from Japanese beaches and rocky shores. A Dynamic Ultra Micro Hardness Tester (Shimadzu) was utilized to measure Martens hardness, and elasticity using a measurement method that we developed. Micro-Fourier Transform Infrared Spectroscopy was employed to identify polymers through ATR on their surfaces and to calculate their carbonyl indexes. The poster will demonstrate the relationship between surface hardness and elasticity and the carbonyl index of weathered PP debris and commercial products.

3.22.P-Tu331 Assessing Microplastic Generation in Rivers by Abrasion Experiments

***Lucas Kurzweg**[1], Martin Socher[2], Andreas Fery[3] and Kathrin Harre[4], (1)Faculty of Agriculture/Environment/Chemistry, University of Applied Sciences Dresden, Germany, (2)University of Applied Sciences Dresden, Germany, (3)Leibniz Institut für Polymerforschung Dresden e.V., Germany, (4)Faculty of Agriculture, Environment, Chemistry, University of Applied Sciences Dresden, Germany*

Rivers are complex ecosystems in which different flow conditions can affect the fate of plastic materials. Fragmentation of plastic debris into secondary microplastic (MP) and nanoplastic (NP) increases the bioavailability and risk potential for aquatic organisms by the change of size, shape and transport behaviour. Abrasion, as one mechanism of fragmentation, might occur at the river bottom due to mechanical interaction of plastic material and the river bottom. Therefore, the generation of MP from the high density plastics polyamide, polyethylene terephthalate, and polystyrene by abrasion was investigated for different roughness and power input in laboratory experiments. A Taber Abraser 5131 equipped with different abrasive wheels was used to simulate the interaction of plastic materials and the river bottom under wet conditions. The released MP mass was determined and the particles were analysed regarding their particle size distribution and shape.

Our results indicates a relatively small size (d_{50}) of the released particles of 40 µm independently of the polymer type and the roughness of sanding paper. However, up to 2 % of the generated particles were in the sub-micron range and can be considered as NP. Thus, the small particle size of released MP would increase the bioavailability of plastic materials. Subsequently, further fragmentation of MP to NP could occur by biological mechanisms or chemical degradation. Nevertheless, abrasion of plastic objects contributes only to a small extent to the formation of NP in riverine ecosystems.

Moreover, we hypothesize that the mass of released MP correlates with the power input and can be described by a linear equation. The parameters controlling the power input of a fluvial system could be derived from empirical equations by Bagnold, Mannig-Strickler or Sipe et al. (2022). Thus, the fate of plastic materials could be predicted in terms of MP and NP formation. In addition, the investigation of their physico-chemical characteristics in combination with abrasion experiments may help to identify polymers, which could generate most secondary MP and MP after release in the environment. Additionally, the knowledge about MP shape is crucial to improve the understanding of the fate of microplastic in river ecosystems. This would contribute to an improved risk assessment of aquatic ecosystems in which high MP release was predicted.

3.22.P-Tu332 Generation Rates of Nano- and Microplastics from Four Thermoplastics by Sunlight-simulated Photooxidation in Water

***Soeun Eo**[1], Young Kyoung Song[2], Sang Hee Hong[3] and Won Joon Shim[3], (1)Ecological Risk Research Department, Korea Institute of Ocean Science and Technology (KIOST), Korea, Republic of (South), (2)Research Institute for Basic Sciences, Chonnam National University, (3)Ecological Risk Research Department, Korea Institute of Ocean Science and Technology, Korea, Republic of (South)*

The production mechanisms of secondary nanoplastic (NP) and microplastic (MP), and the changes in the surface properties during weathering process have been actively studied recently. However, compared to parent plastics, information on these generated particles remains relatively scarce, particularly regarding particle quantification. This study investigated the changes in surface characteristics of four thermoplastics [polypropylene (PP), high density polyethylene (HDPE), polystyrene (PS) and polyethylene terephthalate (PET)] after photooxidation in water, as well as quantified the generated NPs and MPs and calculated their generation rates. The photooxidation was performed using a xenon-arc lamp with a daylight filter to simulate natural sunlight. The weathering under the same conditions enabled direct comparison between four plastics.

PET showed the earliest signs of surface cracks among the tested polymers, followed by PP and PS. Notably, HDPE did not exhibit any surface cracks even after 176 days of photooxidation. The carbonyl index (CI) of HDPE showed gradually increase with increasing exposure duration. Conversely, the CI of PP, PS, and PET initially increased, but then tends to decrease or fluctuate. Given that the weathering of HDPE is relatively slow compared to other plastics, it is possible that the CI of HDPE will show fluctuation with further weathering progresses. The CI could decrease with exposure time due to weathered surface layers, revealing fresh, unoxidized surfaces underneath. The generation rates (y) of NPs and MPs per cm^2 for n years after photooxidation and mechanical abrasion (MA) in water were calculated using an exponential function, and each equation is as follows: $y=30525041\times e^{0.4591n}$ (PP); $y=8044465\times e^{0.3939n}$ (HDPE, no MA); $y=72383709\times e^{0.5326n}$ (PS); $y=73005201\times e^{1.2818n}$ (PET). HDPE for which no equation was derived with photooxidation and MA, was calculated as the case of photooxidation alone.

The NPs and MPs generation rates by photooxidation and MA in this study could provide the basis for developing policies to manage plastic pollution. For example, PET and PS litter is recommended to remove from the enviroments within 1-1.5 yrs before their exponetial increment of microplastic production, and to use HDPE polymer for outdoor plastic facilities to reduce microplastic generation. In addition, they can be used as essential parameters to develop plastic weathering or fragmentation models.

3.22.P-Tu333 Environmental Fate of Nano- and Small Microplastics in Aqueous Environments

***Stine Kylling Mauring**[1], Stefania Piarulli[2], Andy Booth, PhD[2], Hoda Daneshvar[1], Bettie Cormier[3], Martin Wagner[3], Tania Gomes[4] and Lisbet Sorensen[2], (1)NTNU, Norway, (2)SINTEF Ocean, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway, (4)Norwegian Institute for Water Research (NIVA), Oslo, Norway*

Understanding how micro-and nanoplastics (MP and NP) behave in the environment, and how different environmental conditions impact their fate is fundamental to quantifying exposures, assessing hazards and, ultimately, understanding their risks. Unfortunately, there remains a paucity of data on this topic, particularly factoring in environmentally realistic and relevant particle polymers, shapes, and conditions.

Here, we studied the environmental fate of secondary small MP (sMP; 1-100 µm) and NP (<1 µm) in various aquatic matrices. Low-density polyethylene (LDPE) shopping bags and polyethylene terephthalate (PET), polyamide (PA), polyacrylic (PAN) and wool yarns were the primary plastics from which the secondary MP and NP were produced. The sMP (diameter range ~10-80 µm) were obtained by cryomilling and sieving, while NPs (diameter ~200-500 nm) were obtained directly in water by partial dissolution/precipitation using a long-chain alkane. PE sMP were partially degraded under simulated UV exposure. Particle size distribution (NTA and Coulter Counter), shape and morphology (SEM), and surface chemistry (Raman) was characterized.

Environmental fate experiments were conducted in natural fresh-, brackish and seawater collected from around the Trondheim area (Norway). For NP, the impact of varying environmental factors such as salinity, temperature and organic matter type and concentration on suspension stability and aggregation was studied. Dynamic light scattering (DLS) and zeta potential was measured over a time-series. For sMP, the impact of aging in natural waters with varying content (type and concentration) of organic matter and microorganisms (phytoplankton and bacteria), as well as UV-degradation, on particle dispersion and settling rates, was studied.

3.22.P-Tu334 Are microplastics derived from conventional and biodegradable mulching films biodegradable in the aquatic environment?

Ula Rozman[1], Janja Novak[2], Anita Jemec Kokalj[3], Rachel Hurley[4], Andrijana Sever Škapin[5] and ***Gabriela Kalcikova[1]***, *(1)Faculty of Chemistry and Chemical Technology, University of Ljubljana, Slovenia, (2)University of Ljubljana, Slovenia, (3)University of Ljubljana, Biotechnical Faculty, Slovenia, (4)Norwegian Institute for Water Research (NIVA), Norway, (5)Slovenian National Building and Civil Engineering Institute, Slovenia*

Mulching films are widely used in agriculture to increase quality and yield of crops. When applied to the soil, they are exposed to various environmental factors that lead to fragmentation and the formation of smaller plastic particles known as microplastics (MPs). The resulting MPs can remain in the soil and affect its quality or be transported by runoff into surface waters, where the fate of MPs derived from agricultural mulching films has not yet been investigated.

In this context, we investigated how the most commonly used mulching films biodegrade in the aquatic environment. For this experiment conventional low-density polyethylene (PE) and biodegradable polybutylene adipate terephthalate (PBAT) mulching films were selected. The untreated MPs (both PE and PBAT) were produced by shredding and cryomilling larger pieces of film. In addition, both untreated MPs were aged (10 days, UVA340 lamps, UV intensity 35-40 W/m^2) to stimulate the natural abiotic aging under sunlight. The biodegradability in the aquatic environment of all four types of MPs (PE, PBAT, UV-PE, UV-PBAT) was evaluated by measuring the oxygen demand in a closed respirometer over 28 days according to the standardized OECD method. In addition, the changes in morphology and chemical composition after abiotic (UV) and biotic (biodegradability test) aging were investigated using scanning electron microscopy (SEM) and Fourier transform infrared spectroscopy (FTIR), respectively.

The results showed that PE did not degrade in the aquatic environment, even when pre-treated with UV, as biodegradability was less than 1% after 28 days. In addition, SEM images and FTIR spectra showed no changes in morphology and chemical composition. On the other hand, PBAT was not well degraded (the biodegradability was approximately 6%), while UV-PBAT was partially degraded and reached a biodegradability of 16%. These results are also consistent with the FTIR and SEM analysis, as the FTIR analysis showed changes in the peaks at a wavenumber of 2900 cm^{-1} (methylene stretching vibration) and the SEM images revealed disruption of the MPs surface.

The results show that none of the tested MPs can be considered readily biodegradable in the aquatic environment. Nevertheless, PBAT showed an initial degree of degradation in the aquatic environment, but further studies are needed to investigate the mechanisms and time frame of its biodegradation.

3.22.P-Tu335 Activated Sludge Acts as an Efficient Passive Sampler for Microplastics

Guillaume Crosset-Perrotin[1], *Eberhard Morgenroth[2] and Ralf Kaegi[3], (1)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)ETH Zurich, Switzerland, (3)Process Engineering, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*

Quantifying microplastics (MPs) in wastewater treatment plants (WWTPs) remains challenging due to large uncertainties associated with sampling and analysis. However, high removals of MPs in WWTPs indicate the transfer of MPs from the wastewater to the sludge, suggesting that sludge is an efficient passive sampler for MPs. In this work, we assess the accumulation of pristine and UV-exposed MPs in activated sludge. We performed batch experiments to mimick the behavior of MPs in an activated sludge process. Polystyrene (PS), polyethylene (PE), and polyvinyl chloride (PVC) reference MPs of various sizes, shapes, and densities were exposed to UV light. Approximately 5'000 pristine or UV-exposed MPs were spiked separately in bottles with deionized water (blanks) or activated sludge. The content of the bottles was aerated and mixed (120 min), before settling (30 min) in a sedimentation funnel. The resulting supernatant and settled sludge were digested or filtered and the MPs were quantified based on microscopic images. Surrogate standards were spiked in each sample as QA/QC measure. To assess the kinetics of MPs accumulation in sludge, time-resolved batch experiments were carried out with different aeration and mixing times (0, 1, 5, 15, 30, 60 and 120 min), but with the same settling time (30 min). For all samples, the recoveries of the surrogate standards was >70%, indicating limited MPs losses during the sample processing. In the blanks, after 120 min mixing, <50% of the each polymer type settled at the bottom of the funnel. When adding sludge, >90% of the pristine and UV-exposed MPs were captured in the settled sludge, because of the combined effect of fluid shear and differential sedimentation of the flocs and particles. The time-resolved experiments showed that the MPs got increasingly heteroaggregated with sludge during the first 15 to 30 minutes, before reaching a steady state. The relative affinity of MPs with sludge was similar for every polymer type. In conclusion, MPs quickly accumulated in activated sludge, independently of their properties (size, shape, polymer type, aging). Because of the higher solids concentration, longer retention time and continuous mixing of sludge in full-scale WWTP, collecting sludge samples may be more representative than sampling effluent water. Thus, sludge is a very promising passive sampler for MPs wastewater.

3.22.P-Tu336 Long-term Monitoring of Natural Weathering of Microplastics. Study of the Behavior of Adsorbed Metals

*C Moscoso-Pérez[1], V Fernández-González[1], E Concha-Graña[1], J Frias[2], M.L Pedrotti[3], V Lenoble[4], R Casotti[5], P López-Mahía[1] and **S Muniategui-Lorenzo**[1], (1)Universidade da Coruna, Spain, (2)Atlantic Technological University (ATU), (3)Observatoire Océanologique de Villefranche Sur Mer, (4)Université de Toulon, (5)Stazione Zoologica Anton Dohrn*
The presence of plastics in the environment has generated great interest in recent years due to their ubiquity in different environmental compartments. Plastics can be affected by natural environmental conditions, such as ocean currents, solar radiation, temperature variation, salinity or colonization by a wide range of organisms. In general, they will slowly fragment into smaller pieces known as microplastics (MPs) (< 5 mm in size), which will also continue to fragment into even smaller pieces known as nanoplastics (<1 µm in size). MPs have a small size and because of their high hydrophobicity and large surface areas can serve as carrier of pollutants, containing organic contaminants and heavy metals.

As part of the MicroplastiX project's research activities, in-situ experiments were carried out simultaneously in 5 port sites in Europe and in an extra location in Brazil. The experiment aims to assess degradation, fragmentation and weathering of different polymers under environmental conditions.

This study presents the natural weathering study of 9 types of plastics to monitor the changes in the composition of their metallic additives. The weathering experiment has been carried out during the summer, autumn, winter and spring of 2021-2022 in a sport port in Ares, A Coruña, Spain. Subsamples were analyzed at each season at 0, 30, 60 and 90 days of exposure. 15 metals were simultaneously measured by ICP-MS after microwave acid digestion.

As an example, for R-PP, the concentration of some metals such as Mn or Ca increases slightly with exposure time. However, in the case of Cr, it seems to leach. It is the polymer that shows the highest levels of metals at T0. In the case of PLA, there is almost no metal content at T0, while after 90 days of exposure for most of the metals studied, levels above the detection limit are observed. A similar behavior to that of PLA is observed for HDPE. It only presents Ca and Fe at T0 and the metals found increase with exposure time. The levels found in summer are slightly higher than those found in the other three seasons.

3.22.P-Tu337 Microplastics Settling in Turbid Waters: Impacts of Natural Suspended Sediments on Deposition Rates
***Francesco Parrella**[1], Stefano Brizzolara[1], Markus Holzner[2] and Denise M Mitrano[3], (1)ETH Zurich, Switzerland, (2)Swiss Federal Research Institute WSL, Switzerland, (3)Environmental Systems Science, ETH Zurich, Switzerland*
Numerous studies have focused on microplastics (MPs) detection and identification in natural waters, but few have investigated their transport behavior (e.g., settling dynamics) in aquatic environments. When MPs enter water bodies, factors such as particle size, density, and interactions with other particles influence their sedimentation rate. Here, we assessed how the presence of small, natural, suspended sediments (clay and silt) at varying concentrations impact MPs deposition in turbid waters. Our goal was to quantify how sediment concentrations alter MPs settling rates compared to pure water and subsequently evaluate deviations from natural particle settling models. We used model irregular-shaped PET fragments in three size classes (25-63 mm, 63-125 mm, 125-250 mm) stained with Nile Red for easier identification. Sediment suspensions at three concentrations (5 mg/L, 15 mg/L, 30 mg/L) were created by mixing kaolinite, montmorillonite, and quartz flour in equal proportions. A 1.5 m high plexiglass column, illuminated by a laser and filled with synthetic freshwater and the sediments, was used for settling experiments. A system with four cameras was used to track several thousands of particle trajectories, providing robust data for settling velocities. In line with expectations, larger MPs settled faster than smaller ones at a fixed sediment concentration of 15 mg/L. Surprisingly, MPs settled faster in the presence of suspended sediments compared to pure water, irrespective of sediments concentration. While further investigations are still ongoing, we hypothesize that the perturbation flow generated by falling MPs affected the spatial distribution of clay and silt particles, channeling MPs and speeding up their deposition. In a follow-up experiment, we explored the influence of different sediment concentrations on MPs of a given size. While MPs still settled faster in the presence of suspended sediments, there was no significant impact of different sediment concentrations, possibly due to the limited range of turbidity investigated at this stage of research. Ongoing analyses will explore higher and lower sediment concentrations, as well as other parameters, such as differences in salinity. Once completed, collectively our results will provide valuable data for future MPs fate-models and help to further understand the processes of sedimentation and fate of MPs in natural waters.

3.22.P-Tu338 Preliminary field study: vertical difference of microplastics within aggregates from the deep ocean
*Mi Jang[1], Gi Myung Han[1], Sung Yong Ha[1], **Youna Cho**[1], Ha Young Cho[2] and Sang Hee Hong[1], (1)Ecological Risk Research Department, Korea Institute of Ocean Science and Technology, Korea, Republic of (South), (2)KIOST*
In this study, we aimed to characterize marine aggregate and microplastic at the surface and deep sea from East sea (sea of Japan). Thirty litter of seawater was collected from the surface (3m) and deep sea (2100m) by niskin bottle respectively, and samples were obtained by settling seawater for two hours in Imhoff cone. For all samples, aggregates and organisms (mostly planktons) were photographed under microscope, and segregated to separate glass bottles. The seawater (loose fraction) which have aggregates and organisms excluded, and the aggregates and organism fractions were pretreated and placed onto silicon

filter paper for FT-IR analysis of microplastics. The size of aggregates varied from 200 to 5,390 μm, and their concentration was higher at the surface (3900 n/m³) than at the deep sea (1833 n/m³). Organisms were only observed in the surface water (5467 n/m³), and none in deep water. Microplastics were detected in 4 (3%) of 117 aggregates from 30 L of surface water, and 8 (15%) of 55 aggregates of 30 L of deep water. Of the 164 organisms in 30 L of surface water, microplastics were detected in 12 (11%). However, most of the microplastics were in the loose fraction (surface: 96 in 30 L, deep: 36 in 30 L) among the water column. At the surface level, organisms showed a higher proportion of microplastics compared to aggregates. But as we delve deeper, the proportion of microplastic in aggregates increased as the appearances of organisms diminished. This suggested the indirect influence of organisms such as plankton on the settling of microplastics in oceans. The results from this study points out the need for further field monitoring of aggregates in deep oceans.

3.22.P-Tu339 The fate of low density microplastic particles in rivers: an experimental study of turbulence, biofilm and sediment

Guilherme Calabro-Souza[1], *Andreas Lorke*[2], *Alexis Simons*[1], *Lucas Friceau*[3], *Bruno Tassin*[1], *Lorenzo Roveli*[4], *Cedric Chaumont*[5] *and Rachid Dris*[1], *(1)Leesu, Ecole des Ponts ParisTech, Université Paris Est Créteil, France, (2)University of Kaiserslautern-Landau (RPTU), Germany, (3)ParisTech School of Bridges, France, (4)Institute of Environmental Sciences, RPTU Kaiserslautern-Landau, Germany, (5)UR HYCAR, INRAE, University of Paris Saclay, France*

In watersheds, microplastic particles (MP) fate in the air-soil-water continuum impacts aquatic environments, ultimately transporting these particles to the seas. The transfer of MP from densely populated and industrialised areas to watercourses is particularly important but, some rivers crossing these types of territories present no significant MP concentration difference between upstream and downstream. In general, three key mechanisms are hypothesized as governing the MP fate in aquatic environments: particle characteristics, interactions with biota, and hydrodynamics. As low-density MP are often found in sediments the role of these mechanisms on the dynamics of this MP dynamics in running water systems is yet to be determined. This study, in an experimental approach, integrates the water column and sediment compartments, exploring the role of turbulence and biofilm on low-density MP dynamics. In a flume containing sediment and biofilm, the trajectory of standard particles of polyethylene polymer (red-fluorescent spheres, 0.995 g cm^{-3}, ~50 µm) were followed at different water flow velocities. A Particle Image Velocimeter setup (PIV) followed by data processing using Particle Tracking Velocimetry (PTV) allowed to retrace the trajectory of the particles near the sediment providing their orientations, origins and velocities. Increasing turbulence led to higher relative numbers of MP being in contact with the biofilm from ~4% to 10%. It enhanced MP settling requiring lower MP concentrations. Red-fluorescent MP were spotted on the biofilm surface but also in flocs suspended in the water column. In total, 6.000 particles cm^{-2} were observed in flocs, while 4.000 particles cm^{-2} were present in the water. In the complex interaction of the different parameters driving MP in the watercolumn of rivers and streams, the turbulence and the biofilm significantly affect the settling of low-density MP not only on the sediment but also in the water column by biofilm flocs. Further comprehension of biofilm-turbulence role on MP dynamics increase understanding on spatio-temporal variation of MP settling, transport and, thus, fluxes.

3.22.P-Tu340 Metal-Organic Frameworks (MOFs) as an Effective Tool for Nanoplastic Removal from Water

Daniel Pedrero[1], ***Carlos Edo***[2], *Francisca Fernández-Piñas*[3], *Sonia Aguado*[4] *and Roberto Rosal*[2], *(1)University of Alcala (UAH), Spain, (2)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain, (3)Biology, Autonomous University of Madrid (UAM), Spain, (4)Chemical Engineering, University of Alcala (UAH), Spain*

Nanoplastics (NPs) have attracted significant global attention as emerging environmental pollutants, given their heightened susceptibility to organismal internalization, raising concerns about increased ecological and health risks compared to microplastics (MPs). Recently, the focus has shifted towards adsorption as a promising strategy for NP removal, with new adsorbents demonstrating impressive performance. In this study, we aimed to eliminate polystyrene nanoplastics from aqueous environments using a series of mesoporous Metal-Organic Frameworks (MOFs). Mesoporous UiO-66 and its derivatives (-OH and $-NH_2$) were synthesized through a direct solvothermal process, employing cetyltrimethylammonium bromide (CTAB) or Pluronic-type triblock copolymer (P123). The resulting materials exhibited high crystallinity and featured a novel hierarchical mesoporosity.

TEM images provided evidence that NPs did not enter the mesopores of the material; instead, they predominantly adhered to the external surface of the MOF. Despite this, the mesoporosity of the MOF played a crucial role in augmenting the active surface area, positively influencing the adsorption process. This finding underscores the importance of mesoporosity in enhancing the overall adsorptive capacity of the MOF, even when NPs primarily interact with the external surface rather than entering the mesopores. Particularly noteworthy was the exceptional efficiency of UiO-66-NH_2/P123 in NP removal, achieving up to 100% removal efficiency at an initial concentration of 1 $g \cdot L^{-1}$. This outcome underscores the potential of MOFs as highly effective adsorbents for removing NPs from aqueous media.

3.22.P-Tu341 Predicting the Toxicity of Untested Microplastic Particles

Ana Leticia Antonio Vital[1], *Pedro M. da Silva*[2], *Scott Coffin*[3], *Win Cowger, PhD*[4], *Luan De Souza Leite*[5], *Maaike Vercauteren, PhD*[6], *Andrea Bonisoli Alquati*[7] *and Magdalena M. Mair*[1], *(1)Statistical Ecotoxicology, University of Bayreuth, Germany, (2)Potomac-Hudson Engineering, (3)Division of Drinking Water, California State Water Resources Control Board, (4)Moore Institute for Plastic Pollution Research, (5)University of São Paulo (USP), Brazil, (6)Ghent University (UGent), Belgium, (7)California State Polytechnic University, Pomona*

Micro- and nanoplastic particles (MNPs) are highly complex. While chemicals can be assigned unique identifiers (e.g. CAS numbers, SMILES) based on their clearly defined molecular structure and stable properties, this is not possible for MNPs. Each MNP has its own set of traits, including characteristics such as polymer composition, particle size and shape, as well as physicochemical properties like surface charge, surface chemistry, and plastic-associated chemicals. Furthermore, all these traits can change over time, for instance through degradation processes when MNPs are exposed to natural environments. To achieve reliable hazard and risk assessments for MNPs, it may be necessary to predict the toxicity of MNPs with trait combinations that have not been tested directly in the lab. Like Quantitative Structure-Activity Relationship (QSAR) models that link molecular structures to toxic outcomes, models are needed to link MNPs traits to toxicity.

The recently compiled Toxicity of Microplastics Explorer (ToMEx) 2.0 database, consisting of 12,774 data points from 215 published studies of MNP effects on aquatic species, offers a unique opportunity to approach this task. Using ToMEx 2.0 data, we train machine learning models on tasks to predict the toxicity (presence/absence of effects, effect direction, effective concentrations) of untested MNPs via leave-one-out cross validation. We compare the predictive performance of different machine learning algorithms and use methods of explainable AI (average marginal effects) to gain insights into associations of toxic outcomes with MNPs traits, experimental parameters, and species traits. Finally, we discuss how such models can be used to predict the toxicity of environmentally relevant MNPs mixtures and to inform the development of less toxic and more environmentally friendly plastic materials in the future.

3.22.P-Tu342 OCCURRENCE OF COMMON PLASTIC ADDITIVES AND CONTAMINANTS IN RAW, STEAMED AND CANNED MUSSEL SAMPLES FROM DIFFERENT HARVESTING AREAS USING MSPD-HPLC METHODOLOGY

*Esther Garrido Gamarro[1], **Gema Paniagua**[2], Dulce Lucy Soliz Rojas[3], Rosa Mª Garcinuño Martínez[3], Pilar Fernández Hernando[3] and Juan Carlos Bravo Yagüe[3], (1)Fisheries and Aquaculture Division, Food and Agriculture Organization of the United Nations (FAO), Italy, (2)National University of Distance Education (UNED), Spain, (3)Departamento de Ciencias Analíticas, Facultad de Ciencias, Universidad Nacional de Educación a Distancia (UNED), Spain*

Microplastics are a complex mix of chemicals containing polymers and certain plastic additives such as bisphenols and phthalates. These particles are porous materials that can also sorb contaminants from their surroundings, and leach chemicals from the particle under certain circumstances. Aquatic animals can ingest microplastic particles, which mostly bioaccumulate in the gastrointestinal tract of animals. In terms of dietary exposure, small animals consumed whole such as mussels, contribute more to the dietary intake of microplastic particles. Plastic additives and contaminants are not chemically bound to the polymers, and certain processing methods or cooking processes result in the release of these chemicals that leach from the plastic particles, leaving them more available for absorption when ingested.

In this work, the effect of cooking and processing in the presence of compounds derived from microplastic contamination in mussels was studied. For this purpose, an analytical methodology based on matrix solid phase dispersion (MSPD) coupled with high-performance liquid chromatography-mass spectrometry (HPLC-MS) was developed for the simultaneous determination of nine analytes (di (2-etilhexil) phthalate (DEHP), dibutyl phthalate (DBP), diethyl phthalate (DEP), bisphenol A (BPA), bisphenol F (BPF), bisphenol S (BPS), dichlorodiphenyldichloroethane (DDD), dichlorodiphenyltrichloroethane (DDT), and dichlorodiphenyldichloroethylene (DDE)] in raw, steamed, and canned mussels samples of two different harvesting areas (Atlantic and the Mediterranean).

MSPD sample treatments provided satisfactory recoveries for all the analytes and for raw, steamed, and canned mussel samples coming from the two studied areas, being the recoveries between 81–90% (with Relative Standard Deviation, RSD, of 1.7-8.4%) for steamed samples, and between 77-84% (RSD between 1.3-19%) for canned samples, and the detection and the quantification limits between 0.06-4.63 µg/kg. The results showed that the heat and pressure treatment could influence the migration of plastic additives as bisphenols and phthalates from the microplastic particles present in mussels to the processing liquid (water and/or oil), having as a result the decrease in the concentration of analytes in the food matrix. Analytes were always found to be higher in raw samples, followed by steamed. Only DBP and DEP were detected in canned samples. The pesticides DDD, DDT, and DDE were not detected in any of the cases.

3.22.P-Tu343 Leaching of Dissolved Organics and Inorganics From Microplastics and Assessing Their Contribution to Disinfection Byproducts Formation

***Mahyar Ghanadi**[1] and Lokesh P. Padhye[2], (1)University of Auckland, New Zealand, (2)Department of Civil and Environmental Engineering, University of Auckland, New Zealand*

The widespread use of plastics in daily lives has increased the occurrence of microplastics (MPs) in water and wastewater. While much research has been conducted on MP occurrence, additive leaching from MPs, and their adverse effects, relatively little is known about the potential leaching of dissolved organic matter (DOM) from MPs. This study aims to fill that research gap by investigating DOM and inorganics leaching from MPs, including polyamide 6, high-density polyethylene, and polyurethane under accelerated UVC irradiation. Leaching from these MPs was analyzed using gas chromatography-mass spectroscopy and elemental analysis. Finally, their potential role in the formation of disinfection byproducts (DBPs) was evaluated. Under ten days of UVC irradiation, MPs exhibited high levels of dissolved organic carbon and nitrogen leaching, reaching up to 94.1 and 29 mg/L, respectively. The leachates contained various metals, including Na, Mg, Al, K, Ca, Fe, and Cu. Metalloids like Si, and reactive nonmetals, such as P, Cl, and Br, were also detected. Among them, Na, P, K, Cl, and Si were the most frequently detected, with Na reaching the highest levels up to approximately 60.5 mg/g-MP. This suggests that MPs can be a notable contributor to the influx of not only organic compounds but also metals into natural water bodies. Chloramination of leachate did not yield detectable levels of *N*-nitrosodimethylamine or any regulated DBPs. Nonetheless, the chloramination process produced butanedinitrile and diacetamide, which are considered potentially toxic non-halogenated DBPs. Furthermore, chlorination of leachate revealed the formation of unregulated DBPs, such as chloral hydrate and propane nitrile. Given the formation of potentially toxic DBPs during the disinfection of DOM leached from MPs, it is recommended to include the consideration of DOM leaching from MPs as DBP precursors in toxicity analyses. This includes evaluating the toxicity of both the leached DOM and the resulting DBPs. Our results indicate that the leaching of DOM from MPs in aquatic environments may contribute to the formation of non-regulated DBPs during the disinfection process. These findings highlight the importance of monitoring DBP formation from MPs to safeguard both drinking water and the aquatic environment. Overall, the research enhances our understanding of the overlooked negative impacts associated with microplastic pollution in aquatic environments.

3.22.P-Tu344 Leaching of plastic additives in seawater: role of biofilm in colonized plastic

Berta Sala Solà[1]*, Rebeca Mallenco*[1]*, Núria Trilla*[2]*, Naiara Berrojalbiz*[3]*, Alex Campillo*[1]*, Maria Vila-Costa*[4]*, Jordi Dachs*[3] *and Cristina Romera-Castillo*[5]*, (1)Marine Biology and Oceanography (Marine Biogeochemistry, Atmosphere and Climate), Institute of Marine Sciences, Spanish National Research Council (ICM-CSIC), Spain, (2)Global Change and Genomics Biogeochemistry research Group, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (4)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (5)Institute of Marine Sciences, Spanish National Research Council (ICM-CSIC), Spain*

In seawater, plastic leaches out chemical compounds which has implications for the marine fauna and the biogeochemistry of the seawater. These chemicals can be additives or degradation products of the polymer and the process is enhanced by sunlight radiation. The presence of microorganisms in seawater also triggers a fast formation of a complex biological layer on the plastic surface known as 'biofilm'. This is composed of a blend of microorganisms, extracellular compounds, and organic matter adhering to the plastic surface, fundamentally altering its properties and interactions within the environment. All the studies analyzing plastic leaching process in seawater have been made using new virgin plastic ignoring the role of the biofilm in this process. This study explores this phenomenon to understand if the presence of biofilm on plastic enhances or inhibits the leaching process in seawater.

Two experiments were performed to study the plastic leaching of additives in seawater: one with low density polyethylene (LDPE) colonized by biofilm and other, as a control, with new LDPE without biofilm. Plastic pieces were incubated in sterilized seawater under artificial UV and Vis radiation. In the experiment with non-colonized plastic, dark treatments were also performed to study the effect of radiation on the leaching. Samples from water, plastic, and biofilm were meticulously collected at specific intervals. Organophosphates (OPEs) and phthalates (PAEs) released by plastic into seawater were analyzed using Agilent 7890A gas chromatograph coupled to an Agilent 7000B triple quadrupole mass spectrometer.

The experiment with non-colonized plastic revealed substantial concentrations of organophosphates (OPEs) and phthalates (PAEs), indicating their potential for leaching under diverse light and darkness conditions. A notable observation was the distinct response among various OPEs to UV exposure, contrasting with the consistent behavior observed in PAEs. These results will be compared with those obtained from the experiment with colonized plastic. Findings from this study are expected to offer critical perspectives in comprehending the complex dynamics of chemical leaching associated with plastics in marine environments.

3.22.P-Tu345 Microplastics interaction on Hg biotransformations mediated by microorganisms

Neusa Figueiredo[1]*, Marta Dias*[2]*, Joana Antunes*[3]*, Arun Kumar*[4]*, Vasco Branco*[5] *and* ***Marta Martins***[1]*, (1)MARE - Marine and Environmental Sciences Centre, NOVA School of Science and Technology, Portugal, (2)MARE - Marine and Environmental Sciences Centre, NOVA School of Science and Technology, University of Lisbon, Portugal, (3)Nova University Lisbon, Portugal, (4)Department of Civil Engineering, I.I.T Deli, India, (5)Research Institute for Medicines (iMed.Ulisboa), Faculty of Pharmacy, Universidade de Lisboa*

The presence of microplastics (Ø <5 mm, MPs) and mercury (Hg) in aquatic ecosystems is an environmental problem. MPs can be taken up by biota, undergo bioaccumulation and biomagnification and cause oxidative stress, neurotoxicity, genotoxicity, and inflammation. Microorganisms are the key players in the biogeochemical cycle of Hg, performing Hg-reduction, Hg-methylation (formation of the neurotoxic methylmercury), and methylmercury-demethylation. Methylmercury undergo bioaccumulation and biomagnification. Microorganisms isolated from Tagus estuary, one of the most important wetlands of Europe, were found to be involved in these processes. Thus, this study aims to assess the complex interactions between MPs, Hg and Hg-resistant microorganisms to disclose the impacts of MPs on the biogeochemical cycle of Hg and toxicity.

To accomplish this, an urban area of Tagus estuary with port and industrial activities, was selected as study case (Barreiro, 38.6645,-9.0786). Sediment and water samples were sampled for: (1) Microplastics isolation and characterization; (2) total Hg concentration determination, and (3) Hg-resistant microbial communities' isolation. Besides, DNA was extracted from the MPs and sediment samples to assess the presence of Bacteria, Fungi and Archaea via PCR for the amplification of 16S rRNA and

ITS genes. Suspension and microcosms experiments with several MPs polymers with Ø > 1 mm were performed to evaluate the interactions between MPs:Hg:Microorganisms.

The results showed the presence of MPs (109 ± 71.6 to 52.0 ± 8.70 particles/kg of dry sediment), especially fibers and fragments of polypropylene, polyethylene, expanded polystyrene and polyester polymers. Hg concentration above Effects Range Medium (0.71

3.22.P-Tu346 Joint effects of ketoprofen and polypropylene nanoplastics on the morphology and physiology of zebrafish early life stages

Alexandru Chelaru[1], Cátia Venâncio[2], Alexandra Savuca[1], Mónica Almeida[3], Miguel Oliveira[3], Mircea Nicoara[4] and ***Isabel Lopes***[3]*, (1)University of Iași, (2)Department of Biology, CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (3)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (4)University Iasi*

Ketoprofen (Kp) is a non-steroidal anti-inflammatory medicine commonly used worldwide; however, there is no clear legislation regarding its emission into the environment. Concentrations in environmental matrices, particularly in water resources, are known; although their effects on the biota have received less attention. They are likely to affect the health and performance of fish because of their powerful and enduring analgesic and anti-inflammatory effects. Furthermore, in realistic environmental contexts, this drug is possible to interact with emerging compounds, such as nanoplastics (NPLs), which may reduce or potentiate its uptake and, consequently, influence the observed toxicity. Accordingly, two specific objectives were pursued in the present study: I) to quantify the lethal concentrations of Kp causing 20 and 50% of effect (LC_{20} and LC_{50}, respectively) on embryos and larvae of *D. rerio* and II) to understand how the toxicity of Kp (at two levels: LC_{20}, LC_{50}) is shaped by the presence of environmentally realistic concentrations of nanosized polypropylene plastic (PP, 25-101 nm at 0.0001, 0.001, 0.01 mg/L), on a full factorial design. The following endpoints were monitored: mortality (M), malformations (m), heart beats (Hb), hatching rate (Hr), total length (TL) and interocular distance (IO). The PP was selected because it is widely used for food packaging and is one of the most often found in rivers. The estimated LC_{20} and LC_{50} (and respective confidence limits at 95%) for larvae were of 3.52 (2.31 - 5.35) mg Kp/L and 10.09 (6.63 - 15.35) mg Kp/L, respectively, and for embryo were of 4.29 (3.10 - 5.12) mg Kp/L and 6.16 (5.17 – 7.43) mg Kp/L. In plastics' exposure alone, M+m were below 20% in both life stages. For larvae, the $LC_{20,Kp}$ and $LC_{50,Kp}$, M+m summed up to 20 and 35% of effect, whilst up to 30% in $LC_{20,Kp}$+0.01 mg PP-NPLs/L, and up to 40% in $LC_{50,Kp}$+all PP-NPLs concentrations. The M+m for embryos, jointly summed up to 35% and 50% of effect in $LC_{20,Kp}$ and $LC_{50,Kp}$ groups. Significant differences were observedfor IO between controltreatments (except 0.001; 0.01 mg PP-NPLs/L and $LC_{50,Kp}$+0.01mg PP-NPLs/L) and also for Hb, significant differences were observed between $LC_{50,Kp}$ and control. These results highlight that some potential synergistic interaction between pharmaceuticals and NPLs may occur, hindering the true effects of NPLs when studying them isolated.

3.22.P-Tu347 Effect of low food level on chronic toxicity of polyethylene microplastics to Daphnia magna population

Zhihan Cao*, Changhae Kim and Jinho Jung, Environmental Science & Ecological Engineering, Korea University, Korea, Republic of (South)*

Food level has a vital role in population dynamics. However, the role of food level in *D. magna* population dynamics with microplastics (MPs) is not fully understood. In this study, populations of *D. magna* were exposed to polyethylene MP fragments, BP-3 leachate, and MP fragments containing the UV stabilizer benzophenone-3 (MP/BP-3). The food concentrations were 5×10^5 cells/mL (optimum level) and 2×10^5 cells/mL (low level). The test duration was 42 days to observe both the growth and decline of *D. magna* population. Low food levels itself significantly decreased the population size and changed the population structure ($p < 0.05$). Under the low food levels, both MP and MP/BP-3 fragments significantly decreased the population size in the decline phase ($p < 0.05$), but there was no difference between them. Interestingly, BP-3 leachate delayed the *D. magna* development, causing a significant decrease in the population size from the growth phase ($p <$ 0.05). These findings suggest that BP-3 contained in MP/BP-3 fragments was not likely available to D. *magna*. However, the interaction mechanism between MP and BP-3 needs to be further studied.

3.22.P-Tu348 Toxicity of Micro- and Nanoplastic Particles on Daphnia: A Meta-Analysis of the Effects of Dissolved Organic Matter and Ecocorona Formation

Ana Leticia Antonio Vital[1]*, Sophia Salomon[2], Eric Grubmüller[2], Philipp Kropf[2], Elisa Nickl[2], Anna Rühl[2], Selina Weigel[2], Felix Becker[2], Matthias Schott[3] and Magdalena M. Mair[1], (1)Statistical Ecotoxicology, University of Bayreuth, Germany, (2)University of Bayreuth, Germany, (3)Animal Ecology I, University of Bayreuth, Germany*

The toxicity of micro- and nanoplastics (MNPs) has gained attention in recent years, with water fleas of the *Daphnia*being the most tested aquatic invertebrate. However, the majority of studies have focused on the impact of pristine MNPs, neglecting the ecocorona that forms when organic molecules attach to MNP particle surfaces in natural environments. It remains unclear whether ecocorona formation plays a role in mitigating the toxic outcomes of MNP on aquatic species. To address this gap, we conducted a meta-analysis, specifically examining the immobilization rates of *Daphnia* exposed to MNP particles in the presence of dissolved organic matter (DOM) and ecocorona formation. A systematic literature search identified relevant experimental studies, allowing us to compare the effects of MNPs with ecocorona/DOM to those without. Our analysis considered variations in DOM types and experimental approaches (either co-exposure with DOM or incubation of MNP prior to exposure).

The final search was conducted in December 2022 on Web of Science (WoS) and PubMed. In total, 305 data points from 13 publications were included, revealing that DOM has the potential to alleviate the adverse effects of MNPs on Daphnia immobilization. Contrary to some hypotheses suggesting the primary role of ecocorona alone, our findings suggest that DOM in the media contributes additionally to the observed mitigation. Furthermore, the moderating effects of DOM varied based on the type of DOM utilized. Humic acid and lake water had the strongest mitigating effects, reducing the risk of immobilization by nearly 50%.

Based on our findings and literature on other stressors, we hypothesize that DOM mitigates MNP effects by either (1) reducing MNP bioavailability or (2) enhancing the daphnids' general resilience to stressors. Future studies comparing the impact of ecocorona formation during MNP incubation with adding the same type of DOM to the media during exposure will help to untangle the moderating effects of the ecocorona itself and free DOM in the media. In addition, studies comparing different DOM types or investigating interactions with additional stressors, and the more detailed characterization of MNP availability to *Daphnia* in the presence of DOM will improve our mechanistic understanding in the future.

3.22.P-Tu349 The Clone Wars: Daphnia magna Clones React Differently To Microplastics Exposure Under Food Limitation

Simona Mondellini[1], *Michael Schwarzer*[2], *Marvin Kiene*[2], *Gabriël Olthof*[3], *Dipannita Ghosh*[4], *Seema Agarwal*[5], *Martin G.J. Löder*[1], *Martin Wagner*[6] *and Christian Laforsch*[7], *(1)University of Bayreuth, Germany, (2)Animal Ecology I, University of Bayreuth, Germany, (3)Biology, Norwegian University of Science & Technology (NTNU), Norway, (4)Macromolecular Chemistry II, University of Bayreuth, Germany, (5)macromolecular chemistry II, University of Bayreuth, Germany, (6)Norwegian University of Science & Technology (NTNU), Norway, (7)University of Bayreuth, Animal Ecology I, Germany*

Ecotoxicological investigations of microplastic (MP) often report a wide variety of effects, even when relying on a model organism, like *Daphnia magna*, that reproduces via amictic parthenogenesis and should so enable researchers to exclude genetic variability. This could certainly be attributed in part to the diverse physicochemical properties of different MP, however MP ecotoxicological studies on *D. magna* often fail to consider clonal genetic variability, as well as other interacting stressors. In fact, in the environment, parameters like e.g. temperature, light, food availability are not constant. Food levels in particular are often far from those usually provided in laboratory investigations, hence we decided to perform this experiment in a food limiting set up for more environmental relevance (0.5 mg C L^{-1} every second day). The aim of this work is therefore to compare the sensitivity of two *D. magna* clonal strains (Aig and BL2.2) when exposed to MP under food limitation. For the MP exposure we chose to compare the potential effects induced by fragments of two biodegradable polymers (PLA and PBS) to those of a petroleum-based one (PET). Microcrystalline cellulose fragments were included as reference particles (all fragments < 20 µm). We carried out a 21-day chronic exposure experiment during which we recorded life history traits, growth and mortality. The two selected *D. magna* clones were found to have significantly different responses in all the selected sublethal parameters, even when statistically excluding intrinsic clonal differences by centering the obtained results to each separate clonal control, with Aig clone being more sensitive than BL2.2. Furthermore, when considering the effects of petroleum-based MP compared to those induced by biodegradable ones, the latter induced comparable or even higher negative effects. Therefore we conclude that clonal variability can significantly affect exposure studies and this should be considered in MP research. Moreover, despite evidence already exists that biodegradable polymers can have similarly negative effects as commodity plastics, further assessments are still needed to support these findings.

3.22.P-Tu351 Combined effects of global warming and microplastic on the population dynamics of a harpacticoid copepod

Zhiyue Niu[1,2], *Nathan Nault*[1,3,4], *Jana Asselman*[2], *Yasmine De Witte*[1,2], *Colin Janssen*[2], *Gert Everaert*[1] *and* ***Ana I Catarino***[1], *(1)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium, (2)Blue Growth Research Lab, Ghent University (UGent), Belgium, (3)Graduate School IFSEA, University of Littoral Opal Coast, France, (4)Laboratoire d'Océanographie Microbienne, Sorbonne Université, France*

Global warming and plastic pollution are two human-induced environmental stressors of concern due to their potential impact on ocean health. Microplastic is ubiquitously and persistently present in the marine environment, yet knowledge of its effects on populations, especially in a warmed marine environment, is limited. Here, our goal was to assess the potential theoretical population effects of microplastic and global warming. To do so, we followed a two-step approach: First, we exposed the harpacticoid copepod *Nitokra spinipes*, a benthic copepod, to Poly (lactic-co-glycolic acid) (PLGA) microbeads (5 µm), at control (22°C) and increased (25°C) water temperatures. The effects on *N. spinipes* individual were assessed by identifying shifts on filtration rate on microalgal prey, a proxy for energy assimilation. In the next step, the dynamics of a *N. spinipes* population was simulated for projected global warming conditions, and the effects of microplastics on the population density equilibrium were assessed. The empirical filtration rate data was incorporated in an individual-based model implementation of the dynamic energy budget theory (DEB-IBM model) to deduct potential theoretical population level effects (ongoing analysis). Our preliminary results suggest that PLGA microbeads at 0.1 % food content decreased the filtration rate of *N. spinipes* at increased water temperature (25°C) ($P < 0.05$, ANOVA). All *N. spinipes* at the increased water temperature (25°C) have a higher filtration rate compared to the control temperature (22°C). Our study demonstrates that the combined exposure of microplastic and elevated water temperature can induce less energy assimilation, in a high emissions scenario (RCP 8.5, IPCC) and inform the vulnerability of marine populations under current and future environmental conditions.

3.22.P-Tu352 Release of Microplastics from Disposable Surgical Facemasks Under Varying Shear Forces and Its Toxic Effects On Freshwater Algae Scenedesmus Obliquus

***Soupam Das**, Vellore Institute of Technology (VIT), India*

Throughout the COVID-19 pandemic, an extensive quantity of surgical face masks was used, as they emerged as an essential need in the daily routines of individuals worldwide. However, these items were not appropriately discarded, constituting a major contributor to micro and nano plastics throughout the environment. The impact of mask-derived microplastics on aquatic organisms has yet to be extensively investigated. This study aimed to quantify and describe the microplastics emitted from disposable surgical face masks under varying sheer force (100, 200, and 400 rpm). We investigated the acute toxic effects of the released microplastics on freshwater algae *Scenedesmus obliquus*. The findings indicated that greater concentrations of microplastics were leached away as shear forces increased from 100 to 400 rpm. Ecotoxicity results showed that a concentration-dependent decrease in cell viability, photosynthetic yield, and electron transport rate was observed in the algal species. This was accompanied by increased oxidative stress markers such as reactive oxygen species (ROS) and lipid peroxidation (LPO). There was also a significant rise in antioxidant enzymes such as superoxide dismutase (SOD) and catalase (CAT) in the algal cells. Furthermore, morphological changes like cell aggregation and cell deformity were ascertained by Scanning electron microscopy. Our findings show that surgical face masks emitting microplastics represent a significant environmental threat. Additional research involving various freshwater species is necessary to evaluate the ecological consequences of the leachates from masks.

3.22.P-Tu353 Transcriptomic Alteration of Mytilus galloprovincialis Exposed to Virgin and Marine Incubated Microparticles Made of Biodegradable and Conventional Polymers

***Giacomo Limonta**[1], Cristina Panti[1], Maria Cristina Fossi[1], Francesco Nardi[2] and Matteo Baini[1], (1)Department of Physical Sciences, Earth and Environment, University of Siena, Italy, (2)Department of Life Sciences, University of Siena, Italy*

Biopolymers have been proposed as an alternative to conventional plastics to mitigate the impact of plastic litter, but their use in marine environments has raised concerns, especially regarding the potential toxicity to marine life. This study evaluates the potential ecotoxicological effects of both virgin and marine-incubated microparticles (MPs), at relevant environmental concentration (0.1 mg/l), made by different biodegradables polymers (Polycaprolactone, Mater-Bi, cellulose) and conventional polymers (Polyethylene) on *Mytilus galloprovincialis* by using a transcriptomic approach. Whole hepatopancreas *de novo* transcriptome sequencing was performed, individuating 972 genes differentially expressed across experimental groups compared to the control. Overall, through the comparative transcriptomic profiling, emerges that the preponderant effect is attributable to the marine incubation of MPs, especially for incubated polycaprolactone MPs (731 DEGs). These findings highlight the necessity of considering the interactions of MPs with the environmental factors in the marine ecosystem, rather than restrict the ecotoxicological evaluations to virgin material only. All microparticles, regardless of their polymeric composition, dysregulated innate immunity, and fatty acid metabolism biological processes. The results obtained contribute to fill current knowledge gaps regarding the potential environmental impacts of biopolymers and represent a first indication that some bio-based biodegradable polymers may constitute a promising alternative to conventional plastics.

3.22.P-Tu354 Mechanistic Assessment of Cellular Responses to Micro- and Nanoplastic Particles (Aged Polyethylene Terephthalate) in Bivalve Hemocytes (Mytilus edulis)

***Jenevieve Hara**[1,2], Maaike Vercauteren, PhD[3], Colin Janssen[4], Ronny Blust[5], Jana Asselman[4] and Raewyn M. Town[5], (1)ECOSPHERE, Department of Biology, University of Antwerp, Belgium, (2)GhenToxLab, Department of Animal Sciences and Aquatic Ecology, Ghent University (UGent), Belgium, (3)Ghent University (UGent), Belgium, (4)Blue Growth Research Lab, Ghent University (UGent), Belgium, (5)ECOSPHERE, University of Antwerpen, Belgium*

Invertebrate immune cells, particularly hemocytes of bivalve mollusks, play a crucial role in cell-mediated immunity and are valuable models for investigating particle-induced responses. Different subpopulations of hemocytes, such as hyalinocytes and granulocytes, exhibit distinct morphological and functional characteristics, including internal cell signaling pathways that regulate various cellular processes. While there is a growing body of research documenting various biological responses to plastic particle exposure, systematic analyses of effect endpoints at the cellular level remain limited. Hence, this research focuses on assessing the mechanistic interactions of micro- and nanoplastic particles (MPs/NPs) within cellular environments and their influence on the functionality of bivalve hemocytes (*Mytilus edulis*). Two different size ranges of aged polyethylene terephthalate (APET) micro- and nanoplastic particles were utilized: APET MPs (D_{50} = 1.4 µm and D_{90} = 3.1 µm) and APET NPs (D_{50} = 0.57 µm and D_{90} = 1.1 µm). In-vitro experiments were carried out using environmentally relevant concentrations, including low concentration (10 particles/mL), mid concentration (10^3 particles/mL), and high concentration (10^5 particles/mL). A Single Particle Extinction and Scattering (SPES) technique was employed to determine the size distribution and concentration of the particle stock suspension. Prior to the exposure experiments, a secondary characterization of the aged PET was conducted to ensure the stability of the particles under conditions adopted for the in-vitro exposure experiments using Dynamic Light Scattering (DLS). To evaluate the underlying mechanisms induced by plastic exposure at the cellular level, an in-depth assessment was carried out for a series of functional assays using flow cytometry, including cellular viability/mortality, oxidative activity, and lysosome stability. The responses of the hemocyte subpopulations, specifically granulocytes and hyalinocytes were assessed at various time points in-vitro (6 hr, 12 hr, 24 hr, and 48 hr). Differential responses between immune cell types were observed, in particular, lysosome destabilization was evident in the group exposed to the nano-size range plastic particles. The experimental results offer insights into the dose-response relationships for plastic particles at the cellular level.

3.22.P-Tu355 Toxicity of a Multi-Polymer Microplastic Mixture on Mytilus edulis

Tania Gomes[1], *Maria Elisabetta Michelangeli*[2], *Ana Catarina Almeida*[2], *Maria T. Hultman*[2], *Samantha Eslava Martins, PhD*[1], *Emelie Forsman*[2], *Lisbet Sorensen*[3], *Stefania Piarulli*[3], *Veslemøy Navrestad*[4], *Amy Lusher*[2] *and Alessio Gomiero*[4], *(1)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (2)Norwegian Institute for Water Research (NIVA), Norway, (3)SINTEF Ocean, Norway, (4)Norwegian Research Centre (NORCE), Norway*

Microplastic (MP) pollution in marine environments is a topic of emerging concern. Due to their ubiquity and small size, plastic particles are easily taken up by marine organisms, causing adverse biological responses. Research so far has focused primarily on the impacts on organisms by pristine test materials that are often spherical and single polymer made. However, plastics found in the environment are mainly a mixture of different polymers with varying sizes and shapes, which raises questions about their combined impacts in marine organisms. Mussels *Mytilus sp.* are widely acknowledged bioindicators in ecotoxicological and biomonitoring studies for evaluating the health status of aquatic ecosystems, mostly due to their wide distribution, filter-feeding ability, sessile behavior, and ecological and commercial importance. Accordingly, the main objective of this study was to investigate the accumulation and toxicity of a MP mixture of relevant polymers (polypropylene, polyamide and polyethylene, <200 µm) at three concentrations (0.1 mg/L, 1 mg/L and 10 mg/L) in the mussel *Mytilus edulis* over a three-week exposure experiment (14 days exposure and 7 days depuration). A battery of cellular, biochemical and physiological indices of stress (biomarkers) was subsequently determined at different time points, including micronuclei formation, DNA damage, acetylcholinesterase activity, antioxidant enzymes activity, lipid peroxidation, cellular energy allocation, histochemistry and digestive enzymes. The occurrence of the MP mix in mussel tissues was also quantified. Analyses are ongoing, but it is envisioned that the results obtained will contribute to understanding the interactions between different polymers in the environment and their potential toxic effects in organisms. Overall, this study will help assessing the toxicity thresholds, as well as establishing baseline hazard knowledge for a MP mixture of environmentally relevant polymers and support future hazard and risk assessment of MPs in Norwegian ecosystems. This work was supported by the MicroOPT Project funded by the Norwegian Retailers Association – Handelens Miljøfond.

3.22.P-Tu356 Occurrence and metabolic effects of micro - nanoplastics (MNP) in blue mussels from Isle of Cumbrae, Scotland

Nur Azeyanti Norhashim[1], *Daniel Ripley Mr*[2], *Holly A. Shiels*[1], *Badiozaman Bin Sulaiman*[3], *Cyrill Bussy*[4] *and Ian Kane*[5], *(1)Division of Cardiovascular Sciences, Faculty of Biology Medicine and Health, University of Manchester, United Kingdom, (2)Daniel M. Ripley, United Arab Emirates, (3)University of Manchester, United Kingdom, (4)Division of Immunology, Immunity to Infection and Respiratory Medicine, School of Biological Sciences, University of Manchester, United Kingdom, (5)School of Earth and Environmental Sciences, University of Manchester, United Kingdom*

Microplastics (MP) are prevalent in the marine environment. Microplastics (MP) are defined as synthetic polymers less than 5 mm. They have different shapes and forms, such as fibres, spheres, fragments or films and can breakdown into smaller particles known as nanoplastics (NP). MNP have been detected in many marine species. Bivalves are often used to study MNP pollution in the sea as they uptake MNPs from the environment during filter feeding. However, data regarding the accumulation of MNPs in wild bivalves and their impact on whole organismal physiology are still limited. To better understand the metabolic impacts of various types and forms of MNPs, this study measured the oxygen consumption (MO_2) of depurated wild blue mussels (*Mytilus edulis*) from the Island of Cumbrae, Scotland, a hotspot for MP pollution, in the presence and absence of controlled 7-day MNP exposure. Mussels were exposed to 100nm polystyrene (PS) beads at a low (3.64×10^6 L^{-1}) and high concentrations (3.64×10^{13} L^{-1}); to 1 µm PS beads at 4.55×10^6 L^{-1} and to polyester (PES) fibres (1.1×10^4 mL^{-1}). Oxygen consumption was measured using stop-flow respirometry and standard metabolic rate, maximum metabolic rate, and aerobic scope were assessed before and after MNP exposure. We found no impact of MNP exposure metabolic rate under any condition (Before exposure Aerobic Scope; Mean (± SEM) 35.2 ± 3.2, n = 68) and after exposure 37.3 ± 3.2, n = 68) (mg O_2 $Kg^{-1}hr^{-1}$) (two-way repeated measures ANOVA, p = 0.3117). A second aim was to assess MP accumulation in the tissues of mussel from both the controlled exposure that which occurred in the wild and was not eliminated via depuration. We found environmental microplastics in all organs with an average (± s.d) of 16.2 ± 31.5 (n=88) env-MP g^{-1} of tissues with fibres being the majority 19.4 ± 34.9 (n=88) env-MP g^{-1}. Mean (± s.d) tissue specific levels were not significantly different (one-way ANOVA, p = 0.088); digestive gland (10.3 ± 11.5, n=23), mantle (7.6 ± 8.8, n = 22), gonad (28.8 ± 38.7, n=25) and gill (16.4 ± 17.6, n=26). We conclude that 7-day exposure to MNP's does not impact the metabolism in this species. The ubiquitous presence of MNP from the environment in the tissue prior to collection from the wild may negate any impact of additional MNP burden on metabolism.

3.22.P-Tu357 Assessing the toxicity of a multi-polymer and multi-size microplastic mixture on early life stages of Atlantic cod (Gadus morhua)

Stefania Piarulli[1], *Julia Farkas*[1], *Tuva Nordby Falkenhaug*[2], *Lisbet Sorensen*[1], *Christelle Denonville*[3], *Bettie Cormier, Tania Gomes*[5], *Matthew Cole*[6], *Andy Booth, PhD*[1], *Bjørn Henrik Hansen*[1] *and Alessio Gomiero*[7], *(1)SINTEF Ocean, Norway, (2)NTNU, Norway, (3)SINTEF Industry, Norway, (4)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (5)Plymouth Marine Laboratory, United Kingdom, (6)Norwegian Research Centre (NORCE), Norway*

Despite the research attention that the topic of microplastic (MP) toxicity has received in recent years, knowledge remains limited on the impacts of MPs on organisms at higher levels of biological organisation. To date, research has mainly focused on the effects caused by single polymer materials and by spherical particles with a definite size. However, MPs found in the environment are comprised of a complex mixture of different polymers, with different densities and a continuum of particles shapes and sizes, which raises concerns about their cumulative impacts in marine organisms. From an economic and ecological perspective, Atlantic cod (*Gadus morhua*) is a key benthopelagic species for many countries, including Norway. Assessing the impacts of MP exposure to *G. morhua*, particularly on the most sensitive and vulnerable early life stages, is critical for understanding risks related to species and ecosystem health. In this study, we investigate the toxicity of irregular-shaped MP with a broad size distribution (1-200 µm) representing different polymers (PA, PE and PP) on early life stages of *G. morhua*. The different MPs are tested either as individual polymer types or simultaneously as a mixture of different polymers. Each treatment will be tested at three relatively low concentrations 0.1, 1, 10 mg L^{-1} to ensure a more environmentally relevant MP exposure. Differences in the size, shape and chemical composition of particles were verified using different techniques including G3 morphology analysis, two-dimensional gas chromatography mass spectrometry (GCxGC-MS) and pyrolysis GC-MS. A battery of different toxicological endpoints, including survival, hatching success, developmental alterations, will be assessed, as well as other relevant biomarkers such as oxidative stress and DNA damage. The outcomes of this work are expected to help in establishing toxicity thresholds for MP mixtures, in deconvoluting the single-polymer *vs* mixture effects, and in establishing baseline knowledge for supporting the environmental risk assessment of MPs in Norwegian marine ecosystems.

3.22.P-Tu359 ABUNDANCE AND POTENTIAL TOXICOLOGICAL EFFECTS ON PLANTS OF MICROPLASTICS FROM EL GORGUEL BEACH (MURCIA)

Vanessa Aranda Quirós, *Toxicology Laboratory, University of Cadiz, Spain*

One of the environmental problems causing the most concern in recent times is contamination by microplastics, which have been detected in soils, bodies of water (seas, rivers, lakes, and oceans), air, and even in living beings. Determining the level of microplastic contamination in different environmental compartments helps to understand the possible toxic effects that microplastics can have on different organisms.

The beach of El Gorguel (Murcia) is bounded by the Sierra Minera de La Unión and the Sierra Fausilla. This environment is of great ecological importance as a habitat for several species of flora and fauna (e.g. *Sylvia undata*, *Bucanetes githagineus*, *Aquila fasciata*, *Erodium paularense*, *Cheirolophus massonianus*, *Tetraclinis articulata*) catalogued with different degrees of vulnerability according to the IUCN Red List, as well as being home to endemic species (e.g. *Teucrium carthaginensis*, *Limonium carthaginensis*).

For this reason, it belongs to the Natura 2000 Network and has been declared a Site of Community Importance (SCI) and a Special Protection Area for Birds (SPA). However, mining activity has caused this area to be heavily contaminated by heavy metals, but it is also affected by emerging pollutants, such as plastics. Due to the possible interactions that can occur between these pollutants and how they can damage biodiversity, the aim of this work was to determine the presence of plastics on the beach of El Gorguel, as well as their possible toxic effects on the model species: *Solanum lycopersicum* and *Allium cepa*. To this end, the effects caused by exposure to microplastics from plastic plugs found on the beach, as well as leachates from these, on the germination and growth of *Solanum lycopersicum* and *Allium cepa* were evaluated.

The concentrations of microplastics and their leachates used in the tests were selected from the microplastic abundance data found on the beach under study. After 14 days of exposure, the results were analysed. In the case of germination, no significant differences were observed between the control and the different concentrations of the contaminants in either of the two species studied. While elongation of both species was altered by the presence of microplastics, significant differences were observed between the control and some of the higher concentrations of the contaminant. *Allium cepa* was more sensitive to microplastic exposure than S*olanum lycopersicon*.

3.22.P-Tu360 Polystyrene and Polyethylene Terephthalate Microplastics Alter Bioaccumulation and Toxicity of Cadmium in the Polychaete, Perinereis aibuhitensis

***Yi Cong*[1], *Yisong Jiang*[2], *Yadi Lou*[1], *Ying Wang*[1], *Mingxing Zhang*[1], *Zhaochuan Li*[1], *Fei Jin*[1] *and Juying Wang*[1], *(1)National Marine Environmental Monitoring Center, China, (2)Dalian Ocean University, China*

Heavy metal (HM) pollution in the marine environment has been of concern for decades. The potential impact of HMs carried by emerging marine pollutants such as microplastics (MPs) has attracted attention only in recent years. Sediment is potentially one of the biggest pools of HMs and MPs after their interaction and sedimentation. Nevertheless, the combined effects of HMs and MPs to the benthic infauna in marine environment has received little attention yet. In this study, we select sediment-dwelling ragworm, *Perinereis aibuhitensis*, as model organism to investigate (1) the influences of two types of MPs (polystyrene, PS and polyethylene terephthalate, PET) on the cadmium (Cd) bioaccumulation in worms; (2) the single and combined chronic toxic effects of Cd with PS microspheres or PET microfibers on worms. Our results showed that Cd bioaccumulation was significantly higher with the coexistence of PS than those of Cd alone at the medium (Cd_M) and high (Cd_H) exposure groups. Subcellular fractionation result showed that for the low Cd exposure group (Cd_L), the presence of PET microfibers resulted in Cd proportion in subcellular fractions decreasing from 91.0% to 71.5% in the biologically detoxified metal (BDM) fraction, and increasing from 8.6% to 20.0% and from 8.7% to 20.4% in the metal-sensitive fractions (MSF) fraction and trophically available metal (TAM) fraction, respectively. This indicates that the coexistence of PET contributes to the increase of cell damage and the decrease of cellular detoxification capacity, as well as the increasing bioavailability of Cd through trophic level. In addition, the alteration of Cd proportion in different subcellular fractions by the PET is Cd concentration-related, as the reverse phenomenon was observed in the Cd_M group with the presence of PET. Chronic toxicity results demonstrated that Cd_L alone significantly decreased the burrowing time of *P. aibuhitensis* in sediment. The presence of PS mitigated the hormetic effect of Cd on worm burrowing behaviour, and this influence was also Cd concentration-related.

Histopathological analyses demonstrated a trend of epidermal and intestinal damages for Cd alone and their co-exposure group with PS or PET. Overall, our results indicate that the bioavailability and toxic effects of Cd could be altered with the presence of PS or PET for *P. aibuhitensis,* which provide new insight for joint ecological risk assessment of legacy and emerging contaminants in coastal environment.

3.22.P-Tu361 Ecotoxicological characterization of plastics from four Po River tributaries (Northern Italy)

Riccardo Sbarberi[1], *Stefano Magni*[1], *Angela Boggero*[2], *Camilla Della Torre*[1], *Lara Nigro*[1], *Benedetta Ponti*[3], *Erica Tediosi*[3], *Maria Chiara Neri*[3] *and Andrea Binelli*[1], *(1)Biosciences, University of Milan, Italy, (2)National Research Council-Water Research Institute (CNR-IRSA), Italy, (3)ChemService s.r.l., Italy*

The demand of plastics follows a positive trend worldwide, resulting in an increase of plastic production from 365 million tons in 2018 to 391 in 2021. Consequently, a continuous release of these synthetic materials in both marine and freshwater environments is documented. Nonetheless, the effects of plastics to freshwater benthic organisms are poorly studied. Therefore, the aim of this study was to assess the effects of "environmental plastics" collected from four Po tributaries as Ticino, Adda, Oglio and Mincio Rivers (Northern Italy) using *Chironomus riparius* as biological model. Samplings were performed in June 2022 collecting floating plastics with plankton nets (100 µm mesh), and sediments with a Van Veen grab. After plastic extraction by collected samples, the obtained particles were quantified and characterized (shape, size, colour and polymer composition) through the Fourier Transform Infrared Microscope System (µFT-IR). The main results of monitoring campaigns showed a higher contamination of sediments compared to water for all considered rivers, with significant differences ($p < 0.05$) between water and sediments of Adda and Oglio Rivers. We observed a domestic contamination, due to polyester fibers, in water and sediments of Ticino and Adda, and in sediments of Oglio River only, while an industrial pollution, due to polystyrene pellets, was observed in both water and sediments of Mincio and in Oglio River water. Concerning the effect evaluation (chronic toxicity), the characterized particles were used in the exposure of specimens of *Chironomus riparius* following the guideline of Organisation for Economic Cooperation and Development (OECD) number 233. Moreover, a biomarker suite represented by endpoints of cellular stress and neurotoxicity was applied. In addition, we performed the same ecotoxicological tests also using polystyrene beads of 1 µm to compare the toxicity of these standards to those induced by "environmental plastics".

3.22.P-Tu362 Ecotoxicity assessment of hydrophobically-modified and non-modified cationic cellulose originated from Acacia wood

Solange Magalhães[1], *Cátia Venâncio*[2], ***Isabel Lopes***[3], *Luis Alves*[1], *Bruno Medronho*[4] *and Maria da Graça Rasteiro*[1], *(1)University of Coimbra, Portugal, (2)Department of Biology, CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (3)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (4)University of Algarve, Portugal*

Cellulose derivatives can be allied tools in the fight against microplastics, encouraging their sedimentation. However, the development of these derivatives requires fine-tuning so that they do not become a strain on the environment. Therefore, this study aimed at physicochemical characterization of these polymers followed by evaluating ecotoxicity of three cationic-modified and one hydrophobically-modified cellulose polymers with different substitution degrees (DS +0.3, +1, +1.8, and DS -1H) in four freshwater trophic level representative species: *Raphidocelis subcapitata* (biomass and growth rate), *Daphnia magna* (mortality), *H. viridissima* (mortality) and *Danio rerio* (mortality, malformation, and heartbeat rate). Suspensions of 0.007%, 0.01%, 0.015%, 0.023%, 0.034%, and 0.051% (w/w), of the cellulose polymers, plus controls, were tested, with 0.01% being the concentration of interest for plastics flocculation. Parallel characterization of the suspensions was also performed. Whenever possible the median lethal and sublethal concentrations (LC_{50} and EC_{50}) were computed.

All polymers were found to be very toxic for *H. viridissima* (100% mortality at all tested concentrations) and *R. subcapitata*. In *R. subcapitata,* all polymers induced high aggregation and sedimentation of the microalgae cells. Considering the results based on *D. magna* and *D. rerio,* the hydrophobically-modified cellulose polymer (DS -1H) was found to be one of the least toxic polymers for the former and most toxic for the later species. All cationic-modified polymers induced toxicity to *D. magna* in the same order of magnitude (0.022% < LC_{50} < and 0.024%), whilst for *D. rerio* the toxicity ranking of the tested polymers based on mortality was as follows: DS +0.3 < DS +1 < DS +1.8. For cationic polymers with varying substitution degrees, it is hypothesized that low DS impedes complete solubilization in aqueous media, causing interference with biological membranes, whilst high DS leads to strong interaction with the cell wall, potentially causing higher toxicity.

Based on the variety of responses obtained for the four species representing different trophic levels, it is highlighted that the development of eco-friendly methodologies to overcome plastic pollution must be carefully evaluated prior to their marketing, otherwise, they themselves may be a cause for concern in the ecosystems.

3.22.P-Tu363 Biodegradable plastics can mitigate plastic pollution? What marine organisms tell us

Loredana Manfra[1], *Alice Rotini*[1], *Amalia Amato*[2], *Maria Costantini*[3], *Roberta Esposito*[3], *Giovanni Libralato*[4], *Ermelinda Prato*[5], *Gianluca Chiaretti*[6], *Olga Faraponova*[6], *Isabella Parlapiano*[5], *Antonietta Siciliano*[7], *Michela Salamone*[7], *Federica Carraturo*[7], *Thomas Viel*[3], *Luisa Albarano*[7], *Valerio Zupo*[8], *Claudia Sebbio*[9], *Andrea Tornambè*[9] *and Francesca Biandolino*[5], *(1)Italian National Institute for Environmental Protection and Research (ISPRA), Italy, (2)Stazione Zoologica Anton Dohrn, Italy, (3)Stazione Zoologica Anton Dohrn, Department of Ecosustainable Marine Biotechnology, Italy, (4)Department of Biology, University of Naples Federico II, Italy, (5)Institute of Water Research (IRSA) CNR Taranto, Italy, (6)Institute for*

Environmental Protection and Research (ISPRA), Italy, (7)University of Naples Federico II, Italy, (8)Stazione Zoologica Anton Dohrn, Department of Ecosustainable Marine Biotechnology, Ischia Marine Centre, Italy, (9)CN_LAB_ECO, Institute for Environmental Protection and Research (ISPRA), Italy
Environmental pollution caused by plastic is estimated at millions of tons, mostly fragmented into micro- and nano-plastics with major consequences on the environment and for human health. In particular, the marine ecosystem represents a very strong combination of abiotic and biotic factors and a source of food for people too. The sea characteristics differ greatly from the composting, industrial and laboratory conditions for which the plastic polymers were mostly designed. The study of the environmental and human fate and potential toxic effects of micro- and nano-plastics by a multidisciplinary and one health approach (from the environment to humans) is particularly valuable. To evaluate whether the use of biodegradable polymers can mitigate plastic pollution in the marine environment, we assessed the potential ecotoxicity of microplastics, obtained at laboratory scale, from biodegradable and non-biodegradable polymers. The biological response was evaluated on marine organisms with different physiological, behavioural and feeding characteristics: bacteria, algae, rotifers, crustaceans, mussels and sea urchins. Preliminary results highlighted morphological malformations in sea urchin embryos exposed to polylactic acid, which at a molecular level are due to variations in gene expression levels relating to cellular processes such as skeletogenesis, differentiation and development, stress and detoxification response. Investigations are currently underway on the others and an integrated assessment of the ecotoxicological battery will help to establish whether biodegradable polymers are less toxic than non-biodegradable ones.

3.22.P-Tu364 Impacts of polystyrene on growth and nutritional profile of standard freshwater species
Mariana Rodrigues[1,2], Nelson Abrantes[3], Silvia Lomartire[4], Fernando J. M. Gonçalves[5] and ***Ana M. M. Gonçalves***[6], *(1)Department of Biology & CESAM, University of Aveiro, Portugal, (2)University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (3)Department of Biology, University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (4)MARE -Marine and Environmental Sciences Centre, Faculty of Sciences and Technology, University of Coimbra, Italy, (5)University of Aveiro, Portugal, (6)Department of Life Sciences, University of Coimbra, MARE - Marine and Environmental Sciences Centre / ARNET – Aquatic Research Network, Portugal*
The proliferation of plastic waste, including the more recent emergence of microplastics in aquatic systems, has surpassed our ability to manage them effectively. Due to their ubiquity, isolated or combined toxicity, persistence, and high densities, microplastics have become a global concern. Polystyrene stands out as one of the most prevalent polymers in the environment, and as a result, it has been extensively studied in terms of toxicity. However, the impacts of polystyrene on freshwater systems and biochemical parameters (e.g., fatty acids profile) have been overlooked. Fatty acids (FAs) are essential molecules for the maintenance of organisms' physiological functions acting also as bio-indicators of stress conditions. Hence, the aim of this study was to evaluate the effects of 1 µm polystyrene microspheres on the growth, mortality/immobilization and nutritional profile (i.e., FAs) of the four freshwater standard organisms (a microalgae *Raphidocelis subcapitata*, a macrophyte *Lemna minor*, a crustacean *Daphnia magna* and an insect larvae *Chironomus riparius*). Each bioassay included four concentrations of microplastics: 50, 500, 5,000 and 50,000 p L^{-1} – for planktonic species; and 7, 70, 700 and 7,000 p g^{-1} – for benthonic species. Results suggested that microplastics did not affect the mortality/immobilization and the growth of the four freshwater organisms. In fact, when exposed to polystyrene the microalgae growth was even stimulated. Ongoing analysis of fatty acid abundance and composition will provide further insights. We anticipate that our study will shed light on the complex interactions between polystyrene microplastics and freshwater organisms, emphasizing the need for a comprehensive understanding of their implications at a sub-individual level.

3.22.P-Tu365 Fate and effects of an environmental realistic mixture of microplastics in freshwater microcosms
Sara Martínez-Pérez[1], *Theresa Schell[1], Daniel Franco[1], Paula E. Redondo[1], Virtudes Martinez-Hernandez[1] and Andreu Rico[1,2], (1)IMDEA Water Institute, Spain, (2)Cavanilles Insititute of Biodiversity and Evolutionary Biology, University of Valencia, Spain*
The majority of studies assessing the effects of microplastics (MPs) in freshwater ecosystems have been performed using reference materials of a certain size, shape and polymer type. In order to improve realism in the aquatic risk assessment of MPs, experiments should characterize the actual exposure pattern of environmentally realistic mixtures of MPs in water and sediment compartments. The aims of this study were (1) to determine the aquatic fate and the water-sediment fluxes of a MP mixture with different shapes and polymers, (2) to characterize the internal concentration of the MPs in two invertebrate species with different biological traits, and (3) to assess their long-term effects on lethal and sub-lethal endpoints. The MP mixture was selected based on the most common polymers ((high density polyethylene (HDPE), polypropylene (PP) and polyester (PES)) and shapes (fragments and fibres) found in freshwater ecosystems with a particle size range between 36 and 3887 µm. The test species were *Lymnea stagnails* and *Lumbriculus variegatus*. Four MP concentrations were tested ranging from 0.1 to 10 g/kg of sediment. MP ingestion and size as well as mortality, reproduction, and weight or length were assessed in both species to determine No-Observed Effect Concentrations (NOECs). Additionally, samples of the surface water, column water and sediment were collected after a stabilization period and after the chronic test to assess concentrations in each compartment and water-sediment fluxes. Most MPs were retained in the sediment and fluxes of MPs occurred from the floating phase to the sediment, reducing the percentage of total MPs in the floating phase from 3.3% to 0.3% and increasing in the sediment from 96% up to 99%. Uptake showed that ingested PES fibres and PP fragments had a significantly smaller size than the initial mixture. Both species ingested mostly MPs fragments below 250 µm and fibres below 500 µm. Significant reductions were found for shell length and number of egg clutches of *L. stagnails* with a NOEC of 0.5 g/kg and 1 g/kg, respectively. A significant reduction was also found in the number of alive adults of *L. variegatus* with a NOEC of 0.1 g/kg.

These concentrations are found in freshwater sediments in some industrial and urban areas; therefore, this study suggests that realistic concentrations can pose a risk to pelagic and benthic species in freshwater ecosystems.

3.22.P-Tu366 Sediment Matters as a Route of Microplastic Exposure: A Call for More Research on the Benthic Compartment

Monica Hamann Sandgaard[1], *Annemette Palmqvist*[2], *Agathe Bour*[3], *Sara Nicoline Grønlund*[3], *Asta Hooge Poulsen*[4], *Henriette Selck*[3], *Amalie Thit Bruus Jensen*[5] *and Kristian Syberg*[3], *(1)Department of Science and Environment, Roskilde University (RUC), Denmark, (2)Dept. of Science and Environment, Roskilde University (RUC), Denmark, (3)Roskilde University (RUC), Denmark, (4)Science and Environment, Roskilde University (RUC), Denmark, (5)DHI group, Denmark*

Microplastics (MPs) are ubiquitous in marine environments. Here, most MPs are expected to sink and accumulate in the sediment owing to factors like the density of the MP polymer and various environmental processes, such as biofouling and fecal pellet packaging. However, a discrepancy emerges between the expected accumulation of MPs in the sediment and the focus of most MP effect studies, which typically involve pelagic species and employ water-only exposures. To quantify this critical knowledge gap, we conducted a systematic literature search to address pivotal aspects of MP pollution in marine environments, specifically linking ingestion and adverse effects of sediment-associated MPs on benthic invertebrates at various levels of biological organization. An extensive literature search was conducted using various keyword combinations such as "microplastic," "plastic microparticles," or "microfibers" combined with "toxicity," "effect," "impact," or "ecotoxicity," and further associated with "sediment" or "benthic." Specifically, we exclusively included articles that investigated exposure through sediment, (*i.e.*, sediment-associated MP exposure). Studies concentrating solely on ingestion, disregarding associated effects, and those where contaminants were linked to the exposure were systematically excluded from the analysis. The analysis identified 10 effect studies that involved MP exposure via sediment, with the majority concentrating on sub-organismal and organismal effects. Consequently, there is a notable lack of studies that specifically address the effects on benthic invertebrates and those exploring impacts at higher levels of biological organization. To achieve a thorough understanding of the consequences of MPs in marine ecosystems, it is crucial to conduct additional research. Recommended strategies to guide and organize this research include emphasizing the significance of sediment as a pathway for MP exposure, conducting studies with environmentally realistic exposure concentrations and durations to capture potential long-term effects, and focusing on the impacts of MPs at the population and community levels to achieve a comprehensive understanding of their ecological implications in marine ecosystems. Implementing these recommendations will advance our understanding of MP pollution and its implications.

3.22.P-Tu367 Multilevel biological responses of Daphnia magna exposed to nano-size engineered polystyrene and polyvinyl chloride plastics

Andrea Masseroni[1], *Marco Fossati*[2], *Jessica Ponti*[3], *Gabriella Schirinzi*[4], *Lorenzo Federico*[5], *Alessandro Becchi*[6], *Francesco Saliu*[7], *Maddalena Collini*[6], *Camilla Della Torre*[8] *and Sara Villa*[9], *(1)Department of Earth and Environmental Sciences, University of Milan, Milan, Italy, (2)Ambiente e Salute, Istituto Mario Negri, Italy, (3)European Commission - Joint Research Center (JRC), Italy, (4)Joint Research Centre (JRC) - European Commission, Italy, (5)Applied Science And Technology (DISAT), Department of Applied Science And Technology (DISAT), Italy, (6)University of Milano-Bicocca, Italy, (7)University degli Studi di Milano Bicocca, Italy, (8)Biosciences, University of Milan, Italy, (9)Dept Earth and Environmental Sciences, University of Milano-Bicocca, Italy*

A growing number of studies have reported the toxic effects of nanoplastics (NPs) on organisms. However, the focus of these studies has almost exclusively been on the use of polystyrene (PS) nanospheres, while the effect evaluation of other polymers, even more present in the market, is still unexplored.

The present study aims to determine if different NP polymers exhibit comparable toxicity, through the evaluation of the sublethal effects on *Daphnia magna* of two different NP polymers: PS with an average size of 200 nm, and polyvinyl chloride (PVC) with a comparable mean size distribution between 50 and 350 nm. The occurrence of adverse effects at different biological levels, induced by both short-term and long-term exposure, has been assessed. Five environmentally relevant concentrations, from 2.5 to 250 µg/L, were tested for each polymer for an exposure time of 48 h. Additionally, a concentration of 10 µg/L was tested for a longer period of 21 days. After the short exposure of 48 h, NP effects were assessed at the biochemical level by investigating the amount of reactive oxygen species and the activity of the antioxidant enzyme catalase, and at the individual level by evaluating the swimming behavior. We have further investigated the potential role of the NP polymer in the onset of morphological, physiological, survival, reproductive, and behavioral alterations after 21 days of exposure.

The results of the short exposure show that PVC-NPs, in contrast to PS-NPs, can pose sublethal effects on *Daphnia magna* both at the biochemical and individual levels, while those of the long exposure reveal that PVC-NPs can lead to an increase in both the molting behavior and body size of the exposed individuals. Moreover, PVC-NPs affect the reproduction of *Daphnia magna*, causing a retard on the day of the first brood and a general decrease in the number of broods and offspring.

Our research suggests that during both the exposure periods PVC-NPS, in contrast to PS-NPs, can pose sublethal effects on *Daphnia magna*. The role of particle size on the observed impacts cannot be disregarded, given that PVC-NPs exhibited a wider size range than PS-NPs, spanning from 50 to 350 nm. Despite this, it is essential to consider the chemical composition of the plastic polymers in addition to particle size. Since PVC appears to be more hazardous than PS, we therefore suggest continuing to explore the role of the polymer type in the onset of NP hazard.

3.22.P-Tu368 Impact of Weathered and Virgin Polyethylene Terephthalate Nanoplastics on Growth Dynamics and the Production of Extracellular Polymeric Substance (EPS) by Marine Algae

***Marie Roos Sioen**[1], Jana Asselman[2], Maaike Vercauteren, PhD[3], Colin Janssen[2], Raewyn M. Town[4] and Ronny Blust[4], (1)Laboratory of Environmental Toxicology and Aquatic Ecology - GhEnToxLab, Ghent University (UGent), Belgium, (2)Blue Growth Research Lab, Ghent University (UGent), Belgium, (3)Ghent University (UGent), Belgium, (4)ECOSPHERE, University of Antwerpen, Belgium*

In context of the ever-increasing plastic waste accumulation in the marine environment, it is important to understand the interaction between microalgae and nanoplastics (NP), and the role of extracellular polymeric substances (EPS) within this. EPS production is a known algal stress response, and its adhesive properties may induce aggregation of both algae themselves and particles, which in turn may affect ecological and hydrodynamic processes such as trophic transfer of nanoplastics or the vertical transport. Here, the impact of fragmented, polydisperse virgin polyethylene terephthalate (PET, $D_{average}$ = 1400 nm) and weathered polyethylene terephthalate (PET, $D_{average}$ = 680 nm) on algae growth and the production of EPS was studied by exposing the marine microalgae *Rhodomonas salina* to low NP concentrations (10, 100 and 1000 and 10000 NPs ml^{-1}) for 12 days. A positive control with kaolin was included to detangle particle effects from plastic effects. Baranyi parametric growth-models were fit to the data to analyze growth-dynamics. Exposure to weathered PET, virgin PET and kaolin resulted in an initial increased growth rate, followed by significant decreases in algae population density. At low concentrations, the effect was independent of the particles' nature (natural or anthropogenic) or age (virgin or weathered). At high exposure concentrations, the plastic particles caused significantly higher decreases in population density, and the effects were amplified as the particles weathered. The effects on growth of weathered PET were combined with significant increases in cellular EPS production. This suggests that algae exhibit an increase in EPS-production as a stress response. This raises questions about the toxicity mechanisms of NPs in low concentrations, and hints towards the role of EPS production as a defence mechanism, which changes the energy budgets, with less energy allocated to growth. This study underscored the intricate interactions between particle types, age and concentrations, and their distinct impacts on algae density, growth inhibition and EPS production.

3.22.P-Tu369 Impact of secondary biodegradable nanoplastics on the freshwater microalga Chlamydomonas reinhardtii

***Silvia Gómez-Kong**[1], Miguel Tamayo-Belda[1], Gerardo Pulido-Reyes[2], Carlos Edo[3], Irene Verdu-Fillola[4], Francisco Leganés[5], Roberto Rosal[3], Miguel González-Pleiter[5] and Francisca Fernández-Piñas[5], (1)University of Madrid (UAM), Spain, (2)Department of Environment and Agronomy, Institute for Agricultural and Food Research and Technology, Spanish National Research Council (INIA-CSIC), Spain, (3)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain, (4)Biology, University of Madrid (UAM), Spain, (5)Biology, Autonomous University of Madrid (UAM), Spain*

During the last years, there has been a transition from conventional plastics to biodegradable alternatives. Although many works have been published about the ecotoxicological effects of conventional and primary microplastics and nanoplastics (NPs), limited knowledge exists regarding the impacts of biodegradable plastics, and the secondary NPs formed by their fragmentation. This study focuses on elucidating the toxicological effects of secondary NPs obtained from PBAT (Polybutylene adipate co-terephthalate), a biodegradable plastic commonly used in agriculture mulching, on the green microalga *Chlamydomonas reinhardtii*, a key model organism in freshwater ecosystems due to its role as a primary producer. Secondary PBAT nanoplastics (PBAT-NPs) were obtained by mechanical breakdown and photooxidation of pristine PBAT microbeads. For the physicochemical characterization of secondary PBAT-NPs, hydrodynamic size, surface charge, morphological identification, chemical identification, and final concentration were measured and conducted in ultra-pure water using dynamic light scattering (DLS), electrophoretic light scattering (ELS), scanning electron microscope (SEM-EDX), Fourier transform infrared spectroscopy (FTIR) and dry weight, respectively. To investigate the effects of the secondary PBAT-NPs, *C. reinhardtii* was exposed to different concentrations of secondary PBAT-NPs and the following parameters were assessed: cellular growth, photosynthetic pigments contents and fluorescence measurements, photosynthesis, ROS generation, membrane potential, intracellular pH, and metabolic activity measurements. Results showed that secondary PBAT-NPs can heteroaggregate with *C. reinhardtii* and decrease the microalga photosynthesis, trigger ROS overproduction, and cause membrane depolarization. Transcriptomic analyses by RNA-Seq will also be performed. Taken together, this study aims to unravel the underlying mechanisms governing the potential biological impact of secondary biodegradable NPs, evaluating the risk of this novel alternative to conventional plastics in freshwater ecosystems.

3.22.P-Tu370 Influence of Benzo[a]pyrene on the Toxicity of Polystyrene Nanoplastics to Marine Microalgae Isochrysis galbana

***Estefanía Pereira Pinto M.S.**[1], Nagore Gonzalez Soto[2], Miren P. Cajaraville PhD, PhD[3] and Eider Bilbao[2], (1)University of Vigo, Spain, (2)Zoology and Animal Cell Biology, CBET+, PiE, University of the Basque Country UPV/EHU, Spain,*

(3)CBET+ Research Group, Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain
Due to the widespread use of plastics since the 1940s, their annual production continues to rise. Consequently, their release into aquatic environments is also increasing. Once in the environment, plastics can undergo fragmentation into micro (1 µm-1 mm) and nanoplastics (NPs, <1 µm) due to physical, chemical, and biological processes. In addition, NPs can transport environmental pollutants and enhance their bioavailability to organisms. To enable a more comprehensive understanding of the effects of NPs on primary producers and their role as carriers of potentially harmful contaminants, the aim of this study was to determine the toxicity of NPs alone and with the model polycyclic aromatic hydrocarbon benzo[*a*]pyrene (B[*a*]P) on the marine microalgae *Isochrysis galbana*. *I. galbana* cultures were exposed to 0.5 µm polystyrene (PS) NPs (0.0078 µg/L-778 µg/L) or to 50 nm PS NPs (6.86E^{-07}-E^{-01} µg/L) with or without 1 mM B[a]P. These NP concentrations are equal to 1E^{02}-1E^{07} particles/mL. Alterations in microalgae growth (average specific growth rate, ASGR), cell viability and reactive oxygen species (ROS) production were investigated. After 72 h, *I. galbana* exposed to 50 nm NPs exhibited no significant changes in growth. In contrast, 0.5 µm NPs markedly reduced ASGR across all tested concentrations, except for E^{+07} part/mL. Cell viability was significantly reduced after exposure to most concentrations tested while ROS production was not altered. Though B[a]P alone decreased microalgae growth, co-exposure to NPs and B(a)P did not alter ASGR and viability of microalgae, except at the highest concentrations tested (1E^{06}-1E^{07} particles/mL), which resulted in a significant decrease in both endpoints. These results can be related to the increase in ROS production observed at the highest NPs concentrations tested with B[a]P, while a significant decrease was observed in cells exposed to B[a]P alone. Overall, the combination of B[a]P and NPs exhibited increased toxicity to *I. galbana*, particularly at high NP concentrations, compared to NPs alone. Though further analyses are needed, the results obtained could be explained by the different behavior of NPs in the exposure media, concentrations tested and the presence of B[a]P. Work funded by Spanish MINECO NACE project (CTM2016-81130-R), MICINN FIERA project (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and "ERDF A way of making Europe") and the Basque Government grant to consolidated research groups (IT1743-22).

3.22.P-Tu371 Histopathological Analysis of Mussels Mytilus galloprovincialis after Foodborne Exposure to Three Sizes of Polystyrene Nanoplastics

Tania Ramirez[1], Nagore Gonzalez Soto[1], Tamer Amr Hafez[1], Marisa Sarria Pereira de Passos[2], Eider Bilbao[1], Amaia Orbea PhD[3], Douglas Gilliland[4], Miguel-Ángel Serra[5] and ***Miren P. Cajaraville PhD, PhD***[3]*, (1)Zoology and Animal Cell Biology, CBET+, PiE, University of the Basque Country UPV/EHU, Spain, (2)European Commission - Joint Research Centre (JRC), Belgium, (3)CBET+ Research Group, Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain, (4)European Commission - Joint Research Centre (JRC), Italy, (5)European Commission - Joint Research Center (JRC), Italy*
Given the widespread occurrence of polystyrene (PS) micro and nanoplastics in the marine environment, it is important to determine their potential adverse effects on representative sentinel marine species as mussels. Foodborne exposure is more environmentally realistic than waterborne exposure in mussels but it has received less attention. The aim of this work was to assess the histopathological effects of foodborne exposure to PS NPs of different sizes on marine mussels, focusing on inflammatory reactions involving hemocytes, since MPs and NPs have been reported to produce inflammatory responses. Mussels *Mytilus galloprovincialis* were dietarily exposed through algae *Isochysis galbana* to PS NPs of 50, 200 and 1000 nm at nominal low (10^3 NPs/mL) and high concentration (HD) (10^8 NPs/mL for 50 and 200 nm NPs and10^6 NPs/mL for 1000 nm NPs). Exposures took place for 7 days in duplicate and two independent experiments were carried out per NP (E1 & E4 for 50 nm, E2 & E5 for 200 nm and E3 & E6 for 1000 nm PS NPs). All exposures were developed along 3 weeks in September-October 2022 (E1&E2, E3&E4 and E5&E6), in order to minimize the influence of season on studied parameters. High prevalences of hemocytic infiltration, fibrosis and atrophy of the digestive tubule epithelium were detected in the digestive gland. However, these could not be related to the foodborne exposure to NPs because no significant differences were found between exposed and control mussels. Observed alterations could be due to the presence of parasites and/or to the stage of gametogenic development, since mussels were mainly in advanced gametogenesis in E1&E2, spawning in E3&E4 and mature in E5&E6. In the gonad, prevalences of the different alterations were generally lower than in the digestive gland and they could not be related to NPs exposure either. In conclusion, the reproductive status appeared to contribute more to observed alterations than PS NP exposure. It remains to be determined whether longer term exposures could result in more severe histopathological alterations, independent of the physiological condition. Further work is required on environmentally realistic NPs that might pose additional risks compared to pristine ones. *Work funded by the EC CAS NANOPLASTICS project (DG JRC), the Spanish MICINN FIERA project (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and "ERDF A way of making Europe") and the Basque Government grant to consolidated research groups (IT1743-22).

3.22.P-Tu372 Microplastics in Pelagic Fish and Surface Water from the St. Lawrence River and Estuary, Canada

Elisa Michon[1]*, A H M Enamul Kabir[2], Magali Houde[3], Marc Mingelbier[4], Youssouf D. Soubaneh[5], Jennifer F Provencher[6], Huixiang Xie[2], Dominique Robert[7] and Zhe Lu[2], (1)University of Quebec at Rimouski (UQAR), Canada, (2)Institut des Sciences de la Mer de Rimouski (ISMER), University of Quebec at Rimouski (UQAR), Canada, (3)Environment and Climate Change Canada, Canada, (4)Ministère de l'Environnement, de la lutte contre les changements climatiques, de la Faune et des Parcs, Canada, (5)Département de Biologie, Chimie et Géographie, University of Quebec at Rimouski (UQAR), Canada, (6)Ecotoxicology and Wildlife Health Division, Environment and Climate Change Canada, Canada, (7)Institut des Sciences de la Mer de Rimouski, Université du Québec à Rimouski, Canada*

In Canada, the St. Lawrence River and Estuary form an important aquatic system that links the Great Lakes to the Atlantic Ocean and is a vector of emerging contaminants from the land to the ocean. Very limited information is available on microplastics (MPs) contamination in this system, particularly for pelagic fish. To determine the risks that MPs may pose to wildlife and the ecosystem, it is crucial to examine their distribution and fate in the environment. This study aims to investigate the exposure and tissue distribution of MPs in pelagic fish of ecological and economic importance from the upper St. Lawrence River to the fluvial estuary area. For the upper St. Lawrence River, northern pike (*Esox lucius*) (n=40) and its potential prey, the yellow perch (*Perca flavescens*) (n=10), as well as surface water (n=14) were sampled upstream and downstream of Montreal's primary wastewater treatment plant (WWTP). For the freshwater portion of the estuary, walleye (*Sander vitreus*) (n=30), and its potential prey rainbow smelt (*Osmerus mordax*) (n=15) and white perch (*Morone americana*) (n=10), as well as surface water (n=9) were sampled around Québec City. The analysis of MPs was conducted in the gastrointestinal tract (GIT) and the gills of these fish species to elucidate both active and passive ingestion of MPs. Preliminary results showed that the abundance of MPs in northern pike was 1.59±0.37 (mean number of particles ± SE) in GIT and 2.71±0.42 in gills, which was not significantly different from yellow perch (1.0±0.37 in GIT and 0.67±0.22 in gills). The higher number of MPs in gills of pike suggests greater passive ingestion of MPs. The size of MPs was in the range 640 to 1310 µm for the analyzed fish samples. Fiber was the dominant shape of the observed MPs in fish, followed by fragments. The most common color of MPs in fish was blue followed by black. In addition, the abundance of MPs in the samples collected downstream of the WWTP was not significantly different from the upstream samples, suggesting that the WWTP is not a significant source of MPs in downstream water and fish around Montreal. Preliminary polymer identification of particles (n=43) using µFTIR indicated the presence of polyethylene, polyester, nylon, cellulose, and rayon in northern pike tissues. Analysis of the samples from the estuary area is in process and preliminary results will be presented in this poster.

3.22.P-Tu373 Combined Ecotoxicity Effects of Nanoplastицts and the Antibiotic Sulphamethoxazole on the Free-Floating Aquatic Plant Lemna major

*Michela Pirredda[1], **Paola Grenni, PhD**[2], Carmen Martin[3], Stefano Amalfitano[4] and Anna Barra Caracciolo[5], (1)Universidad Politécnica de Madrid, Spain, (2)Water Research Institute (IRSA), National Research Council (CNR), Italy, (3)Biotechnology-Plant Biology, Universidad Politécnica de Madrid, Spain, (4)National Research Council of Italy, Italy, (5)National Research Council - Water Research Institute (IRSA-CNR), Italy*

The exponential growth of plastic production and the resulting contamination of all ecosystems are hallmarks of the Anthropocene. Once exposed to environmental factors, the plastic debris gradually degrades into micro- (1 to 5,000 µm) and nano-scaled (< 1 µm) particles. In particular, owing to the large surface area per unit mass, nanoplastics (NPs) show a considerable higher adsorption capacity than the original bulk material, thus acting as vectors for harmful organic contaminants with underestimated ecotoxicological effects on the aquatic biota. The widespread co-occurrence of NPs and pharmaceuticals (including antibiotics), is an urgent issue that requires immediate attention.

The present study focused on the ecotoxicity of polystyrene NPs and the antibiotic sulfamethoxazole (SMX, commonly used for urinary and respiratory infections). Different NPs and SMX concentrations (from 100 to 5 mg/L) alone or in mixture were tested to assess their ecotoxicological effects on *Lemna major* (ISO 20227:2017), a free-floating aquatic plant with well-known contaminant accumulation and purifying capabilities. EC50 values (for each contaminant and for mixture) and chlorophylls content in plants were determined. Flow cytometry was used for NPs quantification and characterization and for assessing microbial cell number in the mineral growth media. Main results showed that a correlation between contaminant concentration and effects were observed. An additive effect of NPs and SMX seems affect plant development, although further studies are in progress.

3.22.P-Tu374 Ecotoxicological impact of secondary nanoplastics from pristine and recycled low density polyethylene plastics

***Gerardo Pulido-Reyes**[1], Silvia Gómez-Kong[2], Miguel Tamayo-Belda[2], Miguel González-Pleiter[3], Francisco Leganés[3], Roberto Rosal[4] and Francisca Fernández-Piñas[3], (1)Department of Environment and Agronomy, Institute for Agricultural and Food Research and Technology, Spanish National Research Council (INIA-CSIC), Spain, (2)University of Madrid (UAM), Spain, (3)Biology, Autonomous University of Madrid (UAM), Spain, (4)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain*

The rise in recycled plastics usage offers a potential solution to reduce the environmental accumulation of plastic waste. However, it is currently unknown whether these plastics generate particles in the nano-range and whether these nanoplastics (but also additives) may trigger a potential threat to the environment. This study focuses on assessing the toxicological effects of secondary nanoplastics derived from both recycled and non-recycled low-density polyethylene (LDPE) plastics on representative organisms in the aquatic ecosystems. Three model organisms were selected: The green microalga *Chlamydomonas reinhardtii*, the freshwater plant *Spirodela polyrhiza*, along with the water flea *Daphnia magna*. Secondary nanoplastics were obtained through mechanical fragmentation of LDPE microplastics. A comprehensive physicochemical characterization has been conducted to verify the presence of secondary nanoplastics in both types of plastics through several techniques such as dynamic and electrophoretic light scattering, scanning electron microscopy and Fourier transform infrared spectroscopy. The three selected organisms were exposed to increasing concentrations of secondary nanoplastics to evaluate the biological effects of secondary nanoplastics and released by-products. Additionally, mechanistic studies will be conducted to assess potential impacts on specific stress pathways. This study contributes to the assessment of potential toxicity associated with recycled plastics, specifically addressing the impact of secondary nanoplastics on aquatic organisms, and enhances our overall understanding of the environmental implications of plastic recycling.

3.22.P-Tu375 Trophic Transfer Of Contaminated And Uncontaminated Microplastics: Regeneration Study Evaluated In Planarian Sp.

Cristian Alexander Veliz-Quezada Sr.[1] *and* ***Gabriela Veronica Aguirre-Martinez***[2]*, (1)Facultad de Ciencias de la Salud, Universidad Arturo Prat, Chile, (2)Facultad Cencias de la salud, Universidad Arturo Prat, Chile*

Microplastics (MPs) are particles (1µm to 5mm size) that can transport and transfer chemicals such as the insecticide chlorpiryfos (CLP) producing adverse effects on biota. However, information on the thropic transfer of contaminated and uncontaminated MPs is scarce in fresh water organisms such as planarian spp. The objevtive of this study was to evaluate throphic transfer, permanence and potential effect of MPs on the regeneration of planarian sp. fed with *Daphnia magna* previusly contaminated with uncontaminated MPs of polyethylene (27-32 µm) and MPs contaminated with CLP. Observations of entire planarian sp. were done using stereomiscroscope, detecting the presence of MPs by fluorescence. After a second feeding, planarians were decapitated. The effect and permanence of MPs in both segments was recorded from day 4 to day 7, and day 21. Presence of uncontaminated and contaminated MPs were detected even up to day 7 post decapitation. Ocelli appeared after 5 days in all treatments except in those planarians fed with daphnias exposed to uncontaminated MPs, in this treatment a delayed generation of ocelli was observed compared to de control. Presenting one ocellus on day 7 post decaptitation, furthermore the second ocellus appeared asymetrically in size and position on day 21. Head regeneration was significantly affected in planarians fed with daphnias exposed to contaminated MPs compared to the control ($p<0,05$). This study demonstrate that MPs can be transfered to planarians through their prey, inducing alterations during the regeneration process. results also shows that uncontaminated MPs can induce adverse effects, probably due to release of contaminants added during manufacturing of the plastic. In adittion, this study indicates that MPs can act as vector of organic pollutants such as CLP. However, more thophic transfer studies are requiered to understand potential adverse effects of MPs on fresh water ecosystem. Thanks to FONDECYT INICIACION N°11180466.

3.22.P-Tu376 Possible trophic transfer of polystyrene microspheres from B. calyciflorus to its predator A. brightwelli

Lasse Rauert*, Guntram Weithoff and Claudia Drago, Ecology and Ecosystem Modelling, University of Potsdam, Germany*

Microplastics (MP) pollution is one of the biggest threats of our ecosystems, both, terrestrial and aquatic systems. Especially in aquatic ecosystems, MP can affect many species, because animals can mistakenly ingest MP as food items. While the potential for ingestion, accumulation, and the effect in selected organisms is well documented, the transfer and biomagnification over multiple trophic levels are less well studied.

Here we studied potential bioaccumulation and biomagnification of microplastics within limnetic zooplankton. Therefore, we used the herbivorous filter feeder *Brachionus calyciflorus* (Rotifera) and its predator *Asplanchna brightwelli* (Rotifera), as a common predator-prey pair. First, we experimentally exposed *B. calyciflorus* to MP (1, 3, and 6 µm in diameter separately) and quantified the time-dependent excretion of MP. Second, we fed the predator with MP-exposed *B. calyciflorus* recorded the prey ingestion and the potential retention of MP.

We found that *B. calyciflorus* excreted more than 60 % of the MP within 30 minutes suggesting limited long-term uptake. When *B. calyciflorus* with MP was fed to *A. brightwelli*, MP was taken up by the predator but almost completely excreted within 24 hours. We found no clear evidence for the long-term retention of spherical MP in our predator-prey system.

3.22.P-Tu377 Characteristics of microplastics ingested by Acartia spp. in two enclosed bay environments of Korea

Dong-Hoon Im[1]*, Minkyu Choi*[1]*, Won Chan Lee*[1]*, Sunggyu Lee*[1] *and Tae-Hoon Kim*[2]*, (1)National Institute of Fisheries Science, Korea, Republic of (South), (2)Faculty of Earth and Environmental Sciences, Chonnam National University, Korea, Republic of (South)*

The ubiquitous presence and persistence of microplastics (MPs) in various environments have been considered a matter of serious concern due to an increasing threat to ecosystems and even human being. Marine copepods have been traditionally considered the interlink between primary producers and higher trophic levels, although recent studies revealed that most zooplankton are usually opportunistic omnivorous feeders as potential consumer of MPs. We investigated the characteristics of MPs ingested by *Acartia* spp. in the Yeoja Bay and Jinhae Bay of the Korea. The numerical and relative abundances of *Acartia* spp. ranged from 122 to 6,710 indivudals (ind.) m^{-3} and from 0.29 to 0.97, respectively. Microplastics consumed by zooplankton ranged 0 to 0.06 particles $ind.^{-1}$ with 70% occurrence rate. Fragments are the most common type of ingested micropalstics that showed the particle size between 0.03 and 0.13 mm. The microplastic abundance consumed by zooplankton ranged from 1.9 to 67.1 particles m^{-3}. This is the preliminary study to understand an important route via which microplastics enter the food web, posing a risk to higher predators and potentially human health. Therefore, microplastic distributions of seawater, zooplankton, and higher trophic organisms should be further analyzed to understand the accumulation pattern of microplastics along food chain.

3.22.P-Tu378 Transfer of Different Size Microplastics Throughout Marine Environmental Compartments and Their Fate in Organisms

Nagore Blasco[1], *Mary Carolin Kurisingal Cleetus*[1], *Philipp Hobmeier*[1], *Urtzi Izagirre*[1], *Manuel Soto*[2] *and Nerea García-Velasco*[1], *(1)Zoology and Animal Cell Biology, University of the Basque Country (UPV/EHU), Spain, (2)Research Center for Experimental Marine Biology Biotechnology "Plentziako Itsas Estazioa", University of the Basque Country (PiE-UPV/EHU), Spain*

Microplastics (MPs) have been documented in all marine environmental compartments and have been identified as a growing hazard to marine biota. This study sought to analyse the effect of size of polystyrene (PS) MP in the transfer among different environmental compartments (biota, water and sediment), and its influence in the accumulation, localization, and depuration dynamics in the target tissues of Mytilus galloprovincialis, Hediste diversicolor, and Palaemon serratus. Organisms were exposed to an experimental microcosm with two different set ups (1) 1/5 treatment with 1 µm MPs spiked in seawater and 5 µm MP spiked in sediment and (2) 5/1 treatment with 5 µm and 1 µm MP spiked in seawater and sediment, respectively. Both compartments were spiked with 1.5×107 total MPs. Organisms went for 5 days exposure and 14 days depuration period, and were then subjected to procedures for both quantitative (alkaline digestion and filtration) and qualitative (cryosectioning) examination under fluorescence microscope. All species accumulated MPs spiked in the water column and sediment irrespective of their habitat, and MPs appeared to transfer vertically by the influence of biota in relation to particle size. Mussels showed a higher accumulation of MPs spiked in the seawater column with a trend of increased the presence for bigger particles. Particles were found in distinct parts of the digestive tract (lumen of the stomach, intestine) and gills of mussels. Mussels effectively eliminated MPs after depuration, with a significant reduction for smaller particles. Polychaetes accumulated a comparable amount of particles that spiked in the water column and sediment regardless of particle size, being these MPs identified predominantly in the hindgut. After depuration, a considerable increase of 5 µm MP spiked in sediment was noted for polychaetes. Shrimps accumulated both size MPs, but more abundantely bigger particles which imply size specificity, being seawater the route of entry. MPs were mainly localized in the digestive tract and the tegument and pereopods. No discernible reduction in MP elimination was seen after depuration. This work has enabled to understand the influence of size in the transfer of MPs between different environmental compartments and their fate in target tissues of organisms with different feeding behaviors. Funded: Basque Government (IT1743-22, IT-1446-22) and MICINN (PID2020-118685RB-I00).

3.22.P-Tu379 Greenhouse Plastics as Vectors for Antibiotic Resistance Genes and Pathogens

Juan Manuel Valenzuela[1], *Carlos Edo*[2], *Roberto Rosal*[2], *Francisco Leganés*[1], *Amadeo Rodriguez Fernández-Alba*[3], *Miguel González-Pleiter*[1] *and Francisca Fernández-Piñas*[1], *(1)Biology, Autonomous University of Madrid (UAM), Spain, (2)Chemical Engineering, University of Alcala (UAH), Analytical Chemistry, Physical Chemistry and Chemical Engineering, Spain, (3)Chemistry and Physics Department, University of Almería, Spain*

Plastic waste is a critical environmental concern particularly in the context of greenhouse agriculture, as greenhouse agriculture depends on hard to dispose plastic products. This turns it into a source of plastic pollution for surrounding ecosystems, a problem compounded by the fact that plastics can be colonized by microorganisms. Greenhouse agriculture plastic waste could thus act as a vector for pathogens and antibiotic resistance genes (ARGs), facilitating their spread from greenhouses to surrounding environments. This study aimed to investigate the presence of both plant and human pathogens, as well as ARGs and mobile genetic elements (MGEs) in the region of Almería, which harboured the highest concentration of greenhouses globally by 2018. The investigation was conducted across three distinct sampling sites: greenhouses; an unprotected area with substantial pollution close to the greenhouses; and the protected natural reserve *Punta Entinas-Sabinar,* located kms away from the greenhouses. Within each sampling site three replicates of soil (collected from the surrounding environment around plastics) and greenhouse plastic waste were sampled. This comprehensive approach allows for a detailed assessment of the potential environmental impact and spread of pathogens, ARGs and MGEs derived from greenhouse operations to surrounding areas. Sampling sites were chosen based on the local greenhouse plastic waste's life cycle: some reaches the protected natural reserve directly while other is dumped in the unprotected area and eventually ends up in the natural reserve. The presence of five human (*Campylobacter jejuni, Escherichia coli O157:H7, Listeria monocytogenes, Pseudomonas aeurigonosa* and *Salmonella* spp.) and five plant pathogens (*Alternaria* spp., *Botrytis* spp., *Sclerotinia* spp., *Sclerotium cepivorum* and *Oidium neolycopersici*) was studied using quantitative PCR. Resistome analysis was performed by way of SmartChip Real-Time PCR System. Results showed a high diversity of ARGs and MGEs in greenhouse plastic waste, higher than its surrounding soil in two thirds of the samples. The plant pathogen *Botrytis* spp., 18 ARGs and one MGE were only detected in plastic samples in the natural reserve and unprotected area and in both sample types in the greenhouse samples, suggesting that greenhouse plastic waste could have acted as a vector for pathogens, ARG and MGE alike from greenhouse soil through greenhouse plastic waste to the unprotected area and natural reserve.

3.22.P-Tu380 Unravelling the ecocorona using a proteomics approach

Amanda Dawson[1], *Utpal Bose*[1], *Joost LD Nelis*[1] *and Dongdong Ni*[2], *(1)CSIRO, Australia, (2)Agriculture and Food, CSIRO, Australia*

Upon entering the environment, the surface properties of pristine plastics are rapidly altered due to interactions with exogenous biomolecules, contaminants, and even microbiota, which ultimately alter their ecological impacts. When present in biological fluids or high protein environments micro(nano)plastics bind with proteins which form a protein corona around the particle. Although a significant body of literature exists on protein corona formation on nanomaterials, less is known about how physiochemical characteristics of microplastics may influence protein corona formation in the environment. This study utilises

quantitative proteomics to quantify protein binding to pristine and leached microplastics to understand fundamental process driving ecocorona formation. Pristine polyethylene (PE) beads (50 and 500µm), polyamide (PA) fibres (100µm), polyethylene terephthalate fibres (500µm) and fragments (<300µm), as well as pristine and leached textile microfibres comprised of PET, recycled PET, PA or cotton were incubated for 24 hours in bovine serum albumin solution (2mg mL^{-1}) to form a corona. Protein adsorption to microplastics was dependant on particle surface area to volume ratio but only when additives were not present. For environmentally relevant textile microfibres, cotton microfibres adsorbed significantly more protein than synthetic microfibres. Fourteen-day aqueous leaching increased the surface charge of all microfibres, however only PA fibres sorbed significantly higher protein on the leached fibres compare their pristine counterparts. Overall, the presence of chemical additives in microplastic was seen to strongly influence protein corona formation. As the majority of microplastics in the environment are generated from consumer products, chemical additives are likely to play a significant role in corona formation in the environment. Further, proteomic methods developed for this study can be used to quantify the ecocorona formed on microplastics in environmental compartments, facilitating greater understanding of microplastics toxicology.

3.22.P-Tu381 Environmental DNA adsorption onto polymers in environmental waters: A comprehensive study on the protection of adsorbed DNA

Célia Marie, Lucie Paolucci[1]*, Roman Schefer*[2] *and Denise M Mitrano*[2]*, (1)ETH Zurich, Switzerland, (2)Environmental Systems Science, ETH Zurich, Switzerland*

In environmental systems, microplastics (MPs) (1 µm – 5 mm) are found alongside environmental DNA (eDNA). eDNA is genetic material shed by organisms through decayed cells, serving as a valuable tool for non-invasive biodiversity assessments and aiding conservation efforts by enabling species presence monitoring. eDNA that sorbs onto particles have been shown to be longer-lived than when in suspension, likely because of protected from enzymatic degradation. Consequently, measuring adsorbed eDNA on MPs could provide insights into plastics origin and environmental transport pathways. For this, better understanding of binding kinetics, adsorption extent and mechanisms of eDNA onto MPs is needed, including water chemistry parameters influencing adsorption. Furthermore, assessing the longevity of MPs bound eDNA when exposed to a restriction enzyme is crucial when considering its potential for source tracking. In this study, interactions between a model linear eDNA (O.Keta salmon sperm DNA) and thin polymer films (PET, PE) were investigated. Adsorption experiments using Quartz-Crystal Microbalance with Dissipation monitoring (QCM-D) allowed to investigate adsorption of small amounts of eDNA over time and to access viscoelastic parameters such as thickness, viscosity and shear modulus of adlayers. Variations in water chemistry, including ionic strength (similar to marine and very hard freshwater) and cations concentrations and compositions (Na^+, Ca^{2+} and Mg^{2+}) were considered to understand adsorption mechanisms. The protection of adsorbed eDNA against enzymatic degradation using DNase I as model restriction enzyme allowed us to quantify the longevity of surface-bound eDNA. Cation-bridging induced by divalent cations was shown to be the main component driving adsorption, with Ca^{2+} demonstrating a more pronounced effect on the adsorption process compared to Mg^{2+}. Between the two polymer surfaces, PET exhibited stronger affinity and faster adsorption, likely because of surface chemistry. However, eDNA was only partially protected from enzymatic degradation on PET whereas PE exhibited full protection, either because of surface chemistry or eDNA surface coverage. This study provides first insights into adsorption interactions between eDNA and polymer surfaces, allowing us to assess the effectiveness of MPs source tracking through eDNA measurement

3.22.P-Tu382 Diversity of marine bacteria growing on leachates from virgin and weathered plastic: insights into potential degraders

Cristina Romera-Castillo[1]*, Stéphanie Birnstiel*[2] *and Marta Sebastián*[1]*, (1)Institute of Marine Sciences, Spanish National Research Council (ICM-CSIC), Spain, (2)Universidad Autónoma de Barcelona, Spain*

Plastic debris in the ocean releases chemical compounds that can be toxic for marine fauna and which may have an impact in the marine carbon cycle. This leaching process is enhanced by sunlight radiation. It was recently found that some marine bacteria are able to degrade such leachates, but information on the diversity of these bacteria is mostly lacking. Here, we will show the results of a study in which marine bacteria were grown on plastic leachates to search for potential degraders. Two types of leachates were generated using new low density polyethylene (LDPE) and a mix of naturally weathered plastic, collected from beach sand, which were introduced in seawater. Some treatments were exposed to sunlight degradation and others were kept in the dark. The amount of dissolved organic carbon in the leachates and its fluorescence signal were explored. We also analyzed the bacterial diversity growing on the plastic leachates. We used a combination of Catalyzed Reporter Deposition-Fluorescence In Situ Hybridization (CARDFISH) and BioOrthogonal Non-Canonical Amino acid Tagging (BONCAT), and 16S rRNA gene amplicon sequencing to analyze bacterioplankton-groups specific activity responses and the identity of the responsive taxa to plastic leachates produced under irradiated and non-irradiated conditions. We found that material released by plastic in seawater presents a characteristic fluorescence signal with the highest intensity in aged plastic leachates. Regarding the bacteria growing on the plastic leachates, we observed that some generalist taxa responded to all leachates, most of them belonging to the Alteromonadales, Oceanospirillales, Nitrosococcales, Rhodobacterales and Sphingomonadales orders. However, there were also non-generalist taxa responding to specific irradiated and non-irradiated leachates. Our results provide information about bacterial taxa that could be potentially used to degrade the chemicals released during plastic degradation into seawater contributing to bioremediation of plastic pollution and its additives.

3.22.P-Tu383 Toxicity of Methacrylate Nanoparticles of Partially Bio-Based Pressure Sensitive Adhesives (PSAs) to Zooplankton*

Olga Rodríguez-Díaz[1]*, Sumi Murali*[2]*, Radmila Tomovska PhD*[3] *and* ***Amaia Orbea PhD***[1]*, (1)CBET+ Research Group,*

Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain, (2)POLYMAT and Department of Applied Chemistry, Faculty of Chemical Sciences, UPV/EHU, Joxe Mari Korta Zentroa, Spain, (3)POLYMAT and Department of Applied Chemistry, Faculty of Chemical Sciences, UPV/EHU, Joxe Mari Korta Zentroa & Basque Foundation for Science, Spain
Pressure Sensitive Adhesives (PSAs) are instantaneous adhesion materials widely used in tapes and labels for glass or plastic bottles. They are produced by emulsion polymerization as polymeric nanoparticles (NPs) stabilized by surfactants in aqueous dispersions (latex). Nowadays, searching for sustainability, the petroleum-based polymers are replaced with bio-based. Yet, after their life-time, these waterborne polymers easily ended in our oceans, contributing towards increased microplastic pollution. Presence of the surfactants, may affect further their potential toxicity for the aquatic biota. Here, the toxicity of two different latexes of partially bio-based NPs for PSA applications were tested in two zooplankton species: the rotifer *Brachionus plicatilis* and the brine shrimp *Artemia salina.* PSA1 (NP size: 215 nm) was synthetized from a bio-based seed containing methyl methacrylate (MMA) and partially bio-based isobornyl methacrylate (IBOMA) extracted from glucose. For colloidal stabilization, the conventional surfactant alkyldiphenyloxide disulfonate (Dowfax 2A1) was used. PSA2 (NP size: 348 nm), in addition to MMA and IBOMA, contained partially biobased 2-octyl acrylate, which copolymerizes with the zwitterionic monomer 2-(methacryloyloxy) ethyl] dimethyl-(3 sulfopropyl) ammonium hydroxide (DMAPS) for colloidal stabilization. In rotifers, significantly increased mortality after 24 h of exposure was achieved at the highest exposure concentrations, 1000 mg/L for PSA1 and 500 mg/L for PSA2. At 48 h, acute effects were recorded at lower concentrations: 250 mg/L for PSA1 and 125 mg/L for PSA2. In brine shrimps, significant effects were observed only at 48 h at concentrations ≥250 mg/L for PSA1 and at 1000 mg/L for PSA2. The ingestion test revealed sublethal effects at lower concentrations: at 125 mg/L and 62.5 mg/L for PSA1 and PSA2, respectively, in rotifers and at 62.5 mg/L for both PSAs in brine shrimps. Lower values of acetylcholinesterase activity were measured in both species exposed to PSAs compared to control individuals while effects on catalase activity did not show a clear trend. In summary, acute and sublethal toxicity of these formulations was detected only at very high and likely, non-environmentally relevant concentrations. *Funded by the Spanish MICIN project FIERA (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and "ERDF A way of making Europe") and the Basque Government grant to consolidated research groups (IT1743-22).

3.22.P-Tu384 Microplastic Exposure Linked with Decreased Lower Trophic Level Fatty Acid Availability and Reduced Yellow Perch Growth in a Large In-Lake Mesocosm Experiment

Garth Covernton[1], *Bailey C. McMeans*[2], *Adam H. Metherel*[3], *Desiree Langenfeld*[4], *Cody Veneruzzo*[5], *Ludovic Hermabessiere*[1], *Matthew J. Hoffman*[6], *Diane M. Orihel*[7], *Michael Paterson*[8], *Jennifer F Provencher*[9] *and Chelsea Rochman*[10], *(1)University of Toronto, Canada, (2)Department of Biology,, University of Toronto, Canada, (3)Department of Nutrional Sciences, University of Toronto, Canada, (4)University of Manitoba, Canada, (5)Lakehead University, Canada, (6)School of Mathematics and Statistics, Rochester Institute of Technology, (7)Department of Biology, Queen's University, Canada, (8)IISD - Experimental Lakes Area (IISD-ELA), Canada, (9)Ecotoxicology and Wildlife Health Division, Environment and Climate Change Canada (ECCC), Canada, (10)Department of Ecology and Evolutionary Biology, University of Toronto, Canada*
Microplastics (MPs), defined as particles with longest dimension 1-5000 µm, pollute all ecosystems globally in a wide range of polymer combinations, sizes, shapes, and with a large variety of chemicals added during plastic manufacturing. It is accepted that some aquatic environments are currently at risk from MP pollution, but few studies have investigated how MPs affect biologically important nutrients like fatty acids in a food web and the potential for indirect, nutritional effects on consumers. To explore how MPs impact aquatic food web processes, among other research questions, we conducted a large, in-lake mesocosm experiment. We exposed aquatic communities, including plankton and yellow perch (*Perca flavescens*), to MPs with and without chemical additives, and monitored fatty acids in the food web. We predicted that MPs would have greater effects on the base of the food web (phyto- and zooplankton), decreasing the amount of polyunsaturated fatty acids (PUFAs) available to yellow perch, reducing PUFA concentrations in their tissues, and potentially limiting growth. Our experiment had three treatments (n = 3 mesocosms per treatment): negative control, MPs (equal parts polystyrene (PS), polyethylene (PE), and polyethylene terephthalate (PET) with chemical additives (e.g., dyes, UV stabilizers, and antioxidants), and MPs without chemical additives. We added MPs at nominal concentrations of 29,240 particles L^{-1}. Zooplankton were less dense in total fatty acids and PUFAs in the plastic treatments, despite a lack of difference in community composition, and PUFAs were reduced in the detritus and in the non-additive treatment wall biofilm. Yellow perch grew less in the plastic treatments, likely due to reductions in important dietary fatty acids in lower trophic levels. Although the yellow perch were able to mostly maintain ratios and concentrations of PUFAs in their liver and muscle, the substantial impact on PUFA availability at the base of the food web seems to have been growth-limiting. Our findings highlight the presence of sublethal, indirect effects of MPs and the importance of considering how contaminants act on biological systems beyond the organismal level.

3.22.P-Tu385 Biodegradable microplastics: Uptake by and effects on the rockpool shrimp Palaemon elegans (Crustacea: Decapoda)

Lukas Miksch[1], *Chiau Yu Chen*[2], *Anna-Sara Krang*[3], *Maria E. Granberg*[2], *Lars Gutow*[1] *and Reinhard Saborowski*[1], *(1)Alfred Wegener Institute Helmholtz-Center for Polar and Marine Research, Germany, (2)Swedish Environmental Research Institute (IVL), Sweden, (3)Swedisch Environmental Research Institute (IVL), Sweden*
Ingestion of microplastics can lead to deleterious consequences for organisms, which has been documented in numerous laboratory studies. The current state of knowledge is based on a multitude of effect studies conducted with conventional fossil-based and non-degradable plastics. However, there is a lack of information regarding the effects of novel bio-based and

biodegradable plastics. Biodegradable plastics are considered an alternative to conventional plastics and are rapidly growing in their production. Biodegradable plastics can reach the environment in the same way as conventional plastic, becoming available to marine organisms. This study aims to provide new insights into the uptake and effects of biodegradable microplastics on marine invertebrates. Rockpool shrimp *Palaemon elegans* were offered algal flakes coated with polylactic acid (PLA), polyhydroxybutyrate-co-valerate (PHBV) and conventional low-density polyethylene (LDPE) microparticles. Live observations showed that all different microplastics were ingested. After dissection of the shrimp, less LDPE particles than PLA and PHBV particles were found in the stomachs, indicating a longer retention time of biodegradable microplastics. Presumably, less LDPE particles were ingested or preferentially regurgitated. The ingestion of microparticles from all plastics induced enzymatic activity of short-chain carboxylesterases in the midgut glands of the shrimp. However, only PLA induced enzymatic activity of medium-chain carboxylesterases. *P. elegans* showed no oxidative stress response after ingestion of microparticles, irrespective of polymer type. We conclude that biodegradable plastics might have different effects compared to corresponding conventional plastics due to their longer retention times and increased biodegradability, leading to an enhanced exposure to leaching additives and other harmful substances. Our results highlight the need for further research and risk assessment of the new bio-based and biodegradable plastic materials.

3.22.PC The Fate and Effects of Micro- And Nano-Plastics in Relation to Ecosystems

3.23.A Tire-Road Wear Particles: Analytical Possibilities, Challenges, and Current Knowledge of Environmental Impact

3.23.A.T-01 Occurrence and Leaching Potential of Tire Rubber-Derived Compounds from Vancouver Road Dust
Yanru Wang*, Tim Frederick Mainguy Rodgers, PhD and Rachel C Scholes, Department of Civil Engineering, University of British Columbia, Canada*
Tire and road wear particles (TRWP) are non-exhaust particles that typically arise from abrasion, including via brake wear, abrasion of tires by road surfaces, wearing of road material, and agglomeration of tire particles with other road dust particles. The emission of TRWPs is a global challenge, in part because these particles have the potential to release toxic substances. For example, a recent study found a tire rubber-derived chemical called 6PPD-quinone (N-(1,3-dimethylbutyl)-N'-Phenyl-p-phenylenediamine-quinone), a transformation product of the ubiquitous tire rubber antioxidant 6PPD, in road runoff samples collected in Seattle and Los Angeles (USA) at concentrations high enough to induce acute mortality of coho salmon (Oncorhynchus kisutch). The prevalence of 6PPD and 6PPD-quinone in the environment has since drawn increasing concerns. Measuring TRWPs and 6PPD and 6PPD-quinone near their source (roadways) can help us better understand TRWP pollution and the release of associated chemical contaminants to the environment.

The factors affecting 6PPD-quinone production can be divided into traffic and roadway circumstances, which affect TRWP production; and environmental conditions, which may affect the formation rates of 6PPD-quinone on tire rubber surfaces. We will conduct roadside dust sampling and subsequent leaching experiments over one year from 5 locations: a high-speed road, an on- and off-ramps on a high-grade bridge, a busy traffic intersection, and a less-busy residential street. These experimental results will deepen our understanding of the environmental occurrence and fate of 6PPD and 6PPD-quinone. Specifically, we can learn about (i) seasonal trends of 6PPD and 6PPD-quinone concentrations in road dust, (ii) the effects of road type and traffic on 6PPD and 6PPD-quinone concentration in road dust, and (iii) 6PPD and 6PPD-quinone leachability and potential impacts on coho salmon. Our first two sets of leaching experiments indicate that sunny and warm conditions may favor the generation or leaching of 6PPD-quinone in TRWPs. We will continue to evaluate the impact of traffic conditions or driving behavior on the generation of TRWPs and the impact of ground-level ozone concentration on the production of 6PPD-quinone through the collection of additional road dust samples.

3.23.A.T-02 Analysis of tyre wear and other road-derived microplastics collected from urban roadside via atmospheric deposition sampling
*Katherine Rowley[1], **Stefan Krause[1,2]**, Iseult Lynch[1,2], John W. Scott[3] and Sophie Comer-Warner[1,2,3], (1)School of Geography, Earth and Environmental Sciences, University of Birmingham, (2)Institute for Global Innovation, University of Birmingham, United Kingdom, (3)Illinois Sustainable Technology Center, Prairie Research Institute, University of Illinois Urbana-Champaign*
Tyre and road wear particle (TRWP) particle emissions contribute significantly to microplastic concentrations in the urban environment. Tyre materials are extremely complex, containing multiple polymer types (natural rubber-NR, styrene butadiene rubber-SBR, and nylon), inorganic fillers (silica, carbon black), crosslinking agents, vulcanization agents, and additives (up to 10%) at various concentrations. Other emissions can include brake wear particles, road surface wear particles, road paint materials, and polymer modified bitumen. Although TRWP account for 30% of the terrestrial microplastic burden, analytical challenges exist for their detection and quantification. To address this gap, environmental samples were collected adjacent to a busy urban road (the Bristol Road (A38) close to the University of Birmingham, UK) via atmospheric deposition across the Spring and Summer 2023, supplemented by use of Go Pro cameras for determination of traffic counts. TRWP contained in these 68 samples were extracted and organic debris digested using an established and robust protocol developed in-house. Analytical methods based on optical microscopy and pyrolysis gas chromatography mass spectrometry (py-GCMS) were developed to characterize and quantify the TRWP isolated from these samples. This dual mode of detection determines the size of microplastics present (optical microscopy) and the concentrations of polymer types present (e.g., NR and SBR by py-

GCMS) as an estimate of the mass of particles recovered. To target tyre wear particles (TWP) specifically, a py-GCMS method was developed. Exploration of the appropriate pyrolysis products to measure TWP was conducted, and 4-vinylcyclohexene (4-VCH) and dipentene (DP) were found to be the best suited markers for SBR and NR polymers, respectively. Utilizing this information, stock polymer reference materials were obtained, dissolved in the appropriate solvents, and serial diluted to obtain calibration standards in the nanogram/microgram range. A range of sample preparation techniques were explored for TWP analysis by py-GCMS, including hydrofluoric acid digestion, accelerated solvent extraction, microwave assisted extraction, and manual grinding of filter substrates for direct analysis. The workflow developed for roadside sampling, extraction of TRWP from filters, and analysis by optical microscopy and Py-GCMS presented here represents a step-change in analysis capability for these hard-to-measure and quantify particles.

3.23.A.T-03 Breaking Down and Disentangling the Complexity of Road Runoff – Results from Three Comprehensive Road Runoff Case Studies in Aachen, Germany

Markus Schmitz[1]*, Selina Seibold*[2]*, Alexander Maria Pape*[2]*, Jennifer Schmidt*[2]*, Sarah Cüpper*[2]*, Simone Lechthaler*[3,4]*, Regina Dolny*[3]*, Volker Linnemann*[3]*, Markus Brinkmann*[5]*, Ana Cardenas Perez, Environmental Chemistry Specialist and MBA*[5]*, Martin Krauss*[6]*, Werner Brack*[2,6]*, Sabrina Schiwy*[7] *and Henner Hollert*[7,8]*, (1)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Frankfurt, Germany, (2)Evolutionary Ecology & Environmental Toxicology, Goethe University Frankfurt, Germany, (3)Institute of Environmental Engineering, RWTH Aachen University, Germany, (4)Hunziker Betatech AG, Switzerland, (5)Toxicology Centre, University of Saskatchewan, Canada, (6)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany, (7)Evolutionary ecology and environmental toxicology, Goethe University Frankfurt, Germany, (8)Environmental Media Related Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

Recent research recognized road runoff and tire and road wear particles (TRWP) as a pervasive source of pollution, emphasizing, however, knowledge gaps regarding their emissions, environmental effects and sampling standardization. Targeting these gaps, the RoadTox project conducted a thorough investigation into stormwater runoff from heavily frequented roads in Aachen, Germany, from February 2022 to August 2023.

Three distinct road types —federal highway (BAB4), country road (L23), and city road (B57)— were selected based on their daily traffic volumes. Automated sampling of full-stream runoff yielded original, 63µm, and 0.5µm fractions for physico-chemical and ecotoxicity assessments. Physico-chemical analyses included suspended particulate matter (SPM), tire rubber content, polycyclic aromatic hydrocarbons (PAHs), heavy metals, and mineral oils. Ecotoxicity assessments encompassed a comprehensive bioassay battery, covering daphnia, algae, fish embryos, and *in-vitro* assays (µEROD, (anti-)ER/AR and P53 CALUX®).

Our results revealed consistently elevated pollution levels, surpassing EU standards for PAHs and heavy metals. PAH and mineral oil concentrations correlated with SPM, while over 90% of SPM were <63µm, challenging sedimentation-based treatment systems. Targeted and non-targeted screenings identified 30 to >150 chemicals per sample, including prevalent compounds such as Hexa(methoxy-methyl)melamine (HMMM) and diphenylguanidine (DPG), benzothiazole derivatives, and 6PPDQ. Notably, highway samples obtained under freezing conditions contained high salt loads. Overall, acute toxicity varied across test systems, with zebrafish displaying the highest sensitivity, even in diluted samples. Our studies highlighted increased toxicity during winter runoff and prolonged dry periods, supporting the "first flush" hypothesis and first principal component analyses linked toxicity to mineral oil and high molecular weight PAHs.

Despite the complex nature of road runoff, factors such as particle concentration, anti-freezing agents, and hydrocarbon compounds were identified as influential in determining toxicity. However, predicting road runoff toxicity remains challenging, and hence, ongoing research will explore transcriptome-level mechanistic endpoints in zebrafish to support toxicity-driver identification.

The project is funded by the Ministry for Environment, Agriculture, Conservation and Consumer Protection of the State of North Rhine-Westphalia (MULNV), Germany.

3.23.A.T-04 Quo Vadis Tire Wear Leachable? – Suspect Screening for More than 70 Tire Wear Leachables in the Aquatic Environment

Kathrin Müller*, Hochschule Fresenius, Germany*

Tires are a chemically complex and heterogenous mixture and contain up to 200 different additives. Tire wear particles (TWP), generated while driving, are pollutants themselves, but also serve as a source for a variety of organic substances that can enter the aquatic environment. While multiple of those so-called tire wear leachables have been identified in screening studies, their environmental fate remains mostly unknown. This lack of data hinders the assessment of their environmental impact and potential risks. To narrow this knowledge gap, we performed an environmental screening for over 70 tire-leachables and investigated the role of wastewater treatment plants (WWTPs) as entry pathway and the occurrence of the tire-leachables in 35 different hessian surface waters.

Influent and effluent of two conventional wastewater treatment plants were sampled over five consecutive days. 35 grab samples of hessian surface waters were collected to estimate the distribution of tire leachables, of these samples were enriched using solid phase extraction and analysed using a reversed phase liquid chromatography QTOF-MS system and screened for the prioritized leachables.

Based on the median ratio they were sorted into the categories ‘elimination’, ‘decrease’, ‘consistency’, ‘increase’ and ‘formation’. Of the 28 detected tire wear leachables, eleven were classified as eliminated of which six were even below LOD in the effluent samples. DPG and dibenzylamine fell into the category “decrease”. More than a third of the substances were classified as consistent, meaning that WWTPs act as distribution pathway for those tire wear leachables. Five substances showed an intensity increase passing through the WWTP. Thus, these substances seem to be transformation products of other substances present in the WWTP influent. The results of the surface waters showed similar patterns of the WWTP effluent samples. The four substances with a FOD > 60 % in the surface water samples were either among those with the highest intensity in the effluent (DPG) and/or they were classified as consistent (HMMM, benzothiazole-2-sulfonic acid and N-hexyl-N’-phenylfumaramide). This environmental screening demonstrated that previously unknown tire wear leachables can enter the water cycle through WWTP and are detectable in surface waters. However, an assessment of their environmental fate and associated risk is still not possible as there is a lack of data on source, occurrence and emission dynamics.

3.23.B Tire-Road Wear Particles: Analytical Possibilities, Challenges, and Current Knowledge of Environmental Impact

3.23.B.T-01 Tire and road wear particles contamination in infiltration ponds sediments: occurrence, spatial variability, size distribution and correlation with metals

Tiago De Oliveira[1], *Maxime Chaillou*[2], *Du Phuc Tho Dang*[2], *Nadège Caubrière*[2], *Martin Guillon*[2], *David Mabilais*[2], *Sophie Ricordel*[2], *Liliane Jean-Soro*[2], *Béatrice Béchet*[2], *Bogdan Muresan-Paslaru*[2], *Laurence Poirier*[3] *and Johnny Gasperi*[2], *(1)Gers-Lee, Gustave Eiffel University, France, (2)Gustave Eiffel University, France, (3)Nantes University, France*

Efficient stormwater management has become a major challenge. Sustainable urban drainage systems (SUDS) such as infiltration ponds have been implemented in sensitive areas, particularly in urban ones. These SUDS play a critical role in regulating water flow but also reducing pollutant load to downstream environment through decantation, soil filtration, photooxidation and biodegradation. In fact, runoff collected from road surfaces contains several categories of pollutants, including heavy metals, organic micropollutants, and microplastics such as tire and road wear particles (TRWP).

To improve our knowledge on the TRWP levels in runoff discharges and the capacity of SUDS to reduce TRWP load, we investigated the occurrence, spatial distribution and size distribution of TRWP in the sediment of an infiltration pond of the ring road in Nantes city (France). The sediment was fractionated between <36 µm and 500 µm, and analyzed by pyrolysis coupled with gas chromatography-mass spectrometry. Analyzes targeted two polymeric content of tires, namely, styrene-butadiene-rubber (SBR) and butadiene-rubber (BR), with the use of an internal deuterated SBR standard for calibration.

Measurements highlighted an SBR+BR gradient in the infiltration pond with contents ranging from 1.28 ± 0.05 mg/g to 7.15 ± 0.29 mg/g. Three distinct sections were delineated: entrance, middle and overflow. The sediment closest to the overflow was the most enriched in SBR+BR, consistent with the water runoff in the basin and the topography. Upon a closer examination of the size fractionation of SBR+BR content within the sediment from entrance, middle and overflow, the 63-160 µm fraction prevails. Furthermore, positive correlations between SBR+BR levels and particulate organic matter (POM) or metals (As, B, Cd, Cu, Li, Mo, Ni, Zn) ($r > 0.76$, $p < 0.05$) were observed. This suggests that TRWP may act as vector for metallic pollution and a carrier for POM, or behave in a similar way. Using a median SBR+BR-to-TRWP conversion factor of 13.2, the TRWP stock in the pond was determined and compared to the estimated cumulative TRWP input from road traffic. The calculation revealed similar amounts (of the order of 1.0 to 1.1 tons), suggesting that infiltration ponds can be an effective solution to limit the dispersion of TRWP into the environment.

3.23.B.T-02 Bioaccessibility of Antioxidants, Antiozonants and Other Tire Hazardous Chemicals.

Sergio Soñora[1], *Andres Duque-Villaverde*[1], *Daniel Armada*[2], *Maria Llompart*[2] *and Thierry Dagnac*[3], *(1)Department of Analytical Chemistry, Nutrition and Food Science, University of Santiago de Compostela, Spain, (2)Department of Analytical Chemistry, Nutrition and Food Science, CRETUS, Spain, (3)Unit of Organic Contaminants, Apartado 10, Agronomic and Agrarian Research Centre (AGACAL-CIAM), Spain*

Tires, apart from being formed by rubber and filling materials (carbon and silica, principally), are made up of organic compounds which make the tire resistant and durable. The widely used of recycled tire crumb rubber (RTCR), mainly sub-product of shredding process of end-of-life tires, could provoke a high exposure to human beings due to its presence on synthetic football fields and kid's playgrounds. In September 2023, the European Commission banned the use of recycled crumb rubber on synthetic fields giving the manufacturers 8 years to retire the material.

This study intends to assess the oral bioaccessibility of antiozonants, cross-linking and vulcanizing agents present in RTCR. With this purpose, the Unified Bioaccessibility Method was selected to simulate the ingestion of the material. Real RTCR samples from sports and recreational facilities were put in contact with the four biological simulated fluids including saliva, gastric and duodenal juice and bile, attempting to simulate human digestion.

Afterwards, the organic compounds present in the fluids were extracted by Solid Phase Extraction (SPE) technique. The SPE process was optimized to obtain the best extraction conditions. Besides, ultrasound assisted extraction was performed to evaluate the total concentration of the compounds in the rubber matrix. Liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) was the selected technique to identify and quantify the target compounds.

The results showed the bioaccessibility of all analytes studied. The bioaccessibility ranged from 0.01 % up to a high percentage depending on the compound. 6PPD (N-(1,3-dimethylbutyl)-N′-phenyl-p-phenylenediamine) and its transformation product 6PPDq (N-(1,3-Dimethylbutyl)-N′-phenyl-p-phenylenediamine-quinone) showed a moderate bioaccessibility when comparing with the other compounds. Benzothiazole (BTZ) showed the highest oral bioaccessibility. This work demonstrated for the first time the human bioaccessibility of these chemical agents.

The authors thank projects PID2022-140148OB-I00, and RED2022-134079-T (Ministry of Science, Innovation and Universities, Spain), ED431B 2023/04 and IN607B 2022/15 (Xunta de Galicia). This study is also based upon work from the Sample Preparation Study Group and Network, supported by the Division of Analytical Chemistry of the European Chemical Society. All these programs are co-funded by FEDER (UE).

3.23.B.T-03 Effects of Weathered Tire Wear Micro- and Nanoparticles in the Model Estuarine Species Fish Menidia Beryllina and Mysid Shrimp Americamysis bahia

***Clarissa Raguso**[1], Lauren Miki Kashiwabara[2], Samuel Arriola[3], Stacey L Harper[3], Bryan J. Harper[4], Marina Lasagni[5] and Susanne M Brander, (she, her, hers)[2], (1)Milano-Bicocca University - Oregon State University, (2)Department of Fisheries, Wildlife, and Conservation Sciences, Oregon State University, (3)Oregon State University, (4)Environmental & Molecular Toxicology, Oregon State University, (5)University of Milano-Bicocca, Italy*

The increase in plastic production worldwide and the mismanagement of plastic waste are leading the oceans to become a big waste bin. Million tonnes of plastic enter our ocean every year and car tires are one of the biggest sources. In the US almost 1,524,740 metric tons of tire wear particles (TWP) are released each year into the environment, deriving from tires undergoing friction on the road. For our experiments, we used a cryo-milled tire tread (CMTT) composite provided by the U.S. Tire Manufacturers Association. The composite was a representative mixture of what may be in our environment and contained three types of tire in proportions that are estimated for the U.S. (41% Passenger Car Tire, 14% Light Truck Tire, 45% Truck/Bus Tire). To better resemble what is happening in the real environment, leachate and micro- and nanoparticles were weathered through a solar simulator for 72h. Considering the limited available data regarding toxicity of environmentally relevant tire particles on organisms, this study aims to provide information about TWP exposure impacts on larval growth, internalization, behavior and intracellular reactive oxygen species (ROS) level in the model species Fish *Menidia Beryllina* and Mysid Shrimp *Americamysis bahia*. Particularly, 5 day post fertilization *M. Beryllina* embryos and 7-day old *A. bahia* were exposed to weathered and not weathered TP leachate and micro (1-20 μm) and nano (< 1 μm) tire particles at four concentrations (10, 100, 1000 and 10,000 particles/ml). At the end of the exposures, behavioral assays were performed using a DanioVision Observation Chamber, where each fish was subjected to a dark: light cycle stimuli. Growth measurements were assessed through the index (W = width, L = standard length, d = days the organisms were exposed to tire particles) and organisms were cleared with CUBIC^{TM} clearing reagents (Cubic-L and Cubic-R solutions) to visualize and count the internalized particles. ROS level was measured using a total reactive oxygen species assay kit 520 nm. Previous studies have already demonstrated tire particles to have behavioral toxicity and negative effects on growth and ROS level in our study species. This study has the potential to lead to a more comprehensive perspective of what organisms are experiencing in the real environment, reporting for the first time the toxicity due to environmentally relevant tire particles in the two model estuarine species *Menidia Beryllina* and *Americamysis bahia.*

3.23.B.T-04 Cocktail Chronicles: Investigating the Impact of Tire Particle Leachates Across Diverse Biological Models

***Jessy Ledu-Carree**[1], Clara Alejandra Kempkens Palacios, Anna Maria Rotander[3], Maria Larsson[4], Andi Alijagic PhD[5], Oleksandr Kotlyar[6], Magnus Engwall[3], Viktor Sjöberg[3], Steffen H. Keiter[4] and Rodrigo Almeda[7], (1)University of Las Palmas de Gran Canaria (ULPGC), Spain, (2)Orebro University, MTM Research Centre, Sweden, (3)MTM Research Centre, Orebro University, Sweden, (4)Oerebro University, Sweden, (5)School of Science and Technology, Orebro University, Sweden, (6)EOMAR, ECOAQUA, University of Las Palmas de Gran Canaria, Spain*

Tire wear particles (TWP) significantly contribute to microplastic pollution. Despite extensive research on conventional microplastics, the environmental impacts of TWP and their leachates are poorly understood. This study investigates the cocktail effects of TWP leachate on diverse biological models using molecular, cellular, and organismal endpoints. Acute toxicity of TWP leachates (particle size <250 μm) was assessed via growth inhibition tests with marine microalgae (*Rhodomonas salina*), zebrafish (*Danio rerio*) embryotoxicity and behavioral tests, and in vitro assays for intracellular effects and hormonal response using reporter gene assays. Leachates were extracted in artificial seawater, followed by solid-phase extraction, and chemically characterized using spectrometric techniques. Exposure to TWP leachates (1.5 to 1000 mg/L) inhibited algae growth and induced zebrafish embryotoxicity, pigment alterations, and behavioral changes. Cell painting revealed pro-apoptotic changes, including cell rounding, mitochondrial toxicity, endoplasmic reticulum stress, and cytoskeleton disruption. The leachate exhibited potential endocrine disruption, mainly through antiandrogenic effects. Detected organic toxicants include polyaromatic hydrocarbons and 4-tert-octylphenol. The present results indicate water-leachable organic compounds as the main causative agents of acute toxicity, contrary to other studies implicating mainly heavy metals. These findings underscore the multiple acute toxic effects of TWP pollution at various biological levels. Urgent measures are warranted to reduce such pollution in aquatic systems and enhance regulations on highly toxic tire additives.

3.23.P Tire-Road Wear Particles: Analytical Possibilities, Challenges, and Current Knowledge of Environmental Impact

3.23.P-Th400 Exploring the Potential of Proton-Transfer-Reaction Mass Spectrometry for the Analysis of Tire Wear Particles in Air

Nikita Sobolev, *Keerthana Balashankar, Tomas Mikoviny and Armin Wisthaler, Department of Chemistry, University of Oslo (UiO), Norway*

Tire wear particles (TWPs) contribute to the atmospheric particle burden in urban environments, and the increasing use of electric and hybrid vehicles is expected to further increase emissions of TWPs to the atmosphere. The qualitative and especially quantitative analysis of TWPs in air does however present distinct challenges. This is primarily due to the low atmospheric concentrations and complex chemical nature of TWPs, which contain polymers, organic additives and inorganic components (e.g., black carbon and zinc oxide) in variable amounts. Various analytical approaches are currently employed for TWP analysis, with Fourier-transform infrared (FTIR) spectroscopy and pyrolysis/thermodesorption gas chromatography-mass spectrometry (GC-MS) being most widely used. A less explored yet potentially promising technique for the qualitative and quantitative analysis of TWPs is proton-transfer-reaction mass spectrometry (PTR-MS). In our study, we coupled a PTR-MS analyzer to a custom-built pyrolysis unit, whose temperature was ramped from 250 to 700 °C at a rate of 8 °C/min. In our initial studies, we investigated the volatile pyrolysis products generated from pure tire polymers (polybutadiene, polyisoprene, polystyrene polybutadiene), polymer mixtures and real TWP samples. Each polymer generated a distinct mass spectral fingerprint, allowing to clearly differentiate the three polymers in their pure state, in polymer mixtures and in real-world samples. Furthermore, specific markers for each polymer were identified, providing a foundation for the quantitative analysis of TWPs. Real-world filter samples are currently being collected in urban air to investigate if the mass spectral signatures of TWPs can be detected in real-world samples.

3.23.P-Th401 Microplastics and tyre wear particles infiltration in the soil of a roadside biofiltration swale

Max Beaurepaire[1], *Tiago De Oliveira*[2], *Bruno Tassin*[3], *Johnny Gasperi*[4], *Marie Christine Gromaire*[1] *and Rachid Dris*[3], *(1)LEESU, France, (2)Gers-Lee, Gustave Eiffel University, France, (3)Leesu, Ecole des Ponts ParisTech, Université Paris Est Créteil, France, (4)Gustave Eiffel University, France*

Urban roads stand as a major aspect of human activity. Understanding their contribution to microplastic pollution through macrolitter fragmentation and the generation of tyre and road wear particles is crucial to better assess the sources and fate of microplastics in terrestrial environments. In particular, the microplastic infiltration into roadside soils and soils of sustainable urban drainage systems via urban runoff remains to be assessed.

This study focuses on microplastic infiltration in the soil of a filtration swale alongside a high-traffic highway in the north of Paris, France. Ten soil cores were collected manually at a depth of 35 cm and were each subdivided by depth into four samples ([0-5[, [5–15[, [15–25[, [25–35[cm). Each sample represented a mass of 10 g, that was separated into 2 subsamples for separate quantification of microplastics and tyre wear particles.

After specific treatment processes, the microplastic content of the samples was characterized and quantified using an automated micro-FTIR imaging analysis. The tyre wear particles content of the samples was indirectly assessed by quantifying the styrene-butadiene rubber (SBR) and butadiene rubber (BR) content of the samples by Pyr-GC/MS analysis.

Results revealed a median concentration of 5.4 µg MP g^{-1}, for a median abundance of 4.0 MP g^{-1}. Surface samples presented a significantly higher microplastic abundance than deeper layers, with a median abundance of 47 MP g^{-1} against 1.8 MP g^{-1}. SBR concentrations were significantly higher than microplastics for all samples, with a median concentration of 150 µg SBR g^{-1}, suggesting a much higher tyre wear particles concentration in the roadside soils. Interestingly, SBR concentrations presented a similar vertical profile as microplastics, with a decrease in concentration in the deeper samples.

These findings advocate for an increased attention to tyre wear particles in microplastic studies, particularly within urban contexts, as they likely represent high concentrations and follow similar transport pathways as other microplastics.

3.23.P-Th402 Exposure to Cryogenically Milled Tire Tread Contamination May Induce Functional Changes in Periphyton Communities

Sara Isabel Bastos Gonçalves[1], *Alexandra Kroll*[2], *Thibault Masset*[3], *William Dudefoi, PhD*[1], *Alan J Bergmann*[4], *Etienne Vermeirssen*[4], *Florian Breider*[5], *Benoit JD Ferrari*[4] *and Kristin Schirmer*[1], *(1)Environmental Toxicology, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)Swiss Centre for Applied Ecotoxicology, Switzerland, (3)EPFL, Switzerland, (4)Ecotox Centre, Switzerland, (5)Central Environment Laboratory, Ecole Polytechnique Fédérale de Lausanne – EPFL, Switzerland*

Periphyton communities are complex matrixes composed by prokaryotic and eukaryotic organisms embedded in extracellular polymeric substances (EPS) growing on sediments and rocks of freshwater streams. These autotrophic communities are at the base of the aquatic food webs, being involved in crucial ecosystem processes. Changes at this level can have far-reaching effects on the ecosystem.This is the more important as periphyton covering large surfaces of the stream bottom, may act as a sink for a diverse range of pollutans, including tire and road wear particles (TRWP). TRWP are produced due to abrasion, being deposited on the roadside and, consequently, transferred to the surrounding soil and surface waters. Once in the aquatic environment, the potential interactions of TRWP, and respective leachates, with periphyton communities are unknown. In this study, we aimed at exploring the effects of tire wear particles on periphyton, using cryogenically milled tire tread (CMTT) as currently available surrogate to simulate TRWP. Periphyton grown in flow through channels using stream water (14 d), was subsequently transferred to microcosms and exposed to 0, 50, 500 and 1000 mg CMTT/L (+14 d), with medium exchange every 3-4 d. We measured photosynthetic activity and chlorophyll *a* content as functional endpoints, as well as, community structure and composition assessed via flow cytometry (FC) and next generation sequencing (NGS). Additionally, we recovered the CMTT particles, from which metals and organic chemical content of both medium and periphyton matrix were measured. We hypothesized that CMTT particles would accumulate in the matrix overlaying periphyton, along with a potential bioaccumulation of metals and organic chemical resulting from the particles' leaching. CMTT was accumulated on the biofilm surface; however, we could only measure it at 500 and 1000 mg/L, as for lower concentrations, 0 and 50 mg/L were below the limit of detection for weight.. Moreover, the photosynthetic efficiency decreased by 10 % at 1000 mg/L. This decrease in photosynthetic activity was supported by the decrease in chlorophyll *a* content at 500 and 1000 mg/L. Further analysis are being conducted on the community structure and composition. Follow-up experiments will analyse whether the measured effects result from chemical exposure or shading effect, or both.

3.23.P-Th403 Presence of 6PPD, 6PPDq and Related Compounds in Real Water Samples Contaminated by Coming Into Contact with Tire Rubber Surfaces

Andres Duque-Villaverde[1]*, Victoria Carballeira*[2]*, Daniel Armada*[2]*, Thierry Dagnac*[3] *and Maria Llompart*[2]*, (1)University of Santiago de Compostela, Spain, (2)CRETUS. Department of Analytical Chemistry, Nutrition, Food Science, University of Santiago de Compostela, Spain, (3)Unit of Organic Contaminants, Apartado 10, Agronomic and Agrarian Research Centre (AGACAL-CIAM), Spain*

Tire rubber contained many compounds, such as antiozonants, vulcanizing or crosslinking agents. 6PPD (N-(1,3-dimethylbutyl)-N′-phenyl-p-phenylenediamine) is an antiozonant and its degradation product, 6PPDq (N-(1,3-Dimethylbutyl)-N′-phenyl-p-phenylenediamine-quinone), is linked to the mortality of aquatic species. These chemical agents are introduced into the environment through tire wear particles or through crumb rubber, obtained from recycled tires, used as infill in artificial turf fields or as playground flooring. Water leachates from these types of surfaces contribute as well to the introduction of these substances into aquatic ecosystems, as well. Therefore, the identification and quantification of these organic compounds in water matrixes is crucial.

In this study, an analytical methodology for the simultaneous detection of several tire rubber compounds is proposed. The methodology is based on a miniaturized sample preparation technique, Solid Phase MicroExtraction (SPME), for which no solvent extraction is required, and no hazardous chemicals are employed. The methodology was applied to real water samples in contact with rubber materials, some of them collected from playgrounds, football fields, and parking places. Some of the target analytes, including 6PPD and 6PPDq, were found in the real waters demonstrating their leaching from the rubber.

3.23.P-Th404 Biodegradation of tire-related phenylenediamines and their transformation products identification

Limei Han[1]*, Bettina Seiwert*[1]*, Daniel Zahn*[1] *and Thorsten Reemtsma*[2,3]*, (1)Department of Analytical Chemistry, Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Helmholtz Centre for Environmental Research (UFZ), Germany, (3)University of Leipzig, Germany*

Tire-related chemicals are receiving considerable attention as potential contaminants in the environment. N-(1,3-dimethylbutyl)-N'-phenyl-1,4-benzenediamine quinone (6-PPDQ) is a transformation product (TP) of the tire additive 6-PPD and has been reported to contribute to mortality of some Salmon in the US. Although a number of TPs have been identified from tire additives under environmental conditions such as oxidation and photolysis, there has been limited research on their biodegradation products, which may be of greater environmental relevance. In this study, the biodegradation of the most prominent PPDs and their TPs, N,N'-diphenyl-p-phenylenediamine (DPPD), N-isopropyl-N'-phenyl-1,4-phenylenediamine (IPPD), 6-PPDQ, IPPDQ, 4-nitrosodiphenylamine (NO-DPA), and 4-hydroxydiphenylamine (4-HDPA) was stuided. Their corresponding transformation products (TPs) were characterized using ultra-performance liquid chromatography coupled to high resolution mass spectrometry. A total of 41 biodegradation TPs were detected by the non-target screening and tentatively identified from 6-PPDQ, IPPD, NO-DPA, 4-HDPA, and DPPD. Of these, 17 were stable until 28 days. All studied chemicals exhibited complete primary degradation (removal of parent compound): It varied between a few hours (NO-DPA) to 9 days for 6-PPDQ, with 4-HDPA and DPPD showing removal times ≤ 3 days. Nine of the TPs of 6-PPDQ (6PPDQ_342, 6PPDQ_367, 6PPDQ_315, 6PPDQ_313, 6PPDQ_263A and B, 6PPDQ_319A and B, 6PPDQ_317) showed an increasing trend until the 14th

day and then stabilized until the last day. One of the hydroxylation products of 6-PPDQ (6PPDQ_315) has been reported to be formed in liver cells of rainbow trout. All detected TPs differ from those reported from abiotic ozonation studies. This suggests that other moieties of 6-PPDQ react with bacterial enzymes than with the electrophilic ozone. Also, one of the high intensity TP of HDPA, HDPA_204 could be a coupled TP of the two HDPA molecules. Although self-coupled reactions are unlikely to occur in the environment, this suggests that in more complex environments, such addition reactions may occur with other reaction partners. The discovery and identification of biodegradation products of these tire-related chemicals can be used to further assess their occurrene in the environment and supports risk assessment.

3.23.P-Th406 Characterization of the Impact of Standard Soils as Sample Matrix on the Pyrolysis Products of Polystyrene and Tire Particles

Luca Muth[1]*, Kathrin Müller*[2] *and Stephan Wagner*[3]*, (1)University of Applied Science Fresenius, Germany, (2)Institute for Analytical Research, Hochschule Fresenius, Germany, (3)Hochschulen Fresenius Gemeinnützige, Germany*

While Pyrolysis coupled to gas-chromatography mass spectrometry (Py-GC-MS) is widely applied in the field of tire and road wear particle (TRWP) analysis, major limitations remain. Apart from the fact that tire compositions vary significantly between manufacturers and that there are no reference materials, the applied Py-GC-MS methodologies are not harmonized and oftentimes validation data is lacking. This makes it difficult to compare the results. Validation is also important given the uncertain effects of the matrix on pyrolysis but also regarding the generation of marker substances from the matrix. To limit its impact on the analysis additional, validated sample preparation steps are advisable.

Aim of this work is to investigate the effects of three standard soils (sand, sandy loam, clayey loam) on the pyrolysis of polystyrene and a tire particle mix, with and without sample preparation. Here, potassium hydroxide, described as a promising reagent for sample digestion in literature, will be tested. Validation parameters will be determined to investigate, whether the matrix effects can be sufficiently accounted for by the internal standard calibrated Py-GC-MS method.

Measurements are performed on a Curie-point pyrolysis unit coupled to a GC-HRMS. The commercially acquired standard soils are spiked with a polystyrene standard or tire particle mix at three concentration levels. Samples are spiked with deuterated polystyrene and one half subjected to digestion with KOH at 60°C for 24 h as sample preparation. Afterwards fivefold measurements of the samples are performed to enable validation including recovery, as well as intra- and interday repeatability.

The experiment shows the effect of sample matrix on pyrolysis. It reveals whether the Py-GC-MS approach with internal standard calibration used in many papers is able to account for matrix effects caused by different soil types. Furthermore, the suitability of sample digestion with KOH will be assessed. The results of this work will provide insight into the pyrolysis process and matrix effects and help to further the understanding of Py-GC-MS as tool for the analysis of TRWP.

3.23.P-Th407 Trace Metal Adsorption on Tire and Road Wear Particles in Surface Waters – A Problem for Water Quality?

Angus Rocha Vogel*, Yannik Kolberg and Wolf von Tümpling, Central Laboratory for Water Analytics and Chemometrics, Helmholtz Centre for Environmental Research (UFZ), Germany*

German-wide up to 20,000 t/a of tire wear particles (TWP) are emitted into the aquatic environment. Regarding the total amount of microplastic emissions, TWP contribute to about 30%. Since there is an increasing number of motorised vehicles, a decreasing of TWP emissions is not expected. Recent researches mainly focus on the characterization and on the ecotoxicological effects of TWP on aquatic organisms. Thereby the focus lies on the particles themselves and possible leachates but not as a carrier for adsorbed pollutants.

The overly hydrophobic surface of TWP is capable in adsorbing substances like trace elements. The so bonded pollutants can be ingested by organisms and freed up inside their body. So those pollutants may become bioavailable.

Our investigations tried to characterize these adsorptive effects based on environment-related samples. Therefore, we used different kinds of tire wear particles samples with various estimated tire wear particle content. These samples were either produced by filing, collected behind a driving car (industry partner) of by sampling motorway tunnels (Elbtunnel, Hamburg, Germany). This material, so called *tire and road wear particles including road sediment* (TRWP+RS), contains tire wear particles encrusted with road wear and road related particles as well as other fine particles on the road. Water samples were taken from the Freiberger Mulde, Central East Germany, as an example of a river containing a high amount of trace elements and heavy metals.

In the laboratory TRWP+RS samples were weighed into glassware and filtered water samples (0.2 µm) were added to obtain an environmentally relevant concentration of TRWP+RS. After shaking for 24 h the samples were filtered (0.2 µm) and the element content of the solid samples determined by digestion in a microwave and ICP-MS/MS.

Assessing the adsorption results on the particles with the suspended matter classification of LAWA, we could show that the TRWP+RS itself does not display an endangering except for zinc and copper. Compared to the amount already present in the rivers Freiberger Mulde and Elbe, one could argue not to have an endangering at all. However, when it comes to the adsorption of heavy metals and arsenic an endangering due to chromium, nickel, copper, zinc, and cadmium can be seen due to deterioration of the chemical quality class.

3.23.P-Th408 Comprehensive Approach to National Tire Wear Emissions

Maria Polukarova[1]*, Mattias Hjort*[2] *and Mats Gustafsson*[3]*, (1)Environment, Chalmers University of Technology, Gothenburg, Sweden, (2)Vehicle Systems and Driving Simulation, Swedish National Road and Transport Research Institute (VTI), Sweden, (3)Environment, Swedish National Road and Transport Research Institute (VTI), Sweden*

The use of vehicle tires has been identified as a major source of microplastics in the environment and an increasing source of urban particulate air pollution. In light of increasing traffic volumes, increasingly heavier and more powerful vehicles due to trends and electrification, and the lack of regulation of tire wear, methods to estimate and follow changes in national emissions are needed as input for environmental effect assessments. Emission estimations of tire wear are made either based on the mileage approach or the sales approach. Both approaches have drawbacks related to the availability and representativity of data needed. This study aims to investigate if and how the mileage approach can be improved by using emission factors for passenger cars and light-duty vehicles based on own measurements and emission factors from literature for heavy-duty vehicles and buses. An approach with emission factor adjustments based on weight and number of tires, in combination with highly detailed mileage data, has been evaluated. Sales approach calculations have been used to validate the method. A secondary aim has been to use the new mileage approach framework to calculate the national tire wear emissions for Sweden. These calculations resulted in slightly lower total emissions than previous estimations, with higher emissions for passenger cars and light-duty vehicles, but lower emissions for heavy-duty vehicles and motorcycles. Passenger cars constitute more than half of the total emissions. It is concluded that even though the framework offers greater detail, giving increased possibilities to adjust for changes in emission factors and mileages in specific vehicle categories, the challenges posed by, e.g., lack of measured emission factors for heavy-duty vehicles and uncertainty in the quality of mileage statistics makes the estimations uncertain. Important future research suggestions are establishing reliable emission factors, especially for heavy-duty vehicles, and initiating research to better understand how climate, road network, surface properties, and vehicle fleet characteristics affect emission factors.

3.23.P-Th409 The Identification and Quantification of Tire and Road Wear Particles in Osaka Bay, Japan, by Two Analytical Methods

Timothy R. Barber[1]*, Allison Dillon*[1]*, Sophie Claes*[2]*, Steffen Weyrauch*[3] *and Thorsten Reemtsma*[3]*, (1)ERM, (2)ERM, Belgium, (3)Helmholtz Centre for Environmental Research (UFZ), Germany*

Tire and road wear particles (TRWP) are formed at the frictional interface between tires and the road surface. The mixture of tire tread and road pavement material can migrate from the road surface into receiving waters during precipitation events. Based on the density of TRWP, they are expected to partition into sediment. The lack of mass-based measurements in marine environments represents an uncertainty in environmental risk assessments and fate and transport models. This study investigated the abundance and distribution of TRWP in Osaka Bay, Japan. Surface water and sediment grab samples were collected from nine locations within the bay in June 2023. Sediment traps were deployed for a period of approximately nine weeks at three locations along a 13.5 km transect from the mouth of the Yodo River. Surface water samples, collected in large volumes, underwent filtration through 100, 10, and 0.5 µm bag filters using a water pumping system to capture retained solid particles. After drying, large particles (>5 mm) were removed, and the solid samples were homogenized and sub-sampled. Sediment and retained solid samples were analyzed for TRWP using a microfurnace Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS) method (ISO Technical Specification 21396:2017, modified) and a particulate zinc method. In addition to TRWP analyses, sediment samples were analyzed for total organic carbon and grain size distribution. Surface water grab samples were collected and analyzed for total and dissolved organic matter as well as total suspended solids. TRWP results will be compared between the two analytical methods to assess the consistency in detecting and quantifying TRWP in marine samples. The concentrations of TRWP in Osaka Bay will be compared to previously reported findings in Lake Biwa and the Yodo River, contributing to an understanding of spatial and temporal variations of TRWP in this heavily populated and industrialized watershed. The results of this study will enhance our knowledge of TRWP concentrations in a marine environment and inform efforts to assess potential environmental risks, calibrate mass-balance models, and develop strategies for mitigating TRWP in the environment.

3.23.P-Th410 The measurement of tire and road wear particles in road surface, roadside soil and retention basin samples in the Chesapeake Bay watershed, USA

Timothy R. Barber[1]*, Sophie Claes*[2]*, Allison Dillon*[1]*, Steffen Weyrauch*[3] *and Thorsten Reemtsma*[3]*, (1)ERM, (2)ERM, Belgium, (3)Helmholtz Centre for Environmental Research (UFZ), Germany*

When vehicles travel on a road, the tires and road surface interact with each other, resulting in the generation of tire and road wear particles (TRWP). The mixture of tire tread and road pavement material can migrate from the road surface to soils adjacent to the road via wind dispersion and into receiving waters during precipitation events. A comprehensive study of TRWP was conducted from June to September, 2023, across various environmental matrices within the Chesapeake Bay watershed, USA. Sampling efforts included road surfaces, roadside soil, stormwater, surface water and sediment in the Baltimore, Maryland, area. Road surface samples were collected using a high-efficiency vacuum from a tunnel, a high-use road and a low-use road. Surface soil samples were collected from 1 to 30 meters from a high-use road in a series of three transects. Stormwater, surface water and sediment samples were collected from a retention basin receiving runoff from the high-use road.

Stormwater and surface water samples, collected in large volumes, underwent filtration through 100, 10, and 0.5 µm bag filters using a water pumping system to capture retained solid particles. Solids were screened through a 5 mm sieve to remove large particles and homogenized in a ball mill. TRWP concentrations were analyzed using a microfurnace Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS) method (ISO Technical Specification 21396:2017, modified) and a particulate zinc method. Soil and sediment samples were analysis for total organic carbon and grain size distribution. Surface water grab samples were collected and analyzed for total and dissolved organic matter, as well as total suspended solids. Comparison of results obtained from these two methods will provide valuable insights into the consistency between these analytical approaches in detecting and quantifying TRWP in a variety of environmental matrices. Additionally, TRWP concentrations from this study will be compared to previously reported findings in the Chesapeake Bay watershed, contributing to our understanding of spatial and temporal variations of TRWP in aquatic systems. The outcomes of this study will advance our knowledge of TRWP, aiding in estimating emission factors, understanding TRWP migration via wind dispersion and stormwater runoff, calibrating mass-balance models, assessing environmental risks and developing strategies to mitigate TRWP in the environment.

3.23.P-Th411 Exploring the Presence and Spatial/Temporal Patterns of Tire and Road Wear Particles in the Seine River, France

Timothy R. Barber[1]*, Sophie Claes*[2]*, Francisca Ribeiro*[3]*, Allison Dillon*[1]*, Stephanie A. Thornton*[4]*, Kenneth Unice*[4]*, Steffen Weyrauch*[5] *and Thorsten Reemtsma*[5]*, (1)ERM, (2)ERM, Belgium, (3)Queensland Alliance for Environmental Health Sciences (QAEHS), University of Queensland, Australia, (4)Cardno ChemRisk now Stantec, (5)Helmholtz Centre for Environmental Research (UFZ), Germany*

Tire and road wear particles (TRWP), formed at the frictional interface between tires and the road surface, are widely present in the environment. Tire tread and road pavement materials are denser than water but can be washed from the road surface into receiving water bodies, ultimately depositing into sediment. TRWP have been identified in various environmental compartments but limited research has been conducted on estuarine samples. The main objectives of this study were (1) to determine TRWP in surface water and sediment along the Seine River by two different methods: refined Pyrolysis Gas Chromatography/Mass Spectrometry (Py-GC/MS) and particulate zinc, (2) compare the results from the present study with past TRWP data from the Seine River, and (3) understand the sources and fate and transport processes of TRWP. Surface water and sediment samples were collected from eight locations along the Seine River, France. These locations included upstream of Paris, within the Paris metropolitan area, downstream of Paris near smaller urban areas, adjacent to an undeveloped area and near the confluence of the river and the English Channel. At each location, surface water was collected for: the analysis of matrix characterization parameters (i.e., total organic carbon (TOC), dissolved organic carbon, and total suspended solids), retained solids for the analysis of styrene-butadiene/butadiene rubber, natural rubber, and total TRWP, and sediment samples for TOC, grain size, and TRWP analysis. The Py-GC/MS analysis of TRWP in surface water ranged from 0.54 to 10 µg/L and from <180 to 2,300 mg/kg in sediment. Surface water samples showed higher concentrations near Paris - consistent with the increased traffic density and more impermeable surfaces. The highest sediment concentration was observed downstream of a wastewater treatment plant – suggesting a potential source to the environment. TRWP concentrations estimated by the zinc method (1.8 to 5,120 mg/kg) were on average more than three times higher than reported by the refined Py-GC/MS method. Comparisons of the study's results of total Zn with available historical data revealed a decrease in TRWP over the last decade, suggesting an improvement in overall water quality in the region. This study is the first to report TRWP concentrations using two different methods in estuarine samples.

3.23.P-Th412 Tyre Wear and other Microplastics in Snow in Urban Traffic Environments

Ida Jarlskog[1]*, Göran Blomqvist Dr.*[1]*, Mats Gustafsson*[1]*,* ***Maria Polukarova***[2] *and Yvonne Andersson-Sköld*[3]*, (1)Environment, Swedish National Road and Transport Research Institute (VTI), Sweden, (2)Department of Architecture and Civil Engineering, Chalmers University of Technology, Sweden, (3)Swedish National Road and Transport Research Institute (VTI), Sweden*

Microplastics from road traffic, mainly from tyre wear, are globally considered to be one of the largest sources of microplastic contamination in the environment. Plastics can either be deposited in the road vicinity, at the roadside and in ditches or spread via stormwater and air to the environment and receiving water bodies. In cold climates, microplastics, as well as other traffic-related pollutants, can be temporarily stored in snow and ice on and around roads and streets. The location and concentration of these pollutants is influenced by winter operations, where ploughing and skid control contribute to redistribution, and by melting and compaction of ice and snow. This creates reservoirs of microplastics and other pollutants, which are released into stormwater or surrounding soil during thaws, but also provides an opportunity to reduce the spread of microplastics by managing snow and ice appropriately. In this work, a case study of microplastics in snow has been carried out in the municipality of Karlstad in Sweden, to get an idea of the potential variation, both in terms of concentration and total amounts in relation to traffic and the location of the sampling in the street environment. Microplastics have been analysed by pyrolysis GC/MS to identify tyre-specific polymers in combination with eight commonly occurring plastic types. In addition, six municipalities in different parts of the country responded to a questionnaire on microplastics in snow and urban snowmelt management. The results show that microplastics related to tyre wear (rubber polymers) tend to be present in higher concentrations on and near the carriageway. Other plastics show a less clear link to traffic. Along a salted bicycle lane, an elevated level of polypropylene, from which the brush of the sweep-salting machine is made, could be detected in the surface layer of the snow. In general, knowledge about microplastics in urban snow is low in the municipalities that responded to the survey. The results imply a potential to differentiate handling of different urban traffic snow compartments to mitigate microplastic emissions via runoff from snow melting.

3.23.P-Th413 Tyre Wear Particles at a Swedish Highway– Occurrence in Stormwater, Sediments and Snow

Elly Gaggini[1], *Ekaterina Sokolova*[2], *Elisabeth Støhle Rødland*[3], *Maria Polukarova*[1,4], *Ann-Margret Strömvall*[1], *Yvonne Andersson-Sköld*[1,5] *and Mia Bondelind*[1], *(1)Department of Architecture and Civil Engineering, Chalmers University of Technology, Sweden, (2)Department of Earth Sciences, Uppsala University, Sweden, (3)Norwegian Institute for Water Research (NIVA), Norway, (4)Environment, Swedish National Road and Transport Research Institute (VTI), Sweden, (5)Swedish National Road and Transport Research Institute (VTI), Sweden*

The presence of tyre wear particles (TWP) in stormwater runoff and sediments has been previously confirmed and quantified, increasing concerns due to their potential impact on the environment and human health. Understanding tyre wear occurrence, spread, and transport in stormwater can aid prediction of TWP concentrations and prioritisation of remediation measures. The aim is to present a synthesis of a large research investigation of TWP in water, sediments and snow samples at the highway E18 in Sweden. The goals of the investigation were to: i) quantify TWP occurrence in a highway stormwater system, ii) assess TWP transport in the stormwater system during rain, and iii) quantify TWP in snow at different distances from the road. A comprehensive campaign for collecting environmental samples has been conducted at Testsite E18, located by the Swedish highway E18, which is a road research facility belonging to the Swedish Transportation Administration. The facility offers the possibility to sample water and sediments in a stormwater system connected to the highway (gully pots, wells, ditches and receiving water), sample water from direct runoff and sample snow along the highway. Water samples were analysed at size fraction 1.6–500 µm, and snow and sediment samples were analysed at size fraction <500 µm. Part of the samples were also analysed at size fraction 1.6–20 µm. The samples were analysed for styrene butadiene rubber and butadiene rubber using Pyrolysis GC-MS, and the tyre wear mass was calculated using Monte Carlo simulations based on traffic data, as proposed by Rødland et al. (2022) [1]. The median TWP <500 µm concentrations detected in the water grab samples ranged between 0.4 and 17 mg/l. The sediment samples contained median TWP <500 µm concentrations ranging from below detection limit up to 25 mg/g dry weight. In addition to these results, concentrations of TWP in stormwater samples from rain events and snow samples will be presented. This study is one of the first to investigate TWP concentrations in different parts of a stormwater system, the variation of TWP concentration during a rain event, and the occurrence of TWP in snow alongside a highway.

A Novel Method for the Quantification of Tire and Polymer-modified Bitumen Particles in Environmental Samples by Pyrolysis Gas Chromatography Mass Spectroscopy. J Hazard Mater 423 Part A:127092.

3.23.P-Th414 Detection and Effects of pneumatic microparticles in aquatic environments – Case study in run-off water

Coralie Julia Le Picard[1], *Jérôme Cachot*[2], *Arno Bringer*[3] *and Helene Thomas*[4], *(1)University of La Rochelle, France, (2)EPOC CNRS, University of Bordeaux, France, (3)Qualyse, France, (4)LIENSs CNRS, La Rochelle University, France*

Microparticles resulting from tire wear on roads are now recognized as a significant contributor to microplastic pollution. These micrometric residues mainly come from tire tread, which contains chemicals such as plasticizers, antioxidants, reinforcing agents, and fillers. Various studies have demonstrated the toxic potential of these compounds for aquatic organisms. Therefore, studying the kinetics of releasing these particles into the environment and their potential toxicity is essential. The PLASTyre project aims to detect and quantify tire microparticles in runoff water via stormwater retention structures in close collaboration with local stakeholders (Nouvelle-Aquitaine region). To this end, a methodological development in µFTIR verified by GC-MS pyrolysis will be carried out. The project's second objective is to assess the potential toxicity of tire micro-particles using two types of particles: Cryogenically Milled Tire Tread and Tire and Road Wear Particles (TRWP). Macrofragments of tires will also be artificially aged in a UV chamber and then agitated to obtain leachates. Organisms' exposure to these leachates will allow us to assess the effect of the harmful compounds potentially released. Toxicity tests will be performed on various study models, including marine bacteria, bivalves, fish, and amoebae, via direct exposure to particles or leaching. Thanks to a combination of detection techniques and methodological development using state-of-the-art equipment, we could potentially identify the presence of TRWP in areas with dense traffic, as recent studies on the subject suggested. Some articles have revealed some toxic effects of tire microparticles on specific study models. It will, therefore, be interesting to study various other biological models belonging to different taxa using concentrations representative of the environment and lethal and sub-lethal endpoints. This project could provide new insights into the current analytical capabilities, fate, and potential toxicity of these compounds in the environment.

3.23.P-Th415 Tyre and Road Wear Particles and Additive Chemicals in Roadside Sustainable Drainage Systems (SUDS)

Katie McKenzie[1], *Linda A. Lawton*[1], *Angela Pllu*[2], *Iain Campbell*[2] *and Bruce Petrie*[1], *(1)Robert Gordon University, United Kingdom, (2)Balfour Beatty plc, UK Construction Services, United Kingdom*

Tyre and Road Wear Particles (TRWPs) are an understudied source of microplastic (MP) pollution in the aquatic environment. Tyres also leach toxic chemical additives. There are several routes from roads to the environment, including surface runoff. One method of road drainage is by Sustainable Drainage Systems (SUDS) such as retention ponds, which retain runoff for a period before releasing into the wider environment, allowing for sedimentation of particles and removal of contaminants via chemical and biological processes. However, there is a current lack of sampling methodologies for adequate and representative sampling of TRWPs and additive chemicals simultaneously.

A portable stainless-steel sampler was designed for simultaneous sampling for additives and particles over 24 hours utilizing a battery powered peristaltic pump. Stainless-steel sieves (250, 100, and 50 µm) facilitated in-situ fractionation of TRWPs.

Developed analytical methods enabled the quantification of TRWPs by microscopy and analysis of 25 additives by UHPLC-MS/MS in road runoff.

Particles >50 µm were quantified and categorized in samples collected from a SUDS retention pond serving the Aberdeen Western Peripheral Route (AWPR) road in North-East Scotland. A total of 70.7 particles/L were found, 43.4 of which were black particles/TRWPs and 17.6 were white or reflective, likely originating from road paint. 86.5% of particles were within the 50-99 µm fraction, including 83.7% of suspected TRWPs and 97.3% of white/reflective particles. Seven chemical additives, (1H-benzotriazole, 5-methylbenzotriazole, N,N-diphenylurea, 1-cyclohexyl-3-phenylurea, 2-aminobenzothiazole, 1,3-diphenylguanidine, and 2,4,6-tris(bis(methoxymethyl)amino-1,3,5-triazine) were detected. Concentrations ranged from 0.0084±0.000050 - 0.18±0.012 µg/L and 0.073±0.0058 – 0.44±0.14 µg/L in inlet and outlet samples respectively. Interestingly, negative removals were observed for all seven additives between -28 and -774 % suggesting leaching from TRWPs in retention ponds.

TRWPs and suspected paint fragments have been found in samples from SUDS ponds serving the AWPR along with seven additive chemicals. This suggests that road drainage could act as a pathway for plastic pollution into the wider environment. Future work will investigate the impact of weather conditions on the suitability of SUDS to remove TRWPs and additive chemicals and compare different drainage designs serving different road types and driving conditions.

3.23.P-Th416 Chemical Profile and Toxicity of Leachates from Different Types of Tires

Elisabeth Støhle Rødland[1], *Ana Catarina Almeida*[1], *Maria Christou*[1], *Sebastian Kuehr*[2], *Jan Thomas Rundberget*[1] *and Tania Gomes*[3], *(1)Norwegian Institute for Water Research (NIVA), Norway, (2)University of Siegen, Germany, (3)Norwegian Institute for Water Research (NIVA), Oslo, Norway*

Studies have demonstrated that tires contain a wide range of compounds in tires and tire leachates, including synthetic and natural rubbers and natural rubber, metals and organic compounds. To evaluate which types of tires may have the highest impact on the environment based on the chemical profiles and the toxicity of their leachates. Our main aim was to investigate the concentration levels of rubbers, selected metals (zinc, nickel and copper) and selected organic compounds (6-PPD-q (N-(1,3-dimethylbutyl)-N′-phenyl-pphenylenediamine, 6-PPD), HMMM (hexa(methoxymethyl)melamine) and DPG (N,N′-Diphenylguanidine) in leachates from 4 tires (winter studded, winter non-studded, summer, truck) (35mg/L) across 21 days of leaching. We tested the toxicity of the leachates in the freshwater microalgae *Raphidocelis subcapitata* and zebrafish embryos *Danio rerio*, to determine if the chemical composition of the four tires had different effects on these organisms.

The synthetic rubber content was highest in the truck tire (43%). The highest metal levels were found for zinc (4.8-202 µg/L), and levels increased over the 21 days (ANOVA, p<0.0001). A significant difference between tire types were found (p<0.05), with the highest levels coming from the truck tire (111 ± 73 µg/L). All organic compounds increased in the leachates across the 21 days, except for 6PPD and HMMM. The 6PPD-quinone levels increased from 610 to 4230 ng/L across 21 days (p<0.0001). No significant difference in 6PPD-q levels were found between the tire brands (p=0.509) or the tire types (p=0.138). 71% of the variation (RDA, p<0.0001) could be explained by the brand, vehicle type, seasonal tire type and time of leaching. The truck tire was the most toxic to *R. subcapitata* (EC50=28.44 mg/L. In terms of specific toxicity, ROS formation, metabolic activity and neutral lipid content were the most affected parameters. parameters. A small effect in survival and hatching rate were observed for zebrafish embryos, with truck tire showing the highest effects.

The different responses in microalgae and zebrafish suggest a correlation with the chemical profile of the CMTT. Our results demonstrate the importance of assessing the chemical profiles and toxicity of individual tires, as well as in mixtures. This is particularly important to understand the impact from tires and their leachates in different environmental compartments.

3.23.P-Th417 Investigating toxicity pathways of crumb rubber-derived particles and leachates on blue mussels Mytilus edulis

Maria Elisabetta Michelangeli[1], *Steven Brooks*[1], *Emelie Forsman*[1], *Davide Spanu*[2], *Elisabeth Støhle Rødland*[1], *Sebastian Kuehr*[1], *Sicco Brandsma*[3], *Marja Lamoree*[3], *Lisbet Sorensen*[4] *and* ***Tania Gomes***[5], *(1)Norwegian Institute for Water Research (NIVA), Norway, (2)University of Insubria, Italy, (3)Vrije University Amsterdam, Netherlands, (4)SINTEF Ocean, Norway, (5)Norwegian Institute for Water Research (NIVA), Oslo, Norway*

Tyre wear particles together with end-of-life tyres (ELTs) are major contributors to microplastic pollution in aquatic ecosystems. Moreover, increasing concerns revolve around their complex chemical composition. During manufacturing, additives as aromatic heterocyclic compounds, aromatic amines and heavy metals are added to the rubber polymer matrix to enhance its properties. Under environmental conditions, these chemicals can leach into the ecosystem, posing a significant risk to aquatic biota. However, studies with aquatic species have primarily focused on the effects of tyre particles alone and/or individual additives, highlighting a critical gap in the discrimination between their toxicity drivers and pathways. Thus, the main objective of this study was to assess and differentiate the impacts of car tyre particles, using crumb rubber from ELTs (TP, <300µm), car tyre leachates (L) and car tyre particles after 14 days of leaching (TPL, <300µm) on adult mussels *Mytilus edulis*. Mussels were chosen as model organisms due to their ecological and commercial roles. Mussels were exposed for 28 days to 0.1 g/L of TP, L and TPL, followed by 1 week depuration. Three ecotoxicological biomarkers, namely lysosomal membrane stability (LMS), acetylcholinesterase activity (AChE) and lipid peroxidation (LPO) were evaluated at five different sampling points (0, 7, 14, 28 and 36 days) in different mussel tissues. Organisms were also analyzed for particle and chemical bioaccumulation. Preliminary data indicates treatment and time dependent responses. Lower LMS values were observed at day 7 for TP and day 28 for TPL, indicating changes in mussel health status. TP also led to an increase in LPO levels after 7 days of exposure, potentially indicating oxidative stress. AChE activity was significantly inhibited by L at day 7 and TP at day 28, suggesting a neurotoxic effect. Additionally, AChE levels for L and TP remained below the control values even after depuration, indicating continuous neurotoxicity. This study reveals insights into the mechanisms of toxicity associated with tyre-derived particles and their leachates towards marine biota. It further suggests a significant early role of the chemical component, as well as a synergic effect between additives and particles. Nonetheless, there is still a need for further investigation on the specific toxicity pathways of tyre particles and leachates in organisms to thoroughly assess their potential environmental implications.

3.23.P-Th418 Understanding the Impact of Chemical Leachates from Car Tire Rubber on Marine Microalgae: Insights into Toxic Mechanisms and Ecosystem Implications

Ana Catarina Almeida[1]*, Sicco Brandsma*[2]*, Sebastian Kuehr*[1]*, Marja Lamoree*[2]*, Lisbet Sorensen*[3]*, Andy Booth, PhD*[3] *and Tania Gomes*[4]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)Vrije University Amsterdam, Netherlands, (3)SINTEF Ocean, Norway, (4)Norwegian Institute for Water Research (NIVA), Oslo, Norway*

Micronized car tire rubber (CTR) particles contribute significantly to the presence of plastic particles in the environment, raising concerns about the release of chemical additives into the marine ecosystem. Some of these additives are highly toxic to aquatic organisms, posing a serious threat to microalgae, at the basis of the aquatic food web. As keystone organisms, any disturbances in microalgae communities can have far-reaching consequences for the entire aquatic ecosystem. This study investigates the toxic effects of chemicals associated with CTR, released during 7 and 14 days of leaching, on four marine microalgal species: *Skeletonema pseudocostatum*, *Rhodomonas baltica*, *Isochrysis galbana*, and *Tetraselmis suecica*.

Screening tools such as flow cytometry and pulse amplitude modulated fluorometry were initially employed to assess general toxicity, focusing on parameters like growth rate, cell size, complexity, natural pigments content, and photosystem II performance. Results revealed that the 14-day leachate exhibited the highest toxicity across all species, with *S. pseudocostatum* displaying the greatest sensitivity (EC_{50}=3.26 mg/mL). Subsequently, a high-throughput methodology was employed at sub-lethal levels to investigate the specific toxic mechanisms of CTR leachates. Analysed endpoints included metabolic activity, cell viability, cytoplasmic and mitochondrial membrane potentials, reactive oxygen species (ROS) formation, lipid peroxidation, neutral lipids, cellulose, and DNA contents.

The study uncovered the specific toxic mechanisms of CTR leachates on crucial components of microalgae cells, with notable impacts on ROS formation, oxidative stress, and a significant reduction in cellulose content. This comprehensive analysis provides new insights into the toxicity mechanisms of CTR leachates on marine microalgae, emphasizing the importance of understanding the potential impacts of plastic-associated chemicals on the marine ecosystem. This research was supported by the MicroLEACH project (#295174), funded by the Norwegian Research Council.

3.23.P-Th419 A Comparison of the Uptake of Tyre Particles via Suspension and Surface Deposit Feeding in the Estuarine Amphipod, Corophium volutator

Charlotte Ashley Woodhouse[1,2]*, Penelope Lindeque*[1]*, Tamara Susan Galloway*[2] *and Matthew Cole*[1]*, (1)Plymouth Marine Laboratory, United Kingdom, (2)Biosciences, University of Exeter, United Kingdom*

Tyre particles, produced from abrasion between car tyres and roads, have been reported as a major source of microplastic pollution for aquatic environments. The release of tyre particles has been recognised as an environmental pollutant since the 1970s, but only in the last decade has research begun to elucidate the extent of this contamination in the natural environment. In recent years, toxicological research has begun to focus on whether the ingestion of tyre particles can cause deleterious impacts in biota. In this study, I expose the estuarine amphipod *Corophium volutator* to environmentally relevant concentrations of tyre particles to quantify the adherence and ingestion of tyre particles via two different feeding modes: suspension feeding and surface deposit feeding. I hypothesise that *C. volutator* will ingest tyre particles, within their optimal prey size range, via both feeding modes. *C. volutator* were collected from a clean field site and acclimated for 14 days in clean sediment. Cohorts of three *C. volutator* were then placed into their respective exposure treatments dosed with environmentally relevant concentrations of tyre particles (0.1 g L^{-1}) under constant environmental conditions. For the suspension feeding treatment, *C. volutator* were placed in artificial burrows suspended within seawater, and for the surface deposit treatment, *C. volutator* were allowed to create burrows in natural sieved sediment. Following an hour exposure, the individuals were removed from the treatments and imaged for adhered tyre particles and digested using NaClO for the ingested particles. In the suspension treatment, tyre particles were found to be adhered and ingested by all individuals. There was a significant difference in where the tyres aggregated (Kruskal-Wallis, df=6, $p<0.001$). *C. volutator* had higher numbers of adhered particles to the antenna compared to other body parts, this may pose problems for the organism as the role of the antennae is to sense the environment and aid in crawling behaviour. If the antennae are saturated with tyre particles, it may lead to behavioural changes and being more susceptible to predation as their ability to sense their environment may be altered. The outcomes of this study will elucidate the risk tyre particles pose to biota in benthic estuarine and coastal environments.

3.23.P-Th420 It's Getting Confusing: 6PPD-quinone Induces Developmental Cardiotoxicity in Fathead Minnow (Pimephales promelas) Embryos Following Microinjection

Katherine Anderson-Bain[1]*, Phillip Ankley*[2]*, Catherine Roberts*[2]*, Evan Kohlman*[2]*, Xiaowen Ji*[2]*, Alper James Alcaraz*[2]*, Justin Miller*[1]*, Tabitha Gangur-Powell*[1]*, Tony Montina*[1]*, Lynn Weber*[2]*, David M. Janz*[2]*, Markus Hecker*[2]*, Markus Brinkmann*[2] *and Steve Wiseman*[1]*, (1)University of Lethbridge, Canada, (2)University of Saskatchewan, Canada*
N-(1,3-dimethylbutyl)-N′-phenyl-*p*-phenylenediamine-quinone (6PPD-quinone), an oxidation product of the rubber tire antioxidant, 6PPD, is an emerging contaminant of concern that was first identified as the cause of Urban Runoff Mortality Syndrome, a mass lethality event observed in coho salmon (*Oncorhynchus kisutch*). Acute lethality of 6PPD-quinone is highly species-specific, with the only sensitive species identified to date being some salmonids. Using waterborne exposures, we previously found that neither sexually mature fathead minnows (*Pimephales promelas*) exposed to 6PPD-quinone at 9.4µg/L, or embryos exposed to 6PPD-quinone at 40 µg/L suffered acute lethality. Further, embryos did not show any developmental malformations. Using metabolomics and transcriptomics, we showed evidence of sublethal oxidative stress in adults. Based on these findings, we selected fathead minnows as a model species to further investigate potential sublethal effects of 6PPD-quinone. To ensure consistent and precise dosing, newly fertilized embryos were microinjected with 6PPD-quinone at nominal doses of 18.5, 55.5, 166, 500, and 1500 ng/g of egg. Consistent with our previous findings. exposure to 6PPD-quinone did not induce mortality up to 12 days post-fertilization. However, a suite of developmental malformations was observed, including spinal curvature, pericardial edema, abnormal heart morphology, lack of common cardinal vein development, and hemorrhaging at sporadic anatomical areas. Frequency of these effects ranged from 30-100%, depending on dose. To understand the mechanisms of these results, whole transcriptome RNA sequencing and 6PPD-quinone metabolite analysis is currently being performed. These studies will provide novel insight into mechanisms of toxicity of 6PPD-quinone to fishes.

3.23.P-Th421 Chronic Toxicity of Tire Additive 6PPD and its Oxidized Substance 6PPD-Q in the Reproduction and Locomotion of Daphnia magna

Yooeun Chae*, Jung Eun Min, Sooyeon Kim and Hyungmin Kim, Ecological Risk Assessment Center, Korea Institute of Toxicology (KIT), Korea, Republic of (South)*
N-(1,3-Dimethylbutyl)-N'-phenyl-p-phenylenediamine (6PPD; CASNR: 793-24-8), which is added to tires as an antioxidant and antidegradation agent, is known to have excellent anti-ozone properties that help prevent tire wear. While 6PPD has been used in tires since the mid-1960s, it has recently been found to convert to the oxidation product N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine quinone (6PPD-Q; CASNR: 2754428-18-5) during use, and its toxicity to fish has been of particular concern. To evaluate the chronic toxic effects of 6PPD and 6PPD-Q on aquatic organisms, a 38-day toxicity test was conducted using the standard test species, the common water flea (*Daphnia magna*). On post-exposure day 21, the heart rate, body length and total moving distance of *D. magna* were measured. Additionally, total reproduction during 38 days was also counted. In results, the heart rate and body length of *D. magna* exposed to highest concentration of 6PPD-Q (1.0 mg L^{-1}) significantly decreased after 21 days of exposure. In the case of locomotion, it was revealed that both 6PPD and 6PPD-Q promote the movement of *D. magna* exposed to the chemicals. Both chemicals were found to reduce the normal neonate incidence of water fleas in the high concentration exposure group, and it was observed that fertilized eggs that were not fully developed in the mother organisms were expelled from the body, resulting in a decrease in the reproductive rate of water fleas. Consequentially, long-term exposure of *D. magna* to 6PPD and 6PPD-Q induced decrease of individual growth, heart rate, and reproduction and increase of movements of organisms at high concentrations. This suggests that 6PPD and 6PPD-Q may adversely affect water flea populations and ecological health when continuously introduced to the aquatic environment. 3.23.P-Th422 Fate, Effects and Ecosystem Interactions of 6-PPD-Quinone: A Freshwater Enclosure Study

Lauren Timlick[1]*, Kerri Lynn Ackerly*[2]*, Kathleen Roark*[2]*, Carolyn Currie*[3]*, Erin Ussery*[4]*, Vince Palace*[1]*,* ***Jose Luis Rodriguez Gil***[1] *and Kristin Nielsen*[2]*, (1)Experimental Lakes Area (IISD-ELA), Canada, (2)Marine Science Institute, University of Texas at Austin, (3)University of Manitoba, Canada, (4)Environment and Climate Change Canada, Canada*
Tire tread particles consist of rubber left behind on roadways by vehicle traffic that can be washed into waterways by rainfall. These particles contain various chemicals that enhance performance, durability, and safety of the tires. One of these chemicals, 6PPD, is an anti-ozonant, that breaks down into 6PPD-quinone (6PPDq) when exposed to solar radiation and oxygen. 6PPDq is toxic to certain fish species (e.g. coho salmon and brook trout) but there is a large range of sensitivity in even closely related fish (i.e. sockeye or chinook are insensitive). At the IISD-Experimental Lakes Area a whole ecosystem approach was used to investigate the fate and chronic sublethal effects of environmentally relevant 6PPDq concentrations in freshwater. A gradient of single-pulse exposures (5 - 100 µg/L), conducted using in-lake enclosures (~ 5,000 L), allowed us to better understand the effects of 6PPDq on lower trophic levels and how these indirect effects may contribute to fish mortality. Dissolved oxygen was measured using HOBO Dissolved Oxygen Loggers (5 min interval) and was lower (< 8 mg/L) in the highest two treatments (47.3 and 100 µg/L) compared to the control enclosures. Primary production was assessed using biofilm strips colonized for 3 weeks prior to sampling. There were no significant differences in chlorophyll-a production in the biofilm between treatments. Benthic invertebrate communities were assessed using Hester-Dendy substrate samplers and were dominated by chironomids in all treatments. There was significantly less colonization in the two highest treatments 3 days post-addition, but the invertebrates returned by day 8. Analysis of the corresponding emergent insect data is underway to help explain this anomaly. In addition to the in-lake experiment, we collected wild fathead minnow eggs to conduct in lab exposures using water from each enclosure 4 days post-6PPDq addition. The eggs were collected <24 hrs post-fertilization and monitored for 7 days in a temperature and light controlled room. There were no effects on growth or significant differences in the brain, eye, yolk sac or heart sizes relative to the total metabolic area of the larvae. There was, however, a significantly higher mortality rate and a

developmental delay in swimbladder inflation in the highest treatment (100 μg/L) compared to the controls. Additional results including water and sediment chemistry, zooplankton community structure, and emergent insect speciation will be presented.

3.24 Unveiling the Chemical Exposome: Insights From Human Biomonitoring and Its Influence on Adverse Health Outcomes

3.24.T-01 Non-targeted screening for bisphenol related contaminants and restricted or unusual parabens in human milk

*Zhi Hao Chi[1], Lan Liu[1], Jingyun Zheng[1], Lei Tian[2], Jonathan Chevrier[1], Riana Bornman[3], Muvhulawa Obida[3], Cindy Gates Goodyer[4], Barbara F. Hales[1] and **Stéphane Bayen**[1], (1)McGill University, Canada, (2)Food Science, McGill University, Canada, (3)University of Pretoria, South Africa, (4)MUHC, Canada*

Breast milk is a vital source of infant nutrition, yet it contains chemical contaminants that may pose health risks. Contemporary approaches to human milk biomonitoring predominantly rely on targeted methodologies, which are constrained in their capacity to identify emerging contaminants, suggesting the need for novel tools to improve their detection. In our study, non-targeted analysis (NTA) was applied to 194 human milk samples collected from the Vhembe district of Limpopo Province (South Africa), 193 samples collected from Pretoria (South Africa), and 207 samples from Montreal (Canada) to identify the presence of bisphenol derivatives, as well as other conjugated plastic-related unknowns. Liquid chromatography quadruple time-of-flight mass spectrometry (Agilent Technologies) was used to detect 33 tentative bisphenol related unknowns by employing a customized database library of compounds. In total, the identity of twelve different bisphenol related compounds was confirmed using pure analytical standards. NTA was further applied to parabens in South African human milk samples, and the presence of 6 parabens confirmed using pure analytical standards. Notably, our study revealed the presence of several synthetic antioxidants as well as restricted or unusual parabens that have not been previously reported in human milk biomonitoring studies. This study highlights the importance of utilizing non-targeted analysis, demonstrating its potential to improve current human milk biomonitoring by uncovering a wide variety of unexpected or restricted compounds.

3.24.T-02 Longitudinal Profiling of the Human Blood Chemical Exposome

*Kalliroi Sdougkou[1], **Stefano Papazian**[1], Bénilde Bonnefille[1], Hongyu Xie[1], Fredrik Edfors[2], Linn Fagerberg[2], Mathias Uhlen[2], Göran Bergström[3], Leah J.M. Martin[4] and Jonathan W. Martin[1], (1)Department of Environmental Science, Stockholm University / Science for Life Laboratory (SciLifeLab), Sweden, (2)KTH-Royal Institute of Technology / Science for Life Laboratory (SciLifeLab), Sweden, (3)University of Gothenburg / Wallenberg Laboratory and Sahlgrenska Center for Cardiovascular and Metabolic Research, Sweden, (4)Independent researcher, Sweden*

The temporal dynamics of the exposome are poorly understood, yet this is a critical factor at the design stage of long-term studies to minimize exposure misclassification and ensure statistical power for detecting multi-omics interactions or associations with disease. Within the Swedish SciLifeLab SCAPIS Wellness Profiling program, longitudinal profiling of the human blood chemical exposome was performed with repeated individual sampling ($n = 6$) from multiple individuals ($n = 46$) over 2 years.

Plasma samples ($n = 276$) were analyzed following a chemical exposomics protocol which combined solid-phase extraction for the removal of plasma phospholipid background with LC-HRMS (Orbitrap) multiclass targeted and untargeted analysis via data-independent acquisition (DIA) and a deconvolution-based open-source data processing workflow.

Data were analyzed integrating multivariate analysis, hierarchical clustering, mixed-effect models, and intra-class correlation coefficients (ICCs) to explore temporal trends and correlations of chemicals and metabolites, and to assess the individual variability and longitudinal stability of the chemical exposome.

The comprehensive analysis resulted in 129,547 unique untargeted features detected between ESI+ and ESI-, with targeted analytes comprising 0.04% of the dataset. The annotated dataset (0.4% annotation rate) included confirmed identities (Level 1) and confident structural candidates (Level 2a) for 343 environmental chemicals (11 subclasses), 162 endogenous metabolites, and 14 substances of ambiguous origin.

Chemical exposome and endogenous metabolites were classified based on their temporal variability (ICC) and incidence (detection frequency) across the population. Among the most common and stable components of the chemical exposome, PFAS substances were consistently detected in all individuals across all visits. In females, positive correlations were observed between testosterone and specific PFAS, while testosterone in males was negatively correlated with perfluorooctanoate (PFOA). These correlations suggest potential co-exposures and exposome-metabolome interactions, including endocrine disruption.

This study emphasizes the highly dynamic nature of the human blood chemical exposome. Recognizing novel exposures and exposome-metabolome interactions in individuals contributes valuable insight for advancing our understanding of the intricate interplay between environmental exposures throughout the lifecourse and human health.

3.24.T-03 A Step Towards Assessing the Early Exposure to Per- And Poly-fluorinated Compounds (PFAS) in Childhood and Adolescence: A Human Biomonitoring Cohort Study

***Anne San Román**[1], Eunate Abilleira[2], Amaia Irizar[3], Juan Francisco Ayala Cabrera[4], Belen Gonzalez-Gaya[5] and Nestor Etxebarria[1], (1)Department of Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (2)Department of Analytical Chemistry, Epidemiology and public health, BioGipuzkoa Health Research Institute, Spain, (3)Epidemiology and public health, University of the Basque Country (UPV/EHU), Spain, (4)Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (5)ESTACI"N MARINA DE PLENTZIA. UPV/EHU, Spain*

Per- and poly-fluorinated substances (PFASs) have increased the attention as emerging, ubiquitous and persistent contaminants during the recent years. The first exposure to PFAS occurs in utero, and after birth, it continues via breast milk, food intake, environment (through air and dust) and consumer products containing these compounds. A chronic exposure to these compounds from early steps of life pose a relevant threat since it was found to contribute significantly to later health problems in adulthood.

In this scenario, in order to establish a possible causality between environmental or early exposure to PFAS and human health across the course of life, epidemiology plays a key role. In this regard, INMA (Childhood and Environment) research network was founded. Thus, a large survey of PFAS analysis in children plasma was performed, analysing N=623 samples from a Spanish cohort at 4, 8 and 14 years. For that, High Performance Liquid Chromatography coupled to a High-Resolution Mass Spectrometer (q-Orbitrap) was used, and up to 38 compounds were detected above the method limit of detection. The compound detection frequency results show a detection decrease according to age for some legacy PFAS. However, it is necessary to highlight that 26% of children would have levels above the threshold recommended by German Biomonitoring Comission for PFOA (2 µg/L). Likewise, the presence of shorter chain PFAS (PFBS, PFBA, PFPeA) nowadays considered replacement species had increased in more recent samples as well as compounds like GenX, ADONA or 9Cl-PF3ONS. The correlation analyses show a possitive correlation between mother PFAS levels and levels at 4 years. Nevertheless, no correlation was found at 4 and 14 years. This might suggest that diet, breastfeeding and habits according to age may affect PFAS exposure patterns. In order to find which were the predictor factors associated with PFAS exposure, linear regression models were performed. The results show a possitive association for mother levels and levels at 4 years, as well as, levels at 4 years and breastfeeding which may imply these two factors in PFAS early exposure. These findings suggest that the exposure pattern changes according to age. Indeed, a decreasing trend of the most persistent compounds, might be linked to the public health policies applied in recent years. Conversely, the detection of short-chain PFAS or emerging species in most recent samples may imply that the PFAS exposure paradigm is changing.

3.24.T-04 Advanced suspect screening approach for silicone wristbands and urine to reveal the early-life chemical exposome

Camilla Guerrini[1]*, Mahsa Naghavi Sheikholeslam*[2]*, Roger Giné Bertomeu*[3]*, Josep Maria Badia*[3]*, Maria Vinaixa Crevillent*[3] *and Noelia Ramírez González*[2]*, (1)Rovira i Virgili University (URV), Spain, (2)Fundación Instituto de Investigación Sanitaria Pere Virgili -IISPV, (3)University Rovira i Virgili (URV)*

Due to children's vulnerability, exposure to environmental chemicals during early-life represents a significant threat to developing chronic diseases[1]. A comprehensive understanding of chemical exposome is crucial to identify the exposures and devise effective intervention strategies. Target approaches that focus on determining specific classes of compounds overlook the health effects of dynamic chemical exposures. One of the main challenges faced is to develop a wide-scope screening approach to access a broader characterisation of the chemical exposome, and link environmental exposures and health[2]. Silicone wristbands (WBs) have recently emerged as an effective, low-cost, and child-friendly way of capturing volatile and semi-volatile organic compounds.

Our study aims to enhance the characterisation of the chemical exposome via a wide-scope suspect screening workflow based on HERMES[3], using liquid chromatography and high-resolution mass spectrometry. 361 children (4-11 years old) living with smoker and non-smoker parents in the area of Tarragona (Northeastern Spain), home to the largest petrochemical site in Southern Europe, were sampled. HERMES is a molecular formula-oriented and peak detection-free method to generate sample-specific inclusion lists (IL). NORMAN Substance Database and in-house thirdhand smoke database (38147 unique molecular formulas) were used to create the ILs. In the WBs, 634 chemicals have been comprehensively annotated with a level 3, including tobacco smoke toxicants, personal care products, insect repellents, and plastic additives. From those chemicals, 29 were confirmed at level 2, whilst 3 were identified by standards. We also demonstrated that tobacco smoke exposure is underestimated and ubiquitous. Contrary to the reported 36% of children being directly exposed to tobacco smoke at home, we have determined that nicotine, cotinine, nicoteline and myosmine were present in 80% of the participants, indicating the relevance of outside home exposure.

Our work shows how a suspect screening workflow based on HERMES enhances the characterisation of the chemical exposome and confirm the potential impact of tobacco smoke exposure on children. The next step is the characterisation of urines to identify exposure biomarkers and metabolic alterations to find the association between air pollutants and health, to then compare the results from the two matrices.

1)10.1056/NEJMra0708473; 2)10.1186/s13321-021-00489-0; 3)10.1101/2021.03.08.434466

3.24.P Unveiling the Chemical Exposome: Insights From Human Biomonitoring and Its Influence on Adverse Health Outcomes

3.24.P-Th423 Assessing The Pregnant Women Chemical Exposome Through Serum And Placenta (Semi)Quantitative Analysis

Esteban Restrepo-Montes[1]*, Jordi Sunyer*[2]*, Mariona Bustamante*[3]*, Payam Dadvand*[4]*, Oksana Golovko*[5]*, Adria Sunyer*[6]*, Raquel*

Marzo Díaz[7], Ruben Gil-Solsona[1] and Pablo Gago Ferrero[1], (1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Centre for Research in Environmental Epidemiology, Spain, (3)Barcelona Institute for Global Health (ISGlobal), Spain, (4)ISGlobal-CREAL, Spain, (5)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (6)Stockholm University, Sweden, (7)Environmental chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain
The huge exposure to a myriad of pollutants and their introduction through diet, personal care products usage and daily activities have raised several questions related with their bioaccumulation in humans and their subsequent adverse health effects. One of the most concerning subpopulation is pregnant women, since newborns have a high risk associated with exposure, with possible outcomes such as low birthweight or preterm birth, among others. In order to estimate their chemical exposure, different tools have been employed, but the most informative one is through human biomonitoring. In our work (included inside of project AirNB), the main goal was to evaluate the occurrence of xenobiotics in 300 pregnant women from Barcelona, in both women' serum and placenta.

For the serum samples, a deproteinization with acetonitrile followed by centrifugation was made, while for placenta a tissuelysing combined with solid phase extraction (using wide-scope covering homemade cartridge) was applied. Procedural blanks (10%) were also included in the batch to account for possible contamination. Finally, all the samples were analyzed in an LC-HRMS (Q-Exactive) instrument and the data treatment was carried out with an in-house database of >700 contaminants. The quantification of the samples was done using matrix matched calibration curves, when the compound was included,and with an in-house developed semi-quantification tool based on ionization efficiency.

In serum samples, 149 chemicals were detected in at least 1 of the participants ranging from ng/L to mg/L while for placenta a total of 119 were detected. These chemicals included plasticizers (and their metabolites), tire additives, air pollutants, personal care products or flame retardants among others. We could observe 35 common chemicals between both matrices which gives information of the vital biological role of the placenta as a chemical barrier for foetus wellbeing. However many other chemicals detected in the serum (and not in placenta) might be permeating the barrier, posing a potential threat to the foetus and its development. This information will be used for the analysis (currently ongoing) of paired cord blood samples. These results will be used in collaboration with epidemiologists involved in Barcelona Life Study Cohort to identify metabolic dysregulation or health outcomes linkages caused by the presence of these chemicals.

3.24.P-Th424 Potential Association of Endocrine-Disrupting Chemicals with Frontal Fibrosing Alopecia: A Case-Control Study

***Ana González Ruiz**[1], Rodrigo Braz Carneiro[2], Esteban Restrepo-Montes[3], Antonio Lobato[4], Ramón Pujol[4], Montse Marques[5], Ruben Gil-Solsona[3] and Pablo Gago Ferrero[3], (1)Pere Virgili Health Research Institute (IISPV), Italy, (2)São Carlos Institute of Chemistry, University of São Paulo (USP), Butantã, Brazil, (3)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (4)Dermatology, Hospital del Mar, Spain, (5)Rovira i Virgili University (URV), Tarragona, Spain*
Frontal Fibrosing Alopecia (FFA) is the leading cause of scarring alopecia, especially affecting postmenopausal women. Although the exact causes of FFA remain unclear, genetic and hormonal factors are suspected to be involved. Recent research suggests that environmental factors, particularly endocrine-disrupting chemicals (EDCs), may contribute to FFA development by interfering with natural hormones and impacting long-term health.

Our research focuses on the potential impact of EDCs in FFA development. For that purpose, we conducted a *proof-of-concept* case-control study involving 10 FFA patients and 10 age-matched controls, and collected blood, urine, and hair samples for analysis. Serum samples were deproteinized with acetonitrile. Urine samples underwent centrifugation to remove solids, and Captiva cartridges were employed for endogenous chemical filtration. Hair samples were cleansed of surface contaminants with dichloromethane and methanol, ground with bead beating and EDCs were extracted using MeOH. The analysis was performed using liquid chromatography coupled to high-resolution mass spectrometry (LC-QTOF).

Among the 48 EDCs analyzed, 35 were detected, with the highest number of compounds found in hair samples (63%), followed by urine (42%) and serum (27%). Parabens and flame retardants were consistently present in all matrices. The concentration range in hair was notably higher than in the other two matrices, which may be because hair provides information on long-term exposure. To assess differences between FFA group and controls, the Mann-Whitney U test was performed. Statistically significant differences ($p<0.05$) were observed for mono(2-ethyl-5-oxohexyl phthalate) (5-Oxo-MEHP) and triphenyl phosphate (TPhP) in urine samples, and a noticeable trend towards higher concentrations in FFA cases compared to controls was observed in hair and urine, suggesting a potential association with FFA. Serum samples, possibly affected by the limited sample size and the number of detected compounds did not exhibit the same trend.

In conclusion, our study highlights the importance of using diverse biological samples for understanding the chemical exposome. While 5-Oxo-MEHP and TPhP in urine of FFA group is significantly higher ($p<0.05$) than in the control group, a broader trend towards higher concentrations in FFA cases was notable in hair and urine matrices. It is important to note that this study is a *proof-of-concept* and results should be interpreted cautiously.

3.24.P-Th425 Nontarget and Multi-Class Target Chemical Exposomics in Human Plasma by Lipid Removal and Large Volume Injection GC-HRMS

Hongyu Xie[1], *Kalliroi Sdougkou*[1], *Bénilde Bonnefille*[2], *Stefano Papazian*[2], *Ingvar Bergdahl*[3] *and Jonathan W. Martin*[1], *(1)Stockholm University, Sweden, (2)Department of Environmental Science, Stockholm University / Science for Life Laboratory (SciLifeLab), Sweden, (3)Department of Public Health and Clinical Medicine, Occupa, Umea University, Sweden*

Research on the human chemical exposome depends on improved analytical methods, which are still evolving to meet the practical challenges of sensitivity and a wide chemical space. Only 5% of the 350,000 chemicals in global commerce have ever been analyzed in environmental media, primarily by targeted methods. Recent advances have been reported for multi-class target or nontarget chemical exposomics in human plasma by gas chromatography (GC-) with Orbitrap high resolution mass spectrometry (HRMS), however Orbitrap technology can suffer from low sensitivity for trace analytes in complex matrices due to the auto gain control (AGC) function, and co-extracted lipids may lead to instrumental fouling and high demands for maintenance. We hypothesized that a GC-Orbitrap HRMS chemical exposomics workflow for plasma could be enhanced by effectively removing major lipid interferences at the extraction stage, thereby also enabling large volume injection of the extracts for increased method sensitivity. In this study, a representative list of 103 target analytes from 6 chemicals classes were selected for method development, including tests of various lipid removal steps (e.g. liquid-liquid and solid-phase extractions) and different instrumental parameters. Here a simple and potentially scalable liquid-liquid extraction protocol was developed and validated for GC analysis of small plasma sample volumes while optimizing for lipid removal, high-recovery and sensitivity of priority target analytes. The validated median method quantification limit (MQL) was 0.08 ng/mL (range 0.005–4.83 ng/mL) for 200 µL plasma samples. In individual adult plasma (100 µL, n=32), 52 target analytes from 5 classes were detected. Of these, 25 were above MQL and were quantified, 8 of which also showed significant increasing or decreasing temporal trends. In nontarget analysis, a total of 992 molecular features were detectable at least once among all individual plasma samples, and 81 high-confidence annotations were made. Ongoing application of the method to a larger longitudinal cohort will also be discussed.

Keywords: Human exposome, gas chromatography (GC), Orbitrap, high resolution mass spectrometry (HRMS), Chemical exposure, Plasma

3.24.P-Th426 Unveiling the Chemical Exposome of Brain Cancer: A Proof of Concept

Ruben Gil-Solsona[1,2], *Daniel Gutiérrez-Martín*[1], *Albert Pons-Escoda*[3], *Sergi Díez*[1], *Noemí Vidal-Sarro*[3], *Jordi Bruna*[3], *Payam Dadvand*[4], *Carles Majos*[3] *and* ***Pablo Gago Ferrero***[1], *(1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Department of Chemistry, Laboratory of Analytical Chemistry, National and Kapodistrian University of Athens, Greece, (3)Hospital Universitari de Bellvitge, Spain, (4)ISGlobal-CREAL, Spain*

Diffuse gliomas are a highly heterogeneous and aggressive brain tumours with poor prognosis and survival and few established risk factors. Environmental exposures are suspected in the pathogenesis of these tumours; however, results of existing studies are limited and inconsistent, particularly for exogenous organic chemicals, with no available characterization of the chemical exposome of these tumours. Also, better understanding of phenotypic differences in tumour types is needed in order to improve clinical decision making and provision of personalised treatment recommendations. In this proof-of-concept study we analysed 33 glioblastoma samples (Bellvitge Glioma Cohort (BGC), Spain, 2005-present), including 16 methylated and 17 non-methylated tumours combining HRMS-based wide-scope target and suspect strategies [1]. Forty-six exogenous chemicals were identified in the tumour tissue samples (31 confirmed with standard) including a variety of industrial chemicals (e.g. plastic additives or perfluorinated compounds), personal care products and pharmaceuticals. Our findings provide novel evidence on the presence of these chemicals in brain tissue, highlighting the need for comprehensive evaluations of their potential effects in the tumour pathogenesis. Finally, after applying metabolomics methods we observed clear differences in the profiles of endogenous chemicals among the studied glioma subtypes, and identified possible biomarkers. These chemicals have potential to be determined in a non-invasive manner, either by LCHRMS-based blood analysis or using complementary techniques (proton magnetic resonance (1H-MRS)). These are inspiring results since methylation is a strong independent predictor of survival as well as tumour response to chemotherapy for glioblastoma. Indeed, its non-invasive and pre-surgical determination would have a major impact on patient management. Our preliminary data is suggestive for the potential of nontargeted exposome methods to find new valuable biomarkers for diffuse gliomas diagnostic and prognostic stratification.

3.24.P-Th427 Holistic determination of the prenatal exposome for a comprehensive overview of placental barrier

Montse Marques[1], *Ruben Gil-Solsona*[2], *Elena Sánchez Resino*[3], *Ana González Ruiz*[4], *Ana Megia*[5], *Albert Guarque*[6], *José Luis Domingo*[7], *Ana Navas-Acien*[8], *Adrian Covaci*[9] *and Pablo Gago Ferrero*[2], *(1)Rovira i Virgili University (URV), Tarragona, Spain, (2)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Universitat Rovira i Virgili, Laboratory of Toxicology and Environmental Health, Faculty of Medicine and Health Science, Spain, (4)Pere Virgili Health Research Institute (IISPV), Italy, (5)Hospital Universitari de Tarragona Joan XXIII, Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Spain, (6)Gyneocology and Obstetrics Service, Joan XXIII University Hospital, (7)TecnATox | Universitat Rovira i Virgili, Spain, (8)Columbia University Mailman School of Public*

Health, (9)University of Antwerp, Belgium
The complex interplay between pregnancy and environmental exposures, particularly to Endocrine-disrupting Chemicals (EDCs), unveils a compelling avenue for research in maternal-fetal health. The distinctive biological changes that transpire during pregnancy render women uniquely susceptible to the disruptive effects of EDCs. In this proof-of-concept investigation, we embarked on a pioneering endeavor employing a comprehensive and efficient analytical approach, tapping into the full potential of HRMS-based strategies. Our primary objectives were to (1) conduct a thorough characterization of the human chemical exposome in pregnant women and (2) elucidate the physicochemical properties of chemicals capable of traversing the placental barrier, thereby potentially compromising the fetal environment. We applied a wide-scope target analysis encompassing over 2000 chemicals by means of a Q-Exactive Q-Orbitrap instrument coupled to UHPLC to paired samples of urine, maternal blood, cord blood, and placental tissue sourced from 23 pregnant women within the population-based INSULIN mother-child cohort (Ref. CEim 225/2020). Our results unveiled the presence of 81 distinct chemicals observed in at least one of the sampled biofluids. Specifically, our study revealed that 45 of these chemicals demonstrated the ability to traverse the placental barrier, as evidenced by the presence of 10 food components, 5 pharmaceuticals, 8 personal care products, 8 plasticizers, 1 persticide, 4 flame retardants and 9 industrial chemicals. Inverse correlations were observed between placental transfer rates and LogP (ρ= -0.438; $p<0.001$), molar refractivity (ρ= -0.485; $p=0.003$), volume of van der Waals (ρ= -0.386; $p=0.003$), number of heavy atoms (ρ= -0.360; $p=0.005$), number of hydrogen (H) (ρ= -0.361; $p=0.005$) and carbon (C) (ρ= -0.407; $p=0.001$), and eccentricity (ρ= -0.332; $p=0.01$). In conclusion, pregnant women face extensive exposure to a myriad of chemicals, with particular concern directed towards compounds exhibiting heightened hydrophilicity, smaller size, compact structure, and reduced complexity, which possess an elevated likelihood of traversing the placenta, thereby raising concerns about their potential impact on fetal development. Implementing urgent measures tailored to substances characterized by properties conducive to placental crossing is imperative to safeguard the health of future generations

3.24.P-Th428 Advanced HRMS-Based Strategies for Profiling and Semi-Quantification of Exogenous Chemicals in Human Urine.

Daniel Gutiérrez-Martín[1]*, Esteban Restrepo-Montes*[1]*, Oksana Golovko*[2]*, Reza Aalizadeh*[3]*, Rebeca López-Serna*[4,5]*, Nikolaos S. Thomaidis*[3]*, Montse Marques*[6]*, Pablo Gago Ferrero*[1] *and Ruben Gil-Solsona*[1,7]*, (1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (3)National and Kapodistrian University of Athens, Greece, (4)Institute of Sustainable Processes (ISP), Spain, (5)Department of Analytical Chemistry, Faculty of Sciences, University of Valladolid, Spain, (6)Rovira i Virgili University (URV), Tarragona, Spain, (7)Department of Chemistry, Laboratory of Analytical Chemistry, National and Kapodistrian University of Athens, Greece*
Chemical substances permeate our daily lives through various exposure routes, prompting the need for comprehensive assessment tools. Human biomonitoring (HBM) traditionally relied on targeted screening methods employing triple quadrupole instruments and a limited set of chemicals. Advances in high-resolution mass spectrometry (HRMS) have expanded the scope, enabling wide-scope target, suspect, and non-target analyses within acceptable detection limits. Despite these advances, establishing reliable sample treatment protocols remains crucial for broad-range chemical analysis. This research aimed to validate a methodology utilizing HRMS-based approaches for precise profiling of exogenous chemicals and associated metabolites in urine samples. We assessed five extraction protocols, spanning diverse chemical classes such as pharmaceuticals, plastic additives, personal care products, or pesticides. Our assessment considered extraction recoveries, linearity, matrix effect, sensitivity, and reproducibility. The most effective protocol underwent thorough validation with a set of 90 chemicals and was applied to 10 real human urine samples via wide-scope target analysis, covering over 2,000 chemicals. Using an ionization efficiency-based model, we successfully identified and semi-quantified 36 chemicals, demonstrating the robust performance of the methodology. Importantly, our findings challenged the necessity of a deconjugation step, a traditionally labor-intensive and time-consuming process.

3.24.P-Th429 Biomonitoring of Different Endocrine-Disrupting Chemicals Metabolites in Urine Samples

Sandra Callejas Martos[1]*, Carlota Bravo-Novau*[2] *and Ethel Eljarrat*[2]*, (1)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*
A multitude of chemicals and contaminants enter the human body, through various exposure pathways, predominantly via inhalation, ingestion, or dermal contact. A common example is the endocrine-disrupting chemicals (EDCs). These chemicals (e.g. phthalates, organophosphate esters (OPEs), and parabens) mimic endocrine hormones, which can affect the normal physiological mechanisms of human beings, even at low concentrations, leading to some health issues. So the biomonitoring of these compounds in human samples is crucial to understanding the possible adverse effects that global exposures (including all pathways) could cause on human health. Of the many matrices available for human biomonitoring, urine samples stand out due to their high sample volume availability, easy collection, and non-invasive nature.

This study focused on developing and validating a rapid analytical methodology to have a successful approach for the biomonitoring of diverse EDCs including eight OPEs, five phthalates, and three parabens. To set up the method, specific aspects of the extraction procedure were rigorously evaluated for their impact on sensitivity and matrix effect. Furthermore, a systematic optimization of both chromatographic and mass spectrometry conditions was implemented, utilizing ultra-high-performance liquid chromatography (UHPLC) coupled with tandem mass spectrometry (QTOF). Additionally, for later real sample analysis, creatinine concentrations in urine were determined to correct metabolite concentration levels due to urine dilution.

The optimized method exhibited favorable analytical performance, including acceptable recoveries ranging from 46 to 99%, with acceptable relative standard deviations (RSD ≤ 20%), and low LODs and LOQs. This method was finally applied to biomonitoring 16 EDCs in 44 urine samples; 29 samples were obtained from teenagers (ages 13-16), and 15 from workers in an e-waste recycling company (e-waste RC), considered to have higher exposure due to their occupational activities. EDCs metabolites were identified in all urine samples. Notably higher concentrations of EDC metabolites were observed in samples from workers of the recycling company than in teenager samples, particularly for phthalate metabolites, commonly found in their occupational environment. The results obtained from the urine sample analysis were used to calculate the estimated daily intake and the corresponding risk associated with this exposure, for both groups of citizens.

3.24.P-Th430 Wide-scope Target and Nontarget Profiling of the Airborne Chemical Exposome using Polydimethylsiloxane (PDMS) Passive Samplers

Adrià Sunyer-Caldú[1]*, Bénilde Bonnefille*[2]*, Foteini Raptopoulou*[1]*, Camille Fornaroli*[1]*, Hongyu Xie*[2]*, May Britt Rian*[1]*, Jean Froment*[1]*, Stefano Papazian*[2]*, Jonathan W. Martin*[2] *and Edouard Pesquet*[3]*, (1)Department of Environmental Science, Stockholm University, Sweden, (2)Department of Environmental Science, Stockholm University / Science for Life Laboratory (SciLifeLab), Sweden, (3)Department of Ecology, Environment and Plant Sciences, Stockholm University, Sweden*

Air pollution is a major cause of premature mortality worldwide, and exposures to various airborne substances in our homes, workplaces, or in ambient air, have been implicated in disease. Nevertheless, the chemical composition of the air we breathe is poorly characterized. To support next generation research on the airborne exposome, we therefore aimed to develop an inexpensive and easily deployable air sampler that would be suitable for nontarget analysis, and which could simultaneously collect (semi-) volatile organic compounds and particulate matter.

To achieve this, we recently reported on the synthesis and nontarget analysis of polydimethylsiloxane (PDMS) foam disks for passive sampling of airborne contaminants. In the initial investigation, PDMS foam deployed indoors for 1 to 3 months, and analyzed by gas chromatography (GC-) and liquid chromatography (LC-) coupled to high-resolution mass spectrometry (HRMS), revealed accumulation kinetics for polar and non-polar substances that suggested effective uptake of both the gas- and particulate-phase. In the current work we further investigate the sampling properties of PDMS foam disks obtained from a commercial supplier, and report on the optimization and quantitative validation of LC-HRMS and GC-HRMS methods for over 200 target analytes from 20 chemical families with diverse physicochemical properties.

Two pilot studies followed method validation. The first study (indoor and outdoor, 6 weeks) assessed chemical uptake and its correlation with particles adsorbed onto the foam surface. Using microscopy, outdoor foams deployed for 3 weeks and 6 weeks averaged 136 and 260 particles mm^2 respectively, showing a significant increase and linear sampling capacity for particles (R^2 = 0.944, r = 0.972, and p-value = 0.03). The second study (indoor, 8 weeks) evaluated reproducibility between replicates using quantitative (target) and qualitative (nontarget) approaches. Among target analytes, plasticizers (e.g. phthalates), various industrial chemicals (e.g. 4-nitrophenol), insecticides (e.g. DEET), and flame retardants (e.g. OPFRs) were most frequently detected. Nontarget analysis further allowed confident annotation (level 2) of additional industrial and commercial substances not in the target list, in addition to natural products and plant volatiles. Within the framework of the Horizon Europe INQUIRE project, PDMS foam disks are now being deployed in over 200 homes across 8 European countries.

3.24.P-Th431 Exposure level to legacy phthalates and alternative plasticizer metabolites in urine during pregnancy and delivery

Na-Youn Park[1]*, JinYeong Heo*[1]*, Heeyeon Chae*[2]*, Hyeri Jeon*[1]*, SuBeen Park*[3]*, In-Kyu Lee*[3]*, Gowoon Lee*[4]*, Inae Lee*[5]*, Jeong-Won Oh*[6]*, Jeong Jae Lee*[6]*, Gyuyeon Choi*[6]*, Kyungho Choi*[2] *and Younglim Kho*[1]*, (1)Department of Health, Environment & Safety, Eulji University, Korea, Republic of (South), (2)School of Public Health, Seoul National University, Korea, Republic of (South), (3)Department of Food Technology & Service, Eulji University, Korea, Republic of (South), (4)Environmental Health Sciences, Seoul National University of Science and Technology, Korea, Republic of (South), (5)Seoul National University, Korea, Republic of (South), (6)Departmenet of Obstetrics and Gynecology, Soonchunhyang University College of Medicine, Korea, Republic of (South)*

Phthalates have been widely used as plasticizers to soften plastics. When exposed to the human body, they interfere with or disrupt the action of hormones, acting as endocrine-disrupting chemicals (EDCs), and have been reported to exhibit reproductive toxicity, including infertility. Consequently, international regulations have been imposed on the use of phthalates, leading to the development of alternative plasticizers to evade regulations. However, there is limited information on the toxicity of alternative plasticizers and data on human exposure monitoring are lacking. Pregnant women are sensitive to chemical substances, and EDCs can be transmitted to the fetus through the placenta. This study aimed to assess the levels of legacy phthalate and alternative plasticizer metabolites in the urine of pregnant women during pregnancy and delivery.

Sixteen metabolites of legacy phthalates and 20 metabolites of alternative plasticizers were selected as target analytes. Urine samples from the “DearMom cohort” collected in Korea in 2022 (first trimester (n=16), second trimester (n=42), third trimester (n=37), and at delivery (n=27)) were analyzed. Samples were processed by enzymatic treatment, followed by solid-phase extraction, and were quantitatively analyzed using LC-MS/MS.

The results of the urine sample analysis revealed that the detection rates of 10 metabolites of legacy phthalates and eight metabolites of alternative plasticizers were above 70%. As a result of comparing urine concentrations (median) by quarter of pregnancy (1st, 2nd, 3rd trimester, and at birth), MCPP (0.635, 0.561, 0.988, 0.130ng/mL) and DEC (3.860, 4.600, 7.910, 0.049) ng/mL) were significantly lower in urine concentrations at delivery than during pregnancy ($p<0.05$). MEHP (0.862, 1.340, 0.988, and 4.470 ng/mL) and OH-MINCH (0.133, 0.149, 0.140, and 1.400 ng/mL) levels remained at similar levels during pregnancy and then increased at birth ($p<0.05$). Additional research is needed to investigate the association between phthalate and alternative plasticizer levels and the characteristics of mothers (age, pregnancy experience) and infants (birth size, placental pathology).

Acknowledgements: This work was supported by Korea Environment Industry & Technology Institute (KEITI) through Core Technology Development Project for Environmental Diseases Prevention and Management Program(or Project), funded by Korea Ministry of Environment(MOE)(2022003310004, RS-2022-KE002055)

3.24.P-Th432 Lipidomic Changes and Toxicity Induced in Human Lung Cells by a Mixture of Water Disinfection byproducts

Mahboubeh Hosseinzadeh[1], *Cristina Postigo*[2] *and Cinta Porte*[1], *(1)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Civil Engineering / Institute of Water Research (IdA), University of Granada (UGR), Spain*

Complex mixtures of disinfection by-products (DBPs) are present in disinfected waters, but their mixture toxicity has been rarely described. Apart from ingestion, DBP exposure can occur through inhalation, which may lead to respiratory effects in highly exposed individuals. However, the underlying biological mechanisms have yet to be elucidated. This study aimed to investigate the toxicity of a mixture of 10 DBPs, including haloacetic acids and haloaromatics, on human alveolar A549 cells by assessing their cytotoxicity, genotoxicity, and impact on the cell lipidome. A DBP mixture up to 50 µM did not affect cell viability but induced the generation of reactive oxygen species (ROS) up to 3.5-fold, and increased the frequency of micronuclei formation. Exposure to 50 µM DBP mixture led to a significant accumulation of triacylglycerides (TGs) and a decrease of diacylglycerides (DGs) and phosphatidylcholines (PCs) in A549 cells. Lipidomic profiling of extracellular vesicles (EVs) released in the culture medium revealed a marked increase in cholesterol esters (CEs), sphingomyelins (SMs), and other membrane lipids. Overall, these alterations in the lipidome of cells and EVs may indicate a disruption of lipid homeostasis, potentially contributing to the respiratory effects associated with DBP exposure.

3.24.P-Th433 "Exposure Levels of Environmental Phenols in the Urine of Pregnant Women during Pregnancy and Childbirth"

SuBeen Park[1], *Na-Youn Park*[2], *Heeyeon Chae*[3], *Hyeri Jeon*[2], *In-Kyu Lee*[1], *Jeong-Won Oh*[4], *Jeong Jae Lee*[4], *Gyuyeon Choi*[4], *Kyungho Choi*[3] *and Younglim Kho*[2], *(1)Department of Food Technology & Service, Eulji University, Korea, Republic of (South), (2)Department of Health, Environment & Safety, Eulji University, Korea, Republic of (South), (3)School of Public Health, Seoul National University, Korea, Republic of (South), (4)Departmenet of Obstetrics and Gynecology, Soonchunhyang University College of Medicine, Korea, Republic of (South)*

Environmental phenols are one of the major endocrine-disrupting chemicals (EDCs) that act as environmental pollutants. When they are absorbed into the human body, they can disrupt natural hormones. Exposure to environmental phenols during pregnancy can lead to conditions such as premature birth, fetal growth retardation, and low birth weight. Pregnant women are particularly vulnerable to the adverse effects of environmental pollutants, which can harm both the mother and fetus. Therefore, this study aims to investigate the levels of environmental phenol exposure during pregnancy and childbirth by analyzing urine samples.

The target analytes are 28 compounds, including 7 parabens, 4 paraben metabolites, 2 antimicrobials, 4 benzophenones, and 11 bisphenols. Urine samples of the “DearMom cohort” were collected quarterly from pregnant women in Korea in 2022, 16 in the first quarter, 42 in the second quarter, 37 in the third quarter, and 27 during childbirth. The samples were stored at -70°C until analysis. Preparation of urine samples was performed using liquid-liquid extraction. Quantitative analysis was carried out using UPLC-MS/MS.

The results indicate that 7 out of 28 analytes had detection rates above 60%. The median values of 7 compounds are as follows; MeP 66.50 ng/mL, EtP 41.25 ng/mL, 4-HB 697.00 ng/mL, 3,4-DHB 74.25 ng/mL, OH-MeP 1.77 ng/mL, OH-EtP 0.43 ng/mL, BPS 0.31 ng/mL. Among the 7 analytes, MeP, 4-HB, 3,4-DHB, OH-MeP, and BPS showed significant differences across quarters($p<0.05$). The t-test results showed increasing levels of 4-HB, OH-MeP, and BPS during the third quarter, while MeP increased at childbirth. In contrast, 3,4-DHB decreased at childbirth ($p<0.05$). Additional research on environmental phenol exposure is necessary to effectively manage health risks for pregnant women and fetuses.

Acknowledgments: This work was supported by Korea Environment Industry & Technology Institute (KEITI) through Core Technology Development Project for Environmental Diseases Prevention and Management Program(or Project), funded by Korea Ministry of Environment(MOE)(2022003310004, RS-2022-KE002055)

3.24.P-Th434 Identification of exogenous organic compounds in blood plasma, seminal plasma and urine, and their association with human semen quality

Elena Sánchez Resino[1,2,3], Germán Cano Sancho[4], Albert Salas Huetos[5,6,7,8], María Ángeles Martínez[5,6,9], María Fernández de la Puente[5,6,9], Jordi Salas Salvadó[5,6,9], Nancy Babio[5,6,9], Ruben Gil-Solsona[10,11], Pablo Gago Ferrero[10] and ***Montse Marques****[1,3,12], (1)Universitat Rovira i Virgili, Laboratory of Toxicology and Environmental Health, Faculty of Medicine and Health Science, Spain, (2)Center of Environmental, Food and Toxicological Technology-TecnATox, Universitat Rovira I Virgili, Spain, (3)Institut d'Investigació Sanitària Pere Virgili, Spain, (4)Oniris, INRAE, LABERCA, France, (5)Institut d'Investigació Sanitària Pere Virgili (IISPV), Spain, (6)Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y la Nutrición (CIBEROBN), Institute of Health Carlos III, Spain, (7)Unit of Preventive Medicine and Public Health, Faculty of Medicine and Health Sciences, Universitat Rovira i Virgili, Spain, (8)Department of Nutrition, Harvard T.H. Chan School of Public Health, Harvard University, (9)Departament de Bioquímica i Biotecnologia, Unitat de Nutrició, Universitat Rovira i Virgili, Spain, (10)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (11)Department of Chemistry, Laboratory of Analytical Chemistry, National and Kapodistrian University of Athens, Greece, (12)Rovira i Virgili University (URV), Spain*

Decreased semen quality has been described in different industrialized regions worldwide. Published studies suggest that the exposure to a growing number of synthetic chemicals could be responsible of a poor semen quality and contribute to the male fertility decline in the last decade. Hence, it is important to deeply characterize male's chemical exposome. The present study is aimed at identifying the presence of exogenous chemicals in urine, blood plasma and seminal plasma, and explore their associations with semen quality parameters. Hence, we applied a novel LC-HRMS method for an exposome scale profiling of >2000 organic chemicals in these matrices from participants (n=48) to the Spanish LED-FERTYL cohort. Results revealed a total of 49, 48 and 33 chemicals detected in at least one sample of urine, semen or blood plasma, respectively. Among them, we have found pharmaceuticals, industrial chemicals, biocides and food related chemicals. Five of them were simultaneously found over 25% urine and blood plasma samples, highlighting the high positive correlations for the herbicide quinmerac and caffeine (r=0.84-0.82) followed by cyclamic acid(r=0.51). Likewise, four compounds were also simultaneously detected in urine and seminal plasma, highlighting the high positive correlations between matrices for the caffeine and quinmerac(r=0.80-0.75) followed by the theobromine(r=0.31). Some surfactants, methylparaben, nicotinamide, caffeine and quinmerac were concurrently detected in blood plasma and seminal plasma, also exhibiting strong between-matrix correlation for quinmerac and caffeine (r=0.89-0.78). We identify physical activity, body mass index, age, use of solvents and smoking as variability factors for several compounds. The preliminary analysis with semen quality revealed negative bivariate correlations between theophylline and theobromine in urine with sperm motility stands out. In semen, a negative association between nabumetone and sperm concentration was found, and in plasma, the negative association between nicotine and sperm vitality also stands out. These preliminary analysis support that synthetic and other exogenous chemicals are widespread in human biological matrices, including seminal plasma. Further analyses are still ongoing to characterize the potential impact on seminal parameter standard. The analysis of exposure determinants will help to identify modifiable factors to reduce the male's chemical burden and associated decline of semen quality

3.24.P-Th435 Korean National Biomonitoring Programs and Comparative Toxicogenomics Database Analysis Reveals AOP of Atopic Disease by DEHP Exposure: Epidemiology and Toxicology Combined Approach

Hyojung Yoon[1], ***Donghyeon Kim****[2], Suejin Kim[1], Sun-Kyoung Shin[1] and Jinhee Choi[2], (1)Environmental Health Research Department, National Institute of Environmental Research, Korea, Republic of (South), (2)School of Environmental Engineering, University of Seoul, Korea, Republic of (South)*

Biomonitoring programs have been widely adopted in the field of environmental health, and biological data obtained from these programs have been organized based on biobank systems and used for various purposes. Here, using six Korean national biomonitoring programs (i.e., MOCHE and KorEHS-C, KoNEHS (Cycle I, II, III and IV)), the temporal trends of DEHP exposure from 2009 to 2020 and its association with allergic diseases (i.e., atopic dermatitis, asthma, and allergic rhinitis) in the Korean general population were identified. In our analysis, the urinary levels of DEHP metabolites, MEHHP and MEOHP, exhibited a distinct decline as participants aged, with a noticeable reduction, particularly in young children (3–6 years) since 2015. This recent decrease in DEHP exposure may be due to the implementation of the K-REACH Act (2015) as well as product safety policies. The concentration of urinary metabolites was used to derive EDI using reverse dosimetry with a PBPK. The highest EDI was observed in the toddlers (1–2 years), followed by adolescents (13–18 years) and the EDIs remained comparable to adults and the elderly. Then, the relationship between urinary concentrations of three different DEHP metabolites of MEHHP, MEOHP, and MECPP and allergic diseases among children aged 6-11 years in Korea from 2018 to 2020 was examined. Patients with diagnosed atopic dermatitis in the Korean children (6–11 years) had higher urinary concentrations of both creatinine and specific gravity-corrected DEHP metabolites ($p<0.05$). In boys, increased DEHP exposure was positively associated with atopic dermatitis (Odds ratios 1.625–1.938) after adjusting age, BMI, and house income. Based on this, AOP of DEHP leading to atopic dermatitis has been developed by integrating five types of curated interactions within the CTD and KEs from AOPwiki. Our study presents a novel framework for integrating multiple databases in both epidemiology and toxicology. This approach helps unexplored knowledge gaps that exist within individual databases.

3.24.P-Th436 Multi-target analysis and suspect screening of exposome-related xenobiotics in human follicular biofluid

Mikel Musatadi[1], *Paula Bustamante*[2], *Ailette Prieto*[3], *Lide Totorikaguena*[4], *Naiara Aguirregoitia*[4], *Estibaliz Olabarrieta*[2], *Maitane Olivares*[5] *and Olatz Zuloaga*[3], *(1)Research Centre for Experimental Marine Biology and Biotechnology (PiE-UPV/EHU), Spain, (2)University of the Basque Country (UPV/EHU), Spain, (3)Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (4)Physiology, University of the Basque Country (UPV/EHU), Spain, (5)Analtytical Chemistry, Research Center for Experimental Marine Biology Biotechnology "Plentziako Itsas Estazioa", University of the Basque Country (PiE-UPV/EHU), Spain*

The ovarian follicular fluid is a human matrix of great interest in determining infertility, which is a worldwide public health problem. Although the number of studies to date is scarce, follicular fluid could act as a reservoir for many of the xenobiotics that might be directly related to infertility. Therefore, robust analytical methods able to determine a wide variety of exposome-related xenobiotics in that matrix are compulsory. In the present work, a target method for the analysis of almost 200 xenobiotics (industrial chemicals, personal care products, biocides, and pharmaceuticals) in the follicular fluid was developed. Regarding the extraction, a salt-assisted liquid-liquid extraction (SALLE) using acetonitrile was optimized in terms of sample volume (0.5 and 1.0 mL) and nature of the salt (Na_2SO_4 and $MgSO_4$). Moreover, several clean-up strategies were evaluated, such as, protein precipitation by centrifugation, selective filters for the removal of lipids and proteins, and solid-phase extraction using normal- and reverse-phase sorbents. Finally, the extracts were analysed by liquid-chromatography – high resolution mass spectrometry (UHPLC-HRMS/MS). The optimal conditions were selected in terms of recoveries, matrix effects, repeatability, and number of detected analytes and resulted in 0.5 mL of sample and $MgSO_4$ for the extraction, followed by protein precipitation by centrifugation. In fact, more than 90 % of the analytes were recovered with absolute recoveries ranging between 13 % and 65 % with relative standard deviations (n=3) lower than 30 %. Regarding the matrix effect at detection, signal suppression was observed. The optimal protocol was validated at 2 concentration levels (5 and 30 ng/mL) on two different days and the following figures of merit were calculated: instrumental limits of quantification, linearity ranges, instrumental repeatability, procedural limits of quantification (pLOQ), accuracy (absolute and apparent recoveries), and methods´ precision (intra- and inter-day repeatability). All in all, satisfactory figures of merit were achieved considering the complexity of the matrix and the wide variety of analytes included. In addition, suspect screening was performed using a pooled sample (n=28) detecting several xenobiotics and metabolites at different confidence-levels.

3.24.P-Th437 Determination of Aflatoxin B1 and M1 in human breast milk

Noelia Pallares[1], *Houda Berrada*[1], *Cecilia Martínez-Costa*[2], *Francisco J. Barba*[3], *Emilia Ferrer*[1] *and* ***MCarmen Collado***[4], *(1)Faculty of Pharmacy, University of Valencia, Spain, (2)Department of Pediatrics, University of Valencia, INCLIVA Biomedical Research Institute, Spain, (3)Faculty of Pharmacy, University of Valencia, (4)Institute of Agrochemistry and Food Technology, Spanish National Research Council (IATA-CSIC), Spain*

Human milk constitutes a wealth source of nutritive compounds such as lipids, carbohydrates, proteins, amino acids, minerals, vitamins and non-nutritive elements, like enzymes, immunoglobulins, nucleic acids, hormones, growth factors, and cells (including macrophages, lymphocytes, and epithelial cells) that contribute to the infant's development and well-being (Marchant et al., 2018). Despite the numerous benefits associated to human milk, some toxic compounds that occur during the food chain can be detected in human milk (Lindeman et al., 2021). Breastfed infants are more vulnerable and sensitive to toxic compounds due their lower capacity to excrete compounds and body clearance. Aflatoxins (AFs) are carcinogenic, mutagenic, and immuno-suppressive mycotoxins, that have been correlated with liver cancer (Marín et al., 2013). Aflatoxin M1 (AFM1), constitutes on of the principal hydroxylated metabolite of aflatoxin B1 (AFB1), detected in milk, being considered a biomarker of AFB1. This detoxification product is originated as result of AFB1 metabolism and shows about 10% of mutagenicity compared to its precursor (Marchese et al., 2018). In the present study a method for the analysis of AFB1 and AFM1 in samples of mature breast milk collected one month after delivery from 57 mothers was developed. The extraction method consisted in a first step of defatting with hexane, then the extraction was carried out with H_2O and acetonitrile and a mixture of MgSO4, NaCl, DSCPH and TSCPH salts. The determination has been carried out by Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS). The results revealed that AFB1 only was detected in 5% of samples at levels above LOQ with mean concentration in positive samples of 4,5 µg/L. Regarding AFM1, 8 of 57 (14.03%) breast milk samples resulted positive and the levels in positive samples were above the limits established by the legislation in raw milk (0.05 µg/Kg) (EC, 2023/915). Despite some positive results, it should be highlighted that the major part of samples were not contaminated. More data is needed for a more accurate infants risk assessment.

Track 4. Ecological and Human Health Risk Assessment of Chemicals, Mixtures and Stressors and Risk Mitigation Strategies

4.01.A Advancements in Bioremediation and Phytoremediation for Addressing Persistent and Emerging Pollutants in Contaminated and Degraded Ecosystems

4.01.A.T-01 Soil bioresilience through bioavailability reductions: engineering components and policy challenges

Jose Julio Ortega-Calvo, *Instituto de Recursos Naturales y Agrobiologia, Spain*

In a world facing global change, the strategic value of soil cannot be underestimated. The extensive costs associated with remediating polluted sites, compounded by the need for financial recovery from the COVID pandemic and Ukraine war, demand innovative solutions of site remediation. Our solutions prioritize sustainability principles, aligning with the UN Sustainable Development Goals and the European Green Deal. Nature-based solutions (NBS), such as bioremediation and phytoremediation, offer promising avenues for soil restoration. Traditional NBS approaches focused solely on total pollutant removals have proven unpredictable and often fall short of legislative remediation goals. With a focus on hydrophobic organic pollutants and bioremediation, this overview presentation will explore the paradigm shift towards addressing bioavailability reductions, surpassing mere total pollutant removals, to reach soil bioresilience, a new term reflecting the successful restoration of soil functions based on the management of pollutant bioavailability. We will examine the existing bioavailability concepts and methods, options for their application and standardization, as well as nature-based engineering components for addressing bioavailability reductions. Our nature-based engineering components were demonstrated to enhance bioremediation performance and reduce risks at various levels of bioavailability processes, encompassing interactions between contaminants and soil, their transportation, and biological processing. The focus will extend to our research on hydrophobic organic pollutants and bioremediation, unveiling strategies such as the precise targeting of slow-desorption pollutant fractions using (bio)surfactants, fine-tuning the deposition and motility of microbial degraders, co-mobilizing non-motile inoculants, and effectively capturing pollutants through plant-biochar arrangements, showcasing their potential to transform soil remediation practices. The contribution will also encompass insights into how addressing bioavailability challenges may contribute to prominent European initiatives, including the Green Deal, thereby empowering missions related to soil health and food security, the action plan for zero pollution, and the chemicals strategy for sustainability.

4.01.A.T-02 DNA-SIP combined with metagenomics unveil bacterial communities and mechanisms involved in azaarene biodegradation in PAH-contaminated soils

Maria Jordán[1], *Esteban Bustos-Caparros*[2], *Juan F Gago*[2], *Zhenfa Zhang*[3], *David Singleton*[4], *Ramon Rossello-Mora*[2], *Magdalena Grifoll*[1] *and Joaquim Vila*[1], *(1)Genetics, Microbiology and Statistics, University of Barcelona, Spain, (2)Department of Animal and Microbial Biodiversity, IMEDEA (CSIC-UIB), Spain, (3)Department of Environmental Sciences and Engineering, Duke University, (4)Environmental Molecular Biotechnology Laboratory, Duke University*

Nitrogenated-containing polycyclic aromatic heterocycles (N-PAHs), also referred to as azaarenes, are pollutants found in contaminated soils along with polycyclic aromatic hydrocarbons (PAHs). Investigations applying high-resolution analytical methods have unveiled a hitherto unrecognized high abundance and diversity of azaarene isomers in PAH-contaminated soils. The biodegradability of these compounds was isomer-selective, as a function of their molecular weight, degree of methylation, and the position of the nitrogen group.

In this study, an analysis of the microbial community response to distinct azaarene congeners in creosote-contaminated soil revealed that the differential susceptibility to biodegradation could also be associated with distinctive microbial communities involved in the degradation of specific azaarenes. To elucidate the mechanisms involved in azaarene assimilation, a series of experiments were conducted on soil slurry microcosms using acridine as a model three-ring azaarene. High-performance liquid chromatography-mass spectrometry (HPLC-MS) was employed to assess biodegradation kinetics, demonstrating effective acridine removal after a 5-day incubation period. To identify the microbial populations and functions involved in acridine assimilation, DNA-stable isotope probing was performed using uniformly labeled ^{13}C-acridine.

Analysis of the 16S rRNA clone library of ^{13}C-enriched DNA identified a member of *Sphingobium* as the primary acridine degrader. Shotgun metagenomic sequencing provided functional insights into the biodegradation process, enabling the reconstruction of the acridine metabolic pathway in soils. Reconstruction of metagenome-assembled genomes (MAGs) resulted in the assembly of a single MAG. Functional analysis of this MAG revealed nutritional auxotrophies for specific vitamins and amino acids. Based on this information, a molecular-directed isolation strategy was implemented to obtain the first bacterial isolate with the ability to grow on acridine.

4.01.A.T-03 Bioremediation of soils contaminated with PFAS: challenges, successes and future directions

Vladimir Beskoski[1], *Marija Lješević*[2], *Begoña Jiménez*[3], *Latinka Slavković Beškoski*[4], *Juan Munoz-Arnanz*[3], *Pere Colomer Vidal*[3], *Hideyuki Inui*[5] *and Takeshi Nakano*[6], *(1)University of Belgrade, Faculty of Chemistry, Serbia, (2)University of Belgrade, Institute of Chemistry, Technology and Metallurgy, Serbia, (3)Institute of Organic Chemistry, Spanish National Research Council (IQOG-CSIC), Spain, (4)Anahem laboratory ltd, Serbia, (5)Biosignal Research Center, Kobe University, Japan, (6)Research Center for Environmental Preservation, Osaka University, Japan*

Per- and polyfluoroalkyl substances (PFAS) are a class of anthropogenic organofluoride chemicals, widespread in industrial and consumer applications, well known for their unique and advantageous properties, such as their surface activity, thermal and chemical stability. However, the combination of their extensive use, bioaccumulative nature and adverse effects to the environment and human health has put them in the focus of scientific research as well as regulators with the aim to develop suitable remediation measures for polluted locations.

PFAS resistance to degradation is attributed to the C-F bond. Despite being commonly cited as the strongest bond, the strength of C-F bonds in PFAS molecules varies significantly. PFAS structures, analyzed using density functional theory, reveal higher bond dissociation energies for primary C-F bonds than secondary ones, with longer fluoroalkyl chains exhibiting lower dissociation energies.

This work aims to provide an overview on the current state of art of the most effective PFAS soil bioremediation strategies employed until now. Although popularly known as "forever chemicals", based on recently published articles, microorganisms isolated from PFAS polluted environment can have capacities for degradation of these compounds. Some of these microorganisms are: *Acidimicrobium* sp. strain A6, *Pseudomonas parafulva* strain YAB1, *Pseudomonas plecoglossicida* 2.4-D, White-rot fungus, *Phanerochaete chrysosporium*, *Pseudomonas butanovora* and *Pseudomonas oleovorans*. For the microbial communities isolated from Antarctic marine habitats, activated sludge, soil and sediment polluted with PFAS, similar capacity was confirmed.

PFAS biodegradation involves enzymes that remove fluorine atoms through oxidation or reduction of the C-F bond. While experimental evidence has illustrated the biotransformation of some PFAS, the proposed degradation mechanisms differ significantly, and a confirmed biodegradation pathway has yet to be established. In addition, although the bioremediation of PFAS is still in the research and development phase, it should be emphasized that some microbes can break the C-F bond in naturally produced fluoroacetate and fluorobenzoate via hydrolytic defluorination. Knowing that PFAS have been introduced to the environment seventy years ago, one would expect that nature had already developed microbial mechanisms to degrade these chemicals. The hunt for the most potent species and consortium is open.

4.01.A.T-04 Metagenomic Study on Nature-Based Solutions for Bioremediation: Investigating a Bioreactor with Biochar and Polyhydroxyalkanoates as Biomaterials for Biological Anaerobic Dechlorination

***Bruna Matturro**[1], Simona Rossetti[2], Laura Lorini[3] and Marco Petrangeli Papini[4], (1)Water Research Institute (IRSA-CNR), Monterotondo, Italy, (2)IRSA CNR, (3)UNIVERSITA' SAPIENZA - DIPARTIMENTO CHIMICA, (4)Department of Chemistry, La Sapienza University of Rome, Italy*

The use of bio-based materials in bioremediation technologies is appealing for the restoration of contaminated sites. Some studies have demonstrated the effectiveness of the polyhydroxybutyrate (PHB), a bio-synthesized polyester biodegradable in the environment, as a slow-release electron donor to sustain reductive dechlorination (RD) processes [1]. Also the organic waste-derived biochar (BC), produced by the pyrolysis of biomass and used for contaminants' adsorption, is capable to accelerate the electron transfer in several bioprocesses [2]. PHB and BC have been successfully employed in engineered systems for the treatment of chlorinated solvents [3]. Here we describe the composition and metabolic features of the microbiome established in a column bioreactor that couples PHB and BC as bio-based materials to prompt the RD of TCE-contaminated groundwater. In line with the kinetic performances of the reactor, *Dehalococcoides mccartyi (Dhc)* established both in the PHB (1.46E+06 16S rRNA gene copies/g) and BC (5.51E+08 16S rRNA gene copies/g) reactive zones, suggesting for the first time BC as a vehicle for biological RD and a support for the growth of *Dhc*. In addition, the metagenomes of the PHB and BC reactive zones have been analyzed to investigate the central mechanisms occurring in the biofilm growing on these biomaterials. *Clostridiaceae* (Clostridium, 48% of total ASVs) and *Victivallaceae* (15% of total ASVs) families, primarily involved in the fermentation processes, dominated the PHB zone. The results of the genomic-centric analysis highlighted the main metabolic features of the PHB and BC biofilms of the column system and will be discussed in the presentations.

4.01.A.T-05 PHYTOREMEDIATION OF AGRICULTURAL AREAS CONTAMINATED BY HYDROCARBONS

***Tatiana Stella**[1], Andrea Franzetti[2], Sandra Citterio[2], Enrico Casati[2], Gabriele Cerutti[3], Alberto Francioli[3], Camilla Longone[3], Paolo Angelini[4], Marcello Mancini[4] and Marcello Pianu[4], (1)M3R-Monitoring and Management of Microbial Resources Srl, Italy, (2)Università degli Studi di Milano-Bicocca, Italy, (3)HPC Italia s.r.l., (4)ENI – Energy Evolution*

In 2015, in an agricultural area close to Milano, oil spills occurred causing the release of fuel in the soil. A detailed (hydro)geological, chemical, pedological and microbiological characterization was performed to design the best remediation technologies. Based also on the site typology and size and on contamination degree and depth, bioremediation and phytoremediation were selected as the best options in terms of both environmental and economic feasibility and sustainability with the aim of preserving the "soil resource" and avoiding any action that could negatively affect the ecosystems. In the 1st site, Biopile and Phytoremediation pilot-scale tests were carried out. The full-scale phytoremediation of this site started in 2023. In the 2nd site, Biopile, Enhanced Aerobic and Anaerobic Bioremediation, Reactive Barrier and Phytoremdiation were selected for field pilot-tests (ongoing). With regard to phytoremediation, 5 different poplar clones were selected for the 1st site (Populus spp.), while different herbaceous and arboreal plants were tested in the 2nd site with particular attention to oilseed crops for biofuels production. In both sites, morpho-functional plant traits, aerial biomass and root apparatus were monitored, and rhizosphere and bulk soil samples were collected at different depths to perform chemical, agronomic, biomolecular and ecotoxicological analyses. The main evaluations that emerged from these tests are related to the importance to assess the tolerance of the plants to different levels of hydrocarbons and to the climate site conditions and to verify the efficiency of plants to stimulate the growth of specific microbial strains relevant for plant growth and hydrocarbons degradation. Concerning the 1st site, some of the tested poplar clones were able to develop roots that reach even the deeper soil horizon increasing the availability of oxygen and promoting the microbial biodegradation activity; moreover, phytoremediation was also efficient where the level of heavy hydrocarbons concentration was high suggesting the possibility to apply it also for the remediation of the most impacted soils avoiding ex-situ technology. In the 2nd site, only few of the tested species (i.e. castor) were able to grow and develop a root system that supported the biodegradation activity of autochthonous microorganisms. In conclusion, the combination of different Nature-based Solutions has shown to be a suitable strategy for the remediation of both sites.

4.01.B Advancements in Bioremediation and Phytoremediation for Addressing Persistent and Emerging Pollutants in Contaminated and Degraded Ecosystems

4.01.B.T-01 Differential Distribution of Pharmaceutical Compounds in Water, Sediments and Biota of a full-scale Constructed Wetland

Maria Eugenia Valdes[1,2], *Oriol Sacristan-Soriano*[1,2], *Jose Luis Balcazar*[1,2], *Carlos Omar Lomeli*[1,2], *Sara Rodriguez-Mozaz*[1,2] *and Carles Borrego More*[1,2], *(1)Catalan Institute for Water Research (ICRA), Spain, (2)University of Girona (UdG), Spain*

Pharmaceutically active compounds (PhACs), including antibiotics, are ubiquitous emerging pollutants that pose potential risks for ecosystems and human health. One of the greatest concerns is their effect on the spread of antibiotic resistance, due to the continuous release of these compounds and antibiotic-resistant determinants through wastewater effluents. Constructed wetlands (CW) offer a cost-efficient and eco-friendly solution for the remediation of wastewaters. However, limited studies have evaluated their efficiency in fullscale systems and the accumulation of PhACs in sediments and biota. This study aimed to assess the distribution of 70 PhACs, including 30 antibiotics, through the treatment chain of a full-scale Free Water Surface CW (FWSCW) operating as tertiary treatment of an urban Wastewater Treatment Plant (WWTP). Sampling was conducted in July 2023 in the Empuriabrava CW (ECW, Girona, Spain). Water, sediments, and biota (zooplankton, duckweed and common reed (Phragmites australis)) were collected at 5 treatment stages. A set of 70 PhACs, including 30 antibiotics, were analyzed, following extraction, by liquid chromatography coupled to tandem mass spectrometry. Macrolides, quinolones, sulfonamides and trimethoprim were the main antibiotic families detected, at ng/L range. The total sum of antibiotics removal in the combined treatment (WWTP + CW) was 97%, with exception of clindamycin, which increased its concentration during the treatment. Additionally, 17 PhACs from 7 therapeutic families were detected at ng/L, with some compounds decreasing, remaining stable, or even increasing in concentration after treatment (carbamazepine and metoprolol acid). A lower number of PhACs was detected in sediments and biota, at ng/g dried weight level. P. australis accumulated β-blockers, psychiatrics and antibiotics, preferentially in roots, even though a few were present in aerial parts. Antibiotics and other PhACs have different removal and distribution behavior along the treatment chain in a FWS-CW. Antibiotics are mostly removed from water after complete treatment, proving the effciency of CW as tertiary treatment for these compounds. A few of them accumulated in sediments and biota. However, other therapeutic families of PhACs presented positive, zero or even negative removals. They accumulated mostly in P. australis roots, which demonstrates the usefulness of this macrophyte for the remediation of PhACs from secondary effluents.

4.01.B.T-02 Reduction of Perfluoroalkyl Acids in Leachate from Industrial Waste Disposal Sites by Bacteria Isolated from Contaminated River Sediments

Hideyuki Inui[1,2,3], *Chisa Tanaka*[2], *Takuya Kakoi*[4], *Hiroshi Kameoka*[5], *Junko Ono*[5], *Yoshinori Yabuki*[5], *Chisato Matsumura*[4], *Yutaka Kobayashi*[2], *Vladimir Beskoski*[6] *and Takeshi Nakano*[7], *(1)Biosignal Research Center, Kobe University, Japan, (2)Graduate School of Agricultural Science, Kobe University, Japan, (3)Faculty of Biology and Environmental Protection, University of Lodz, Poland, (4)Hyogo Prefectural Institute of Environmental Sciences, Japan, (5)Research Institute of Environment, Agriculture and Fisheries, Osaka Prefecture, Japan, (6)University of Belgrade, Faculty of Chemistry, Serbia, (7)Research Center for Environmental Preservation, Osaka University, Japan*

Per- and polyfluoroalkyl substances (PFASs) have been detected in the environment and in living organisms around the world.These PFASs are physically and chemically very stable, due to the C-F bond. They have been widely used in industrial materials because of their water- and oil-repellent properties. However, they can accumulate in high concentrations in humans and wildlife, causing in adverse health effects. Perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA), which are a type of perfluoroalkyl acids (PFAAs), are known to be persistent, high accumulative, long-range mobile, and toxic. As a result, they still remain in the environment for decades or longer. Bioremediation, which aims to degrade or remove such pollutants by harnessing the biological functions of microorganisms and plants, has attracted attention for the degradation of pollutants. However, there are few reports on PFOS/PFOA-degrading bacteria. The aim of this study is to isolate and identify PFOS/PFOA-degrading bacteria in order to achieve environmental remediation of PFAAs using bacteria. In addition, the selected bacteria will be used to reduce the concentration of PFAAs in actual contaminated water, including leachate from industrial waste disposal sites.

Several bacterial colonies were isolated from PFOS/PFOA supplemented Bushnell Haas Broth (BH) liquid medium iincubated with sediments collected from PFOS/PFOA contaminated river sediments. The isolated bacteria were identified by sequencing analysis of the 16S rRNA gene. PFOS and PFOA concentrations were significantly reduced by 9-31% and 4.7-11%, respectively, by some of the identified bacteria. So far, it is proposed that monofluorinated fatty acids are one of the PFAA metabolites produced by the bacterial consortium isolated from the contaminated sediments. The selected bacteria cultured in the leachate showed a 25% reduction in PFOA concentration.

The isolation and identification of bacteria involved in PFOS/PFOA degradation, and the potential of these bacteria to reduce the concentration of PFAAs in the actual contaminated water, will provide important insights into the application of bioremediation to PFASs.

4.01.B.T-03 Thinking Out of the Box: Daphnia as a Sentinel Species for Environmental Health and Water Reclamation

Nooshin Marvasti[1], Muhammad Abdullahi Mr[1], Mohamed Abou-Elwafa Abdallah Dr[2], Karl DD Dearn Prof[3], Robert Gregory Lee Prof[4], Iestyn Stead[5] and ***Luisa Orsini***[6]*, (1)Biosciences, University of Birmingham, United Kingdom, (2)University of Birmingham, United Kingdom, (3)Mechanical Engineering, University of Birmingham, United Kingdom, (4)Law School, University of Birmingham, United Kingdom, (5)Engineering, University of Birmingham, United Kingdom, (6)School of Biosciences, University of Birmingham, United Kingdom*

Rapid urbanisation, pollution and climate change have put unprecedented pressure on water resources, culminating in a global water crisis. The sustainable management and reuse of water is paramount for ensuring societal, economic, and environmental well-being. However, persistent chemical pollutants are not efficiently removed by conventional wastewater treatment and prevent the safe reuse of treated water. When wastewater effluent is released into rivers, it eventually finds its way into reservoirs, irrigation systems, and aquifer recharges. These chemical pollutants then enter the human food chain and water supply, detrimentally impacting the health of approximately 92 million individuals annually.

Sustainable technologies that remove persistent chemicals from wastewater are urgently needed. While *Daphnia* have long been recognised as a ‘sentinel species’, used to identify and set exposure limits on toxic chemicals by regulation, they have not been applied to their full potential. We broaden the use of this sentinel species offering a much-needed advance in the way existing and new risks from chemical pollution are assessed and mitigated. We show how *Daphnia* works as a canary in a coal mine, providing an early warning system of toxicity. And where prevention fails, we develop a *Daphnia*-based scalable, low-cost, low-carbon, and retrofittable technology for tertiary water treatment applications. We demonstrate our technology performance in a first test trial in a real-world environment. We demonstrate bioaccumulation or biotransformation of chemical pollutants and envisage a photocatalytic treatment to break down residual chemicals, enabling the reuse of organic portion of the *Daphnia* sludge.

Our technology could improve the quality of wastewater effluent, meeting current and upcoming regulatory requirements to produce reusable water suitable for irrigation, industrial applications, and household use. By preventing persistent chemicals from entering waterways, we can also prevent environmental pollution. Our circular system promotes the reuse of water and resource for a sustainable future accessible to both developing and developed countries.

4.01.B.T-04 Shifts in the Nitrogen Cycle of a Metal- and Polycyclic Aromatic Hydrocarbon Contaminated Soil Amended with Biochar and Peat

Ingrid Rijk[1]*, Alf Ekblad[2], Sigrun Dahlin[3], Anja Enell[4], Maria Larsson[5], Prune Leroy[6], Dan Berggren Kleja[7], Charlotta Tiberg[4], Sara Hallin[6] and Christopher Jones[6], (1)School of Science and Technology, Oerebro University, Sweden, (2)School of Science and Technology, Orebro University, Sweden, (3)Department of Soil and Environment, Swedish University of Agricultural Sciences (SLU), Sweden, (4)Swedish Geotechnical Institute, Sweden, (5)MTM Research Centre, Orebro University, Sweden, (6)Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences (SLU), Sweden, (7)Soil and Environment, Swedish University of Agricultural Sciences (SLU), Sweden*

Soil is an essential and non-renewable resource, and its human use and ecological functioning is threatened by soil contaminants. Soil amendment with biochar is a sustainable remediation method with a high potential to immobilize many soil contaminants, improve soil health and reduce the need for eternal landfilling. However, it is not known how ecological soil functions, such as nitrogen (N) cycling, in polluted soils benefit from soil amendments of biochar, peat and their combination. Importantly, more field studies are needed that consider the effect of realistic outdoor conditions on pollutant and microbial behavior.

A field trial was established in 2019 with soil contaminated with polycyclic aromatic hydrocarbons (PAH) and multiple metals. The soil was treated with biochar (0, 3 or 6 w/w%) combined with peat (0, 1.5 and 3 w/w%) in a complete factorial design resulting in nine different treatments (n=3). After one growing season analyses were made of grass biomass, soil physicochemical properties, contaminant leaching, plant and earthworm contaminant uptake, and ecotoxicity (acute toxicity and reproduction of earthworms). The focus of our study was to detect effects on soil N cycling using N elemental and stable isotopic ($\delta^{15}N$) measurements of the system, combined with microbial parameters such basal respiration, microbial biomass and abundances of different N cycling microbial communities.

We showed that peat and biochar additions resulted in a reduced solubility and bioavailability of PAH and heavy metals along with an improvement of soil quality and reduced ecotoxicity. Peat and biochar amendment resulted in an increased microbial biomass and basal respiratory activity, but a decrease in grass biomass and leaf N content. Changes in the $\delta^{15}N$ signatures of leaf, root, and soil indicated that more N was retained in the soil microbial N cycle. Biochar and peat amendments also increased abundances of denitrifying and nitrous oxide reducing organisms, while effect on various nitrifying guilds were less consistent.

Taken together, we demonstrate that soil pollutants and N are immobilized simultaneously, while creating a more favorable environment to microorganisms. Ongoing research at the field trial will demonstrate if the beneficial effects of peat and biochar amendment will remain.

4.01.B.T-05 Effectiveness of the Orion poplar clone in phyto-assisted bioremediation from polychlorinated biphenyl and heavy metals

Valeria Ancona[1], *Aurora Rutigliano*[2], *Cristina Cavone*[2], *Pietro Cotugno*[3], *Ludovica Rolando*[4], *Daniela Losacco*[5], *Paola Grenni, PhD*[6], *Vito Felice Uricchio*[1], *Pasquale Mariano Carmignano*[7] *and Anna Barra Caracciolo*[8], *(1)Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (2)Water Research Institute, Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (3)University of the Studies of Bari Aldo Moro, Italy, (4)Italian National Research Council (IRSA-CNR), Italy, (5)National Research Council (CNR), Italy, (6)Water Research Institute (IRSA), National Research Council (CNR), Italy, (7)ReAgri srl, Italy, (8)National Research Council - Water Research Institute (IRSA-CNR), Italy*

Plant-assisted bioremediation (PABR) is a sustainable technology for recovering contaminated soils. It is based on the synergistic interactions occurring between root systems and microorganisms of the rhizosphere for removing, transforming, and containing hazardous xenobiotics. Poplars were demonstrated to be very effective in favoring the degradation of persistent organic pollutants such as polychlorobyphenils (PCBs) and inorganic contaminants such as heavy metals (e.g. Zn, Pb, Sn, etc) both in laboratory and field scale applications. This work describes a case-study study related to a historically contaminated area, located in Southern Italy, characterized by different levels of PCBs and HMs (medium and high concentrations for both organic and inorganic pollutants).The Monviso poplar clone has been previuosly planted in 2013 and 2015 in two different areas inside the same site and it was demonstrated to be effective in promoting soil quality restoration, PCB rizodegration and HM phytostabilization in soils. The present work reports a new PABR perfomed in a third area still contaminated, using a different poplar clone, the Orion one. The poplar clone was planted in 2022 (about 700 poplar cuttings) for evaluating its capabilty to promote PCB and HM decrease and compare its adaptability and efficiency with the Monviso clone.

Chemical analysis of soil properties (pH, EC, available P), contaminants (PCBs and HMs), and microbiological analyses (microbial abundance and dehydrogenase activity) were performed before the poplar plantation and at 18 months. Moreover, the structure of the main microbiological groups was assessed by qPCR assays. Pollutant analyses were also performed on biomass tissues (roots and leaves). The main results of the PABR strategy applied with the Orion poplar clone for recovering a historically multi-contaminated area will described and discussed.

4.01.P Advancements in Bioremediation and Phytoremediation for Addressing Persistent and Emerging Pollutants in Contaminated and Degraded Ecosystems

4.01.P-Mo316 A QUEST FOR NOVEL FUNGAL SPECIES WITH THE ABILITY TO BIOREMEDIATE POLYETHYLENE IN THE EASTERN REGION OF THE FREE STATE, SOUTH AFRICA: AN ECO-FRIENDLY SOLUTION TO ELIMINATE PLASTIC POLLUTION

Nozipho Kheswa, *University of Free State, South Africa*

Landfill standards of operation and management are decreasing in South Africa, leading to an accumulation of plastic waste that harms the environment. To address this issue, our study sought to identify fungal species with the potential to bioremediate packaging plastic waste from local landfill sites. We isolated fungal strains from soil samples collected from these sites using an agar medium supplemented with a plastic solution to selectively identify strains with bioremediation properties. Thereafter, plastic strips were inoculated with the isolated fungal strains and the effect of fungal strains was evaluated after 45 days of incubation at room temperature, and plastic bioremediation was evaluated by examining the weight loss of the strips, and changes in plastic chemical composition and intensity using Fourier-transform infrared (FTIR) spectroscopy. Our results identified two promising isolates, SP17MK and SP3MK, that caused significant plastic weight loss of 23% and 33%, respectively. FTIR analysis revealed weaker absorption peaks at 719 and 1,472 cm-1 after fungal treatment compared to the control, and plastic strips treated with SP13INT showed a stretch of the carbonyl group at 1700 cm-1. South Africa is in dire need to embrace novel approaches to tackle its growing plastic pollution challenges. The present findings could lay the first step towards the use of local fungal species for the bioremediation of plastics.

Keywords**:** Waste management, Landfills, Plastic pollution, Bioremediation, Plastic biodegradation

4.01.P-Mo317 Constructed wetlands as a nature-based solution for removing emerging contaminants

Anna Barra Caracciolo[1], *Arianna Mingoli*[2], *Edoardo Parisi*[2], *Gian Luigi Garbini*[3], *Paola Grenni, PhD*[4], *Alba Martinez I Quer*[5], *Vaidotas Kisielius*[6] *and Pedro N Carvalho, PhD*[6], *(1)National Research Council - Water Research Institute (IRSA-CNR), Italy, (2)Water Research Institute, National Research Council, Italy, (3)CNR-IRSA, Italy, (4)Water Research Institute*

(IRSA), National Research Council (CNR), Italy, (5)Department of Environmental Science, Aarhus University, Denmark, (6)Environmental Science, Aarhus University, Denmark
Treatment wetlands are among the most efficient and frequently implemented nature-based solutions for wastewater treatment. As for all wastewater treatment systems, there are increasing concerns on how such systems deal with contaminants of emerging concern. While treatment wetlands application for classical pollutants is well described in the literature, data on organic micropollutants is still mostly from laboratory and mesocosm scale studies. The potential to control the emission of pharmaceuticals by such systems is reported. However, works on the performance of full-scale systems over long monitoring cycles are still scarce. Moreover, the fate of antibiotic resistant genes in such systems remains unknown, as existing literature points in different directions (either removal or accumulation). To address these gaps, a full-scale treatment wetland has been monitored for one year to gain knowledge on real-life efficiency and seasonal performance.

The selected treatment wetland is in full operation since 2014, and treats the wastewater from a small village with 100 PE in the Danish countryside. Water and sediment were sampled to analyse organic carbon and nitrogen, microbial community, organic micropollutants (mostly pharmaceuticals and antibiotics), and antibiotic resistance genes.

Results show not only the efficiency of the treatment wetland for nutrient removal from wastewater, but also its capacity to reduce, in general, organic micropollutants. From the overall compounds measured in the system, few antibiotics were sporadically quantified. The removal efficiency for organic micropollutants seems to be influenced by seasonality (lower in winter than autumn, spring and summer), presumably due to the different plant vegetative states during the year. No correlation was found between resistant genes and occurrence of antibiotics. Although antibiotics were not always detected, the *sul1*, *sul2* and *IntI1* genes (linked to sulphonamide resistance) were identified in all microbiological samplings and points. Interestingly, the vertical flow bed resulted effective in decrease both emerging contaminants and antibiotic resistance genes. These results can be ascribed to synergic interactions between *P. australis* and its rhizosphere microbiome in the vertical flow sediment.

4.01.P-Mo318 Microbial characterization of a Multicontaminated Marine Sediment in Mar Piccolo Site (Taranto, Italy) and selection of Aerobic and Anaerobic Hydrocarbon-Degrading Bacteria.

***Bruna Matturro**[1], Maria Letizia Di Franca[2], Barbara Tonanzi[2], Carolina Cruz Viggi[2], Federico Aulenta[2], Magda Di Leo[2], Santina Giandomenico[2] and Simona Rossetti[2], (1)Water Research Institute (IRSA-CNR), Monterotondo, Italy, (2)IRSA CNR*
Marine sediments act as a sink for the accumulation of various organic contaminants such as polychlorobiphenyls (PCBs). These contaminants affect the composition and activity of microbial communities, particularly favoring those capable of thriving from their biodegradation and biotransformation under favorable conditions. Hence, contaminated environments represent a valuable biological resource for the exploration and cultivation of microorganisms with bioremediation potential. In this study, we successfully cultivated microbial consortia with the capacity for PCB removal under both aerobic and anaerobic conditions. The source of these consortia was a multicontaminated marine sediment collected from the Mar Piccolo basin in Italy, one of Europe's most heavily polluted sites. High-throughput sequencing was employed to investigate the dynamics of the bacterial community of the marine sediment sample, revealing distinct and divergent selection patterns depending on the imposed redox conditions. Shifts in bacterial communities were observed, shedding light on the adaptation of microorganisms to the tested conditions and their potential roles in PCB transformation processes, but also the biodegradation potentialities of other co-contaminant hydrocarbons such as polycyclic aromatic hydrocarbons (PAHs). From the indigenous microbial community in the highly contaminated sediment, we successfully obtained three distinct enrichment cultures and two isolates. One bacterial consortium showed the potential to reduce the presence of PCBs and PAHs under aerobic conditions (consortium *Ae*), and allowed us to extrapolate two bacterial isolates (*Marinobacter salinus* and *Rhodococcus cerastii*) known to play a role in the biodegradation of hydrocarbons. In addition, two anaerobic cultures were obtained, able to perform PCB biodegradation via reductive dechlorination (consortium *Ana*) and to perform the complete reductive dechlorination of chlorinated ethenes (*consortium Ana**). Details about the microbial characterizations will be discussed during the presentation. The establishment of consortia with biodegradation and biotransformation capabilities expands the toolkit available for effectively implementing bioremediation strategies, thus enhancing the comprehensive nature-based restoration approach.

4.01.P-Mo319 Investigation of the effectiveness of phytoremediation of dredged sediment contaminated with heavy metals

***Nina Đukanović**[1], Jelena Beljin[1], Tijana Zeremski[2], Mrijana Kragulj Isakovski[3], Srdjan Roncevic[3], Nadežda Stojanov[2] and Snezana Maletic[1], (1)University of Novi Sad, Serbia, (2)Institute of Field and Vegetable Crops, Novi Sad, (3)University of Novi Sad, Faculty of Sciences, Serbia*
Sediment is equally at risk of heavy metal pollution, because the contaminants present in the water system can be absorbed onto the particles, deposited and accumulated in the sediment. In order to remediate soils and sediments contaminated with heavy metals, phytoremediation has attracted great interest from researchers. Given the large number of contaminated sites that cannot currently be used for agricultural production, the goal of our research was to connect the cleaning of polluted sites with phytoremediation and the production of biomass that can be used to obtain clean biofuels. The energy plant rapeseed, which is known for its high phytoaccumulation potential, was sown at the landfill for the purpose of phytoremediation. The rapeseed was sampled in December, April, and June. The samples were subjected to analysis of the total metal content on ICP-MS, and bioaccumulation and translocation factors were calculated. An extremely high yield of biomass was achieved that can be used to obtain biofuel (2.6-2.9 t/ha). The concentration of metal in the energy crop was generally higher in the contaminated soil, compared to the control plot. For Cu, Zn, Pb and Cd, the BAF is approximately at the same level in above-ground and below-

ground biomass, which is consistent with the obtained TF. The high degree of bioaccumulation and translocation of Zn and Cu as essential elements for plants may be due to a higher rate of transpiration to maintain the growth and moisture content of plants. The high BAF and TF of Cd can be attributed to its high bioavailability and physicochemical properties similar to essential micronutrients, which allows it to be easily absorbed and translocated by plants. Pb is toxic in leaves, so sometimes the root prevents its transport to the aerial part and keeps it in the root. The lowest TF observed for Cr is consistent with its lowest mobility and consequently lowest accumulation potential and this is indicated by the higher BAF. We can conclude that an extremely high yield of biomass was achieved that can be used to obtain biofuel. The level of metal uptake and translocation is consistent with the properties and mobility of the metal. However, the choice of plant species is one of the main factors on which the effectiveness of phytoremediation depends.

4.01.P-Mo320 Ibuprofen-enhanced Biodegradation in Solution and Sewage Sludge by a Mineralizing Microbial Consortium. Shift in Associated Bacterial Communities
Jaime Villaverde, *Inés Aguilar-Romero, Fernando Madrid and Esmeralda Morillo, Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain*
Ibuprofen (IBP) is a widely used drug of environmental concern as emerging contaminant due to its low elimination rates by wastewater treatment plants (WWTPs), leading to the contamination of the environment, where IBP is introduced mainly from wastewater discharge and sewage sludge used as fertilizer. This study describes the application of a bacterial consortium obtained from sewage sludge acclimated with IBP (consortium C7) and some bacterial strains isolated from C7 to accelerate IBP biodegradation both in solution and sewage sludge. Microbial community changes in the enriched IBP-degrading biomass was investigated using high-throughput sequencing techniques to identify the main bacterial groups potentially involved in IBP bioremoval.

The biodegradation of a wide variety of IBP concentrations in solution by consortium C7 was carried out, reaching 100% IBP degradation in 28 hours for the concentration of 500 mgL^{-1}, and 66% IBP was mineralized in 3 days. The toxicity of the solutions towards *Vibrio fischeri* was measured throughout the biodegradation process, being nule when IBP was completely degraded. IBP adsorbed in sewage sludge (10 mg kg^{-1}) was quite irreversible (only 12-15%), but after bioaugmentation with C7 a drastic degradation up to 90% IBP was reached in 16 days, with a 5-fold increase in degradation rate.

The bacterial community of consortium C7 was significantly enriched in *Sphingomonas wittichii, Bordetella petrii, Pseudomonas stutzeri* and *Bosea genosp.* after IBP degradation, with a special increase in abundance of *S. wittichii*, probably the main potential bacterial specie responsible for IBP mineralization. Thirteen bacterial strains were isolated from C7 consortium. All of them degraded IBP in presence of glucose, especially *Labrys neptuniae*. Eight of these bacterial strains (*B. tritici, L. neptuniae, S. zoogloeoides, B. petrii, A. denitrificans, S. acidaminiphila, P. nitroreducens, C. flaccumfaciens*) had not been previously described as IBP-degraders. The bacterial community that makes up the indigenous consortium C7 could facilitate IBP bioremediation in contaminated effluents as well as in sewage sludge generated in WWTPs. This is the first time that bioaugmentation with bacterial consortia or isolated bacterial strains have been used for IBP degradation in sewage sludge.

4.01.P-Mo321 Saponin-Enhanced Biodegradation of PAHs from Nonaqueous-Phase Liquids: Towards the Application of Phytogenic Surfactants in Bioremediation
Alicia Fernandez-Vazquez, *Rosa Posada and Jose Julio Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia, Spain*
Polycyclic aromatic hydrocarbons (PAHs) are hydrophobic pollutants often introduced into the subsurface as nonaqueous-phase liquid (NAPL) mixtures, such as creosote or coal tar, that represent long-term sources of risk. The limited bioavailability of these slowly desorbing contaminants must be taken into account when developing nature-based solutions to soil pollution. Saponin is a plant biosurfactant with many advantages, as compared with chemical and microbial surfactants, in terms of sustainability and cost, which has shown a great potential in bioremediation of PAH-polluted soils. The present study seeks to investigate the mechanisms of action of *Quillaja* saponin biosurfactant on biodegradation of ^{14}C-phenanthrene and ^{14}C-pyrene with the compounds present either as crystals or dissolved in two NAPLs (heptamethylononane and creosote).

Radiorespirometry assays with a representative PAH degrader bacterium (*Mycobacterium gilvum VM552)* and with the authoctonous microbial population from a long-term creosote-polluted soil were developed in a biphasic NAPL/water system with a constant interface area. Experiments were carried out with saponin at its critical micelle concentration (CMC, 0.1 g/L) and well above that value (1 g/L). The results showed that saponin, especially above its CMC, promoted the mineralization of crystalline and NAPL-dissolved phenantrene and pyrene, both with the pure *Mycobacterium* strain and the intact soil microbial population. When present in the NAPLs, the lower chemical activity of the PAHs led to significantly reduced mineralization rates, as compared with the crystalline chemicals, but these rates were enhanced by saponin. Ongoing studies examine the role in this enhancement of the attachment and growth of bacterial cells at the NAPL/water interface, how biosurfactant molecules can interfere in this process, and the balance between bacterial attachment and PAH partitioning into the water phase in the presence of the biosurfactant. Further studies will be carried out to determine if saponin can efficiently reduce end-point PAH concentrations when applied to creosote-polluted soils after conventional bioremediation.

Keywords: bioremediation, pyrene, phenantrene, PAH, biosurfactants, saponin, NAPL.

4.01.P-Mo322 Tactic-Mediated Pore Sealing by Bacteria: Prospecting a New Engineering Component for Risk Reduction

José Luis García *and Jose Julio Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia, Spain*

The immobilization of organic pollutants, such as PCBs, PAHs and PFAS through sorbents (modified clays, activated carbon) is currently accepted as a remediation strategy for polluted soil and sediment. If the toxic organic chemicals are immobilized, the flux from the soil or sediment to the pore water is low, what results in significant risk reductions. Inspired in this technology, and given the sealing potential of the bacterium *Bacillus subtilis*, already demonstrated for cement bioreparation, we proofed the concept of pore sealing by bacteria as a new bioengineering strategy for reducing the bioavailability of organic pollutants present in microporous media. We employed the strain *B. subtilis* DSM10, a gram-positive, motile bacterium (cell dimensions 2.5 µm x 1.2 µm) with known capabilities for chemotactic mobilization through appropriate chemoeffectors, biofilm formation, and calcium carbonate precipitation. In our study, we employed a strong chemoattractant, gamma-aminobutiric acid (GABA), a chemical signal which is present in many plant root exudates, to trigger the chemotactic response. After 30 min, the bacterial cells were massively attracted into GABA-containing capillaries (1 µL, 200 µm internal diameter), as evidenced by optical microscope observations and quantification through colony forming units inside the capillaries. The incubation in agar plates of the capillaries containing the attracted cells led to bacterial growth and the establishment of cilindrical biofilms inside the capillaries, what was microscopically visible as bacterial plugs formed at the capillary mouth. This process was scaled down to micrometer-sized pores by using membranes with 5 µm and 12 µm pore sizes, through which the tactic response to GABA was tested in bioreactors composed of two chambers separated by the membranes. While the bacterial dispersal through the membranes was severy limited in the GABA-free controls, the GABA gradient generated through the membrane pores caused the masive mobilization of the bacteria through chemotaxis. Similarly to capillaries, GABA-impregnated membranes that were exposed to bacterial suspensions attracted a high number of bacterial cells inside the micropores, which proliferated upon incubation, causing pore clogging. Ongoing studies examine in bioreactor experiments the sealing capacity for organic pollutant transport through the membranes.

4.01.P-Mo323 Enhanced rhizoremediation of a kerosene-contaminated military air-base soil with sunflower and plant-growth promoting bacteria

Carmen Fernandez-Lopez[1]*, María Balseiro-Romero*[2]*, Pol Martin*[3]*, Alicia Fernandez-Vazquez*[4]*, José Luis García*[4]*, Joaquim Vila*[5]*, Jose Carlos Castilla Alcantara Sr*[6]*, Rosa Posada*[4]*, Magdalena Grifoll*[5] *and Jose Julio Ortega-Calvo*[4]*, (1)University Center of Defence (CUD), Spanish Air Force Academy, MDE-UPCT, Spain, (2)Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (3)Department of Genetics, Microbiology and Statistics, Section of Microbiology, Virology and Biotechnology, University of Barcelona, Spain, (4)Instituto de Recursos Naturales y Agrobiologia, Spain, (5)Genetics, Microbiology and Statistics, University of Barcelona, Spain, (6)Instituto de recursos Naturales y Agrobiologia, Spain*

Organic pollutants introduced into the soil by military activities include energetics, chemical warfare agents and other military chemical compounds, generally grouped as potentially toxic compounds (PTC). Contamination by PTC on military bases is mainly caused by spillage of chemicals in storage areas (fuels, oils, lubricants, paints, solvents and corrosives). Their concentrations in the soil of military areas can be unacceptably high and, together with their high toxicity and persistence, can give rise to environmental hazards. Bioremediation promotes the biodegradation of contaminants in soil by stimulating the activity of indigenous microorganisms through the improvement of soil conditions (biostimulation) and through the addition of microbial inocula with specific metabolic characteristics (bioaugmentation). In soils contaminated with organic xenobiotics, it is essential to ensure the dispersion of inoculants over the soil volume and to promote the bioavailability of the contaminants, which in turn will improve the efficiency of bioremediation. The main objective of this study was to design a rhizoremediation strategy for a soil contaminated with kerosene from a military air base (southern Spain), based on the combination of biostimulation and bioaugmentation in the presence of a model plant (sunflower, *Helianthus annuus*). The experiment was carried out under greenhouse conditions using pots with 2 kg of soil. The microbial inoculum used was a mixture of a motile strain (*Pseudomonas putida G7*), which is chemotactic against sunflower root exudates, and a biosurfactant producing strain (*Bacillus subtilis* DSM10). This inoculant was designed to enhance the dispersion of the biosurfactant-producing strain throughout the soil volume by chemotaxis-mediated co-mobilisation together with a mobile strain of *P. putida* G7. Analysis of the soil after treatment showed that kerosene degradation by indigenous microbial communities was more efficient in the presence of plants. Inoculation with *B. subtilis* DSM10 had a negative influence on bioremediation performance, possibly due to potential inhibitory effects of the biosurfactant on native kerosene-degrading microbial communities. However, its co-inoculation with mobile chemotactic strain *P. putida* G7 had beneficial effects on bioremediation performance. Microbial community response to treatments were assessed by 16S rRNA amplicon sequencing and qPCR targeting total and inoculated bacterial communities.

4.01.P-Mo324 Microbiological Investigation of the Combined Addition of Biochar, Bioactivators and Plants on a Soil Contaminated with Petroleum Hydrocarbons

Valentina Mazzurco Miritana[1]*, Ana Carolina Agnello*[2]*, Laura Passatore*[1]*, Massimo Zacchini*[1]*, Fabrizio Pietrini*[1]*, Serena Carloni*[1]*, Eleonora Peruzzi*[1]*, Sara Marinari*[3]*, Luisa Massaccesi*[3]*, Anna Barra Caracciolo*[4]*,* ***Ludovica Rolando***[4]*, Gian Luigi Garbini*[4] *and Maria Isabel Nogues Gonzalez*[1]*, (1)Italian National Research Council (IRET-CNR), Italy, (2)Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina, (3)Tuscia University (DIBAF), (4)Italian National Research*

Council (IRSA-CNR), Italy
Biochar, a vegetal black carbon produced by the pyrolysis of biomass, is receiving much attention in recent times in soil remediation due to its physicochemical characteristics. Among them, the surface area and adsorption capacity of the pore structure make biochar a suitable substance for toxic compounds immobilization. The use of biochar in synergy with other biological techniques aimed to enhance microbial activity, such as rhizoremediation and bioaugmentation, can represent a powerful strategy to accelerate the removal of organic pollutants from soil. The experiment was designed in order to evaluate the remediation potential towards petroleum hydrocarbons (PHs) from different soil treatments: biochar (SB) and biochar plus bioactivators (SBB), in presence or absence of plants (P) for 9 months. We analysed at different stages the PHs determination and the microbial community structure in terms of thetotal microbial abundance, composition and diversity. Differences in the microbial community were evident among treatments and time. Interestingly, after 9 months of treatments, the strategy of adding biochar and bioactivators promoted both microbial abundance and specific bacterial groups within the microbial community structure. Moreover, when comparing the biochar plus bioactivators treatment (SBBP) at nine 9 months versus the initial time (SBB) an increase in the number of ASVs (Richness), but a decrease in Simpson and Shannon diversity indexes were observed. Microbial community structure changed from the start to the end of the experiment in all conditions. According to the PCoA analyses, both time and type of treatment (presence of the plant/amendment of biochar/bioactivator addition) shaped microbial community structure and composition. Concurrently, PHs decreased in all treatments and reached a maximum of 70% of removal in the presence of biochar and bioactivators. Preliminary results evidenced that, despite the high PH contamination, the agricultural soil affected by an accidental oil spill maintained an abundant and vital microbial community. The most effective treatment for PHs removal was the concomitant use of biochar and bioactivators. The present study was performed in the framework of BIOCHAR LATIUM Project, CUP J85F21000410002, funded by Lazio Region within POR FESR Lazio 2014-2020 programme.

4.01.P-Mo325 Metatranscriptomics reveal a succession in bacterial communities and functions driving the decontamination of polycyclic aromatic compounds-polluted soils

Maria Jordán[1]*, Sara Nienke Jiménez-Volkerink*[1]*, Margalida Tauler*[1]*, Aurélie Cébron*[2]*, Joaquim Vila*[1] *and Magdalena Grifoll*[1]*, (1)Genetics, Microbiology and Statistics, University of Barcelona, Spain, (2)LIEC, Faculté des Sciences et Technologies, Université de Lorraine*
The microbial metabolic pathways and the bacterial populations involved in the degradation of polycyclic aromatic hydrocarbons (PAHs) have been extensively studied. However, most research has been focused on pure cultures or defined consortia in batch experiments. Currently, the challenge lies in exploring the actual *in-situ* processes, considering complex soil microbial networks and encompassing all polycyclic aromatic compounds, extending beyond the 16 regulated PAHs.

A lab-scale biostimulation treatment was conducted on creosote-contaminated soil with nutrient addition (urea and K_2HPO_4, C:N:P of 300:10:1) under aerobic conditions for 150 days. Identification and quantification of PAHs, N-PACs, oxy-PAHs were carried out through Soxhlet extraction, followed by fractionation and subsequent analysis using gas chromatography coupled to mass spectrometry (GC-MS). The microbial community dynamics involved in the dissipation of PAHs were analyzed by tracking quantitative (qPCR) and structural (16S rRNA gene metabarcoding) changes at both genomic and transcriptomic levels. Based on recent findings, the potential of native microbial communities to cycle PAH transformation products was evaluated by quantifying Baeyer-Villiger monooxygenases (BVMO).

Transcriptomic analysis of the biostimulated soil revealed a succession in the microbial communities, that extensively removed over 90% of the ∑16 PAHs and 80% of the 7 quantified N-PACs. The rapid and nearly complete removal of low molecular weight-PAHs (2- and 3-rings, LMW-PAHs) occurred during the first month and was mainly attributed to members of *Pseudomonas*. Degradation of high molecular weight-PAHs (4- and 5-rings, HMW-PAHs) started afterwards and progressed with slower degradation rates until the end of incubation, with members of *Sphingobium, Immundisolibacterales* and *Mycobacterium* identified as major contributors. Expression of PAH-ring hydroxylating dioxygenases (RHD) genes from Gram-negative bacteria showed good correlations with the activity of members of *Pseudomonas* and the removal of LMW-PAHs. RHD gene and transcript copy numbers of Gram-positive bacteria increased during the last month of incubation, correlating with the activity of mycobacteria and the removal of residual fractions of HMW-PAHs. A transient accumulation and subsequent disappearance of various known PAH-metabolites were detected, requiring the participation of specialized native bacteria carrying BVMO to mitigate the associated risk.

4.01.P-Mo326 Investigating the production of sulfonated and hydroxy-sulfonated-PCBs by several organisms through microcosm experiments

Jessica Palladini[1]*, Antonio Di Guardo*[2] *and Elisa Terzaghi, PhD*[3]*, (1)Department of Science and High Technology, University of Insubria, Italy, (2)Department of Science and High Technology (DiSAT), University of Insubria, Italy, (3)DiSAT, University of Insubria, Italy*
Sulfonated and hydroxy-sulfonated-PCBs are recently discovered PCB metabolites. Being new chemicals, they are not well characterized yet. Neither information on their fate in the environment nor on their ecotoxicity and toxicity is available. In addition, organisms with the ability to degrade PCBs into sulfonated and hydroxy-sulfonated-PCBs are unknown, such as the metabolic pathway(s) they are involved.

In this work preliminary 3-months microcosm experiments (i.,e, flasks) were performed to investigate the production of these metabolites by several organisms: microorganisms isolated from a heavily PCB contaminated soil, from the gut of earthworms (*Eisenia fetida*) collected from the same soil, from leaves of *Quercus ilex* and their associated phyllosphere microorganisms and the *Pleurotus ostreatus* mushroom. Appropriate controls were also set up to investigate photodegradation as well as PCB impurity. 8 PCBs were used as mixture and two of them as single congeners. Metabolites were measured by using an HRMS (i.e., UHPLC-Orbitrap).

PCB metabolites were found in all the flasks but with different levels, and their fingerprint changed depending on the organisms. OH-PCBs was the class for which the highest number of congeners (i.e., different retention time) was produced (53), followed by hydroxy-sulfonated-PCBs (32). Sulfonated-PCBs appeared just 80 days after the start of the experiment. The most efficient system in terms of number and amount of PCB metabolites were leaves of *Quercus ilex* and their associated phyllosphere microorganisms. Even microorganisms deriving from a heavily PCB contaminated soil produced a great number of different congeners. In addition, comparing the experiments, different metabolite congeners were identified in the PCB single congener flasks with respect to the PCB mixture flasks, indicating that probably dechlorination led to the production of other PCB in the mixture flasks that were then or simultaneously sulfonated and/or hydroxylated. This preliminary experiment with different treatments allowed to investigate the most efficient systems in the production of sulfonated and hydroxy-sulfonated PCBs. Moreover, the results represent the first step to hypothesise the metabolic pathway leading to the formation of these metabolites from their parent compounds. However, further experiments will be performed to better understand the environmental fate of these new contaminants.

4.01.P-Mo327 Individual and combined effects of temperature, CO2, and soil water content on Summer Rape (Brassica napus) potential to remediate Cd contaminated soil

Inesa Kniuipyte[1]*, Austra Dikšaitytė*[2]*, Marius Praspaliauskas*[1] *and Jurate Zaltauskaite*[2]*, (1)Lithuanian Energy Institute, Lithuania, (2)Vytautas Magnus University, Lithuania*

Heavy metals are the main group of contaminants contributing to soil pollution, in Europe they constitute up to 35 % of potentially contaminated sites. Phytoremediation is a promising bioremediation technology for the restoration of heavy metal sites by utilizing harvestable plants and posing no adverse effect to soil and environment. Using the energy plant summer rape it is possible to clean the soil while obtaining bioenergy at the same time. The application of phytoremediation is significantly limited by several factors, such as climatic conditions, soil characteristics, rhizosphere microbial community, fertilizer application, the presence of other contaminants. Since phytoremediation is an on-site remediation technology, its efficiency might be also impaired under the ongoing climate change.

This study aimed to analyze the individual and combined effects of soil water content (optimal, reduced, and elevated), temperature, and CO_2 concentration (21/14 °C, 400 ppm CO_2 in the current climate vs. 25/18 °C, 800 ppm CO_2 in the future climate) on the remediation efficiency of Cd-contaminated soil (1-50 mg kg^{-1}) for the energy crop summer rape (*Brassica napus* L.). Results showed that summer rape had good resistance to low and moderate Cd soil pollution, as well as the ability to extract Cd from soil, with a significant potential for bioenergy production. Elevated temperature and elevated temperature paired with elevated CO_2 decreased Cd toxicity in *B. napus* by stimulating plant growth, resulting in lower Cd plant tissue concentrations. However, the effect was depending on soil water content (SWC) and Cd soil concentration. Under current climate circumstances, appropriate soil water content resulted in the best Cd removal efficiency with the fewest number of plant harvesting cycles. Future climate conditions enhanced *B. napus* Cd remediation, with the maximum Cd removal rate reported at low and moderate soil Cd contamination (1-10 mg kg^{-1}) under higher temperature and SWC. SWC adjustment in response to climate change is critical for boosting phytoremediation capacity since it influences plant biomass development, heavy metal uptake and translocation.

Keywords: *Brassica napus*, cadmium, climate change, phytoremediation, soil water content

4.01.P-Mo328 Bioremediation of Chlorinated Ethenes: Distribution and Abundance of Functional Genes in Situ

Aday Amirbekov[1]*, Kristyna Markova*[2]*, Jakub Riha*[3]*, Jan Nemecek*[3]*, Alena Sevcu*[4] *and Iva Dolinova*[5]*, (1)Technical University of Liberec, Liberec 1, Czech Republic, (2)Technical University of Liberec, Czech Republic, (3)Technical University Liberec, Institute for Nanomaterials, Advanced Technology and Innovation, Czech Republic, (4)Technical University of Liberec, Institute for Nanomaterials, Advanced Technology and Innovation, Czech Republic, (5)Regional Hospital in Liberec, Czech Republic*

Chlorinated ethenes (CE), categorized as organochlorines (OCs), globally persist as environmental pollutants, threatening air, soil, and water quality due to toxic metabolites. While conventional treatments are essential, the increasing recognition of natural or substrate-enhanced bacterial degradation of CE and their metabolites is noteworthy. OC biotransformation, primarily through anaerobic reductive dechlorination facilitated by rdhA genes (bvcA, vcrA, tceA), involves additional processes like aerobic metabolic degradation. Diverse anaerobic microorganisms, including Dehalococcoides, Dehalobacter, Geobacter and Dehalogenimonas utilize OCs in organohalide respiration. Utilizing qPCR, our study assessed the relative abundance of genes associated with total bacterial biomass, oxidative markers (etnC, mmox), and reductive markers (vcrA, Dhc, Dsb, Geo, apsA). In 2022, we introduced nanofibrous biomass carriers into drilled wells at two highly polluted sites in Czechia to capture bacteria with CE degradation capabilities. Through the relocation of nanofibrous carriers from contaminated to non-contaminated aquifers in same sites, our findings shed light on the significant contribution in shaping the genetic landscape of

CE-degrading bacteria. The non-contaminated sites show a low relative abundance of the selected markers compared to contaminated sites. Notably, in both sites, samples from the transferred biomass carriers exhibited an elevated relative abundance of genes, specifically vcrA and Dhc, compared to levels observed at the low contaminated site. Some bacterial populations rapidly changed, while others maintained a stable profile with slower alterations under varying conditions. The observed increase underscores the potential influence of environmental factors or microbial interactions during the relocation process, warranting further investigation into the mechanisms driving these variations. In summary, our investigation reveals nuanced patterns of chlorinated ethenes-degrading genes, providing valuable insights into their distribution and abundance across diverse environmental conditions, essential for advancing our understanding of microbial bioremediation capabilities.

4.01.P-Mo329 Application of Novel Bacterial Strains for Paracetamol Mineralization in Aqueous and Sewage Sludge Systems

Alba Lara-Moreno[1], Fernando Madrid[2], Esmeralda Morillo[2], Antonio Vargas-Ordóñez[2], Inés Aguilar-Romero[2], Jorge Carlier[3] and ***Jaime Villaverde**[2]*, (1)Department of Microbiology and Parasitology, Faculty of Pharmacy, University of Seville, Spain, (2)Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (3)Centre of Marine Sciences (CCMAR), University of Algarve, Portugal*

Wastewater treatment plants (WWTPs) are identified as significant contributors of Paracetamol (APAP) to the environment. The environmental impact results from the WWTPs inability to fully degrade it. Consequently, the continuous release into the environment, particularly in aquatic ecosystems, is a matter of general concern. Microbial biodegradation is widely recognized as an efficient approach to remove APAP.

This study designed a strategy of bioremediation using bioaugmentation to achieve APAP mineralization in solution and in sewage sludge. *Pseudomonas extremaustralis* CSW01 and *Stutzerimonas stutzeri* CSW02, isolated from sewage sludge by enrichment cultures in the presence of APAP, were able to mineralise around 30% (10 mg L^{-1} initial concentration) after 28 days and a DT_{50} of 1250 days in the case of CSW01 and for CSW02, a degradation rate of 50% will never be achieved. However, when each of them was inoculated forming two consortia with *Mycolicibacterium aubagnense* HPB1.1 **(**isolated from a mine sample in the presence of hydroquinone, the main metabolite of APAP) the extent of mineralization significantly increased (up to 58% and 73% for CSW02+HPB1.1 and CSW01+HPB1.1, respectively) and the DT_{50} was reduced compared to the treatment by inoculating individual strains at 1 and 9 days for CSW01+HPB1.1 and CSW02+HPB1.1, respectively. After testing the effectiveness of the treatment in the aqueous system, the strategy was extrapolated to a more realistic system (sewage sludge). Similar results were obtained when the bacterial isolates (CSW01 or CSW02) were inoculated individually or together with HPB1.1, achieving an extent of mineralization of around 15% after 28 days (from 50 mg kg^{-1} of initial concentration).

4.01.P-Mo330 An Evaluation of the Effluent Quality from The Tshiame Wastewater Treatment Plant (Free State, South Africa), and the Potential Use of Mycofiltration for Improvement in Wastewater Treatment

***Sanele Michelle Mnkandla**[1,2] and Patricks V. Otomo[3], (1)Applied Biology and Biochemistry, National University of Science and Technology, Zimbabwe, (2)Zoology and Entomology, University of the Free State, South Africa, (3)Zoology and Entomology, University of The Free State, South Africa*

In the eastern Free State, South Africa, there have been reports of high levels of heavy metals in effluent receiving rivers, owing to the release of inadequately treated effluent. Due to infrastructure vandalism at the Tshiame Wastewater Treatment Plant (WWTP), wastewater treatment solely relies on waste stabilisation ponds. Stabilisation ponds are nature-based, and their efficiency could be improved by augmenting with other biological technologies such as Mycofiltration, which is the treatment of contaminated water by passing it through a network of saprophytic fungal mycelium. Mycelia have high biosorption potential for metals. To date, there are no reports on the use of fungi as mycofilters for the remediation of metals from WWTPs.

The present study sought to assess the performance of the Tshiame WWTP pond system, through observing selected physicochemical parameters and heavy metals, and to investigate metal removal by Mycofiltration in both untreated influent and treated effluent.

Physicochemical parameters assessed were pH, Temperature, Electrical Conductivity (EC), Salinity and Total Dissolved Solids (TDS), while the heavy metals were Al, As, Cd, Cr, Cu, Fe, Pb, Mn, Hg, Se, Zn, Mg, Ni, Co, Na, K, Ca, Mo, Ti, P. A mycofilter (made of thatching straw and *Pleurotus ostreatus* mycelia) was cultured for a laboratory small-scale Mycofiltration trial. Mycofilters were packed into pyrex columns (3.3 x 15 cm) and the influent and / or effluent was passed at a constant rate, and the heavy metal content in mycofiltered media assessed. Used mycofilters were characterized using Fourier Transform Infrared Spectrophotometry (FTIR).

Physicochemical parameter values for both influent and effluent were within the recommended guidelines, except for pH which was acidic (pH= 3.7-2.9). The pond system significantly reduced EC and TDS evidenced by lower values in the effluent compared to influent. Levels of Na, K, Mg, P, Fe and Cu were also significantly lower in the effluent compared to the influent, falling within recommended guidelines. While metal analyses of mycofiltered samples is pending, FTIR analysis of mycofilters revealed significant changes in transmittance intensity in the mycofilter used for the influent vs the one used for the effluent, suggesting greater biosorption of influent. The Tshiame WWTP stabilisation ponds are fairly efficient. Mycofiltration of influent could potentially further improve wastewater treatment.

4.01.P-Mo331 BIOREMEDIATION AND PHYTOMANAGEMENT STRATEGIES APPLICATION IN SOILS AMENDED WITH SEWAGE SLUDGES

*Alejandra Pérez-Vázquez[1], **Erik Urionabarrenetxea**[2], Camila Fatima Rutkoski[3], Artetxe Artetxe[4], Maria Teresa Gomez-Sagasti[4], Nerea Garcia-Velasco[4], Beñat Zaldibar[5], Antonio Hernandez-Hernandez[4], Mikel Anza[6], Lur Epelde[6], Carlos Garbisu[7], Jose Maria Becerril[4] and Manuel Soto[5], (1)Zoologia y biologia celular animal, University of the Basque Country (UPV/EHU), Spain, (2)Zoology and Animal Cell Biology, University of the Basque Country (UPV/EHU), Spain, (3)Universidade Regional de Blumenau, Brazil, (4)University of the Basque Country (UPV/EHU), Spain, (5)Research Center for Experimental Marine Biology Biotechnology "Plentziako Itsas Estazioa", University of the Basque Country (PiE-UPV/EHU), Spain, (6)NEIKER-Basque Institute for Agricultural Research and Development, (7)NEIKER, Spain*

During the last decade 2.7-6.5% of the Basque Country surface was considered contaminated. Thus, Basque Country Government developed an inventory of soils that support or had supported potentially polluting activities (Law 4/2015). In this inventory "Landfill 17" located in Gernika-Lumo is included, where sewage sludges from the local WWTP were poured as amendment for decades. In order to decontaminate and recover soil functionality, a combination of bioremediation technologies (involving micro-, phyto- and vermiremediation) was applied. Afterwards, as an additional remediation tool to restore the ecosystem health and diversity a phytomanagement strategy based in natural attenuation and the promotion and maintenance of the native vegetation was carried out *in situ*.

In order to assess the effectiveness of the bioremediation together with the phytomanagement strategy different bioassays including OECD standard toxicity tests or EPA seed tests, were carried out with earthworms and lettuce seeds. To provide a holistic, comprehensive and summarized information about the ecosystem general status, an integrative biomarker response index (IBR/n) was performed. Regarding the results, soil chemical analyses showed a decrease in most of the critical pollutants (Cd, Cr, Ni, Pb, Benzo(a)pyrene) in all the treated plots. Although, microbial parameters did not show a remarkable difference among points, aboveground biological indicators pointed non-phytomanaged plot (MN8) as the area with the worst soil health. Thus, the results obtained indicate that phytomanagement strategies help to eliminate contaminants, help recovering the ecosystem biodiversity and also improve soil health and quality.

Acknowledgments: Interreg PhytoSUDOE project (SOE1/P5/E0189), Basque Government (Grant to Consolidated Research Groups; IT1743-22 and IT1648-22) and Gernika City Hall.

4.01.P-Mo332 MICROTOX Ecotoxicity Test for Assessing Pesticide Soil Toxicity: A Case Study on the Application of Bioremediation Techniques.

*Esmeralda Morillo[1], Alba Lara-Moreno[2], Fernando Madrid[1] and **Jaime Villaverde**[1], (1)Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (2)Department of Microbiology and Parasitology, Faculty of Pharmacy, University of Seville, Spain*

Trifluralin (TFL) and chlorpyrifos (CLP) are highly persistent pesticides with a strong adsorption capacity on soil particles. Biological strategies are considered as a good option to remediate different environmental compartments. Prior to this study, assisted natural attenuation was used to find the ability of different kinds of soils to biodegrade TFL and CLP. Different specific bacterial strains capable of degrading various pesticides were isolated from soil using the soil enrichment technique. Among the TFL-degrading strains, the most efficient bacterial strain was *Arthrobacter aurescens* CTFL7 (55% degradation of TFL in solution, 10 mg L^{-1}), which had not been previously reported in the literature as a TFL-degrading bacterium. For CLP degradation, two CLP-degrading strains, *Bacillus megaterium* CCLP1 and *Bacillus safensis* CCLP2, were isolated from soil and showed the ability to degrade up to 99.1% and 98.9% of CLP in solution (10 mg L^{-1}). Different strategies were evaluated to increase the effectiveness of TFL and CLP degradation in soil. These techniques included: i) biostimulation using a nutrient solution; ii) bioaugmentation using a natural microbial consortium, individual bacterial strains isolated from soil, and an artificial bacterial consortium formed by these isolated bacterial strains; iii) bioavailability enhancement using a biodegradable compound, randomly methylated β-cyclodextrin (RAMEB). In this work, ecotoxicity studies were conducted to assess the effectiveness of the studied bioremediation strategies, considering not only their ability to biodegrade a specific pesticide in soil, but also their ability to reduce toxicity, since metabolites can become more toxic than the parent compound. For this purpose, the MICROTOX acute toxicity test was used, which is based on the use of the luminescent bacteria *Vibrio fischeri* as biosensors. In the case of TFL, the ecotoxicity test showed that after application of *A. aurescens* CTFL7 and *A. aurescens* CTFL7 + RAMEB, the TFL-contaminated soil, which initially presented acute toxicity, became non-toxic at the end of the biodegradation experiments. In the case of CLP, it was observed that when the selected degrading strains were individually inoculated into the soil, the toxicity was reduced to undetectable levels.

4.01.P-Mo333 Ecotoxicological assessment of the aqueous soil extracts from post-remediated mining soil in the former Cartagena-La Unión mining district (south-east of the Murcia Province, Spain).

***Juan Carlos Beltrá Castillo**[1], Susana Loureiro[2], Marija Prodana[3], Fábio Campos[4], José Nereu Pinto[3], Madalena Vieira[5], Silvia Martínez Martínez[1], José Alberto Acosta[1] and Angel Faz Cano[1], (1)Polytechnic University of Cartagena, Spain, (2)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal, (3)CESAM & Department of Biology, University of Aveiro, Portugal, (4)CESAM - Centre for Environmental and Marine*

Studies and Department of Biology, University of Aveiro, Portugal, (5)University of Aveiro, Portugal
Mining activities, particularly those involving metal extraction, pose a significant risk to aquatic systems due to the potential contamination and accumulation of heavy metals. To mitigate these risks, several strategies can be employed to reduce the discharge and accumulation of heavy metals in aquatic environments. These strategies include organic and inorganic amendments addition, as well as remedial actions such as waste management and recycling to minimize the adverse impact on ecosystem and organisms health. One potential organic amendment is biochar, which has been shown to effectively adsorb heavy metals and reduce their leaching into water systems. Composts and manures can be adequate alternatives, as they can enhance soil fertility and promote the uptake of heavy metals by plants, consequently reducing their availability in aquatic ecosystems. Additionally, inorganic amendments such as zeolites and calcium carbonate are also proposed due to their capacity to trap and immobilize heavy metals. The main goal of this work was to evaluate the impact of the range of soil amendments applied to the mining soil on the soil functioning in contaminant and nutrient retention, using direct ecotoxicity assessment with aquatic bioassays. To study this, we produced the aqueous soil extracts, i.e., elutriates, as a proxy to run-off. The elutriates were produced out of the soil sampled from the field plot experiment - non-amended mining soil, and soil amended with different treatments such as compost, biochar, zeolite, calcium carbonate, and their combinations. Freshwater species from different trophic levels – green algae *Raphidocelis subcapitata,* water flea *Daphnia magna* and zebrafish *Danio* rerio were exposed to these elutriates. The evaluated endpoints were algae growth, water flea immobilization and oxidative stress biomarkers, hatching and mutagenicity of zebrafish. Non-amended mining soil elutriate induced toxicity in all the species. The incorporation of amendments substantially decreased the toxicity of the elutriates of the mining soils, with the responses being treatment dependent. Complementary data analysis of the physicochemical characterization (pH, metals, nutrients, etc.) of the elutriates is ongoing, and overall data integration is expected to provide better insight on the adequacy of different treatments and/or their combinations in terms of reducing the pressure from contaminated mining soil on aquatic ecosystem.

4.01.P-Mo334 Field Aging of a Commercial Biochar: Effect on the Retention of Sulfamethoxazole and Ethofumesate Over Time
***Rocío López-Cabeza*[1]*, Beatriz Gámiz*[1,2]*, Jose Antonio Galán-Pérez*[1,3]*, Lucía Cox*[1] *and Rafael Celis*[1]*, (1)Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (2)Departamento de Química Inorgánica, Instituto de Química para la Energía y Medioambiente (IQUEMA), Universidad de Córdoba, Spain, (3)Environmental Sustainability and Health Institute, Technological University of Dublin, Ireland*
The high mobility of organic pollutants in soils may represent an obstacle to their bioremediation and/or natural attenuation. The addition of adsorbents to soils is an excellent strategy to enhance their retention providing the residence time needed for their degradation by bacteria, fungi, or plants. Biochar (BC), the carbonaceous material produced by pyrolysis of biomass, has been proposed as a soil amendment due to its optimal adsorption properties. However, once in the soil, BCs undergo changes which alter their physicochemical properties and impact their adsorption capacity. Evaluating BC aging under real field conditions is thus crucial to determine its long-term efficiency as an adsorbent. In this work, a commercial BC was aged for one year in the top 0-5 cm of soil plots of an experimental farm located in southern Spain. Unamended and amended soil samples were periodically taken (t = 0, 1, 3, 6, and 12 months) and their retention capacity for the antibiotic sulfamethoxazole and the pesticide ethofumesate was assessed by batch adsorption and leaching experiments. Changes in the physicochemical properties of the BC particles upon aging were evaluated by determining their elemental composition and registering their Fourier-transform infrared spectra and scanning electron micrographs. The results showed that the addition of the BC to the soil greatly increased the adsorption of both compounds compared to unamended soil. However, the adsorption capacity of the adsorbent decreased gradually over time, affecting leaching rates. The characterization of the adsorbent indicated that aging mainly consisted of physical changes at the BC particles´ surface. Despite the loss of adsorption capacity of BC over time, one-year aged BC-amended soil samples retained the pollutants to a much greater extent than unamended soil samples. This means that, after one year of residence in the soil, the BC could continue retaining much of the investigated pollutants, which would favor the restoration of the contaminated soil through suitable bioremediation processes. Acknowledgment: Financed by project P20-00746 of Junta de Andalucía (Spain) and projects PID2020-112563RB-I00 and PID2022-137187OB-I00 of the Spanish Ministry of Science and Innovation, with (EU) FEDER funds.

4.01.P-Mo335 Evaluating the Significance of Two Different Biochar Dissipation Pathways in Soil
***Marko Šolić*[1]*, Bruno Glaser*[2]*, Arthur Gross*[2]*, Heike Maennicke*[2]*, Tobias Bromm*[2] *and Snezana Maletic*[3]*, (1)Faculty of Sciences, University of Novi Sad, Serbia, (2)Martin Luther University Halle-Wittenberg, Germany, (3)University of Novi Sad, Serbia*
Biochar, as a product derived from the pyrolytic conversion of biomass, can perform several ecosystem functions, two of which are particularly important: long-term soil quality improvement and carbon sequestration. The degree to which these benefits will be realized is largely determined by the stability of the biochar within the soil. Despite generally being considered highly persistent, a mild depletion of biochar stocks, specifically the Pyrogenic C fraction, was observed during a 12-year field experiment set up in Donndorf/Eckersdorf, Germany. Hence, the question arises: can the identified loss over this relatively short time period be attributed to some transformation of biochar, or is it simply the result of its physical transport. To address this question, samples collected from the Donndorf/Eckersdorf trial were analyzed for the amounts of free benzene polycarboxylic acids (BPCAs), as they serve as molecular markers for the degradation of Pyrogenic C. The samples were obtained from two experimental variants: one with the individual application of a high dose of biochar (31.5 t/h), and the other combining biochar (31.5 t/h) with composted material (70 t/h). Sampling was conducted in 2009, prior to the experiment's establishment, and subsequently at two-year intervals in 2013 and 2021. In 2009 and 2013, samples were taken at depths of 0–

10 cm and 10–30 cm, while in 2021, samples were collected at a depth of 0–30 cm. The soil pH ranged from 5.4 to 5.8, and the texture was as follows: 62% sand, 12% silt, and 26% clay. The biochar was produced through the pyrolysis of beech and pine wood chips. The analysis of free BPCAs was conducted using GC-FID. In most of the analyzed soil samples free BPCAs were not detected. In the remaining cases, free BPCAs were identified, at both investigated soil depths, but only in amounts that can be considered relatively low, ranging from 3.96×10^{-5} to 5.51×10^{-2} g/kg. Given that the pH and sandy loam texture of the examined soil did not favor the loss (further oxidation or leaching) of free BPCAs, their absence or low abundance can be considered a clear indication of the high stability of the applied biochar. Therefore, the observed loss of biochar should be attributed to its physical transport. However, as absence or low levels of free BPCAs may also result from the high detection limit of the GC-FID method, to confirm the obtained results, samples will be further analyzed using the LC-VWD.

4.01.P-Mo336 Effectiveness of a hydrocarbon contaminated soil bioremediation process

Simona Schiavo[1]*, Sara Accardo*[2,3]*, Sonia Manzo*[3]*, Flavia Tasso*[4]*, Patrizia Paganin*[5]*, Laura Caiazzo*[6]*, Riccardo Tognon*[5] *and Chiara Alisi*[1]*, (1)National Agency for New Technologies, Energy and Sustainable Economic Development (ENEA), Italy, (2)University Parthenope, (3)ENEA CR Portici, Italy, (4)ENEA CR Casaccia, (5)ENEA Casaccia, (6)ENEA Environmental Chemistry Division, Italy*

Bioremediation of total petroleum hydrocarbons soil (TPH) can be achieved through various techniques. Bioaugmentation upon injection of selected functional microbial strains, among others, enables immediate degradation. The use of microorganisms that produce surface-active compounds enhances solubility, mobility, bioavailability, and subsequent biodegradation of hydrophobic organic compounds by emulsifying or solubilizing the hydrocarbons.

The evaluation of soil toxicity becomes an additional but fundamental step of the bioremediation process, being an indicator of the success of the biological treatment. In fact, the effectiveness of the bioremediation process cannot be evaluated only through analytical monitoring, which is complex due mainly to the characteristics of the matrix.

In the framework of Italian PNRR project “Return”, the goal of this work was to determine the effectiveness of a microbial formula in soil TPH bioremediation by pollutant biodegradability assessment and the toxic effects attenuation with an approach that involves chemical, microbiological, respirometry and ecotoxicological evaluation.

This work started with the selection of microorganisms for biosurfactant production using 50 aerobic bacterial strains from the ENEA-MIRRI Microbial Collection. The strains were grown on selective liquid media (BDH) and the surfactant production was followed up to 10 days using Oil Spreading Assay and E24 assay on the supernatants, to test their capacity to produce biosurfactant. The best biosurfactant producers, (i.e. A2-5 *Pseudomonas glycinis*, OSS19 *Rhodococcus qingshengi*, SM41, *Kokuria polaris*, SME 2.4 *Arthrobacter humicola*, SME 2.18 *Microbacterium hydrocarbonoxydans*) were further investigated. Cross-streak tests among strains were performed to check the compatible strains to be pooled to set-up the formula for bioaugmentation in biometer flasks.

Ecotoxicological tests were carried out on either the solid fraction and aqueous and organic extract of TPH soil at different bioremediation stages. Root elongation toxicity test with *Lepidium sativum*, *Sinapis alba* and *Sorgum saccharatum* assessed toxic effect directly in soil fraction. The bacteria *Aliivibrio fischeri* and the crustacean *Daphnia magna* were used to assess the acute toxicity of leachates while a chronic test was performed with the algae *Raphidocelis subcapitata*. The combined use of these test organisms proved to be a viable tool for demonstrating the recovery of soil quality and health.

4.01.P-Mo337 Amplicon Sequencing Reveals Active Functionalities in Petroleum-Degrading Microbiome

Professor Chioma Blaise Chikere, PhD*, Department of Microbiology, UNIPORT; CAES - UNISA, Nigeria*

Bioremediation of a heavily polluted soil with varying fractions of hydrocarbons ranging from n-C8 to n-C40 was investigated. Total petroleum hydrocarbons (TPH) concentrations were 490,631 mg kg–1 in the surface (0 − 15 cm), 320,971.60 mg kg–1 at 1 m depth and 81, 434.86 mg kg–1 at 1.5 m depth. Remediation of the oil-polluted site began with site mapping where approximately 2 plots of land (Length = 120; Width = 125) were cordoned off from the massively polluted expanse of land. Prior to remediation proper, samples were taken from different points of the mapped site (4°47'41.1"N 6°51'47.2"E - 4°47'42.4"N 6°51'46.4"E) representing the surface soil (0 – 15cm) and subsurface soil (30cm – 1m and 1m – 2m depth). Unpolluted soil samples were also collected approximately 1000 meters away from the artisanal refining site (4°47'26.3"N 6°53'32.1"E) to serve as reference soil for comparison. Remediation involved making, breaking and re-making of ridges at 2 weeks interval to improve aeration and proper mixing of all components. Microbiome analysis was done using16S rRNA amplicon sequencing on Ilumina MiSeq platform. To determine the core bacteria across the different operational taxonomic units (OTUs) in all polluted samples, only OTUs with at least 20% abundance were screened and selected. At least 7 of the core bacterial classes were found to have a minimum prevalence of 70% and included *Alphaproteobacteria, Betaproteobacteria, Actinobacteria, Acidobacteriia, Anaerolineae, Gammaproteobacteria* and Bacilli. At the family level the core bacteria with minimum prevalence of 70% included *Acetobacteraceae*, *Koribacteraceae*, *Bradyrhizobium*, *Anaerolinacea, Hyphomicrobiaceae, Commamonadaceae, Burkholderiaceae, Alcaligenacea, Sphingomonadaceae, Xanthomonadaceae* and *Bacillaceae*. Further investigation of the core microbiome during remediation revealed six bacterial genera had at least 70%

prevalence across the samples and included *Anaerolinea*, *Candidatus Koribacter*, *Acidocella*, *Burkholderia*, *Bacillus* and *Parvibaculum*. High-throughput sequencing and bioinformatics revealed signature biomarkers (for pollutant degradation and biosynthesis), functionalities and keystone bacterial phyla involved in field-scale remediation and site recovery. These high-end techniques unequivocally established ecosystem and biodiversity restoration thereby promoting citizen science, indigenous knowledge, UN SDGs 4, 12, 13, 15 and 17.

4.01.P-Mo338 Phytoremediation: a tool to remove chemically distinct antimicrobial resistance drivers?

*Kaniz Fatema Chowdhury[1], **John Nightingale**[2] and Laura Carter[1], (1)School of Geography, University of Leeds, United Kingdom, (2)University of Leeds and Fera Science Ltd, United Kingdom*

The environment is increasingly being recognized for the role it might play in the global spread of clinically relevant antimicrobial resistance (AMR). Evidence is emerging that in addition to antibiotics, biocides and heavy metals also contribute to the growing problem of AMR. Following release into the aquatic systems (e.g. rivers, lakes), these contaminants may contribute to the dissemination of AMR by enriching resistance gene determinants via co-selection mechanisms. There is an urgent need to develop tools and processes to remove these contaminants from the environment to challenge the spread of antimicrobial resistance. Aquatic phytoremediation is a recently adopted methodology to remediate contaminated matrices via sequestration and enhanced degradation of chemical pollutants in aquatic environments. However, to date our understanding of the potential role phytoremediation can play in contaminant removal has largely focused on contaminants from particular chemical classes and rarely considers true environmental complexity. A common aquatic hyper-accumulator plant, *Lemna minor,* was selected to assess the potential for phytoremediation of common AMR drivers (metals, antibiotics, biocides), individually and together as a co-contaminant mixture. Under controlled laboratory exposure two metals (cadmium (Cd) and chromium (Cr), two antibiotics (trimethoprim and ciprofloxacin), and two biocides (diazinon and atrazine) were used to assess the potential of co-contaminant competition on uptake and accumulation by *Lemna* sp over four days. Contaminants were spiked into the exposure media at 150 ng/L. At the end of the exposure media was sampled for analysis and plant material was harvested and extracted using a validated method (0.1M Na2EDTA McIlvaine buffer and 2mM phosphoric acid in acetonitrile) and solid phase extraction clean up step. Quantification of analytes of interest was achieved using LC-MS/MS. Mitigation measures to combat AMR are needed which account for chemical complexity in the natural environment and the fact that exposure does not occur in isolation to a single driver.

4.01.P-Mo339 Photocatalytic Transformation of PFOS

***Marija Lješević**[1], Kristina Kasalica[2], Nenad Radić[2], Jelena Radulović[3], Stefan Lekić[2], Ljubodrag Vujisić[4], Latinka Slavković Beškoski[3] and Vladimir Beskoski[5], (1)University of Belgrade, Institute of Chemistry, Technology and Metallurgy, Serbia, (2)University of Belgrade - Institute of Chemistry, Technology and Metallurgy, Serbia, (3)Anahem laboratory ltd, Serbia, (4)University of Belgrade - Faculty of Chemistry, Serbia, (5)University of Belgrade, Faculty of Chemistry, Serbia*

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals widely used in industrial and consumer products for their water- and grease-resistant properties. They are known for their persistence in the environment and resistance to degradation, and adverse health effects. Perfluorooctane sulfonate (PFOS), C8-PFAS, was one of the most widely applied PFAS, due to low surface tension and great surfactant properties. Although PFOS use is now restricted, the past applications resulted in widespread contamination, posing a challenge in managing their impact on ecosystems and human health. The process of photochemical degradation has demonstrated itself as an economical, effective, and environmentally sustainable method for the degradation of various compounds. Processes employing titanium dioxide (TiO_2) and aluminum oxide (Al_2O_3) have gained attention as a promising avenue for the photocatalytic degradation of PFAS.

In this study, eight different Ti and Al based catalyst were employed for the investigation of photocatalytic PFOS degradation. The maximum PFOS concentration used was 50 ppm. The experiments were conducted at 20 °C in an open cylindrical polypropylene reactor, and a simulated solar radiation lamp (Solimed BH Quarzlampen) was used as a light source. Photocatalysis was monitored up to 8 hours. The range of degradation was 50-78%. Analysis of degradation products indicated that the dominant method of transformation is oxidation. Additionaly, ecotoxicity to *Allivibrio fischeri* of both PFOS and photocatalytic degradation products was assessed. The obtained results confirmed the possibility of remediation of PFOS and related compounds in aquatic environment. Further studies will focus on the optimization of this approach and elucidation of the complete transformation mechanism.

4.02 Biodiversity, Ecosystem Services and Ecological Risk Assessment: Advances and Challenges

4.02.T-01 Navigating Management Strategies in Mediterranean Coastal Wetlands: An Ecosystem Services Perspective

***Pablo Amador**[1], Lorraine Maltby[2], Andrew Beckerman[2] and Andreu Rico[1], (1)Cavanilles Institute of Biodiversity and Evolutionary Biology, University of Valencia, Spain, (2)School of Biosciences, University of Sheffield, United Kingdom*

Mediterranean coastal wetlands provide a wide range of ecosystem services. However, their ability to deliver these services can be disrupted by human activities, impacting both the ecosystems and the benefits society obtains from them. Research on eutrophication's impact on wetlands has been thorough, but the wider effects of agricultural chemicals on ecosystem dynamics are less explored, with traditional toxicity tests focusing on individual species rather than whole ecosystems. The AQUATOX model overcomes this limitation by simulating the combined effects of various stressors on ecosystem structure and functions, aiding in more effective ecosystem conservation efforts. In this study, we used the AQUATOX model to assess the effects of nutrient and pesticide inflows in Mediterranean coastal wetlands, using the Albufera lake (Valencia, Spain) as a case-study.

We quantified trade-offs between ecosystem services under various management scenarios, identified critical thresholds for nutrient and pesticide levels, and formulated sustainable management recommendations. To do so, we entered meteorological and hydrological data into our model and created a time series for nutrient and pesticide inflows based on this data and existing research. We integrated biotic community data, established trophic links from literature, and after calibrating with phytoplankton and zooplankton data, we used the model to simulate various management scenarios, including different nutrient and pesticide inputs reflective of agricultural practices. Then, we quantified Albufera Lake's ecosystem services in monetary terms, covering provisioning services like hunting and fishing, calculated from game bird abundance and eel biomass, and recreational services such as recreational fishing, birding and tourism based on carp biomass, bird abundance, and water clarity. We also assessed three regulation services—carbon sequestration and water depuration of nitrogen and phosphorus—estimating their economic value through market prices and cost savings in water treatment. By applying this workflow, we provide a holistic understanding of the necessary trade-offs between agricultural use, biodiversity conservation, and ecosystem service provision in Mediterranean coastal wetlands.

4.02.T-02 Accounting for the Impact of PPPs on Ecosystem Services by Ecological Models: An Example for Pest Control

***Andreas Focks*[1]**, *Leonhard Urs Bürger*[2], *Grzegorz Sylwester Sowa*[3] *and Lorraine Maltby*[3], *(1)Institute of Mathematics, Osnabrück University, Germany, (2)Systems Science Group, Institute of Mathematics, Germany, (3)School of Biosciences, University of Sheffield, United Kingdom*

In the currently ongoing, EFSA-funded AENEAS project, a protocol for evaluating the impact of plant protection products (PPPs) on the ecosystem functions that provide ecosystem services is developed. The protocol provides a step-by-step approach for linking effects on vulnerable taxa to ecosystem function delivery within agricultural landscapes. Population models or additionally field studies are proposed in this protocol to assess the impact of PPP exposure on the population dynamics of vulnerable taxa within agricultural landscapes. This contribution provides an example on how population models can be utilized to simulate pesticide impacts on ecosystem services delivered by non-target arthropod species. We illustrate this by using *Erigone atra* as an example species, based on an implementation for *E.atra* in the ALMaSS framework to simulate population abundances with and without pesticide application in an agricultural landscape. Simulated population abundances were translated into the potential for pest control by using the concept of ecological functional responses.

Resulting Erigone abundances extracted from ALMaSS for the whole landscape window, showed that 90% (and 99.9%) mortality led to an average reduction of abundances of about 20% in the summer months. The potential ecosystem function of pest control was calculated based on the specific functional response and was found to be decreased by stronger pesticide effects at population levels. When aphid numbers are lower, the potential for the ecosystem function is also lower.

Analyses of derived NORs of the population abundances with and without the impact of pesticides come close to the conceptual ideas as outlined in the EFSA scientific opinion on recovery. Simulated population abundances can be connected via functional relations to ecosystem functions, so that a quantitative link from population effects of a pesticide to impacts on ecosystem functions can be calculated. Landscape-level assessments consider subpopulation impacts, metapopulation dynamics, and landscape heterogeneity, providing a comprehensive assessment of PPP impacts on ecosystem function (i.e. potential ecosystem service delivery). Data scarcity points towards the need for models for the support of the calculation of NORs and the impacts of pesticides on ES delivery. The calculation of model-derived NORs as demonstrated for *E.atra* in this study appeared absolutely feasible.

4.02.T-03 Individual effects to Ecosystem Services: Insights from DEB IBMs on Freshwater Shredder Species

***Niamh O'Connor*[1]**, *Philip Warren*[1] *and Lorraine Maltby*[2], *(1)University of Sheffield, United Kingdom, (2)School of Biosciences, University of Sheffield, United Kingdom*

An ecosystem services approach to environmental risk assessment aims to understand how chemicals impact the ecological processes and functions that underpin the delivery of ecosystem services. Ecological functions are performed by populations of species. While toxicity tests often rely on single-species endpoints, an ecosystem services approach requires consideration of population responses – which can be influenced by intraspecific interactions. Mechanistic effect models, like Dynamic Energy Budget Individual-Based Models (DEB IBMs), offer a bridge from individual-level effects to population-level responses, accounting for ecological complexity and changes in population structure and activity – important for monitoring ecological functions.

In freshwater systems, invertebrate populations, particularly shredders, play a crucial role in ecological functions. This study focuses on the energy dynamics of two freshwater shredder species, *Gammarus pulex* and *Asellus aquaticus,* linking individual responses to the performance of ecosystem services: provisioning (i.e., food) and cultural (i.e., angling) services provided by fish and regulation and maintenance services related to nutrient cycling and leaf decomposition. We explore both direct and indirect effect scenarios, including reductions in feeding rate, assimilation efficiency, and resource availability and resource quality (from 10 to 100% effect level).

Utilising DEB IBMs, we simulated populations of the two shredders for 20 years. Treatments were applied at year 10 following the initial model stabilisation period. The 95th percentile values of adult shredder biomass and population consumption rate of the 100 replicates were tracked over 10 years. The findings highlight the differential sensitivity of mechanisms studied. Reductions in assimilation efficiency, food quality, and quantity significantly impacted adult biomass, emphasising their pivotal role in shaping population dynamics and potential effects on food for fish. Diminished resource availability led to reduced leaf processing power in both species. In conclusion, both direct and indirect effects on energy uptake by shredders influenced ecological functions, that underpin the delivery of ecosystem services. DEB IBMs can provide a valuable tool for understanding the intricate relationships between individual responses and ecosystem services, facilitating informed decision-making for aquatic ecosystem management.

4.02.T-04 Evidence of Chemical Impact on Biodiversity

Marta Baccaro[1], *Alessandro Carletti*[2], *Eleonora Chinchio*[3] *and Stephanie K Bopp*[3], *(1)European Commission - Joint Research Centre (JRC), Belgium, (2)European Commission - Joint Research Centre (JRC), Italy, (3)European Commission - Joint Research Center (JRC)*

Although the European Green Deal and in particular the Zero Pollution Action Plan, the Chemical Strategy for Sustainability (CSS), and the Biodiversity Strategy for 2030 acknowledge pollution negative impact on biodiversity, still this threat seems to be misestimated because of a lack of a crystallized body of evidence that establish causality between chemical exposure and biodiversity. Identifying studies which extrapolate eco-toxicological endpoints measured at the (sub)individual level to assess the effects on diverse biodiversity measures would provide the basis to build such evidence. To this purpose, we are performing a review study based on a PEO framework (Population/Exposure/Outcome). In particular, population included the biota observed and tested within an ecotoxicological study, exposure included any exposure to defined chemical(s) and concentration(s), and outcome of interest was defined as any biodiversity measure (e.g. loss of number of individuals in a wild population, loss of a functional trait) or toxicological endpoint(s) likely to negatively affect biodiversity (e.g. reproductive endpoints). Twenty-five thousand peer-reviewed publications were obtained from Scopus and Web of science Core Collection databases. Using predefined inclusion/exclusion criteria, all articles are screened first on titles and abstracts, then on full-text. This step is currently ongoing. Afterwards, the data extraction will mainly focus on the following key information: type of chemical(s), type of study (lab, semi-field, field and single, multiple species), biological organization level and toxicological endpoint(s) tested, method of extrapolation to higher biological organization levels, inclusion of any species interaction. Data analysis of the extracted data will highlight the main classes of chemicals and taxa for which evidence of impact of exposure on biodiversity exists, and the main methods that have been used to generate such link. The outcome of the analysis will be presented at the conference.

4.02.T-05 Assessing Risks to Biodiversity from Exposure to Chemicals: Findings of an ECETOC Task Force on Biodiversity Definitions, Metrics, and Methodologies

Aaron Stoler[1], *David A Bohan*[2], *Sian Ellis*[3], *Anja Gladbach*[4], *Volker Grimm*[5], *Jutta Hellstern*[6], *Philippe Lemaire*[7], *Lorraine Maltby*[8], *Christoph Mayer*[9], *Anna-Maija Nyman*[10], *Michael Riffel*[11], *Hans Sanderson*[12], *Marco Thines*[13], *Johannes Tolls Dir*[14], *Nico van den Brink*[15] *and Nika Galic*[16], *(1)Exxon Mobil, (2)INRAe, (3)Corteva Agriscience, United Kingdom, (4)Bayer AG - Crop Science Division, Germany, (5)Helmholtz Centre for Environmental Research (UFZ), Germany, (6)F. Hoffmann-La Roche Ltd., Switzerland, (7)Total Special Fluids Division, France, (8)School of Biosciences, University of Sheffield, United Kingdom, (9)BASF SE, Germany, (10)European Chemicals Agency (ECHA), Finland, (11)RIFCON GmbH, Germany, (12)Aarhus University, Denmark, (13)Goethe University Frankfurt, Germany, (14)Corporate Scientific Services, Henkel AG & Co. KGaA, Germany, (15)Wageningen University & Research (WUR), Netherlands, (16)Syngenta AG, Switzerland*

In accordance with global efforts to reduce the negative impacts of chemicals on biodiversity, the EU Commission has set ambitious goals for mitigating the entry and effects of chemicals in the environment. However, these goals are hindered by unclear definitions, metrics, and relationships of biodiversity with chemical regulation. The European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC) initiated a Task Force to address some of the challenges. Here we report on the outcomes from the Task Force subgroup overviewing biodiversity definitions and metrics, as well as methods for assessing and quantifying biodiversity. We surveyed the peer-reviewed literature, with a primary focus on reviews, perspectives, and meta-analyses. Preliminary results revealed a wide array of both definitions and metrics for assessing biodiversity. Definitions ranged from descriptive to quantitative and probabilistic. Metrics either focused on a single measurement or integrated multiple measurements into a single index. Proxies for biodiversity (e.g., provision of ecosystem services) were also identified as metrics. The majority of metrics were associated with taxonomic diversity, whereas functional diversity received comparatively less – although increasing attention. More dynamic metrics included temporal and spatial turnover instead of focusing on snapshots of community composition. Metrics varied in their scalability from local to global assessment, and also varied in their ability to be normalized for use across different sectors and applications. As the world moves towards unifying goals of environmental stewardship, emerging frameworks (e.g., The Global Biodiversity Framework, The Essential Biodiversity Variables) are helping to consolidate these definitions and metrics. This will be vital to ensuring that chemical regulations prescribe risk assessment approaches that fully align with those goals.

4.02.P Biodiversity, Ecosystem Services and Ecological Risk Assessment: Advances and Challenges

4.02.P-Th438 Modeling Chemical Source-to-Damage Pathways in Terrestrial Ecosystems

Susan Oginah[1], *Martina G. Vijver*[2], *Laura Scherer*[2], *S. Henrik Barmentlo*[2], *Marissa B Kosnik*[3], *Paola Movalli*[4], *Gabriele Treu*[5], *Peter von der Ohe*[5], *Jaroslav Slobodnik*[6], *Guy Duke*[6], *Nikiforos Alygizakis*[6,7], *Nikolaos S. Thomaidis*[7], *Koos Biesmeijer*[4] *and Peter Fantke*[1], *(1)Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering,*

Understanding the intricate relationship between chemical exposure and its multifaceted impacts within terrestrial ecosystems is pivotal for effective terrestrial biodiversity conservation and chemical regulation. However, we still lack consistent methods to quantify various chemical pollution damages within terrestrial ecosystems. To address this gap, we introduce a systematic approach to model chemical source-to-damage pathways and their repercussions on various dimensions of terrestrial ecosystems. First, we focus on modeling chemicals' fate and ecological exposure using geospatial multimedia models. These models aid in unraveling the complex fate of chemicals across environmental media and their propagation in terrestrial species networks. Second, ecological exposure is combined with organism-level effects to derive ecotoxicity effects. These are then linked to species loss by mapping ecotoxicity pressure to species abundance and richness patterns. Third, we model damage on genetic diversity going beyond species loss by merging multi-level data linking chemical activity with adverse phenotypic outcomes within and across species, where genetic targets for chemicals serve as fundamental markers in this exploration. Fourth, we model damage on functional diversity by establishing relationships between species-specific ecotoxicity data, species abundances, and functional traits to inform the derivation of metrics representing functional diversity loss across varying chemical concentrations. Finally, we link the aforementioned metrics (species and functional diversity) to damage on terrestrial ecosystem services, exploring their interconnectivity and quantitatively modeling the propagation of chemical effects across trophic levels and their subsequent damage on relevant services provided. Model results are spatialized and scaled up to cover wider geographical regions and evaluated against existing and new monitoring data along the modeled source-to-damage pathway. Our systematic approach offers a comprehensive understanding of chemical exposure's complexities and its profound implications for terrestrial biodiversity, aiming at providing valuable insights for more efficient environmental assessment of chemicals.

Keywords: ecotoxicity assessment; species loss; genetic diversity, functional diversity, ecosystem services

4.02.P-Th439 Scaling Up: An Ecosystem Services Approach To Assess Chemical Risk To Recreational Fisheries Within A River Network

Susanna Mölkänen[1]*, Lorraine Maltby*[2] *and Philip Warren*[3]*, (1)University of Sheffield, Sheffield, United Kingdom, (2)School of Biosciences, University of Sheffield, United Kingdom, (3)University of Sheffield, United Kingdom*
Freshwater recreational fisheries are an important cultural ecosystem service enjoyed by millions of anglers globally but are threatened by multiple stressors, including chemical pollutants. Here we investigate how an ecosystem services approach can be applied to assess the risk of chemicals to recreational fisheries and explore how this assessment varies depending on whether it is performed at the river reach or the river network scale. Our study is focused on trout fisheries and uses a spatially explicit individual-based ecological model (InSTREAM v 7.3), adapted to consider toxic effects, combined with an evaluation of angler satisfaction. The model was applied to a simulated river network of 20 reaches and three stream orders. To investigate the influence of toxic chemicals at the landscape scale, ten reaches were randomly selected where common effect endpoints (growth rate, fecundity, and survival) in trout individuals were inhibited. Varying levels of inhibition (low, medium, and high) were simulated and outputs of angling stock abundance and location within the network were analysed. Outputs were compared to results for single reaches simulated independently. Results show that the responses of the angling stock to chemical stress vary depending on stream order, reach location, and the endpoint inhibited. Results also show that patterns identified on a reach scale are not simply mirrored at the network level as chemical stress effects are mitigated from the point of exposure when part of a metapopulation. Implications for angler satisfaction and ecological risk assessment will be discussed. This study illustrates the potential complexity of scaling ecosystem service assessment risk assessment from local to landscape scale.

4.02.P-Th440 Understanding the Impact of Anthropogenic Environmental Change on Freshwater Biodiversity across Spatiotemporal Scales

Niamh Eastwood[1]*, Arron Watson*[1]*, Jiarui Zhou*[2]*, Jonathan Warren*[3]*, Kerry Walsh*[3]*, Jo-Anne Pitt*[3]*, Henner Hollert*[4]*, William A. Stubbings Dr*[1]*, Mohamed Abou-Elwafa Abdallah Dr*[1]*, Thomas Davidson*[5] *and Luisa Orsini*[2]*, (1)University of Birmingham, United Kingdom, (2)School of Biosciences, University of Birmingham, United Kingdom, (3)Environment Agency, (4)Evolutionary ecology and environmental toxicology, Goethe University Frankfurt, Germany, (5)Aarhus University, Denmark*
Threats to biodiversity, such as land use change, chemical pollution and climate change, occur over multiple spatial and temporal scales. To understand the future impact of different climate and pollution scenarios, we must study the combined impact of these threats and, where possible, establish a baseline of pre-impact biodiversity. Here we put forward and demonstrate the use of a holistic biodiversity monitoring method, combined with machine learning analysis, to identify the effects of anthropogenic environmental change.

Our work focuses on lakes as they are key in delivering numerous ecosystem functions and services and they act as receivers of pollution to the landscape. By using multi-marker metabarcoding of environmental DNA, we are able to monitor the whole community, over time (using lake sediment cores) or through space (using multiple contemporaneous lake samples). We find that combinations of stress (eg insecticide pollution and extremes of temperature) have the greatest impact on biodiversity, and

that traditional monitoring metrics do not adequately capture the dynamics of the community as a whole. We present and demonstrate the use of machine learning approaches to identify and prioritise the most impactful environmental changes.

4.02.P-Th441 Linking ecological and ecotoxicological risk to ecosystem services degradation of Alento catchment (Southern Italy)

***Sara Accardo**[1], Simona Schiavo[2], Luisa Parrella[3], Pier Paolo Franzese[4], Vincenzo Pasquale[5] and Sonia Manzo[3], (1)University Parthenope, (2)National Agency for New Technologies, Energy and Sustainable Economic Development (ENEA), Italy, (3)ENEA CR Portici, Italy, (4)Science and tecnology, University of Parthenope, Naples, (5)University of Parthenope, Naples*

Assessing and managing risks of anthropogenic activities to ecological systems is necessary to ensure sustained delivery of ecosystem services (ES) for future generations. Aquatic ecosystems provide essential benefits to our global society and human wellbeing. Food, drinking water, cultural services, and recreational fishing are among the obvious ES provided by river catchment.

However, river catchment is continually threatened by human activities, which interferes with species diversity as well as ecosystem function, both of which are essential for sustaining the environment.

The Cilento region hosts a National Park and exhibits a territorial context with a combination of cottage industrial, domestic/touristic, and agricultural activities. Consequently, organic, inorganic, and emerging contaminants are released into aquatic environment, posing serious threat due to their hazardous characteristics. This area represents an interesting case study due to its integrated system of storage dams, which accumulates stream flow rates throughout the year. The water is then supplied to the Vallo della Lucania network, supporting irrigation, drinking, energy production, recreational activities, and maintaining high biodiversity. GIS analysis was used to integrate available territorial and environmental data to select sampling areas to be seasonally monitored. Water matrix was characterized by chemical analyses, and by a battery of ecotoxicological tests with organisms from different trophic levels (bacteria, algae and crustaceans).

The propose of this study is to assess how to integrate the risk posed by chemicals on Alento catchment with the measured ecotoxicological effects in the view of ES protection. In fact, among the advantages of using an ES approach for ecological risk assessment (ERA) the increased integration of the risk deriving from multiple stressors and multiple environmental compartments is particularly relevant and allows a more effective communication by highlighting the direct and indirect benefits stakeholders.

4.02.P-Th442 Enhancing Government Processes and Communication Through Bayesian Networks

*April D Reed and **Wayne G. Landis**, Western Washington University*

This research focused on creating and communicating a Bayesian Network (BN) decision support tool designed for application in United States government processes with a specific focus on the Natural Resource Damage Assessment and Restoration (NRDAR) program. Stakeholders from diverse backgrounds contributed to the tool's development, addressing the intersection of environmental science, law, and economics. A case study was conducted on the fish resources of the Little Mississinewa River, a PCB-contaminated Superfund site in mid-eastern Indiana and the larger Mississinewa River, to ensure comprehensive coverage of potentially injured riverine habitat. For the case study, we developed a BN as a framework to evaluate the connections between chemicals released at the study site and the resulting injury to fish species. The resulting BN not only provides utility to government agencies as an injury assessment tool, but also facilitates effective science communication. The graphical nature of BNs simplifies visualization of complex relationships through graphical representation. Nodes and arrows represent variables and causal relationships making it accessible for experts and non-experts alike. Bayesian networks explain not just associations but also the cause-effect relationships within a system which is crucial for decision support in programs like NRDAR. Bayesian networks inherently convey uncertainty for more nuanced and realistic interpretation of data. Bayesian networks can be adapted for varying levels of expertise presenting detailed analyses for experts and simplified visualization for non-experts. Bayesian networks can act as a common language, facilitating collaboration among experts, ensuring a unified model that incorporates the knowledge and needs of all stakeholders. Using Bayesian networks for government processes and programs such as NRDAR not only provides transparent support and communication of decision-maker choices and the associated uncertainties, but also enhances science communication by offering a versatile method for representing, analyzing, and conveying the complex and interconnected relationships of ecosystems in a way that is accessible to diverse audiences, including government agencies.

4.02.P-Th443 Assessing risks to biodiversity from exposure to chemicals: findings of an ECETOC Task Force on the regulatory context

***Christoph Mayer**[1], David A Bohan[2], Sian Ellis[3], Anja Gladbach[4], Volker Grimm[5], Jutta Hellstern[6], Geoffrey Hodges[7], Sarah A. Hughes[8], Philippe Lemaire[9], Lorraine Maltby[10], Anna-Maija Nyman[11], Michael Riffel[12], Hans Sanderson[13], Aaron Stoler[14], Marco Thines[15], Johannes Tolls Dir[16], Nico van den Brink[17] and Nika Galic[18], (1)BASF SE, Germany, (2)INRAe, (3)Corteva Agriscience, United Kingdom, (4)Bayer AG - Crop Science Division, Germany, (5)Helmholtz Centre for Environmental Research (UFZ), Germany, (6)F. Hoffmann-La Roche Ltd., Switzerland, (7)Unilever - Safety and Environmental Assurance Centre (SEAC), United Kingdom, (8)Shell Global Solutions, (9)Total Special Fluids Division, France, (10)School of Biosciences, University of Sheffield, United Kingdom, (11)European Chemicals Agency (ECHA), Finland, (12)RIFCON*

GmbH, Germany, (13)Aarhus University, Denmark, (14)Exxon Mobil, (15)Goethe University Frankfurt, Germany, (16)Corporate Scientific Services, Henkel AG & Co. KGaA, Germany, (17)Wageningen University & Research (WUR), Netherlands, (18)Syngenta AG, Switzerland
In accordance with global efforts to reduce the negative impacts of chemicals on biodiversity, the EU Commission has set ambitious goals for mitigating the entry and effects of chemicals in the environment. However, these goals are hindered by unclear definitions, metrics, and relationships of biodiversity with chemical regulation. The European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC) initiated a Task Force to address some of the challenges. Here we report on the outcomes from the Task Force subgroup focussing on EU chemical regulation and strategic documents, that looked into regulatory context for considering biodiversity in chemical risk assessments. We mapped EU legislative documents and overarching strategies concerning biodiversity conservation and/or regulation of chemicals, as well as selected global initiatives influential at EU level. A deep dive into the most relevant documents analysed i.a. how biodiversity metrics, protection goals and impact assessments are defined and how all would link into the EU's political ambitions and strategies. Preliminary results revealed a broad definition of biodiversity requiring further specification for implementation. Likewise, protection goals are usually provided on a rather general level. Metrics vary based on definition and specification level applied in the regulatory documents, as well as on the scope and purpose of the regulatory documents and the expected site of chemical action in the environment. Biodiversity is indirectly addressed via protection of surrogate groups or functions. The further evaluation of the EU Biodiversity Strategy in relation to chemical regulation is currently ongoing. The aim is to identify how existing chemical regulations may align with the EU Biodiversity Strategy, if quantitative links can be established and how these may expand on the existing regulations. The findings provide a starting point for a multi-stakeholder discussion aiming to advance the chemical regulations with respect to biodiversity impacts. The outcome of the work of this ECETOC Task Force will be a short overview/perspectives paper and a workshop involving relevant stakeholders for EU regulations.

4.02.P-Th444 Assessing Risks to Biodiversity from Exposure to Chemicals: Findings of an ECETOC Task Force on Current and Future Research Directions

Anja Gladbach[1]*, David A Bohan*[2]*, Sian Ellis*[3]*, Volker Grimm*[4]*, Jutta Hellstern*[5]*, Geoffrey Hodges*[6]*, Sarah A. Hughes*[7]*, Philippe Lemaire*[8]*, Lorraine Maltby*[9]*, Christoph Mayer*[10]*, Anna-Maija Nyman*[11]*, Michael Riffel*[12]*, Hans Sanderson*[13]*, Aaron Stoler*[14]*, Marco Thines*[15]*, Johannes Tolls Dir*[16]*, Nico van den Brink*[17] *and Nika Galic*[18]*, (1)Bayer AG - Crop Science Division, Germany, (2)INRAe, (3)Corteva Agriscience, United Kingdom, (4)Helmholtz Centre for Environmental Research (UFZ), Germany, (5)F. Hoffmann-La Roche Ltd., Switzerland, (6)Unilever - Safety and Environmental Assurance Centre (SEAC), United Kingdom, (7)Shell Global Solutions, (8)Total Special Fluids Division, France, (9)School of Biosciences, University of Sheffield, United Kingdom, (10)BASF SE, Germany, (11)European Chemicals Agency (ECHA), Finland, (12)RIFCON GmbH, Germany, (13)Aarhus University, Denmark, (14)Exxon Mobil, (15)Goethe University Frankfurt, Germany, (16)Corporate Scientific Services, Henkel AG & Co. KGaA, Germany, (17)Wageningen University & Research (WUR), Netherlands, (18)Syngenta AG, Switzerland*
In accordance with global efforts to reduce the negative impacts of chemicals on biodiversity, the EU Commission has set ambitious goals for mitigating the entry and effects of chemicals in the environment. However, these goals are hindered by unclear definitions, metrics, and relationships of biodiversity with chemical regulation. The European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC) initiated a Task Force to address some of the listed challenges. Here we report on the outcomes from the Task Force subgroup that overviewed EU-commissioned research projects to better understand how new knowledge can be leveraged to inform regulatory frameworks as well as to identify research gaps that could become the scope of future funding calls. Preliminary findings indicated that only recently EU Horizon calls start to focus on research questions related to biodiversity and measures to halt the decline, thus the acknowledgement of their respective research findings in shaping chemical regulation is yet to come. However, while the EU Biodiversity Strategy and the relation to chemical regulation is focusing on a defined regional scale, to effectively address the challenges of biodiversity loss and ecological imbalance efforts need to be coordinated globally and unified regulatory measures implemented to avoid e.g. exporting of environmental footprints. The effective assessment of cross-links between regional frameworks and regulations and their global implications could become an additional research focus area in EU Horizon projects. Designing a pragmatic, implementable holistic impact assessment framework remains a challenge for the foreseeable future.

4.02.P-Th445 CSRD and TNFD, learnings from the sustainability reporting journey

Christian Bogen[1]*, Patricia Tognetti*[2]*, Francesc Xavier Dot Codina*[3]*, Nicolas Schweigert*[4]*, Martina Wuttke*[4]*, Tomas Zaborowski*[2]*, Sebastian Leins*[4] *and Jens Reismann*[4]*, (1)EMEA Public Affairs, Science & Sustainability, Bayer AG - Crop Science Division, Germany, (2)CropScience, Bayer AG, Germany, (3)NTT DATA, Spain, (4)Corporate, Bayer AG, Germany*
One of the aims of the European Green Deal is to channel private investments towards activities the EU considers sustainable and therefore a comprehensive regulatory framework on sustainable finance has been established in the past years, which is subsequently entering into force. The Corporate Sustainability Reporting Directive (CSRD) requires European businesses to disclose how they perform according to criteria defined within the European Sustainability Reporting Standards (ESRS). At the same time, the Taxonomy is an additional framework that defines from an European perspective whether an economic activity is considered sustainable or not.

While CSRD, ESRS and Taxonomy are part of a mandatory European framework for companies headquartered within the EU, other voluntary frameworks like the Taskforce on Nature-related Financial Disclosures (TNFD) evolve, with the ambition of a global perspective on sustainability reporting.

An overview of the various frameworks and their interactions will be presented. This will be complemented with concrete examples how businesses currently approach sustainability reporting related to CSRD and TNFD. Key learnings from the current efforts will be provided, e.g. from the locate and evaluate steps of the LEAP (Locate, Evaluate, Assess and Prepare) assessment. Opportunities and limitations in relation to metrics and reporting scope will be discussed.

Taking upstream and downstream reporting into account, metrics require a broad applicability and reliability (e.g. being able to be audited) throughout the value chain to improve outcomes and avoid regretful substitutions. Therefore, a solution-oriented collaboration between regulators, academia and industry on these metrics is suggested, including the opportunity for providing feedback and regularly re-evaluating metrics in terms of legal compliance and financial feasibility.

4.02.P-Th446 Increasing transparency of the environmental profile of agriculture to inform sustainability improvements and environmental protection goals with a pragmatic two-phase methodology
*Elise Webb[1], Sarah Wynn[1] and **Christian Bogen**[2], (1)ADAS Ltd., United Kingdom, (2)EMEA Public Affairs, Science & Sustainability, Bayer AG - Crop Science Division, Germany*
Agricultural systems are complex, with many interacting parts, and it is therefore crucial to take a holistic approach to the multiple tools and their wider impacts for a more cohesive understanding of changes in practice. To be able to increase the sustainability of agricultural systems, including their essential ecosystem services and biodiversity, a broad and holistic perspective is required, especially to avoid unintended trade-offs and consequences.

Within this work, a methodology is suggested that builds on the environmental categories of environmental risk assessment processes for plant protection products and uses a rapid evidence approach (REA) to create a broad perspective of the various interactions that can be expected from different agronomic tools.

As a second step, the environmental implications of production systems were investigated. For this purpose, findings from the first step were combined with an additional scientific literature research to fill remaining gaps.This approach supports decision-making by disclosing both benefits and limitations, and may allow further exploration of synergies and trade-offs in agricultural productions systems. This can inform cost-benefit frameworks to improve sustainability using key environmental metrics. While ecotoxicological assessments for chemical products play an important role, it is important to consider them in relation to the ecological implications of other decisions taken by a farmer in the field.

Both, the effectiveness of the practices at managing weeds, pests and diseases, and the environmental implications of applying corresponding tools require consideration. The findings can also inform specific protection goals for environmental risk assessments, to ensure that protection goals in terms of biodiversity and ecosystem services will be not undermined by the use of alternatives that are not assessed within a corresponding framework.

In the future, to enable outcome-based business models, which can be more inclusive of biodiversity and ecosystem services outcomes, this transparency can steer decision-making and reduce potential trade-offs between the different tools used in the field.

4.02.P-Th447 Linking Freshwater Mussel Habitat Conditions to Restoration Outcomes and Ecosystem Services
*Jeff A. Steevens[1], Mandy Annis[2], Megan Bradley[2], James L. Kunz[1], Brandon Sansom[1], Jessica Pruden[2], Allison Sieja[1], **Nile E. Kemble**[1] and Peter Badra[3], (1)U.S. Geological Survey (USGS), (2)U.S. Fish and Wildlife Service, (3)Michigan State University*
Native freshwater mussels are among the most imperiled taxa globally. Once prevalent in the landscape, anthropogenic stressors such as habitat alteration, contaminants, and climate change have led to steep population declines. Such declines have altered habitat functionality through the loss of ecosystem services they provide, such as water quality improvements, sequestration/processing of nutrients, stream stability, and diverse food web structure. This project aims to restore mussel assemblages and their ecosystem services, as well as provide systematic habitat assessments for locations of variable land usage. We studied the Clinton River, an urban watershed river near Detroit, Michigan, USA, with varying water quality issues, strong urban influence, and wastewater input. In the initial phase of the study, we conducted a field study that integrates water quality, habitat conditions, and in situ mussel exposures to assess the potential role of contaminants and habitat stressors on the suitability for mussel restoration. The field study incorporated measures of sediment and water contaminants, water quality analysis, passive samplers, water quality sensors, and monitoring native Fatmucket Mussel placed in situ. The native Fatmucket mussel, *Lampsilis siliquoidea*, was placed in “silos” in the river to assess their survival and growth in the river system. Contaminants were measured in sediment, water, mussel tissue, and passive samplers. Per and polyfluoroalkyl substances (PFAS) were measured using passive samplers. Water samples and mussel tissues were measured for pharmaceuticals. These data will be used to inform the placement of mussels in the river in 2024 and to predict the likelihood of restoration success. Ultimately, we seek to re-establish diverse representative mussel assemblages and evaluate the resulting ecosystem services provided by freshwater mussels including the impacts on water quality and increased macroinvertebrate diversity.

4.02.P-Th448 Using DECOTABs to evaluate organic matter decomposition by aquatic hyphomycetes in pesticide-contaminated environments

Lais Conceição Menezes da Silva[1], *Karla Fernanda González Pedroza*[1], *Alexander Feckler*[2] *and Mirco Bundschuh*[3], *(1)RPTU Kaiserslautern-Landau, Germany, (2)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (3)Institute for Environmental Sciences, RPTU Kaiserslautern-Landau, Germany*
DEcomposition and COnsumption TABlets (DECOTABs) contain cellulose powder embedded in an agar matrix that were developed with the aim to standardize the assessment of leaf decomposition in aquatic environments. The decomposition of organic matter helps to understand how efficiently decomposers (such as fungi) contribute to nutrient cycling, which is a central ecosystem function. Fungi, such as aquatic hyphomycetes, are important members of the decomposer community. For this reason, it seems logical, to better understand the responses of these organisms and the functions they perform under exposure to chemicals. Despite this, fungi are not included in standardized testing schemes, even if in environments contaminated, for example, by pesticides, fungal performance may be altered. Considering the high representation of fungicides in the pesticide sales in the European Union and the fact that aquatic fungi are, due to their mode of toxic action, very likely to be affected, the aim of this study is to evaluate fungicide effects on the decomposition rate of these organisms using a modified version of DECOTABs. For this, we apply the fungicide trifloxystrobin at 0, 5, 25, 125 and 625 µg/L. In addition, we adjusted the compositions of DECOTABs by increasing the share of leaf powder (LP) in the agar matrix increasing ecological relevance. Using this design, the DECOTABs will contain 100% cellulose powder (CP), 66% CP/33% LP, 33% CP/66% LP and 100% LP. Three species of aquatic hyphomycetes will be inserted into the test containers: *Alatospora acuminata, Articulospora tetracladia* and *Tetracladium marchalianum.* The tests are planned to last 21 days and decomposition will be assessed through the weight loss of the DECOTABs. The abundance of aquatic fungi will be estimated using species-specific quantitative Polymerase Chain Reaction (qPCR) assays. Through this approach, we hope to increase the substrate complexity of DECOTABs approaching natural leaf litter and by this increase ecological relevance. With the homogenisation of large amounts of leaf litter during the production of LP, we still generate a rather standardised substrate using *Alnus glutinosa* powder. The latter might be an important step in paving the way for including aquatic fungi in standardised ecotoxicological testing schemes.

4.03.P Characterization, Testing and Assessment of Complex Substances (MCS, UVCBs & MOCS)

4.03.P-We280 Tripartite Perspectives on Challenges and Opportunities For The Environmental Testing and Assessment of UVCBs

Sarah A. Hughes[1], *Marc Fernandez*[2], *Athena Keene*[3], *Delina Lyon*[4], *Philipp Mayer*[5], *Ursula Sauer*[6], ***Julie Krzykwa***[7] *and Sandrine Estelle Deglin*[7], *(1)Shell Global Solutions, (2)Environment and Climate Change Canada, Canada, (3)Afton Chemical Corporation, (4)Concawe, Belgium, (5)Department of Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark, (6)Scientific Consultancy – Animal Welfare, Germany, (7)Health and Environmental Sciences Institute (HESI)*
Complex substances such as multi-constituent substances (MCS) and unknown or variable composition, complex reaction products, or biological materials (UVCBs) usually result from the industrial processing or extraction of natural substances or from chemical reactions. Because of the variable and complex nature of source materials, and the potential variability inherent to production processes, these substances can contain many, sometimes uncharacterised, constituents whose concentrations may vary between batches. UVCBs make up approximately 20-25% of chemicals registered globally. To identify and advance the various challenges associated with UVCB testing and assessment, the Health and Environmental Sciences Institute (HESI) organized an international workshop on *Exploring the complexities of UVCB testing and risk assessment* that took place on September 18th and 19th, 2023, in Reykjavik, Iceland. The 25 workshop participants represented academia, governments, and agencies, as well as, the private sector, and originated from Belgium, Canada, Denmark, France, Germany, the Netherlands, Norway, the United Kingdom, and the United States of America. The HESI UVCB workshop was aimed at initiating multi-sectoral, tripartite discussions on the advantages and disadvantages of the whole substance vs. representative constituent testing and assessment approaches, at identifying further research needs, and at establishing potential consensus for solutions for UVCB environmental risk assessment. Ultimately, the insight from the workshop contributed to keep refining and further strengthen the exposure-centric tiered approach developed for the environmental risk assessment of UVCBs and multi-constituent substances.

4.03.P-We281 Determining Whole UVCB Mineralisation & Constituent Specific Primary Degradation in a Modified OECD 301 Ready Biodegradability Test of an Essential Oil

Karen Scharling Dyhr, Heidi Birch and ***Philipp Mayer****, Department of Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark*
Standard OECD 301 guidelines are presently not suitable for assessing the ready biodegradability of “Substances of Unknown or Variable composition, Complex reaction products or Biological materials (UVCBs)” such as essential oils. The main challenges are that (1) respiration alone is insufficient to prove degradation of the entire UVCB mixture, (2) volatile constituents are easily lost from standard test systems, and (3) hydrophobic constituents can be difficult to dose and can also sorb to the plastic components of certain test systems.

The aim of this study was to assess the ready biodegradability of an essential oil based on a biodegradation test that yields whole UVCB mineralisation (oxygen respiration) as well as constituent specific primary degradation (substrate depletion). The determination of whole UVCB mineralisation requires gastight and inert test flasks, aerobic conditions, and contactless oxygen measurements. The determination of primary degradation requires alignment of the test system with constituent specific analysis.

The biodegradation test was conducted in glass flasks with PTFE-lined gastight caps. Activated sludge was used as inoculum (30 mg suspended solids/L) at a test concentration of 10 mg/L black pepper essential oil. Test systems were incubated at 20°C for 28 days with daily oxygen measurements. At pre-determined time points, subsamples were taken for solid-phase microextraction (SPME) GC-MS analysis and constituent specific biodegradation was determined based on peak area ratios between triplicate biotic and abiotic test systems.

Whole UVCB mineralisation and primary biodegradation of all major constituents fulfilled the OECD 301 pass levels for ready biodegradability. A respiration of 77% of the Theoretical Oxygen Demand indicated that most of the UVCB mixture was mineralised, and the GC-MS analysis proved primary degradation of all 8 constituents specified in the certificate of analysis and of additional 14 minor constituents.

4.03.P-We282 Applying the principles of grouping and read-across to different lines of evidence to support the development of an ecotoxicity testing strategy for hydrocarbon UVCBs

Leslie J Saunders[1]*, Sylwia Kosmala-Grzechnik*[2]*, Rhiannon Smith*[2]*, Yves Verhaegen*[1]*, Louise Camenzuli*[3]*, David MV Saunders*[4]*, Sandrine Sourisseau*[5]*, Kat Colvin*[6] *and Delina Lyon*[1]*, (1)Concawe, Belgium, (2)wca environment Ltd., United Kingdom, (3)ExxonMobil, Belgium, (4)Shell Global Solutions, Netherlands, (5)TotalEnergies, France, (6)BP I&E Applied Sciences, United Kingdom*

Substance grouping and read-across are commonly employed to reduce the amount of testing required for chemical registrations under the EU REACH regulation (EC 1907/2006). These approaches use relevant information from analogous (‘source') substances to predict the properties of ‘target' substances. While available guidance tends to be tailored for mono-constituent substances, similar concepts can be applied for ecotoxicity testing of more complex UVCB substances (substances of Unknown, Variable composition, Complex reaction products, or Biological origin). In the present effort, we apply multiple lines of evidence, aligned with read-across principles, to design a testing program for hydrocarbon UVCBs.

Petroleum substances (PS) are comprised of complex combinations of hydrocarbons for which the precise identity of all constituents is usually unknown, and the composition is often variable. Despite these uncertainties, PS may be categorized according to their manufacturing process and their broadly similar physical-chemical properties. Using a comprehensive GCxGC analytical program, the composition of each hydrocarbon UVCB substance can be broken down into relative concentrations of groups defined by carbon number and chemical class, termed hydrocarbon blocks (HCB). Using non-polar narcosis as the common primary mechanism of toxic action for hydrocarbons, toxicity would be correlated with bioavailability. It is then possible to use representative constituents for each of the relevant hydrocarbon blocks to estimate the toxicity of the whole substance.

For the testing strategy, we determine the “worst-case”, or most toxic, sample using two independent methods: (i) an experimental biomimetic extraction-solid phase microextraction (BE-SPME) approach which mimics aqueous exposure to PS in the environment; and (ii) the PetroTox QSAR model that utilizes two sub models (i.e., target lipid model and an oil dissolution model) to estimate PS toxicity to ecological receptors. The outcomes of these two exercises allow for the selection of a “worst-case” PS sample for testing and account for the range in compositional variability across samples. The concepts and various lines of evidence applied here will support testing strategies for multiple PS categories and could inform chemical prioritization initiatives or other regulatory assessments of UVCBs.

4.03.P-We283 Contrasting, Characterizing and Predicting the Toxicity and Risk of Natural Complex Substances

Floriane Larras *and Paul Thomas, KREATiS SAS, France*

Testing of Unknown or Variable Composition, Complex Reaction Products or Biological Materials (UVCB) poses a regulatory challenge. Indeed, Natural Complex Substances (NCS1) are characterised at >90% while NCS2 are UVCB of which often <50% of the composition is known. Based on two projects combining complex mixture toxicity testing and toxicity predictive approaches, this work aims to show the potential of *in silico* methods for NCS1&2 toxicity prediction and environmental risk assessment.

Project 1 consisted to test daphnids (pelagic) and *Lumbriculus* (sediment) sensitivity to an equimolar mixture of 4 constituents with log P values of 1, 2, 3 and 4. The WAF (Water Accomodated Fraction) *in silico* method considering constituents chemical activity accurately predicted the acute and chronic ecotoxicities in the pelagic phase as well as the chronic toxicity in the sediment phase, when modified to include the Equilibrium Partition (EP). Also, EP method accurately predicted constituents concentration in sediments. Finally, Predicted Environmental Concentration (PEC) were estimated using the chemical activity method and the PEC/Predicted No Effect Concentration ratio characterised as activities.

In project 2, the NCS2 Galbanum resinoid was fractionated resulting in a volatile, a non-volatile, and an inert fraction. Volatile and non-volatile (including the inert one) fractions represented up to 35% and 65% of the whole substance, respectively, with specific composition. Acute and chronic sensitivity of algae and daphnids to the whole substance and each fraction was determined experimentaly and predicted using additivity and *in silico* WAF approaches. The WAF provided the best results for the whole substance when based on the theoretical composition for acute toxicity and based on the refined composition for chronic toxicity, when analytical monitoring exhibited a compound loss during the test.

In summary, the *in silico* WAF approach was promising to predict acute and chronic ecotoxicity of NCS1&2. NCS1 example showed that mixture environmental risk assessment in multiple compartments is possible using a chemical activity approach. Modelling allow to identify the constituents leading NCS toxicity but experiments allow to identify constituents behaviour over-time and to refine composition in calculation. For now, modelling and experimental approaches are complementary. The approach reproducibility to other NCS2 is undergoing on clary sage concrete.

4.03.P-We284 Predicting Dermal and Inhalation Exposure from Mixtures: Two Case Studies
Alena K.D. Celsie[1], *Trevor N Brown, PhD*[2], *James M Armitage*[3], *Jon A. Arnot*[2], *Alessandro Sangion*[2] *and J. Mark Parnis*[1], *(1)Trent University, Canada, (2)Arnot Research and Consulting Inc. (ARC), Canada, (3)AES Armitage Environmental Sciences, Inc, Canada*
Many commonly used consumer and industrial products are chemical mixtures. Evaluation of human exposure requires knowledge of a substance's physico-chemical (PC) properties and components of the mixture can change the effective properties of the chemical of interest in the mixture. It is desirable to be able to confidently predict the properties of constituents of interest in a mixture to save time and money and to avoid the environmental impacts of carrying out experimental procedures. We have developed a new tiered system for estimating the properties of known constituents in defined mixtures. The framework is freely accessible in the Exposure And Safety Estimation (EAS-E Suite; www.eas-e-suite) on-line platform. Here we apply this framework to two case studies for predicting human exposure of substances originating from a mixture source: inhalation exposure of diesel fuel spilled in an indoor environment and dermal exposure of a transdermal drug from a skin cream product. PC properties including vapour pressures, partition ratios, and dermal permeation coefficients (K_P) are predicted using different models and compared to exposure concentrations predicted using experimental PC properties. The different models for predicting PC properties include COSMOtherm, Raoult's law, ten Berge QSPR model, Atobe QSPR model, and several newly developed IFSQSAR/ppLFER models including the log-linear ppLFER, log-linear with Binary Interaction Parameters ppLFER, log K_P Thermodynamic Cycle ppLFER, and the log K_P Thermodynamic Cycle treating penetration enhancers pp-LFER. PC property predictions from the different methods are then used to parameterize the Risk Assessment IDentification And Ranking – Indoor Consumer Exposure (RAIDAR-ICE) model to examine the accuracy of predicted exposure concentrations resulting from different PC prediction methods. Results show that while it did not make much of a difference whether mixture effects were accounted for in the diesel fuel, the skin cream mixture showed a large variability in exposure concentrations, up to a factor difference of 130 between the exposure concentration predicted using K_P from a PC prediction method and predicted using a measured K_P value. Finally, a sensitivity analysis demonstrates how partitioning behaviour changes due to mixture effects for each of these mixtures which are very different in nature.

4.03.P-We285 Environmental Classification of Ferromolybdenum - Impact of Copper Impurity Levels
Dagobert Heijerick[1] *and Sandra Carey*[2], *(1)ARCHE Consulting, Belgium, (2)International Molybdenum Association, United Kingdom*
Ferromolybdenum, also named FeMo, is an alloy manufactured and used in both the powder and massive form. Alloys are considered as special mixtures, and for the purpose of a hazard assessment and classification under the EU Classification, Labelling & Packaging of Substances and Mixtures (Regulation No. 1272/2008), the mixture rules as outlined in this Regulation are applicable for FeMo.

Copper - an element for which an EU harmonized classification of Aq.Acute 1 (M=10), and Aq.Chronic 1 (M=1) has been established for the powder form – is the main environmentally hazardous impurity relevant for classification assessment: its maximum concentration exceeds the threshold above which it is required to include the concentration of a hazardous impurity in hazard classification calculations. The harmonized Cu-classification, however, is only applicable on Cu in FeMo when there is evidence that Cu-release rate from FeMo-powder is similar or lower than that of Cu powder. In the absence of such information the worst-case assumption that all Cu is bioavailable must be followed, resulting in an Aq. Chronic 2/3 classification for FeMo with a Cu content of >0.4% and >0.04%, respectively.

The release of Cu from FeMo was therefore assessed with three different FeMo-powders from various producers, with each sample having its specific impurity levels, particle size distribution and specific surface area. 24h-screening Transformation/Dissolution protocol tests at pH 6 and 8 were performed and Cu-release was determined, with the highest release observed at pH 6.

Average Cu-content of the FeMo samples was 0.31% (CV: 26.1%), with an average Cu-release of 0.372 mg Cu/m^2 at pH 6. Normalization of this value to a Cu-content of 100% and taking an extended exposure period of 7 days into account (assumption: linear time-dissolution relationship) resulted in an average 7day release of 0.78 µg Cu/mm^2. This value falls within the range of known 7-day Cu-release rates for copper in massive, powder wire or granulated forms (0.41 – 1.83 µg Cu/mm^2 at pH 6). Equivalence in Cu-release from FeMo and Cu-powder is thus established, and consequently the harmonized classification of Cu-powder is valid for the Cu-fraction in FeMo. Application of the CLP-mixture rules on FeMo results in a no-classification of massive FeMo, and FeMo-powder containing < 0.25% Cu. FeMo-powder containing 0.25% - 2.5% Cu will be classified as Aq. Chronic Cat.3 in the absence of further data.

4.03.P-We286 Navigating the Complexity: Challenges in Ecotoxicity Testing of UVCB Substances
Sylwia Kosmala-Grzechnik *and Rhiannon Smith, wca environment Ltd., United Kingdom*
The European REACH Grease Thickeners Consortium (ERGTC) has registered several grease thickeners under the REACH regulation. Most of these substances are poorly soluble, surface active, and/or Unknown or Variable compositions, Complex reaction products and Biological materials (UVCBs), falling under the category of difficult-to-test substances. Testing these substances, especially for aquatic toxicity, poses considerable challenges, including the preparation of test solutions to achieve and maintain the required test concentration and analysis of the test item during exposure.

As part of extensive testing programs to improve the data quality in the REACH registration dossiers, the ERGTC has developed an approach focused on preparation of Water Accommodated Fractions (WAFs) to meet some of these challenges with UVCBs. Preliminary trials were conducted to determine the maximum dissolved concentration achievable in the test solution and the procedures required to obtain this concentration were established.

For test solution preparation, adjustments were made to the test media preparation methods. One of the critical factors was stirring duration which varied between 24 hours and 7 days, depending on the substance's properties. Solutions requiring over 72 hours of stirring were initially prepared in reversed-osmosis water, followed by filtration and the addition of nutrients to form the test media, due to concerns about the test medium stability over the combined stirring and exposure duration.

A further challenge arose from the substances' poor solubility and analytical limitations, affecting the measurement of test item concentration in test media. Although solvents should be avoided during test media preparation as this may lead to testing concentrations above the solubility limit, a solvent evaporation approach was considered suitable to overcome the issues with preparation of low volumes of media at low concentrations and to enable analytical verification of the test item levels.

This poster will provide an overview of the challenges during ecotoxicity testing and outline the 'best practice approach' developed from the experiences gained with the grease thickeners. These approaches can be used to generate reliable data for risk assessment and the formulation of effective environmental management strategies.

Acknowledgement - The authors would like to thank the members of the European REACH Grease Thickeners Consortium for allowing the work to be shared.

4.03.P-We287 Optimising Testing Strategies for UVCB Substance Categories to Minimise Vertebrate Testing for Aquatic Toxicity
Alberto Martin-Aparicio[1]*, Louise Camenzuli*[2]*, Yunzhou Joe Chai*[3]*, Adriana C. Bejarano, PhD*[4]*, Victoria Benson*[5]*, Giovanni Maria Condina*[6]*, Markus Junker*[7]*, Albania Grosso*[8]*, Maria Cristina Quintana-Guerrero*[9]*, Kat Colvin*[10]*, Gaia Vegezzi*[6] *and Jordan Davies*[11]*, (1)Penman Consulting BVBA, Belgium, (2)ExxonMobil, Belgium, (3)Dow Chemical Company, (4)Shell Global Solutions, (5)Penman Consulting, United Kingdom, (6)Intertek Italia SpA, Italy, (7)GBP/RA, BASF SE, Germany, (8)AG-HERA Consulting, Spain, (9)CEPSA Quimica S.A, Spain, (10)BP I&E Applied Sciences, United Kingdom, (11)LyondellBasell, Netherlands*
Under the EU REACH Regulation high volume chemicals must provide a dataset of aquatic toxicity for acute and chronic toxicity data covering 3 trophic levels. One way of optimising efforts and reduce unnecessary animal testing is by read-across of relevant data from similar substances. This approach is particularly strong when using several analogue substances (category approach) instead of only one (analogue approach). However, this approach requires the demonstration of structural similarity between the substances in the category, as well as evidence of similar properties, making it particularly challenging for UVCBs due to the uncertainties and variability of their composition.

We present a successful strategy for category read-across within categories of olefinic streams, using several lines of evidence integrated in a tiered approach, in order to assess the aquatic toxicity of those substances with considerable reduction in the number of tests needed. The strategy uses: a) detailed compositional analysis, b) toxicity screening via alternative approaches and c) testing of the UVCBs in the category, starting with algae and proceeding to invertebrates and fish. The strategy has been designed so that all the substances in a category are screened with the lower tier approaches, thereby “bracketing” the ecotoxicity covered by all the chemical space of the category. If lower tier data are consistent, this builds confidence that allows to read-across for higher tier data with minimal testing. The advantage of this multi-faceted approach is that the difficulties in the read-across, caused by the complex composition of the UVCBs assessed, are balanced by the coherence in several different types of activity data, indicating that the aquatic toxicity can be well predicted across category members. In addition, because the lower tier data are all non-vertebrate tests, and the necessary higher tier tests are minimal, the reduction in the number of vertebrate tests conducted is substantial. The approach has been piloted with several categories of hydrocarbon streams, and could potentially be expanded to other UVCBs.

4.03.P-We288 Application of PBT and PMT Criteria to Complex Substances: A Case Study of Essential Oils
Mylène Leger, Cyril Durou, Kevin Georges Antoine Bonnot and Mathieu Rolland, Consultancy for Environmental & Human Toxicology and Risk Assessment (CEHTRA), France
Essentials oils (EOs) are part of the Natural Complex Substances (NCS) family often referred to as UVCB substances (substances of Unknown or Variable composition, Complex reaction products or Biological materials). Assessing their risks and properties is not straightforward, since complex substance typically contain a large and variable number of constituents, and often a high concentration of unknown constituents.

The update of the CLP regulation in 2023 introduced PMT and PBT hazard class and criteria, plus the notion of MOCS (more than one constituent substance). This regulatory change has led to a new approach to the evaluation of persistent (P) and bioaccumulative (B) criteria for UVCBs.

PBT and PMT classification in CLP by 2025 will have to be dealt with the PBT assessment already required for substances registered under Annex VIII of REACH (above 10 t/y). The CLP regulation does not require testing, but use of existing data on biodegradation, log K_{OW}, and EC_{50} on aquatic invertebrate and on algae are required in Annex VII and will therefore be available as screening data to be used in the PBT assessment. Thus, to satisfy CLP regulation, a PBT assessment will be required for essentials oils already registered under REACH. However, the absence of screening information on the mobility criteria (log K_{oc}), only required in annex VIII of REACH regulation, will make PMT assessment difficult for the majority of EOs.

First, our study details and compares the current approach used and described in ECHA and industry guides (IFRA / EFEO) with the MOCS approach to PBT and PMT assessment. We discuss the impact of assessing the P, B, and M criteria on the known constituents, but the T criterion on the whole substance.

In the second step, examples of substances with available data demonstrate that the constituent approach and experimental data obtained on the whole substance are sometimes not concordant for the P and B criterion. We conclude that interactions between constituents in natural substances are more complex than a simple additivity effect.

A proposed amendment to exempt "substances of renewable botanical origin that are not chemically or genetically modified" from the use of the MOCS approach is currently under discussion at European level. We hope that these data will inform stakeholders and support discussions on the application of the MOCS approach to natural substances.

4.03.P-We289 Investigation Into the Impact of a Substances' Physicochemical Properties on its Suitability to be Dosed at High Flow Rates into Aqueous Media Using Saturator Columns.
*Thomas Hawkins Mr[1], Saskia Storey Miss[1] and **Kathryn Gerry**[2], (1)Analytical Chemistry, Scymaris Ltd., United Kingdom, (2)Analytical Chemsitry, Scymaris Ltd., United Kingdom*
A saturator column is a device used to generate a substance solution at up to its maximum solubility (in, for example, water), without the inclusion of a separate solvent to aid dissolution. The use of such devices to generate test solutions is one of the recommended methods in OECD guidance document N.23 for the aqueous-phase aquatic toxicity testing of difficult test chemicals. The use of saturator columns is not generally recommended when testing complex mixtures of chemicals (e.g. UVCB's) due to the potential disparity in depletion rates for the different component chemicals, however, generating a constant flow of aqueous media, dosed at the functional limit of solubility (for all individual components of a mixture) without the use of a solvent is not otherwise easily achieved.

To conduct toxicity testing at concentrations approximating the solubility limit of a substance using a flow through study design (for example in a fish early life stage toxicity test, or an aquatic exposure bioaccumulation study), the saturator column(s) flow rate needs to match that of the flow through test system.

This study investigates the saturator column eluate concentration of a range of chemicals with varying physicochemical properties, at column flow rates appropriate to the aforementioned study types. The study aims to better understand the physiochemical characteristics of a chemical that make it a viable target for use in dosing into high flow rate aquatic toxicity tests using saturation columns. The components are tested individually and as a mixture to determine if understanding of the individual component properties is applicable to complex mixtures.

4.03.P-We290 Studying the Effects of Oil Sands Process-Affected Water Composition on PAH Henry's Law Constants
***J. Mark Parnis**[1], Alena K.D. Celsie[2], Rachelle Robitaille[3], Maryam Moradi[4], Miriam L. Diamond[5], Liisa Jantunen[6] and Tom Harner[7], (1)Trent University, Canada, (2)Chemistry, Trent University, Canada, (3)2Department of Earth Sciences, University of Toronto, Canada, (4)Air Quality Processes Research Section, Environment and Climate Change Canada, Canada, (5)University of Toronto, Department of Earth Sciences, Canada, (6)Atmospheric Science and Technology, Environment and Climate Change Canada, Canada, (7)Environment and Climate Change Canada, Canada*
The Canadian oil sands industry generates large volumes of oil sands process-affected water (OSPW) as a waste byproduct. These waters contain significant amounts of naphthenic acids, along with a variety of inorganic salts and other

solutes. Environmental monitoring of such waters requires knowledge of the properties of the various OSPW constituents. In particular, the Henry's law constant is a key property for the monitoring and assessment of atmospheric emissions originating from OSPW.

A key question is whether the Henry's law constants of OSPW solutes can be approximated by their corresponding values in pure water, an assumption utilized by most prediction methods. This study addresses this concern by studying the extent to which the Henry's law constants of PAHs in OSPW are affected by the constituents contained within OSPW, namely naphthenic acids and inorganic ions. We present here results from COSMO-RS modelling of Henry's law constants for a set of 16 polycyclic aromatic hydrocarbons (PAHs) in OSPW, in the presence and absence of typical OSPW constituents. The absolute deviation in predicted Henry's law constants between pure water and the simulated OSPW ranged from 0.011 to 0.017 log units. Our results demonstrate that the use of Henry's law constants predicted assuming a pure water medium is an acceptable approximation for modelling the atmospheric emission of OSPW constituents. Temperature variation effects are shown to be significantly more important in terms of influencing the Henry's law constant compared to the influence of any OSPW constituents at the concentrations that they are found in typical OSPW.

4.03.P-We291 Towards Improving the Reproducibility and Linearity of the Preparation of Water Accommodated Fractions of Esterification Reaction Products

*Kate Louise Hendley[1] and **Kathryn Gerry**[2], (1)University of York, United Kingdom, (2)Analytical Chemsitry, Scymaris Ltd., United Kingdom*

Unknown or variable, complex reaction products and biological materials (UVCBs) are a developing area of concern, comprising up to 40% of new chemicals registered in Europe. Of particular interest are UVCBs prepared from esterification reactions with starting materials such as pentaerythritol and ethylene glycols; their unique structures allow the production of a myriad of materials for use in a wide range of industries (adhesives, lubricants, polishes, fertilizers, and coating products, to name a few) dependant on the type of free acid used in the reaction. Poorly soluble and hydrolytically unstable, the physicochemical properties of these UVCBs pose additional challenges when assessing environmental risk in comparison to other multi-component substances.

The largest challenge in assessing the aquatic toxicity of these types of UVCBs is their dosing, for which the Water Accommodated Fraction (WAF) has been the standard regulatory practice for over thirty years. Although WAFs are the principal method of dosing difficult-to-test substances, the reproducibility between preparations is generally considered poor despite attempts at standardisation. The competing thermodynamics of phase equilibration and hydrolytic instability have historically yielded low reproducibility between saturated solutions. The complexity of the system is often further exacerbated by the creation of stable suspensions that can overestimate the saturation concentration.

In this work, we present a novel approach to WAF preparation which aims to improve reproducibility by shortening equilibration times and reducing the formation of colloidal matter via a solvent-dosed solid support membrane. This hybrid system utilises the ease of solvent dosing with the fast equilibration and reduction of suspension formation observed in passive dosing, all whilst maintaining the principles of WAF preparation. We present the degradation and phase equilibration kinetics for a range of esterification reaction products, with recommendations for obtaining a linear response to WAF loading using solvent-dosed solid supports.

4.03.P-We292 Searching for slowly-biodegrading constituents using whole petroleum substance biodegradation testing with deconvolution and non-target analysis of GCxGC-FID/TOFMS data

*J. Samuel Arey[1], Mari Creese[2], Lisbet Sorensen[3], Andy Booth, PhD[3], Robert K Nelson[4], Sandrine Sourisseau[5], Louise Camenzuli[6] and **Delina Lyon**[7], (1)Oleolytics LLC, (2)SINTEF, Norway, (3)SINTEF Ocean, Norway, (4)Marine Chemistry & Geochemistry, Woods Hole Oceanographic Institution, (5)TotalEnergies, France, (6)ExxonMobil, Belgium, (7)Concawe, Belgium*

Petroleum substances contain thousands of constituents that biodegrade at widely varying rates. Recently, we developed a workflow to search for slowly biodegrading constituents using whole petroleum substance biodegradation testing with constituent-tracking methods, based on analysis by comprehensive two-dimensional gas chromatography coupled to flame ionization detector (GCxGC-FID) and to high-resolution time-of-flight mass spectrometry (GCxGC-HR-TOFMS). However, chromatographic coelutions challenged our efforts to quantify, track, and identify constituents in these highly complex UVCBs. In the present study, we re-design the workflow to include deconvolution and non-target analysis approaches to improve the detection, quantification, and identification of slowly-biodegrading constituents. The screening method detects, quantifies, and identifies constituents that exceed the following criteria: (i) the constituent concentration in the original product exceeds 300 mg g^{-1}; and (ii) the percentage of remaining (non-degraded) mass exceeds 30% after 64 days of biodegradation. We test the screening method on a diesel fuel previously analyzed by GCxGC-FID/TOFMS. We found 50 constituents that met the screening criteria. Among these, 43 constituents (86%) are interpreted as C_{15}-C_{23} two-ring naphthenes, of which 30 likely contain a quaternary carbon. Five constituents (10%) are C_{21}-C_{23} acyclic isoprenoids, and two constituents (4%) were not successfully interpreted. Example results are shown for a peak interpreted as a C_{15}-naphthene. The re-designed workflow improves on the detection, quantification, and identification of peaks, compared to the previous method. This conclusion is illustrated by the finding that most of the screened constituents are identified as naphthenes containing quaternary carbons, a structural feature associated with recalcitrance to biodegradation. Information gained from the screening method can be used to prioritize further testing of constituents expected to biodegrade slowly. The data analysis workflow can be extended to other endpoints requiring time-lapsed information, such as bioaccumulation potential.

4.03.P-We293 Application of MOSH/MOAH GCxGC methods to support bioaccumulation testing of hydrocarbon UVCBs in fish

Leslie J Saunders[1]*, Martin Lommatzsch*[2]*, Louise Camenzuli*[3]*, Aaron Redman*[4]*, Christopher Prosser*[5] *and Delina Lyon*[1]*, (1)Concawe, Belgium, (2)Laboratory Lommatzsch & Säger, Germany, (3)ExxonMobil, Belgium, (4)ExxonMobil Biomedical Sciences, Inc., (5)ExxonMobil*

The assessment of chemical bioaccumulation in fish is an important component of global chemical assessment and regulatory programs. Bioaccumulation assessments for petroleum substances remain difficult because (i) they are comprised of complex and variable combinations of hydrocarbons (i.e., UVCBs); and (ii) there are limited test data for the thousands of possible hydrocarbon constituents in petroleum substances, due to limited commercial availability of the individual constituents and their incompatibility with standard test systems. To deal with these issues, we are running whole substance OECD 305 dietary bioaccumulation test paired with supporting two-dimensional gas chromatography (GC×GC) analysis to analytically track individual constituents, or groups of constituents, over time. This approach of generating constituent-level information in a whole substance test design has been successfully applied in seawater biodegradation tests. However, the increasing complexity of biological sample matrices (e.g., due to lipids and other biogenic compounds) can present challenges for adequate peak separation and identification. In the present study we aim to optimize and test analytical methods needed to characterize the dietary accumulation of middle distillate oils in trout and highlight analytical challenges associated with the generation of bioaccumulation data using GCxGC analysis. To improve peak separation and recovery, fish samples were subject to alkaline digestion and epoxidation steps to remove residual lipids and polyenes which thereby reduced analyte interference and carryover between chromatogram runs. Addition of an HPLC pre-fractionation step to separate saturated (MOSH) and aromatic (MOAH) hydrocarbon fractions also greatly reduced peak overlap and interference. Preliminary analyses revealed the presence of MOSH contaminants in control fish, possibly from the prepared fish food or sample homogenization procedures. Food-derived oils may naturally contain MOSH/MOAH and are commonly added to fish feeds in bioaccumulation studies. Caution should therefore be taken in sample preparation to avoid MOSH/MOAH cross-contamination. Following a blank-correction, apparent detection of C10-C15 hydrocarbons in exposed trout was observed. These data are being used to optimize the sample processing and analytical methods so that additional analyses can be performed to determine the bioaccumulation and biotransformation behaviour of these compounds.

4.03.P-We294 Outcomes from the 2023 Concawe workshop “Analytical technology exchange to meet health & environmental regulatory challenges for UVCBs”

Delina Lyon[1]*, Leslie J Saunders*[1]*, Yves Verhaegen*[1]*, David MV Saunders*[2]*, Sandrine Sourisseau*[3]*, Evangelia Tzoumani*[1]*, George Hinkal*[1]*, Elisabetta di Caprio*[1]*, Nicholas Synhaeve*[1] *and Carol Banner*[1]*, (1)Concawe, Belgium, (2)Shell Global Solutions, Netherlands, (3)TotalEnergies, France*

The EU REACH Regulation requires registrants of substances of Unknown or Variable composition, Complex reaction products or Biological materials (UVCBs) to provide detailed and comprehensive analytical information on the constituents present in these substances. Concawe currently manages over 140 registered hydrocarbon UVCB substances grouped into multiple categories ranging from light (e.g., naphtha) to heavy (e.g., bitumen) substances. Comprehensive substance characterization is required both to assess the potential environmental and human health impacts of these substances and to assess the degree of similarity between substances. The latter is particularly important so that the results obtained from toxicity tests can be applied from one substance to another (i.e., read-across). In addition, targeted analysis of specific constituents of concern is also important. Recognizing the challenges to characterize UVCB substances, Concawe convened a workshop for analytical chemists, (eco)toxicologists, and product stewards from industry, academia, and regulatory authorities to identify the state of the science and paths forward in defining the composition of petroleum substances for the purposes of hazard assessment.

The Concawe workshop enabled cross-sector and cross-disciplinary exchange on the need for and methods of identification and quantitation of UVCB substance constituents/ constituent groups. As will be shared in the poster, the discussions started with clarifying the regulatory requirements for health and environment and the need for additional analytical data. Several laboratories then presented their current and evolving analytical technologies to support comprehensive description of constituents / constituent groups and to improve targeted resolution and constituent identification. Finally, the analytical methods and their potential were assessed against regulatory requirements to identify the opportunities and gaps. The outcomes of this workshop will be used as guidance for experimental interrogations of a set of UVCB substances by Concawe to understand the capabilities and limitations of current technologies to deliver the type of analytical information being requested for human health and environmental hazard assessment.

4.03.P-We295 Development of a Pilot Database of UVCB Chemical Characterization Information

Erin Maloney[1]*, Marc Fernandez*[2]*, Antony John Williams*[3]*, Lilly Cesh*[2]*, Charles Lowe*[3]*, Emma Schymanski*[4]*,* ***Julie Krzykwa***[5] *and Sandrine Estelle Deglin*[5]*, (1)Shell International, Netherlands, (2)Environment and Climate Change Canada, Canada, (3)U.S. Environmental Protection Agency (US EPA), (4)Luxembourg Centre for Systems Biomedicine (LCSB), University of Luxembourg, Luxembourg, (5)Health and Environmental Sciences Institute (HESI)*

Substances of “unknown or variable composition, complex reaction products or biological materials” (UVCBs) pose challenges to risk assessors, registrants, scientists, and regulators. To address these challenges, the tripartite UVCB Committee of the Health and Environmental Sciences Institute (HESI), is developing an exposure-based, tiered approach for UVCB prioritization and risk assessment. The first step of the proposed approach (aka Tier 0) involves "Tier 0 information" that can be used to prioritize UVCBs and streamline their safety evaluation. Tier 0 information includes exposure, composition, and hazard data such as use profiles, production volumes, physicochemical properties, and (eco)toxicological data. Despite the prevalence of UVCB substances in the chemical space, there is no public-facing database specifically for relevant chemical characterization data for UVCB substances. Thus, there is an opportunity to develop a fit-for-purpose, publicly accessible database addressing this need.

To assess feasibility and develop robust/efficient methodologies for data collation, a subgroup of the HESI UVCB committee is developing a pilot database of Tier 0 information for ~100 commercially relevant UVCBs. Information has been collected from scientific publications, databases, and reports, including substance identifiers (i.e., CAS Registry numbers, EC Numbers, names), structural descriptors, registration data, physicochemical properties, use/exposure profiles, and hazard data for whole substances and representative constituents. Methods and challenges encountered have been documented for reproducibility and improvement in future data collection efforts. Steps to automate the data mining processes were investigated to aid in database maintenance and future expansion efforts.

This exercise both demonstrates the feasibility of, and highlights the challenges associated with, developing and potentially scaling up such a database. Moreover, this effort progresses the implementation of a UVCB risk assessment framework, providing information that can be utilized by registrants, risk assessors, and regulators for prioritization, risk assessment, and read across. Obtaining buy-in from industrial and regulatory partners will be key to further the data collection process and realization of the full potential of such a database.

4.03.P-We296 A Linear Regression Model for Predicting COSMO-RS Sigma Profiles

Alena K.D. Celsie[1] *and J. Mark Parnis*[2]*, (1)Chemistry, Trent University, Canada, (2)Trent University, Canada*

Linear regression models can be very useful for predicting chemical properties with high environmental significance. Quantitative structure-activity relationships (QSARs) and linear free energy relationships (LFERs) are examples of linear regression type models often used in environmental science to predict properties such as partition ratios or biotransformation half-lives.

Sigma profiles are chemical properties that have a graphical form which show the distribution of local charges over the molecule's surface area. Andreas Klamt has shown that sigma profiles can be used to characterize any chemical or mixture of chemicals and has used this as the basis for developing the statistical mechanics-based COSMO-RS theory. COSMO-RS has been implemented into the software COSMOtherm for predicting chemical properties such as partition ratios, solubilities, vapour pressures, Henry's law constants (HLCs), and others.

In this study, a multi-parameter linear regression (MRE) model has been developed using HLCs as descriptors to predict sigma profiles of chemicals. Predictions can be made for pure chemicals or for mixtures including Multi-Constituent Substances (MCS), More-than-One-Constituent Substances (MOCS), and substances of Unknown or Variable composition, Complex reaction products, and Biological materials (UVCBs). In this work, sigma profiles were predicted for a 49 neutral organic compound test set using the generated MRE equations. Sigma profiles were then indirectly input into COSMOtherm and used to predict partition ratios for a group of 264 neutral organic compounds in a medium containing a binary mixture of water and each of the 49 test set compounds. R^2 values for partition ratios predicted using the MRE-generated sigma profiles compared to partition ratios from actual sigma profiles ranged from 0.8794 for the 264 compounds in a 1-nonanol/water medium to 0.9969 for the same set of 264 compounds in an acetonitrile/water medium. The average log RMSE for the partition ratios was 0.48.

These results are promising with respect to the use of experimentally determined HLCs (which can be converted from vapour pressure) to characterize relevant properties of environmental media, especially for UVCB substances, without knowing their actual composition.

4.03.PC Characterization, Testing and Assessment of Complex Substances (MCS, UVCBs & MOCS)

4.04 Effect Modelling in Regulatory Science: In the Service of Environmental Risk Assessment and Risk Management?

4.04.T-01 Three Perspectives on Model Calibration for Ecological Risk Assessment

Nele Schuwirth[1]*, Roman Ashauer*[2]*, Marco Baity-Jesi*[3]*, Sandrine Charles, PhD, HDR*[4]*, Nika Galic*[5]*, Helen Moor*[6]*, Damian V Preziosi*[7]*, Andreas Scheidegger*[6]*, Amelie Schmolke*[8] *and Tido Strauss*[9]*, (1)Systems Analysis and Modelling, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)Syngenta Crop Protection, Switzerland, (3)Siam, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (4)Umr Cnrs 5558, University Claude Bernard*

Lyon 1, France, (5)Syngenta AG, Switzerland, (6)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (7)Integral Consulting, Inc., (8)RIFCON GmbH, Germany, (9)Research Institute gaiac, Germany
Mechanistic effect models are useful tools to support environmental risk assessment of chemicals. The development and application of mechanistic models require decisions on the model type, model structure and parameterization. "To calibrate or not to calibrate" is still under debate, especially in the field of mechanistic modelling. In this paper, we discuss three complementary perspectives on model calibration, including model selection and parameterization. They differ in their way to deal with prior knowledge and with data for calibration and validation. We discuss implications on model performance and transferability to different application scenarios. Furthermore, we discuss implications on the quantification of model output uncertainty.

With this presentation, we hope to bridge between different modelling communities from mechanistic to statistical modelling and machine learning fields. We provide motivation and guidance for the use of transparent concepts and reproducible procedures to include different sources of information for decision support in environmental risk assessment. We also provide a perspective on future developments to increase the robustness of model predictions and transparency regarding model uncertainties.

4.04.T-02 Parameter Estimates Using the GUTS Modelling Framework: Biological or Statistical Reality?
***Annika Mangold-Döring*[1]*, Jan Baas*[2]*, Anna Huang*[2] *and Sanne van den Berg*[3]*, (1)Environmental Risk Assessment team, Wageningen Environmental Research (WUR), Netherlands, (2)Wageningen Environmental Research (WUR), Netherlands, (3)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands*
It is common practice in ecotoxicology to derive an LC_{50} (the concentration at which 50% of the exposed organisms die, at some specified point in time) from laboratory experiments. This LC_{50} is subsequently treated as the single value summary of the test and is considered to be a measure for the toxicity of a compound and is subsequently used to derive a safe environmental concentration. This approach has a number of disadvantages, most notably the time-dependence of the LC_{50} and the fact that the LC_{50} is only valid for the exposure conditions under which it was derived, usually a constant exposure.

These disadvantages can be overcome with the use of a toxicokinetic-toxicodynamic (TKTD) model for the interpretation of effects. The most elaborate modelling framework that is currently in place is the General Unified Threshold model of Survival (GUTS) modelling framework and currently has a formal status for use in risk assessment by EFSA. Most frequently the GUTS model is used in its reduced form where the external concentration is the driving force for effects. We’ve applied the standard model to some datasets generated in the laboratories of Wageningen University and Research, that comply with the EFSA standards on data quality to evaluate the outcome. This showed that the best fiitting parameter values in the standard settings may significantly underestimate the intrinsic senstitvity of the species in a test.

The main lessons that can be learned from this exercise are:

- Fit the control mortality on the whole dataset
- Check if the obtained parameter settings are plausible
- Non-dedicated experiments will often result in correlated parameter values, hampering the extrapolation potential of a TKTD approach
- If more than one interpretation of the data is possible; explore every interpretation individually

4.04.T-03 Spatio-temporal coupling of soil exposure modelling with toxicokinetic-toxicodynamic models: a case study based on a field trial
***Kim Rakel, MSc Ecotoxicology RWTH University*[1]*, Natalie Carmen Dallmann*[1]*, Gregor Ernst*[2]*, André Gergs*[2] *and Vanessa Roeben*[2]*, (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Bayer AG - Crop Science Division, Germany*
The environmental risk assessment of plant protection products aims at the prevention of unacceptable adverse effects on the environment. Therefore, the risk assessment for soil organisms, such as earthworms, is based on two key elements: the exposure assessment and the effect assessment which are conducted currently independend from each other. Regarding the exposure, the behavior of an active ingredient in the soil is evaluated and, as a major output, predicted environmental concentrations are estimated. The effect assessment is based on toxicity endpoints derived from the investigation of the concentration–response relationships in laboratory studies or a NOEC in field experiments.

Laboratory tests conducted for earthworm risk assessment are worldwide agreed and standardized (OECD 207 & OECD 222). The standard test species is *Eisenia fetida*, conducted at constant and optimal temperature, with artificial soil and controlled humic conditions. This allows to detect lethal and sublethal effects.

In the field we have different earthworm species like *Aporrectodea caliginosa* and *Lumbricus terrestris* which experience fluctuating environmental conditions, e.g. temperature, humidity and food. In addition this fluctuation changes in depth of the soil column and depend on soil type. Soil type and weather also influence the fate of pesticides in the soil column and have effects on the movement and behaviour of the earthworms and their life-history.

In this approach we added species-dependent movement from Gergs et al. (2022) due to moisture and food gradients as well as life-history development after Dynamic energy budget (DEB) theory to the EEEworm from Johnston et al. (2014, 2015 & 2018). The "FORESEE" model - a spatial and temporal explicit (DEB-)TKTD (toxicokinetic-toxicodynamic) model for earthworms - was provided with fate exposure profiles of carbendazim, FOCUS weather data (see Figure 1) and DEB & DEB-TKTD-parameters for both earthworms derived from the Add-my-Pet database & laboratory tests. The model performance was compared to data from a field study with carbendazim for both species.

The here presented FORESEE model can help to understand effects of enviromental fluctuations on earthworm populations. In addition it gives insights in the mechanistic processes during exposure situations and can support field studies by screening exposure scenarios and timing of application beforehand.

4.04.T-04 Linking Landscape Models, Field Data and Pesticide Effects Using Normal Operating Ranges (NOR)

Leonhard Urs Bürger[1]*, Grzegorz Sylwester Sowa*[2]*, Lorraine Maltby*[2] *and Andreas Focks*[1]*, (1)Institute of Mathematics, Osnabrück University, Germany, (2)School of Biosciences, University of Sheffield, United Kingdom*

Arthropods play diverse roles in agricultural ecosystems, from pests to providers of crucial ccosystem services like pollination and pest control. Assessing declines in beneficial arthropod populations, influenced by factors such as pesticides, is challenging due to variability in inter and intra-annual species abundances. Natural variability in an ecosystem is therefore first assessed using Normal Operating Ranges (NOR) quantifying 'normal' species abundance throughout the year. This concept is then used to link landscape-scale modelling results with field data and pesticide effects. Modelling is performed in the Animal Landscape and Man Simulation System (ALMaSS) from Topping et al. (2003) for the predatory money spider *Erigone atra*. ALMaSS uses landscapes derived from real aerial imagery together with factors like weather, crop management and species behaviour in the simulation. The model-derived NOR results are compared with a pitfall trap field data for *E. atra*. For this purpose, field data surveys are extracted from literature, interpolated, pooled and then used to calculate a data-derived NOR. Data and model-derived NORs show similar patterns during the year and thus indicate comparability between model results and field data. Pesticides are then introduced in the model with different generic properties, like lethality, longevity and application rate to assess effects on species abundance. Effects are analysed according to the EFSA scientific opinion on recovery (2016) based on whether abundance reductions exceed NOR boundaries. Using the Normal Operating Range (NOR) concept can therefore aid the linkage between landscape-scale models, field survey data and assessment of pesticide effects. Abundance results can further be related to their ecosystem function to analyse risk on the level of ecosystem service provision. Future assessment of pesticide effects on a landscape scale can thus be supported by modelling.

4.04.T-05 xLandscape – A Modular Modelling Framework for Landscape-Level Exposure and Effect Modelling and Risk Characterisation

Sascha Bub[1]*, Thorsten Schad*[2] *and Julian Heinrich*[2]*, (1)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (2)Bayer AG - Crop Science Division, Germany*

More realistic environmental risk assessment of pesticides requires to operate exposure and effect models based on real-world (geo)information. Established models for the different domains need to be technically linked and provided with environmental and agricultural data. To overcome ad-hoc solutions, to assure consistency and to manage complexity, a modular framework has been developed to integrate individual models into a new, larger model of combined capabilities (xLandscape). xLandscape allows to deliver risk assessment endpoints in explicit dimensions and scales as defined in Specific Protection Goals. Here, we introduce the concepts and design of xLandscape and show example model applications.

We exemplarily show how xLandscape models are built and demonstrate simulation results for aquatic and off-field-soil exposure and effect modelling as well as for bee risk scenario development. The results show how new insights into real-world systems are gained and how these complex multidimensional data can be summarised into intelligible endpoints for risk assessment and risk management purposes.

4.04.P Effect Modelling in Regulatory Science: In the Service of Environmental Risk Assessment and Risk Management?

4.04.P-We297 The MAD book - Acceptability of Regulatory Models

Jeremias Martin Becker[1]*, Magnus Wang*[2]*, Alpar Barsi*[3]*, Udo Hommen*[4]*, Thomas G Preuss*[5]*, Oliver Jakoby*[6]*, Benoit Goussen*[7]*, Stefan Reichenberger*[8]*, Melissa Reed*[9] *and Sabine Duquesne*[10]*, (1)German Federal Environmental Agency (UBA), Germany, (2)WSC Scientific GmbH, Germany, (3)Board for the Authorisation of Plant Protection Products and Biocides (Ctgb), Netherlands, (4)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (5)Bayer AG - Crop Science Division, Germany, (6)RIFCON GmbH, Germany, (7)ibacon GmbH, Germany, (8)knoell France SAS, France, (9)HSE, United Kingdom, (10)German Environment Agency (UBA), Germany*

In the European Union, mechanistic effect models (MEMs) have to be thoroughly evaluated before they may be used for the regulatory environmental risk assessment of plant protection. MEM evaluation has been mainly described in the EFSA Scientific Opinion on Good Modeling Practice (2014). The evaluation process in that document follows typical steps in modeling, but does not separate the development and the application of a MEM. So far, no fit-for-purpose models other than GUTS and the *Lemna* model have been acknowledged by EFSA. In consequence, often a rapporteur member state has to fully evaluate a model each time a new application of a MEM has been proposed. This is inefficient and can lead to inconsistency in the evaluation and acceptance, because MEMs for risk assessment are typically not developed for a single application.

Therefore, we suggest to separate the evaluation of a MEM in general and of its application in a specific risk assessment. Additionally, the evaluation of a general MEM may be broken down to building blocks (modules) for specific processes in a model. Accepted modules may then be assembled to a new modelling framework for risk assessment, where only the interplay of the components, its suitability to address a specific question, the environmental scenario and the pesticide-specific information need to be evaluated. We consider such a modelling framework to consist of a fate model with an associated exposure scenario and a coupled MEM with an associated ecological scenario. The MEM is considered to consist of two main parts: The toxicology module simulates the immediate effects of a pesticide on the modelled entity (e.g., decreased nutrient uptake in a TKTD model or decreased survival in a population model), while the ecology module simulates the ecological consequences (e. g., changes in organism growth or in population dynamics).

The proposed evaluation of such a modelling framework, the embedded MEM and its modules allow for more flexibility as compared to the evaluation of a ready-to-use but rigid regulatory model as described in the EFSA scientific opinion on Good Modelling Practice.

4.04.P-We298 The MAD-Book - Potential Applications of Mechanistic Effect Models in Environmental Risk Assessment of Pesticides

***Jeremias Martin Becker**[1], Magnus Wang[2], Alpar Barsi[3], Thomas G Preuss[4], Udo Hommen[5], Oliver Jakoby[6], Benoit Goussen[7], Stefan Reichenberger[8], Melissa Reed[9], Johan Axelman[10] and Sabine Duquesne[11], (1)German Federal Environmental Agency (UBA), Germany, (2)WSC Scientific GmbH, Germany, (3)Board for the Authorisation of Plant Protection Products and Biocides (Ctgb), Netherlands, (4)Bayer AG - Crop Science Division, Germany, (5)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (6)RIFCON GmbH, Germany, (7)ibacon GmbH, Germany, (8)knoell France SAS, France, (9)HSE, United Kingdom, (10)Swedish Chemicals Agency, Sweden, (11)German Environment Agency (UBA), Germany*

In the last years, mechanistic effect models (MEMs) have been increasingly developed and proposed for application in the environmental risk assessments of plant protection products. The MAD book (Model Acceptability and Scenario Development) is the product of a multi-partite working group of the SETAC Europe Interest Group on Mechanistic Effect Models with the aim to provide some means to adequately assess mechanistic effect models for their use for the environmental risk assessment of chemicals, here specifically of pesticides. In this poster we summarize chapter 1, giving an overview on realized and potential uses within the regulatory framework of the European Union.

MEMs have been used to dynamically simulate effects on organisms, populations, communities and ecosystems. So far, they have been proposed mainly in a number of predictive ways as refinement options within the tiered approach. However, MEMs may be also used in a retrospective way to improve the analysis of ecotoxicological data and to understand the margin of safety associated with established assessment factors. MEMs may be more complex than currently used methods. Still they may increase our understanding of the level of uncertainty associated with predictions of environmental effects. However, MEMs stand and fall with an understanding and appropriate implementation of relevant mechanisms. Therefore, dynamics and pesticide effects predicted by MEM simulations are required to be validated, i.e. tested with independent data or knowledge. The question of how (e. g. at which scales and with which precision) this can be done remains a challenge, especially for large scale ecological models or models for vertebrates.

The EFSA Scientific Opinion on Good Modeling Practice (2014) and protocols such as TRACE and ODD are supportive for the development, application and assessment of MEMs in regulatory risk assessment. The MAD book provides modelers and risk assessors with recommendations to develop the necessary explicit quality criteria for the various aspects of the modeling process, including the underlying data, the conceptualization, implementation, the environmental scenario, model validation, the model performance and the documentation.

4.04.P-We299 The MAD book - Development of Environmental Scenarios for the Application of Mechanistic Effect Models in Environmental Risk Assessment

***Sanne van den Berg**[1], Sabine Duquesne[2], Oliver Jakoby[3], Udo Hommen[4], Thomas G Preuss[5], Magnus Wang[6], Alpar Barsi[7], Stefan Reichenberger[8] and Andreas Focks[9], (1)Wageningen University & Research (WUR), Netherlands, (2)German Environment Agency (UBA), Germany, (3)RIFCON GmbH, Germany, (4)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (5)Bayer AG - Crop Science Division, Germany, (6)WSC Scientific GmbH, Germany, (7)Board for the Authorisation of Plant Protection Products and Biocides (Ctgb), Netherlands, (8)knoell France SAS, France, (9)Institute of Mathematics, Osnabrück University, Germany*

Mechanistic effect models (MEMs) offer a comprehensive platform for analyzing the environmental risk of pesticides across various biological, spatial, and temporal scales. In essence, MEMs make predictions about the environmental effects of pesticides or other stressors based on mechanistic principles embedded in the model. These principles derive from physical, chemical, and biological rules, often influenced by environmental conditions such as temperature, pH, and food availability. Environmental scenarios, defined as combinations of abiotic, biotic, agronomic, and sometimes landscape conditions, are crucial when utilizing MEMs for meaningful assessments. The differentiation between ecological and exposure scenarios is made, with certain factors belonging exclusively to one or the other, and some (primarily abiotic factors) encompassing both. The dual influence of certain factors on exposure and ecological scenarios underscores the importance of consistent environmental scenario definitions. The lack of standardization in defining environmental scenarios, coupled with a dearth of guidance on formulating and evaluating such scenarios in model assessments, is addressed in this presentation of a chapter of the MAD book. We review historical approaches to defining exposure, ecological, and environmental scenarios in environmental risk assessment, offering a vision for future definitions and evaluations. To aid modelers and risk assessors, we propose a catalog of questions, designed to establish well-founded, comprehensive, and structured environmental scenarios for MEM-based risk assessments. Finally, three examples are given how environmental scenarios can be defined in MEM-based chemical risk assessments, accompanied by a brief discussion of each. This comprehensive overview and proposal provide valuable insights, setting the stage for future advancements in environmental scenario definition and evaluation within the context of MEM applications

4.04.P-We300 The MAD book - Documentation and Evaluation of Data Used in Mechanistic Effect Models
Benoit Goussen[1]*, Michael Fryer*[2]*, Melissa Reed*[3]*, Thomas G Preuss*[4]*, Josef Koch*[5]*, Magnus Wang*[6] *and Peter Vermeiren*[7]*, (1)ibacon GmbH, Germany, (2)Ecotoxicology, UK Health Security Agency, United Kingdom, (3)HSE, United Kingdom, (4)Bayer AG - Crop Science Division, Germany, (5)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (6)WSC Scientific GmbH, Germany, (7)RIFCON GmbH, Germany*
Pesticide regulation in the European Union requires a robust evidential basis to underpin decision-making. When an applicant relies on a mechanistic effect model to demonstrate that the use of a plant protection substance will not lead to unacceptable effects, it is crucial to clearly illustrate how the model has been utilised to address specific risk assessment questions. The utilisation of available empirical data in addressing these questions is equally important, as the quality and appropriateness of the input data significantly impact the model outputs. Consequently, regulatory risk assessors need to scrutinise the underlying studies providing the data used in the model implementation. Given the relatively novel use of mechanistic effect models in pesticide risk assessment, transparent documentation of the quality and appropriateness of input data is of particular significance. This documentation must demonstrate the suitability of a mechanistic model for risk assessment to regulators who may be less familiar with this approach. Clarity and transparency in presenting the development and utilisation of a model in risk assessment will enhance confidence in its suitability, establish a solid foundation for future applications, and promote greater adoption of mechanistic models. In general, the data used in the model should align with the regulatory problem formulation for which they are employed, particularly in the context of higher tier risk assessment questions. This necessitates a detailed description of the relevant data used for specific parameters or aspects of the model, clarifying their purpose and the derivation of parameters from the study/studies, including any data transformations. Currently, mechanistic effect models are primarily used as part of a higher tier modelling approach in pesticide risk assessment. As such, this chapter covers documenting and evaluating the use of data for the modelling for environmental risk assessment of pesticides.

4.04.P-We301 The MAD book – Evaluation of modular models in ERA
Tido Strauss[1]*, Fabienne Ericher*[2]*, Benoit Goussen*[3]*, Joachim Ulrich Kleinmann*[4]*, Josef Koch*[1]*, Hanna Samantha Schuster*[5] *and Thomas G Preuss*[6]*, (1)Research Institute gaiac, Germany, (2)Syngenta, (3)ibacon GmbH, Germany, (4)WSC Regexperts, Germany, (5)Cambridge Environmental Assessments (CEA), United Kingdom, (6)Bayer AG - Crop Science Division, Germany*
Mechanistic effect models (MEMs) are increasingly considered to be useful tools for ecological risk assessment (ERA) of chemical stressors, amongst others, as they can predict population dynamics of non-target species under toxic stress for different environmental scenarios. So far, the evaluation of complex models that consist of several sub-models or modules for ERA purposes has largely ignored strengths and weaknesses of individual sub-models, modules or specific model parts.

This MAD book chapter aims to introduce the concept of modular model evaluation for the specific case of complex MEMs and its effective implementation in risk assessment. We will highlight the advantages and benefits of considering modularity for the evaluation of the model structure, of parametrisation, and also for validation (including the domain of applicability).

Dividing complex, modular models (e.g., coupled population or ecosystem models including TKTD models) into meaningful and clearly defined modules allows for their individual documentation, testing, evaluation and assessment. Such modular consideration of MEMs would simplify communication about complex models, reduce the workload for model development and evaluation, and allow better differentiation between robust and uncertain parts of the models. In addition, modularisation can help to overcome challenges related to the over-parameterisation of complex models through partial and independent parameterisation and validation of modules.

Questions about transferability to other environmental scenarios and applications could be answered more precisely: Which modules are already sufficiently validated and can be reused in other models? Can already documented and accepted modules be combined in new models, or replaced by simpler or more complex alternatives? These and other considerations highlight the importance of designing modules and system architecture using robust software engineering principles, with clearly defined and consistent interfaces between modules.

From these considerations, a decision scheme was derived that could be used for the validation of modular models for specific risk assessment questions.

4.04.P-We302 The MAD Book - On the Evaluation of Calibration and Validation Outputs with Mechanistic Effect Models

Simon Ewald Hansul[1]*, Peter Vermeiren*[2]*, Evgenia Chaideftou*[3,4]*, Michail Gioutlakis*[2]*, Udo Hommen*[5]*, Mira Kattwinkel*[6]*, Judith Klein*[5]*, Stefan Reichenberger*[7]*, Pernille Thorbek*[8]*, Johannes Witt*[9] *and Sandrine Charles, PhD, HDR*[10]*, (1)Institute of Mathematics, Osnabrück University, Germany, (2)RIFCON GmbH, Germany, (3)Benaki Phytopathological Institute, Greece, (4)RECETOX, Faculty of Science, Masaryk University, Czech Republic, (5)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (6)University of Kaiserslautern-Landau (RPTU), Germany, (7)knoell France SAS, France, (8)Apd/EE, BASF plc, United Kingdom, (9)Bayer AG - Crop Science Division, Germany, (10)Umr Cnrs 5558, University Claude Bernard Lyon 1, France*

Before mechanistic effect models (MEMs) can be applied to support environmental risk assessment, rigorous checks of model outputs are critical to evaluate the goodness -of-fit and the model suitability for further predictions. In this book chapter, we prioritized a collection of qualitative, visual assessments as well as quantitative statistics and metrics to support model output evaluation when MEMs are calibrated and validated on experimental or observed data. These criteria are reviewed for their use and limitations. Guidance is given regarding key issues to consider during the evaluation process, how they relate to the methods used, and how the methods can be integrated into a general approach. MEM outputs are of inherent complexity, including multiple state variables, outputs at different levels of biological organization, and a diversity of output patterns and types. We therefore argue for a multi-criteria approach, where methods should be combined to ensure a robust and balanced assessment of the quality of model outputs in reference to both data used for the calibration step and the external data to which predictions are compared. Note that also these data may be diverse and of different quality and types. We further highlight the non-binary, gradual outcome of model evaluation, assigning models a degree of validity with respect to the area of application, rather than a generic judgement about validity/invalidity. While there is not a one-size-fits-all solution to MEM calibration and validation, our evaluation approach should help model developers in choosing the right methods for the different tasks, while also supporting model users and assessors to follow the reasoning behind the methods applied so that they can evaluate and interpret them in the context of evaluating the output of calibration and validation with MEMs.

4.04.P-We303 The MAD Book - Sensitivity and Uncertainty of Mechanistic Effect Models

Simon Ewald Hansul[1]*, Peter Vermeiren*[2]*, Evgenia Chaideftou*[3,4]*, Michail Gioutlakis*[2]*, Udo Hommen*[5]*, Mira Kattwinkel*[6]*, Judith Klein*[5]*, Stefan Reichenberger*[7]*, Pernille Thorbek*[8]*, Johannes Witt*[9] *and Sandrine Charles, PhD, HDR*[10]*, (1)Institute of Mathematics, Osnabrück University, Germany, (2)RIFCON GmbH, Germany, (3)Benaki Phytopathological Institute, Greece, (4)RECETOX, Faculty of Science, Masaryk University, Czech Republic, (5)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (6)University of Kaiserslautern-Landau (RPTU), Germany, (7)knoell France SAS, France, (8)Apd/EE, BASF plc, United Kingdom, (9)Bayer AG - Crop Science Division, Germany, (10)Umr Cnrs 5558, University Claude Bernard Lyon 1, France*

The application of mechanistic effect models (MEMs) to risk assessment is inherently associated with uncertainty. The accurate characterization of this uncertainty, it's magnitude, direction, and sources, is a critical step in the utilization of MEMs to support decision making for risk assessment. The uncertainty of MEM output can be quantified by means of uncertainty analysis (UA). Uncertainty in model outputs originates from a variety of sources, including uncertainty in the available data and knowledge, as well as the model structure, parameters, scenario definitions, and the simulation of stochastic processes. Uncertainty propagates throughout stages of the model development process to the application of the model, and thus requires careful attention all along the modelling cycle. UA is tightly linked to sensitivity analysis (SA), which focusses on quantifying the variability in model output relative to the variability in model input factors. In the case of MEMs, the model input factors are mainly the biological and environmental parameters. Performing both UA and SA is part of a comprehensive model development and application process, but they can be performed during different stages of the model development process with slightly varying motivations. We classify sources of uncertainty and provide suggestion for how to account for them in the modelling process. In doing this, we argue for a multicriteria approach, considering uncertainty using different metrics and evaluations from various perspectives. A comprehensive evaluation of MEMs generally requires an approach tailored to the specific MEM aims and objectives. We provide some general guidance on when and how to perform SA and UA and provide a simple example to illustrate the process, using a population model to assess the uncertainty in population-level effects resulting from biological baseline and toxicity parameters. Finally, we provide a concise list of non-technical, high-level considerations in order to aid the evaluation of UA and SA by both model developers and evaluators. A well-balanced, multifaceted UA and SA dramatically increases the usefulness of MEMs for risk assessment by providing a systematic approach to map uncertainty about the knowledge of a system to uncertainty in model predictions, and therefore answers to extrapolation problems in risk assessment.

4.04.P-We304 Use of Toxicokinetic-Toxicodynamic (TKTD) Models in Pesticides Risk Assessment for Aquatic Organisms – Feedback from a National Regulatory Agency

Harry Byers, Claire Blondel, ***Fannie Chouvellon****, Emilie Perrat, Pierre-François Chaton, Emilie Farama and Vanessa Mazerolles, French Agency for Food, Environmental and Occupational Health & Safety (ANSES), France*

According to the European regulation (EC) No 1107/2009, a regulatory risk assessment (RA) is performed for all Plant Protection Products (PPP). For aquatic organisms when exposure cannot be excluded, a RA, conducted following the EFSA

Guidance Document on Aquatic Ecotoxicology (2013), is required. This document anticipated the use of TKTD models for risk assessment. The EFSA TKTD scientific opinion, released in 2018, covers the state-of-the-art of TKTD models for aquatic organisms and provide recommendations for their use within the EU's regulatory framework for plant protection products.

This scientific opinion focuses on prospective environmental RA and proposes TKTD models as a refinement option (Tier-2C) in acute and chronic RA schemes, aligned with EFSA PPR Panel approaches as described in the EFSA Guidance Document on Aquatic Ecotoxicology (2013). The opinion provides guidance on TKTD model application in RA and outlines specific validation steps for inclusion in the process.

Since the publication of the TKTD opinion 2018, around 25% of Active Substance (re)approval dossiers received by ANSES, acting as Rapporteur Member State, integrate TKTD models, notably GUTS and *Lemna* models, for risk assessment refinement. Despite their prevalence, challenges and advantages in practical application have emerged.

The assessment of these models supports the initial argumentation favouring TKTD models in risk assessment, as outlined by the EFSA opinion (2018). A key advantage lies in considering the complete aquatic exposure profile of the studied chemical, either for the toxicity studies or for the Predicted Environmental Concentration profile used in the risk assessment. However, challenges persist. Although the 2018 opinion streamlines model assessment, the evaluation process for TKTD models remains time-consuming due partly to inconsistencies in interpreting opinion recommendations. This necessitates additional time for standardization efforts.

The objective of this poster will be to present the view of a national regulatory agency on the use of TKTD models in aquatic risk assessment. The poster will provide feedback from regulatory risk assessors on the advantages and limitations of using these models in a regulatory framework for predicting the risk of chemicals to aquatic organisms. Technical and practical aspects will be tackled. The poster will also touch upon potential areas for improvement in this field.

4.04.P-We305 New perspectives on the body burden model for bird risk assessment of pesticides

***Sandrine Charles, PhD, HDR**[1], Miléna Kaag[1], Christelle Lopes Dr[1] and Alberto Linguadoca[2], (1)Umr Cnrs 5558, University Claude Bernard Lyon 1, France, (2)European Food Safety Authority (EFSA), Italy*

Introduced in 2016 as a refinement option for vertebrate environmental risk assessment, the body burden model (BBM) was initially not very popular, and very little use was made of it either in the scientific literature or for regulatory purpose. However, the BBM is a simple toxicokinetic model that easily allows the description of the internal dose through time when individuals are exposed to contaminated food via different feeding patterns. The BBM is considered as a possible option by in its most recent updated guidance on risk assessment for birds and mammals. This talk proposes a fully revisited BBM, in terms of mathematical writing, computer implementation and simulation interface. After a quick overview of the founding equations and the web interface, two case studies will be shown to illustrate the operative use of the BBM for regulatory purposes.

4.04.P-We306 Effect of Time Variable Concentrations on Green Microalgae: Evaluating the Robustness of a Laboratory Comparison Test using Toxicokinetic-Toxicodynamic Modelling

***Johannes Witt**[1], Cecilie Rendal[2], Sibylle Eck[1], Roger Baetscher[3], Ian Sims[2], Eric Bruns[4], Emily Scorgie[5], Roman Ashauer[3] and Thomas G Preuss[1], (1)Bayer AG - Crop Science Division, Germany, (2)Syngenta, United Kingdom, (3)Syngenta Crop Protection, Switzerland, (4)Environmental Safety, Bayer AG - Crop Science Division, Germany, (5)Global Science Delivery, Syngenta Seeds B.V., Netherlands*

ToxicoKinetic-ToxicoDynamic (TKTD) modelling has become an increasingly recognized option in risk assessment. For algae, the lack of a standardised and ring tested test setup for time variable exposure has so far been the major drawback for the application of TKTD modelling, according to the European Food Safety Authority’s (EFSA) opinion on TKTD modelling for use in risk assessment.

A laboratory comparison test has therefore been organised by CropLife Europe, to evaluate the robustness and reproducibility of two methodologies, a semi-static and a flow-through setup, for generating data for time-variable exposure on green microalgae.Traditional ring test statistics have been used to demonstrate the robustness of the semi-static method.

However, due to the time-variable exposure pattern, selection of appropriate robustness criteria is not straightforward. Amongst others, it is unclear which statistics should be used to compare time-variable exposure with constant exposure (i.e. in a standard algae study).

We therefore additonally evaluate the robustness of the semi-static test design using TKTD modelling. For this aim, we calibrate an algae TKTD model separately to each test run in each of the laboratories. Each of these calibrated models is then used to predict *in silico* the ErC_{50} of a standard OECD 201 algae test.

The resulting set of ErC_{50} values allows for a straightforward comparison of the results to standard algae studies.

4.04.P-We307 Global Sensitivity Analysis of the Harmonised Lemna Model

*Chloé Guisnet[1], **Stefan Reichenberger**[1] and Frank Voss[2], (1)knoell France SAS, France, (2)knoell Germany GmbH, Germany*

Ecological and effect modelling is becoming more and more important for environmental risk assessment in the framework of pesticide authorization. For instance, the EFSA Scientific Opinion on TKTD modelling has judged the GUTS model for lethal effects and the model for the standard aquatic macrophyte test organism Lemna as “ready for use”. Nevertheless, national regulatory authorities are still hesitant to accept ecological and effect modelling studies because they do not have sufficient experience with these models.

One way to increase the confidence in a model is to perform a Global Sensitivity Analysis (GSA) to analyze the contribution of the different model input factors to the variance of the model output(s).

In the case of ecological and effect models, a GSA notably allows to identify and rank the importance of i) toxicokinetic and toxicodynamic parameters, ii) physiological and ecological parameters of the organism, and iii) environmental driving variables (e.g. radiation, temperature, nutrient concentrations).

In this study we performed a two-step global sensitivity analysis (GSA) of the refined and harmonized Lemna model, which is publicly available as an R package. In a first step a Morris sensitivity screening was conducted. This semi-quantitative global method is very parsimonious and allows to filter out non-influential input factors. In a second step, a true variance-based GSA was carried out with the Sobol’ method and a reduced set of input factors. The GSA was conducted for four different concentration levels and three different exposure regimes: i) constant exposure, ii) two exposure pulses with varying intervals between peaks, and iii) realistic exposure time series generated with the FOCUS surface water models. Moreover, two different sets of input distributions of TKTD parameters were examined: i) distributions reflecting the parameter range for a specific substance (example: metsulfuron-methyl); ii) distributions reflecting the whole realistic parameter range (different substances). The main target variables were the effects of the pesticide on biomass and on growth rate.

Both Morris and Sobol GSA showed that for a specific substance three physiological parameters and the initial biomass BM0 were more important than the TKTD parameters. Hence, for predictive applications of the model outside a laboratory context, BM0 must be chosen carefully, and uncertainty in the main physiological parameters must be reduced to a minimum.

4.04.P-We308 Predicting Effects of Time-Variable Exposure Concentrations on Primary Producers using the cvasi Software Tool

***Johannes Witt**[1], Nils Kehrein[1], Dirk Nickisch[2], Torben Wittwer[2], Oliver Jakoby[2], Peter Vermeiren[2], André Gergs[1], Julian Heinrich[1] and Thomas G Preuss[1], (1)Bayer AG - Crop Science Division, Germany, (2)RIFCON GmbH, Germany*

Toxicokinetic-Toxicodynamic (TKTD) modelling is increasingly used in European regulatory risk assessments of plant protection products, following the publication of EFSA’s scientific opinion on TKTD modeling. This creates a demand for software that allows quickly and smoothly going through the whole workflow required for regulatory submissions: from model calibration and validation, over effect calculation for exposure scenarios, up to calculation of the respective regulatory endpoints such as LP_{50} and EP_{50} values.

A first version of our software tool ‘cvasi’ (calibration, validation, and simulation of TKTD models in R) is planned to be released before SETAC Europe as open source. The tool enables prediction of time-variable exposure concentrations on primary producers, use of models for algae, *Lemna*, and *Myriophyllum* at Tier 2C. It includes a user friendly and interactive R-Shiny interface, as well as routines for plotting and calculation of EP50 values, based on the whole profile or on a moving time window.

In future versions of the tool, we intend to include functionalities for calibration and validation, calculation of confidence intervals using likelihood profiling, and mixture toxicity. The structure of the tool also allows for integration of other TKTD models, such as GUTS and DEB, or even custom models, as the tool develops in capabilities.

To demonstrate the tool, we predict the effects of time-variable exposure concentrations on primary producers (algae, *Lemna*, and *Myriophyllum*) for a set of example substances.

4.04.P-We309 Toxicokinetic-Toxicodynamic Modelling Application (for Lemna sp.) in Regulatory Risk Assessment Scheme: Conceptual Stepwise Approach

***Elena Alonso, PhD**[1], Stefan Reichenberger[2] and Frank Voss[3], (1)knoell Iberia S.L., Spain, (2)knoell France SAS, France, (3)knoell Germany GmbH, Germany*

Toxicokinetic-toxicodynamic (TKTD) models are becoming increasingly reliable in approximating the effects of a chemical in organisms by considering time-varying exposure. Its use for the risk assessment of Plant Protection Products (PPPs) under Regulation 1107/2009 is an acceptable approach according to the regulatory guidelines currently in force. Indeed, in 2018, EFSA published a scientific opinion stating that some of these models, such as the *Lemna* model, can be considered “ready to use”. In addition, EFSA has recently made available a new platform for TKTD modelling of chemicals to apply new methodologies for approaching chemical risk assessment. In practice, however, regulatory acceptance of such models is uncertain. The lack of a reference case or a clear scheme on how these models should be used to support the risk assessment of PPPs hampers the acceptance of these modeling approaches. In this presentation, we describe the stepwise application of a TKTD model for *Lemna* in the context of a risk assessment for a hypothetical herbicide, taking into account the standard ecotoxicological data packages that are required for the European authorization of PPPs. Firstly, we detail the assumptions needed to consider the applicability of these models for covering all sensitive species in the assessment. Secondly, we explicitly describe the minimum data that should be available for validation and calibration of the model and the additional ecotoxicological data that could be used as supplementary information. This is followed by a description of the various steps that need to be considered in order to apply the model, together with the potential challenges associated with each of them. As a result, a conceptual stepwise approach is presented by identifying the ways in which the information provided by the TKTD model can be used within the risk assessment procedure. In conclusion, this work provides a practical example of the applicability of a TKTD model for *Lemna* in the different steps of the risk assessment scheme, highlighting its use to reduce the uncertainty associated to the rest of available ecotoxicological data. This hypothetical case could therefore be seen as a 'blueprint' of how TKTD modelling can be used to support the decision-making process for PPPs.

4.04.P-We310 Using Mechanistic Modelling to Understand Species Sensitivity to Xenobiotics: A Case Study in Birds
*David Heckmann[1], Vanessa Baier[2], Markus Ebeling[3], André Gergs[1], **Thomas G Preuss**[1], Pavel Balazki[2] and Stephan Schaller[2], (1)Bayer AG - Crop Science Division, Germany, (2)esqLABS GmbH, Germany, (3)Environmental Safety, Bayer AG, Germany*
Environmental risk assessment for xenobiotic substances needs to account for effects on a plethora of wild species, but effect data is usually only available for a small number of model species. Since an increase in animal testing is generally not desired and might be unfeasible, mechanistic toxicokinetic toxicodynamic (TKTD) modelling can be used to assess species-specific risk by integrating knowledge on species physiology and/or species-specific *in vitro* data. Nevertheless, differences in species sensitivity are rarely understood mechanistically, making the required datasets for species extrapolation unclear and limiting the confidence in model-based extrapolation approaches. There is thus a need for case studies that mechanistically elucidate differences in species sensitivity.

For the fungicide and nematicide fluopyram, bird reproduction studies resulted in notably lower reproductive effect concentrations in the bobwhite quail (*Colinus virginianus*) compared to the mallard duck (*Anas platyrhynchos*). In order to understand differences in reproductive endpoints between the two avian species, we developed physiologically based kinetic (PBK) models of the compound in chicken, bobwhite quail and mallard duck. These models were based on the previously developed generic models for the three species in the Open-Systems-Pharmacology Suite (OSP Suite with PK-Sim® and MoBi®) and used available chicken *in vivo* data and species-specific *in vitro* data to capture fluopyram toxicokinetics. The predictions of the PBK model for the quail have been previously combined with a dynamic energy budget (DEB) TKTD model of embryo and hatchling growth to successfully predict the endpoints of the quail reproduction study. We now used the duck fluopyram PBK model to simulate the mallard duck reproduction study. The model predicted notably lower concentrations of the benzamide metabolite in eggs of mallard ducks compared to bobwhite quail, suggesting that differences in fluopyram toxicokinetics could explain the observed lower sensitivity of the mallard duck. The model set-up can now be used to mechanistically analyze the physiological factors that underly the differences in species sensitivity to fluopyram, thus providing a case study for the mechanistic elucidation of species sensitivity.

4.04.P-We311 A Dynamic Energy Budget Model of Anuran Larval Development for Environmental Risk Assessment.
*Carlo Romoli[1], Erik B Muller[1], Douglas J. Fort[2], **Benoit Goussen**[1], Lennart Weltje, Prof. Dr.[3], Joachim Ulrich Kleinmann[4] and Pernille Thorbek[5], (1)ibacon GmbH, Germany, (2)Fort Environmental Laboratories, Inc., (3)Agricultural Solutions - Ecotoxicology, BASF SE, Germany, (4)BASF SE, Germany, (5)Apd/EE, BASF plc, United Kingdom*
The metamorphosis of anuran amphibians is a plastic process that can be influenced by environmental conditions and/or toxicant exposure. This is considered to be a strategy adopted to increase the chances of survival. In a favorable environment, development can be slower and a more advantageous larger size at metamorphosis can be attained. In unfavorable environments, the development is accelerated, even at the cost of a smaller size after metamorphosis, in order to escape lethal conditions, such as the drying out of a pond or a high predation pressure.

A mechanistic model that would take into account the plasticity of metamorphosis would aid the assessment of endocrine disruptor compounds (EDC), among other toxicants. Such a model can provide a mean of comparison between the toxic effects on the development, as detected from regulatory amphibian tests (OECD TG 231, 241, 248), and the natural variability of the metamorphosis process due to the environmental factors.

We developed a Dynamic Energy Budget model that includes details of the metamorphosis process, as well as its response to environmental conditions. We focus here on temperature, a well-studied factor that has the double effect of accelerating biological rates, and to be a natural stressor that in several species can accelerate metamorphosis at the expense of final froglet/toadlet size.

We evaluate model performance with published data on the species widely used in laboratory testing (e.g., *Xenopus laevis, Rana temporaria*) and with data on *Dryophytes versicolor*, which were generated specifically for this project.

4.04.P-We312 Comparative Energetics and Toxicant Response of Standard Laboratory Fish Species and European Edge of Field Species – Are We Really Protective?

*Erik B Muller[1], **Benoit Goussen**[1], André Gergs[2], Thomas G Preuss[2] and Yvonne Wolf[3], (1)ibacon GmbH, Germany, (2)Bayer AG - Crop Science Division, Germany, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Standard fish toxicity tests are conducted with a limited number of species chosen for standardization, cost and convenience reasons. The extent to which those laboratory species are representative for other fish species remains a major open question in Environmental Risk Assessment (ERA). We investigate how bioenergetic properties of European edge-of-field (EoF) species compare to those of standard laboratory fish (SLF) species and evaluate the implications those (dis)similarities may have on expected impacts on common endpoints due to toxicant exposure. For this purpose, we use the publicly available Add-my-Pet (AmP) collection of Dynamic Energy Budget (DEB) parameters and derived traits. We identified 10 standard laboratory species and 20 EoF species with widespread distribution in the EU with representation in the AmP collection. Eco-physiological properties of EoF species are generally in line with those of ray-finned fish of similar size, while maintenance demands and assimilation capacities of SLF species tend to be high. This implies that, among other things, that SLF tend to grow relatively fast to their maximum size. In addition, SLF tend to allocate a relatively large fraction of their resources to reproduction. Those properties contribute to their suitability as laboratory species. We explored the implications of toxicant exposure by assuming physiological modes of action (PMoA) on DEB parameters, including those indicative for endocrine disruptive action, of equal strength for all species. The results show a mixed bag, with expected relative changes in endpoint depending on species, PMoA and choice of endpoint, as will be presented in detail during the meeting. This study is an example demonstrating the utility of the AmP collection and associated software applications for ERA purposes.

4.04.P-We313 Comparative Energetics for Environmental Risk Assessment of North American Birds

*Erik B Muller[1], Carlo Romoli[1], **Benoit Goussen**[1], Jonathan D. Maul[2], Richard Brain[2] and Nika Galic[3], (1)ibacon GmbH, Germany, (2)Syngenta Crop Protection, (3)Syngenta AG, Switzerland*

A major challenge in Environmental Risk Assessment (ERA) is to evaluate the implications of data from standard toxicity tests with a limited number of species in the context of species diversity. The question, then, is if and how we can combine the extensive ecotoxicological knowledge we have for a limited number of species with the little we know about the majority of species, including vulnerable and endangered species. Additionally, identifying focal species and species groups with field relevance is further challenged by data scarcity, which also hampers the development of population models for risk assessment. To address this challenge, we compare eco-physiological traits across avian species, specifically of test species with species of ERA interest and terrestrial Holarctic birds as a whole. These traits are drawn from the Add-my-Pet (AmP) collection, a data base of Dynamic Energy Budget (DEB) parameters and derived trait values of more than 4,000 animals, including 446 terrestrial Holarctic birds and 72 species of ERA interest. Reproductive abilities of standard lab species were high compared to other birds of similar size. However, traits of other terrestrial-focused species and waterfowl typically were in agreement with other birds of similar size, suggesting the important role strain selection in and experimental design of standard toxicity tests have on data collected for DEB model parameterization. Multidimensional scaling analysis of parameter and trait values of Holarctic birds in the AmP collection shows clustering of major taxonomic avian groups. Clustering of species of ERA interest grouped according to their feeding guild during the breeding season appeared weak, with most of the clustering reflecting taxonomic identity rather than guild membership. This study is an example demonstrating the utility of the AmP collection and associated software applications for ERA purposes.

4.04.P-We314 DEB-TKTD analysis of avian reproduction studies: overview of two case studies

*Marie Trijau[1], **Benoit Goussen**[2], Nika Galic[3] and André Gergs[4], (1)IBACON GmbH, Germany, (2)ibacon GmbH, Germany, (3)Syngenta AG, Switzerland, (4)Bayer AG - Crop Science Division, Germany*

Mechanistic modelling to analyse the effect of chronic exposure of chemicals to birds is rapidly gaining interest in the environmental risk assessment field. The new EFSA Guidance document on risk assessment for birds and mammal includes the possibility to use toxicokinetic-toxicodynamic (TKTD) models. In particular, the use of a TKTD module in combination with a physiological model like the Dynamic Energy Budget (DEB) model is recommended. However, examples of case studies using DEB-TKTD models to analyse toxicity test data for birds are currently lacking. Here we present two recently developed DEB-TKTD models to analyse avian reproduction studies. While both studies implemented their own adaptation of the standard DEB model to the specificities of bird physiology and avian reproduction studies, they differ by their predicted endpoints and their level of complexity. In the first study, food ingestion data as model input was used in order to account for the observed up-regulation of feeding during egg-laying. This also allows disentangling and quantifying possible behavioural effects from direct toxic action of the pesticides. The second study offers a deeper mechanistic approach of the feeding upregulation phenomenon and also predicts effects on offspring growth but does not include behavioural responses yet. The two models are compared, stressing their strengths but also the possible model improvements needed to enhance their use and their acceptability in environmental risk assessment.

4.04.P-We315 Feeding inhibition : starvation : chronic mortality – a dynamic energy budget approach

***André Gergs**, Bayer AG - Crop Science Division, Germany*

The risk assessment of pesticides makes use of acute (short-term) and chronic (longer-term) toxicity tests. The aquatic assessment typically focusses on mortality for acute and sublethal endpoints for chronic toxicity. Sublethal endpoints include growth, development, and reproduction, but also chronic mortality may play a major role. Toxicokinetic-toxicodynamic (TK-TD) models, such as the General Unified Threshold model of Survival (GUTS), allow the extrapolation of endpoints across different time scales, such as acute and chronic. In cases where underlying toxicity mechanisms are different for acute and chronic effects, the extrapolation potential of GUTS might, however, be limited. One example is prolonged starvation upon chemically induced feeding inhibition which may result in chronic mortality: In this study, a short-term feeding inhibition test with the non-biting midge *Chironomus riparius* and imidacloprid was conducted to quantify sublethal effects. I applied a Dynamic Energy Budget based TK-TD model to analyze the feeding inhibition test and simulate subsequent starvation to explain observed chronic effects.

4.04.P-We316 To DEB or not to DEB – Earthworm Modelling using Standard Ecotox Data

Joachim Ulrich Kleinmann[1]*, Trung-Hieu Mai*[1]*, Frank Staab*[1]*, Sonja Braaker*[1]*, Matthias Bergtold*[1] *and Pernille Thorbek*[2]*, (1)BASF SE, Germany, (2)Apd/EE, BASF plc, United Kingdom*

The risk assessment of earthworms considers in the lower tier only exposure in the top 5 cm of the soil. However, in natural conditions exposure dramatically varies in space and time which leads to a much more complex exposure pattern. Therefore, modelling options which help to understand how exposure leads to effects are urgently needed.

In the presented case-study we evaluated the data needs of two existing modelling approaches (Dynamic Energy Budget, DEB modelling and Physiological Energy Budget, PEB modelling) for parameterization and validation.

Toxic effects in the widely used DEB models can only be parameterized if data on the development of effects over time is available. Since sampling in earthworm studies is destructive, the production of such data is very labor- and cost expensive and not part of the standard toxicity dataset of earthworms. This means, such a standard toxicity dataset is not sufficient to parameterize DEB models. In the alternative PEB model, energy is not distributed in parallel to somatic and reproductive processes (kappa rule) as in the DEB model but sequentially to maintenance, reproduction, growth and reserve. Therefore, this approach saves several parameters and toxic effects are reflected by a dose-response model.

We were able to parameterize the PEB model for the standard earthworm species in laboratory studies *Eisenia fetida* for three example substances using the control dataset and the toxicity model using the treatment data of the corresponding study. To validate the models, we used product studies (single active and mixture products) of the same active ingredient. In mixture products, the model was able to distribute the relative effects to the two active ingredients. To increase the confidence in the models, also validations against (semi-)field data could be done.

For the presented substances, PEB modelling worked very well without additional tailor-made laboratory studies. We believe that if a PEB model can be calibrated and validated, the model should be acceptable for the risk assessment of the corresponding substance. Since for this model also versions for *Aporrectodea caliginosa* and *Lumbricus terrestris* are available, we think that it can be a useful lower-tier modelling option to refine the earthworm risk assessment even when only standard toxicity data is available.

If validation is not possible for a substance, additional data can be created for DEB modelling as a higher modelling tier.

4.04.P-We317 A Conceptual Approach to Determining Normal Operating Ranges: Outcomes from a Multi-Stakeholder Workshop

Nika Galic[1]*, Thomas G Preuss*[2] *and Pernille Thorbek*[3]*, (1)Syngenta AG, Switzerland, (2)Bayer AG - Crop Science Division, Germany, (3)Apd/EE, BASF plc, United Kingdom*

Normal operating ranges (NOR) are defined as any natural variability in a system property, including population density or abundance. There is an increasing regulatory focus on determining NORs as both a mean to facilitate the design of field studies that can reliably demonstrate a certain effect level, and for consideration in population modelling. However, there are currently no approaches that have been sufficiently developed and tested for the purposes of NOR determinations. Possible approaches include mechanistic models as well as analyses of field data, but they both have advantages and disadvantages. For instance, field data are often incomplete, cover only a subset of environmental contexts, and of limited duration and spatial extent. Mechanistic models can provide predictions across relevant temporal and spatial scales and extrapolate across relevant environmental context. However, whether they are fit for the purpose of NOR determination is not always clear as they are not commonly developed to predict variability realistically. Rather, they aim to predict typical, or worst-case, responses and system properties.

To address this gap and propose a conceptual approach for quantifying NORs for the purposes of ecological risk assessments, CropLife Europe organized a multi-stakeholder workshop. Experts with background in data analysis, mechanistic modelling, and risk assessment were brought together in a 2-day workshop. The workshop consisted of presentations and discussions on the use of models and data – in isolation and in combination – and the advantages and limitations of each were considered. Workshop participants proposed an approach on how current knowledge and state-of-the-art methods can be leveraged and further developed to establish normal operating ranges of focal species and systems that are both comprehensive and operational.

4.04.P-We318 Determining Normal Operating Ranges from Field Data: A Wood Mouse Case Study

Nika Galic[1]*, Jochen P. Zubrod*[2] *and Steven Kragten*[3]*, (1)Syngenta AG, Switzerland, (2)Zubrod Environmental Data Science, Germany, (3)Syngenta Agro GmbH, Germany*

Normal operating ranges (NOR) are defined as any natural variability in a system property, such as population density or abundance. There is an increasing regulatory focus on determining NORs as both a mean to facilitate the design of field studies that can reliably demonstrate a certain effect level, and for consideration in population modelling. Recently, mechanistic effect models have been used to determine NORs, but it is not yet clear if and under which conditions they are fit for this purpose. A complementary approach is to derive NORs based on available data to better understand this variability in the field. Here we present the results of an analysis focusing on a species important for mammal risk assessment - the wood mouse, *Apodemus sylvaticus*. For the analysis, data published in peer-reviewed literature were used in addition to data compiled from generic field studies conducted by agrochemical companies. Data contained information on mice densities in different environmental contexts, including agricultural and more natural habitats. Data were analysed with generalized linear and generalized additive models, as well as with machine learning approaches. Results were interpreted as variability in abundance or densities across relevant habitats and environmental contexts, e.g., NOR of densities across hedge-dominated margins in cereal fields in summer months. Data gaps and challenges were identified. Possible uses and applications of these outcomes for population modelling are discussed, as well as suggestions on how to better integrate existing data with modelling approaches for a comprehensive analysis of NORs of non-target populations in the field.

4.04.P-We319 Ecological modelling in support of sediment remediation: impact of nature-based remediation on Hyalella azteca populations

Karel Vlaeminck[1]*, Karel Viaene*[1]*, Jaap Postma*[2] *and Marnix Vangheluwe*[1]*, (1)ARCHE Consulting, Belgium, (2)Ecofide, Netherlands*

The EU-LIFE project NARMENA (Nature-based Remediation of Metal pollutants in Nature Areas) aims to evaluate the efficacy of Nature-Based Remediation (NBR) techniques in mitigating metal pollution in soil and sediment within select nature reserves in Flanders, focusing on three target sites. A crucial component of this project involves the development of an ecological modelling tool to assess the positive impact of NBR techniques on the ecological risk within the local area in comparison with alternatives. The ecological modelling aspect is centred on three indicator species in the water column and sediment. This poster presentation focuses on the sediment-dwelling amphipod, *Hyalella azteca*, and its exposure to heavy metals, including cadmium (Cd), arsenic (As), and chromium (Cr).

To evaluate the effects of heavy metal pollution on the amphipod, we used a Dynamic Energy Budget (DEB) based approach. Toxic effects were incorporated based on data from standard laboratory chronic toxicity experiments for Cd, As, and Cr. Additionally, the influence of physicochemical parameters affecting metal bioavailability was considered. Furthermore, we extrapolated these effects to the population level using an individual-based modelling (IBM) approach, with population abundance and biomass as the key endpoints for risk assessment. Models were applied to monitor the effectiveness of non-invasive remediation techniques in three target rivers in Flanders: Grote Laak, Grote Calie, and Winterbeek.

NBR techniques offer promising alternatives to conventional and more disruptive soil remediation methods. This study assessed the impact of different remediation approaches, differentiating between scenarios of no action, conventional techniques (e.g., excavation), and NBR techniques (e.g., phytoremediation and artificial wetlands). Our findings underscore the value of combining laboratory data, in-field measurements, and mechanistic effect modelling to comprehensively evaluate the impact of mitigation strategies in real-world environmental settings. The study will provide insights into the potential of NBR techniques to effectively reduce metal pollution in Flanders' nature reserves while preserving local ecosystems.

4.04.P-We320 Evaluation of Two Different Individual-Based Models to Simulate the Population Dynamics of Daphnia Magna in a Long-Term Laboratory Experiment

Natalie Carmen Dallmann*, Monika Hammers-Wirtz, Josef Koch and Tido Strauss, gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany*

In order to generate a corresponding data set that reflects also the fluctuating pattern after the first exponential population growth period, we conducted a 120-day *D. magna* population test under stable temperature and food conditions with two different initial populations (only few neonates versus high abundant and mixed-age start density). This four-month experiment with continuous algae feeding was followed by a starvation phase to determine the time that daphnids can survive by using their energy reserves.

Next, we evaluated the performance of two different types of individual-based models (IBM) for *D. magna* using this long-term data set: The empirical IDamP model, and a new generic implementation of an IBM based on dynamic energy budget theory, termed DEBgen. Both IBMs were embedded in the biogeochemical lake model StoLaM using the same interfaces to environmental and food modules to ensure comparable test conditions.

The comparative model test focused on i) the amplitudes and periodicity of total abundance and age structure under different starting conditions, ii) the synchronisation of reproductive cycles under given feeding regimes, and iii) the representation of survival time under starvation conditions.

In this study, we deliberately use a modular modelling approach in which models can be analysed as modules in an overarching model, allowing comparisons of relatively simple models under more complex and realistic conditions.

4.04.P-We321 Simulating field-realistic effects to Chironomus riparius populations from exposure to insecticides: the role of density dependence and food availability

Tido Strauss[1]*, Jana Gerhard*[1]*, Josef Koch*[1]*, Maxime Vaugeois*[2] *and Nika Galic*[3]*, (1)Research Institute gaiac, Germany, (2)Syngenta Crop Protection, LLC, (3)Syngenta AG, Switzerland*

Population models combined with toxicokinetic-toxicodynamic (TKTD) effect models are powerful tools for predicting population dynamics of species under different and field-realistic environmental scenarios. As they can consider natural and anthropogenic stressors, they are increasingly used in ecological risk assessment. Such models should include important regulating processes for population dynamics such as density-dependent effects through intraspecific competition for food or cannibalism, which in turn depend strongly on ecological scenarios.

To study the role of density-dependence and food availability in the sensitivity of *Chironomus* populations to insecticides, we used a model for *Chironomus riparius* which combines an individual-based model (IBM), based on physiological dynamic energy budget (DEB) modules and complemented by TKTD effect models for lethal and sublethal processes, driven by dynamic environmental conditions. The core of the model is an individual DEB-TKTD model that has been parametrised for a systemic neonicotinoid insecticide using laboratory tests at different temperatures as well as experimental results on density dependence.

In a comprehensive experimental laboratory study, we found that *Chironomus riparius* experiences a food-dependent development rate, but also a density-dependent mortality rate of more than 60 % at high larval densities, which is probably due to cannibalism. In principle, at high population densities, lethal effects from exposure to the insecticide can be partially compensated by a reduction in density-dependent mortality. Conversely, populations with a low larval density can be assumed to be more sensitive to insecticides. In this simulation study, we analyse and discuss the effects of varying larval densities and food conditions on the sensitivity of populations of *Chironomus riparius* exposed to different insecticide levels under field-realistic conditions.

4.04.P-We322 Challenges for estimating exposure experienced by moving organisms: a movement modelling concept

Pernille Thorbek[1]*, Joachim Ulrich Kleinmann*[2]*, Luke C Evans Dr*[3] *and Thomas G Preuss*[4]*, (1)Apd/EE, BASF plc, United Kingdom, (2)BASF SE, Germany, (3)University of Reading, United Kingdom, (4)Bayer AG - Crop Science Division, Germany*

Ecological risk assessments of plant protection products assess both exposure and effects. Much effort has gone into improving the modelling of exposure and effects. However, the location of the individual relative to the area of application largely controls the exposure of the individual, especially in terrestrial habitats, and movement controls location. For many species movement means that exposure is not static, but highly heterogeneous over time. While recommendations for good modelling practice have been issued for TKTD models, population models, and mechanistic effect models in general, the development of movement modules is often ad hoc. Here, we present a review of movement in population models used for ERA and summarise a Workshop ‘Towards unified principles for movement modelling’ held at ECEM2023, where a general framework for movement modelling was discussed and outlined.

The literature review showed that seven factors (Direction, Speed, Motivation, Energetics, Memory, Response to landscape features, Response to other organisms) cover all movement processes included in the models. However, not all models included all factors and there was a great deal of diversity in how complex movement was represented. The models ranged from no movement to correlated random walks and further to sophisticated models including responses to landscape elements and other organisms. Overall, models for terrestrial species were more complex than aquatic species and vertebrate models were more complex than invertebrates. This diversity to some extent reflects the ecology of the species modelled, and the role movement plays in exposure assessment. Nevertheless, we found that justification for the complexity (or lack thereof) was often lacking or sparse.

The workshop at ECEM2023 was attended by ecological modellers with a broad range of expertise. The workshop took the form of a brainstorm followed by a discussion about the broad outline of a framework. Based on the discussions we formulated a preliminary universal framework for movement modelling, which will be presented. A universal movement modelling framework will help the development and assessment of models. It is not the intention that all movement models must include all factors, but rather that it will help the modellers make informed decisions about what to include and what to exclude. When factors are excluded, justification should be given for why the factors are not considered to be important.

4.04.P-We323 Quantification of Risk from Pesticide Exposure in Landscape-scale Population Models

Bas Buddendorf[1]*, Louise Wipfler*[1]*, Wim Beltman*[1]*, Maarten Braakhekke*[2]*, Héloïse Thouément*[1]*, Annika Mangold-Döring*[3]*, Sascha Bub*[4]*, André Gergs*[5]*, Thorsten Schad*[5] *and Hans Baveco*[6]*, (1)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands, (2)Environmental Risk Assessment, Wageningen Environmental Research (WUR), Netherlands, (3)Environmental Risk Assessment team, Wageningen Environmental Research (WUR), Netherlands, (4)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (5)Bayer AG - Crop Science Division, Germany,*

(6)Wageningen Environmental Research (WUR), Netherlands
The risk that pesticide exposure on landscape scale poses to organisms can be assessed using spatially-explicit models of the dynamics of the species in the landscape. In a landscape-level approach protection goals relevant to the spatial population need to be defined, as well as the endpoints and specific metrics required to evaluate whether goals are reached. In this presentation we explore such endpoints and metrics, specific to the landscape scale.

Simulations were run with an individual-based population model for aquatic macro-invertebrate, Asellus aquaticus. The model contained Dynamic Energy Budget and toxico-kinetics toxico-dynamics (GUTS) submodels for individual growth and development, and for impact of the pesticide on daily survival. Simulated exposure was obtained from the Rummen catchment case-study.

Elements of the modelling and risk assessment approach include 1) a meta-population represention of the spatial population structure, assuming that each reach in the catchment potentially supports a local population, 2) ecological threshold approach, focussing on population dynamics over multiple years with exposure, 3) a margin-of-safety approach, evaluating effects under a range of concentration multiplication factors.

Impact can be quantified at different spatial and/or ecological aggregation levels, and analysed in non-spatial, spatially-implicit or spatially-explicit ways. We test metrics of the total (meta)population and the number of non-extinct local populations. In more spatially explicit metrics catchment branches were defined and population characteristics per branch were analysed. The structure of the functional ecological network was analysed defining groups of functionally connected and persisting local populations.

Total metapopulation size and average number of occupied (non-extinct) local populations are easily observed metrics. Maps of ecological networks indicate the areas where the catchment populations are least threatened. Maps of average local (reach) population characteristics, aggregated into branches, provide insight into how local populations perform.

In the presentation, the pros and cons of approaches to aggregation will be discussed.

4.04.P-We324 Exposure and Effect Modelling for Aquatic Primary Producers at Catchment-scale
Bas Buddendorf[1]*, Thorsten Schad*[2]*, Sascha Bub*[3]*, Héloïse Thouément*[1]*, Maarten Braakhekke*[4]*, Wim Beltman*[1]*, Louise Wipfler*[1]*, Johannes Witt*[2]*, André Gergs*[2] *and Robin Sur*[5]*, (1)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands, (2)Bayer AG - Crop Science Division, Germany, (3)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (4)Environmental Risk Assessment, Wageningen Environmental Research (WUR), Netherlands, (5)Environmental Safety, Bayer AG - Crop Science Division, Germany*
Risk assessment for aquatic primary producers due to pesticide entries into surface water bodies is conducted in a tiered approach (EFSA Guidance on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters, 2013). At higher-tiers, more realistic exposure modelling is combined with effect models using real-world environmental and agricultural data. This level of realism allows to quantify effects and their related spatial and temporal extents as required by the definition of Specific Protection Goals.

A catchment-scale model has been developed for this purpose (https://github.com/xlandscape/xAquaticRisk). The underlying xAquatic framework has a modular design. When used in a regulatory risk context, components (i.e., modules) are typically built from models which are accepted in the regulatory scientific environment. We employed components already existing in xAquatic on pesticide use, drift exposure and aquatic efate together with newly developed ones on drainage and runoff exposure, to model herbicide entries into streams and their transport and fate in the stream network. Components to model effects of aquatic primary producers (for algae, Lemna and Myriophyllum) were integrated into the catchment-scale model xAquatic. To the user, xAquatic appears as one model with one parameterisation. The spatiotemporally explicit outcome on exposure and effects is stored in a multidimensional storage and can be analysed using common tools (e.g., R, Python, Knime). A set of standard tools on data analysis and reporting are being developed (Jupyter notebooks) which provide modelling endpoints that can be directly compared to defined Specific Protection Goals for aquatic primary producers.

The xAquatic model was applied to an agricultural catchment 'Grote Kemmelbeek' in Belgium. This catchment was subject to an intense monitoring campaign on herbicide residues in the stream network. The connection of modelling and monitoring is expected to provide new insights into agricultural (eco)system behaviour with respect to pesticide use induced exposure and effect levels to primary producers and their spatiotemporal extents, as well as the importance of risk mitigation effects.

4.04.P-We325 Consistent wildlife modelling across Tiers of the European environmental risk assessment
Dirk Nickisch, Alexander Singer, ***Thomas Martin*** *and Jan-Dieter Ludwigs, RIFCON GmbH, Germany*
According to new EFSA wildlife guidance for environmental risk assessments (ERA) of pesticides, the toxicological effects of a substance on the wild rabbit (*Oryctolagus cuniculus*) must be considered as standard scenario. Following the guidance, toxicodynamic-toxicokinetic (TKTD) models have been proposed as a refinement at Tier 2 of the effect assessment and as highest tier, population modelling is considered a possible refinement option.

A population model should be consistent with the modelling of TKTD-processes at Tier 2. Consistency can be achieved by incorporating the effects on individual reproduction predicted by the TKTD model into the population model to assess potential population level effects or recovery.

The wild rabbit has a great reproductive potential, and several litters per female and year are common. On the other hand, mortality within the first year can be as high as 90%. Therefore, modelling the effects on growth and reproduction using a DEB-TKTD for many individuals could provide information on whether high reproduction could buffer toxicological effects or exacerbate the effects, e.g. by carryover toxicity.

Our DEB-TKTD-IBM for the wild rabbit can be used as a first step of the higher tier effect assessment of ERAs. It is integrated in a modular software environment, which allows modelling the individual's life cycle. The model follows assumptions and outcomes of lower Tier risk assessment, such as foraging patterns. This ensures consistence among Tiers.

Commonly, population models for application at higher tier consider different environmental and behavioural complexities and their interactions, such as resulting from animal movement and dispersal. Constructing such models requires substantial effort. Model development usually takes years. Further, the complexity often impedes consistency with lower Tier assessments. In contrast, our spatially implicit modelling approach is readily available and based on the underlying risk assessment Tiers. If necessary, its modular approach even allows step-wise additions of additional processes.

4.04.P-We326 Mapping the Watershed: A Landscape Modeling Approach for Higher Tier Risk Assessment of Lemna in Surface Waters

*Dirk Nickisch[1], Mohammad Hatamjafari[2], Torben Wittwer[1], **Oliver Jakoby**[1], Joachim Ulrich Kleinmann[2], Sebastian Gebler[2] and Sebastian Multsch[2], (1)RIFCON GmbH, Germany, (2)BASF SE, Germany*

Landscape-scale modelling of hydrology, chemical fate and exposure and resulting ecological effects represent the highest tier to refine the surface water risk assessment for plant protection products (PPP) as mentioned in the Aquatic Guidance Document. Based on local environmental and agronomical information, it can support stewardship activities and the contextualisation of the increasing abundance of public monitoring data. However, regulatory guidance on model or data selection is not in place and further research is needed to evaluate applicability and reliability in a regulatory context.

The present study aims to provide an additional environmental catchment scenario for usage with the recently published open-source model xAquaticRisk (https://github.com/xlandscape/xAquaticRisk). The modular model integrates other baseline catchment-scale scenarios and several accepted environmental fate and ecological effect models to run landscape-scale modelling experiments. For the present study, a new scenario was set up for a meso-scale agricultural catchment (54 km²) in North Rhine-Westphalia, Germany. The catchment is characterized by a high fraction of arable areas (>50%) and strong variability in rainfall (500-1000mm) causing very heterogenous hydrological conditions in space and time. This scenario considers relevant land use and land cover information and a representative hydrological characterisation of the area.

The study comprises a set of PPP application experiments (herbicide applications typical for crop rotations including alfalfa, cereals and oilseed rape to investigate the landscape-scale impacts on *Lemna sp.* using a toxicokinetic–toxicodynamic (TKTD) model with an extensive set of existing surface water scenarios as external forcings to drive the model. The model results are used to predict the EPx, effect profile multiplier, using the 7-days moving time window approach to assess the margin of safety of each of the surface water scenarios.

Overall, the results highlight the possibilities and limitations of linking exposure and effect modelling at the landscape level in a regulatory context by expanding the existing modular open-source model xAquaticRisk.

4.04.P-We327 Predicting Extinctions in Food Webs

***Thomas Malpas**[1], Lorraine Maltby[2], Claudia Rivetti[3] and Andrea Gredelj[4], (1)University of Sheffield, United Kingdom, (2)School of Biosciences, University of Sheffield, United Kingdom, (3)Unilever - Safety and Environmental Assurance Centre (SEAC), United Kingdom, (4)Unilever, United Kingdom*

Risk assessors generally rely on extrapolation methods to extend toxicity predictions from a handful of studies on standard test organisms to long-term effects for entire ecosystems. However, the question remains as to whether endpoints used in these systems translate into broader ecosystem-level scenarios. A commonly-used endpoint for ecosystems is the extinction of the species within.

Previous research on predicting species extinctions in food webs has utilised either the food web's properties or information on species dynamics (e.g., changes in biomass, early warning signals) to assess extinction risk. However, it's unknown how these properties compare to each other, and the impact on their relative performance of how far in advance extinction is being predicted. This study compares the predictive performance of biomass metrics, early warning signals and network properties within the same time series using a multi-species biomass dynamics model and a series of generated food webs subjected to simulated stress.

Extinctions were predicted from data cut-off increasingly far away from the extinction event to determine how far in advance reliable predictions could be made by different predictors, and how their relative influence changed. Our findings suggest that while biomass trends initially dominated predictions, network properties and early warning signals became more influential predictors as the time between the last point of observation and the extinction event increased.

4.05 Emerging Remediation Technologies for Contaminated Environmental Matrices

4.05.T-01 Evaluation of Intensified Constructed Wetlands for the Persistent, Mobile and Toxic Compounds Removal From Groundwater and Wastewater

Alicia Cano López[1]*, Monica Escola Casas*[2]*, Jessica Subirats Medina*[3] *and Victor Matamoros*[4]*, (1)Institute of Environmental Assessment and Water Research - Spanish National Research Council (IDAEA-CSIC), Barcelona, Spain, (2)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Department of Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (4)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

The occurrence of compounds such as per- and polyfluoroalkylated substances (PFAS) and other industrial compounds in surface and groundwater (GW) bodies is a matter of concern due to their persistence, mobility and toxicity (PMT). Intensified constructed wetlands (CWs) present promising solutions for addressing PMT pollutants. However, there is scarce data on using CWs, using materials like coke, to treat polluted water. This study aims to evaluate the efficiency of utilizing coke-based intensified CWs, incorporating vegetation for the removals of six PMTs and to seek to elucidate the mechanisms behind these removals.

In order to achieve it, twelve vertical columns under down-flow conditions were designed. Each column was filled with coke of different granulometric sizes (6 columns with particle size of 5-2mm and 3 columns with 2-0.5mm) or washed sand (2mm Ø). 9 of the 12 columns were planted with *Cyperus alternifolius*. All columns were fed with real GW or secondary treated wastewater (WW) at a flow of 40 and 70mm/d. The system was operated spiking at 5µg/L (benzotriazoles and some pharmaceuticals) and 10µg/L (ultra-short and short PFAS). During the operational time, every week inlet and outlet water samples from each column were collected in order to analyse physico-chemical properties, general quality parameters, target compounds removals and their transformation-by-products with a UHPLC-HRMS. After the operational time, an adsorption experiment and 16S rRNA gene sequence were produced in order to obtain a general perspective of the total removal process.

In comparing sand with coke based CWs, coke significantly improved PMTs removal, with 89% in contrast with 50% with sand. Larger coke granules increased efficiency, hitting 89% removal, compared to 48% for 0.5-2mm granules. Vegetation boosted PMTs reduction from 34% to 89%. Coke's adsorption revealed that was less than 1% and differed on the water matrix. Columns with larger coke granules increased DNA quantification (13.7ng/µL/g) improving pollutant removal. Moreover, microbial 16S rRNA preliminary results showed that Gammaproteobacteria and Micrococcaceae are the predominant classes exclusively found in the most efficient treatment.

These results suggest that an intensified coke-based constructed wetland could be an effective natural solution to eliminate PMTs from GW and WW. These results highlight the importance of understanding the pollutant removal process to be able to completely remove them.

4.05.T-02 Waste biochar sorbents as sustainable alternatives for PFAS soil stabilization

Erlend Sørmo[1,2]*, Hans Peter Arp*[3]*, Katinka Muri Krahn*[1]*, Clara B. M. Lade*[4] *and Gerard Cornelissen*[1]*, (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Mina, Norwegian University of Life Sciences (NMBU), Norway, (3)Norwegian University of Science & Technology (NTNU), Norway, (4)Norwegian University of Life Sciences (NMBU), Norway*

Biochars produced from excess biomass could be used as sorbents to stabilize per and polyfluorinated alkylsubstances (PFAS) in soils, to reduce their leachable, bioavailable and bioaccessible fractions. Fossil based activated carbons generally have a better effect, but the use of biochars brings environmental benefits. Biochar properties vary greatly based on pyrolysis conditions and feedstocks used, hence it was necessary to identify key properties that determine sorbent performance for PFAS. To this end, clean wood chips (CWC), waste timber (WT) and digested (DSS-1, DSS-2) and raw (DWSS) sewage sludges were pyrolyzed at 700 ºC in an industrially relevant Biogreen unit and WT was, furthermore, activated with with CO_2 at 900 ºC in a Pyreka unit. We found that nonactivated wood biochar (CWC: log K_F 4.44 – 5.22 (µg kg^{-1}) (µg $L^{-1})^{-nF}$) was in fact inferior to the sludge biochars (DSS-1 and DWSS: Log KF 3.30-5.61 (µg kg^{-1}) (µg $L^{-1})^{-nF}$), in sorbing perfluorinated carboxylic acids (PFCAs) in batch shaking tests, due to a well developed mesoporosity (pores >1.5 nm) suited for accomodating the large PFCA molecules. Activation enhanced this system of mesopores in WT biochar, in addition to the amount of condensed aromatic carbon, which is likely responsible for hydrophobic interactions between long chain (>6xCF) PFAS and biochar surfaces, thus making excellent sorbents to reduce leaching of several legacy PFAS from field contaminated soil by up to 99% in batch shaking tests. Ex situ column tests were further used to demonstrate that although the affinity of the non activated wood biochars (CWC and WT) were high for PFAS, their capacity, as measured through available mesopores, were not sufficient. The sludge biochars (DSS-1, DSS-2, and DWSS) and activated biochar (aWT), however, efficiently reduced PFOS leaching by >90% at doses of only 1%. Meanwhile, as waste biochars do not necessarily retain short chain

PFAS sufficiently, future work should be focused on biochar modifications or sequential treatments that increase the sorption of said compounds. Nevertheless, this work has demonstrated the potential for circular economy value chain creation in waste handling and soil remediation.

4.05.T-03 Scale-up of a photocatalytic reactor for the degradation of pesticides at source

Indira Menezes, *Carlos J. Pestana, Bruce Petrie and Linda A. Lawton, Robert Gordon University, United Kingdom*

Heterogenous photocatalysis is a water treatment technology that has been widely explored in research. The scale-up of this technology, however, has been a challenge due to several reasons. First, nano powder catalysts are usually applied during photocatalysis at bench scale, therefore, it is very difficult to separate the powdered catalyst from water after the treatment is complete. Another problem to overcome is the high cost associated with the illumination of catalysts, which is usually achieved by ultraviolet irradiation (UV). Both acquisition and energy consumption of UV irradiation increase the costs of photocatalysis application. The aim of this study is to develop an economical photocatalytic treatment unit for the removal of pesticides at source from aquatic environments.

Porous beads made of recycled glass were used as an immobilization matrix for coating with graphitic carbon nitride (g-C_3N_4) as the catalyst. The coated beads could be removed from the water and reused after each treatment cycle. The catalyst was activated using ultraviolet light with a wavelength of 365 nm (UV-A) in the format of light emitting diodes (LEDs), which is an economical alternative for UV irradiation with a long life-span. After the selection of catalyst and light source, UV-A LEDs and g-C_3N_4 coated beads were tested on the photocatalytic removal of a mixture with nine pesticides (1 mg L^{-1} each in artificial fresh water; acetamiprid, clothianidin, imidacloprid, thiacloprid, thiamethoxam, diuron, atrazine, dimethoate and 2,4-dichlorophenoxyacetic acid). Pesticide concentration was determined by high-performance liquid chromatography coupled to photo diode array detector (HPLC-PDA).

All pesticides were completely removed within 24 hours of treatment (e.g., diuron with rate constant k=0.021 min^{-1} and 2,4-dichlorophenoxyacetic acid k=0.011 min^{-1}), except from acetamiprid which was completely removed within 48 hours (rate constant k=0.0004 min^{-1}). Photocatalysis based on g-C_3N_4 coated beads illuminated by UV-A 365 nm LED irradiation was demonstrated to be a potential approach in the removal of pesticides from aquatic environments. Other factors also need to be taken into consideration for the scale-up of this technology, such as the system waterproofing. All materials used need to be made of stainless steel to avoid corrosion. Also, epoxy resins with high resistance to water pressure and other water components should be used to seal electrical components.

4.05.T-04 Selective Degradation of Organic Micropollutants and Organic Metabolites in Source-Separated Human Urine using Sulphate-radical-based Advanced Oxidation Process

Ali Peter Mehaidli, *Swedish University of Agricultural Sciences (SLU), Sweden*

Human urine contains plant-essential nutrients like urea and phosphate which can be recycled back to farmland as crop fertilizer. However, food industry actors are concerned about organic micropollutants (OMPs) like pharmaceutical drugs which are also excreted in human urine, as they could potentially pose a health risk to consumers of food grown using urine-based fertilizers. This study aimed at addressing this gap by developing an Advanced Oxidation Process (AOP) that selectively oxidized >30 different OMPs in real human urine without loss on plant-essential nutrients like urea. The fate of >30 OMPs, >200 organic metabolites, and plant-essential nutrients in urine after oxidative treatment was determined.

The first set of experiments evaluated the effect of process parameters (temperature, dose of sodium persulfate, type of urine and time) on the activation of persulfate as well as the fate of COD, urea, total ammonia nitrogen, total nitrogen, and chloride in urine. In addition, targeted quantitative metabolomics were conducted to analyze the fate of >200 organic metabolites in urine by using a combination of direct injection mass spectrometry with a reverse-phase LC-MS/MS custom assay and an ABSciex 5500 QTrap mass spectrometer. The second set of experiments aimed to evaluate the fate of >30 OMPs in urine during sulfate-radical-based AOP, and analyzed using ultra-high pressure liquid chromatography tandem mass spectrometry.

The experiments resulted in an AOP where 85% of the sodium persulfate was activated, COD removal of 23%, urea recovery of 90%, total nitrogen recovery of 95% and Cl^- loss of 3%. Additionally, metabolomic analysis of treated urine showed that on average, 73% of the organic metabolites were degraded by the sulphate-radical based AOP. Moreover, the average ΣOMP degradation in urine by the AOP was 75%. If only the OMPs listed in the new EU water directive are considered, then average ΣOMP degradation was 81%.

Overall, this study demonstrated the feasibility of heat-activated sodium persulfate-based AOP to selectively and preferrentially oxidise OMPs and organic metabolities over plant-essential nutrients in human urine. It is evident that sulphate-radical-based AOP favors oxidation of OMPs > organic metabolites > macronutrients. The results also show that treating human urine using the developed AOP degrades 81% of the OMPs and thus meets the criteria listed in the new EU water directive on the safe reuse of wastewater in society.

4.05.T-05 Mesocosms and multiparametric approaches for the environmental assessment of technologies aiming to reduce the impact of mining activities

Julio Lopez-Doval[1], *Meritxell Abril*[2], *Lluís Bertrans Tubau*[2], *Lidia Vendrell Puigmitjà*[2], *Sergio Martínez-Campos*[2], *Laia Llenas*[2] *and Lorenzo Proia*[2], *(1)University of Vic - Central University of Catalonia (UVic-UCC), Spain, (2)BETA Technological Center, University of Vic-Central University of Catalonia (UVic-UCC), Spain*
Mining industry is a generator of waste in the EU and may cause considerable impacts on aquatic ecosystems. One of these impacts are the release of metals and the acid mine drainage that flows into aquatic ecosystems. Several technologies have been developed to mitigate the impact of mining but there is not a standardized method to assess whether these technologies suppose a significant improvement in water and environmental quality. To cover this gap, we have developed an easy, reliable and cost-effective mesocosms approach based on the analysis of functional and structural parameters in freshwater biofilms.

Our approach consists in artificial streams with 5L of capacity and controlled flow. Experiments are performed in a chamber with control temperature and light. Natural biofilm inoculum for experiments is collected in reference pristine rivers to growth and develop biofilm communities in sandblasted glass substratum. Experimental treatments usually consist in a control condition, raw effluents of the mine and treated effluents and exposure period last for 2 weeks. Biological responses observed when exposing communities to their respective untreated and treated mine effluent are compared with those observed in the control condition.

We are going to focus in two experiments to test the reduction of the ecological impacts achieved by treatment of mining effluents with different technologies. Exp. 1 compared effects of the raw effluent with high conductivity and concentration of metals with those of the same effluent treated with reverse osmosis. Exp. 2 compared effects of the raw effluent with high concertation of metals with those of the effluent treated by nanofiltration and electrocoagulation. Functional (photosynthetic efficiency) and structural parameters (total biomass/cm^2, total Chl. *a*/cm^2 and community composition) of the biofilm were measured after 14 days of exposure.

The use of communities taxonomically diverse and the measurement of functional and structural parameters helps in the obtention of ecologically relevant results in the environmental assessment of these technologies because: **i**) this approach covers different modes of action of toxicants at different levels of biological organization; ii) key communities for the sustenance of aquatic food webs are assessed; iii) acute and chronic responses are integrated.

Work supported by the European Commission LIFE DEMINE (LIFE16 ENV/ES/000218) and H2020 RAWMINA (958252) projects

4.05.P Emerging Remediation Technologies for Contaminated Environmental Matrices

4.05.P-Mo341 Testing a biochar filter for removal of a pesticide cocktail and nutrients at environmentally relevant concentrations

Alina Koch[1], *Harald Cederlund*[2], *Mikaela Gönczi*[1] *and Ove Jonsson*[1], *(1)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (2)Department of Molecular Sciences, Swedish University of Agricultural Sciences (SLU), Sweden*
Drainage systems are widely used to remove excess water from agricultural fields. In Sweden, about 47% of arable land has subsurface drainage systems installed. Throughout the growing season, these systems inadvertently transport pesticides and nutrients to the aquatic environments downstream. Implementing cheap and effective filters directly connected to the drainage systems has significant potential to reduce such transport.

We aim to develop a cost-effective filter, designed from readily available organic materials, to reduce pesticide transport into surface water, contributing to sustainable agricultural practices. Consequently, the initial phase of our research involved testing various materials (such as biochar, sand, wood chips, straw, Leca, etc.) in laboratory columns using different surface waters spiked with a diverse pesticide mix (up to 160 plant protection substances) at environmentally relevant concentrations (0,1-1 µg/L).

In our preliminary investigations, one particular biochar, exhibiting a BET surface area of 334.6 (m^2/g), outperformed all other materials tested. It demonstrated a remarkable concentration reduction of >95% for all 108 measured pesticides from inlet to outlet. The capacity test revealed that a 10 g quantity of this biochar in the filter could maintain a concentration reduction of >95% for a pesticide cocktail mixture in up to 8 L of surface water (equivalent to 223 pore volumes) with low organic content (DOC 4.9 mg/L). Additionally, it demonstrated effectiveness in high-organic-content surface water (DOC 27 mg/L), sustaining a concentration reduction of >95% in up to 4 L (equivalent to 441 pore volumes).

Subsequent stages of this study will involve a more comprehensive capacity test and a field campaign where the filter will be deployed in drainage pipes. We will closely monitor its performance in removing pesticides and nutrients. Our ultimate goal is to provide a practical solution for reducing pesticide transport, thereby enhancing water quality and the ecological well-being of aquatic environments within agricultural landscapes.

4.05.P-Mo342 Synthesis of Granules from Polyaluminum Chloride (PAC) Sludges for Environmental Application in As(V) Removal: Influence of Calcination Temperature on As(V) Adsorption Ability

Jungho Ryu *and Dong-Wan Cho, Geo-Envionment Research Center, Korea Institute of Geoscience and Mineral Resources, Korea, Republic of (South)*

Arsenic (As) contamination in soil/groundwater is one of the challenging global issues that should be urgently addressed due to its severe environmental risk. Specifically, the need to properly remove arsenate (As(V)) from aqueous system is strongly emphasized in developing countries that adopt groundwater as drinking water. In terms of the environmental sustainability, it is highly reasonable to utilize waste-derived materials as raw feedstock for the development of functional adsorbent. In this study, we aimed to fabricate granular As(V) adsorbent by calcination of polyaluminum chloride (PAC) sludge, and optimize the calcination temperature by focusing on enhancement of As(V) adsorption in batch- and column modes. The physicochemical characteristics of calcined sludges were analyzed by XRD, XRF, BET/BJH, TGA, and Zeta-potential instruments. Porous framework creation in the sludge matrix were achieved through the calcination process up to 500℃, but the adsorbents fabricated at temperature above 500℃ exhibited less adsorption of As(V) due to crystalline phase transformation. By the comparison of As(V) adsorption, the sludge calcined at 500℃ (PA500) was chosen as an optimal adsorbent. The adsorption of As(V) by PA500 was terminated within 6 h, and its maximum adsorption capacity was found to be 15.9 mg/g in the Langmuir isotherm model fitting results. The adsorption of As(V) exhibited the low pH dependence and was highly impacted by the existence of P(V) in form of PO_4^{3-}. The column test results represented that a column filled with 7 g PA500 successfully controlled As(V) to below 10 μg/L during 200-h operation at 50 μg/L As(V) and 1 mL/min flow rate. The stability of calcination process was well demonstrated with less leaching of trace metals from the sludge at 500℃ calcination and exposure to >pH 3 solution. In conclusion, calcination of PAC sludge at optimal temperature can be a promising method to fabricate As(V) adsorbent.

4.05.P-Mo343 Removal of diclofenac by filtration: experimental results and modelling

José Manuel Jiménez-Barrera[1]*, Shlomo Nir*[2]*, Manuel Arenas-Álvaro*[1] *and Tomás Undabeytia*[1]*, (1)Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (2)The R.H. Smith Faculty of Agriculture, Food and Environment, University of Jerusalem, Israel*

The occurrence of organic micropollutants in surface waters is of serious concern because of their ubiquity and adverse effects on humans and environment. Wastewater treatment plants are the main disposal of these pollutants into the environment due to their inefficient removal in the course of water purification. The European Union established a watch list of substances for their potential inclusion in a list of priority substances in the field of water policy, in which diclofenac (DC) was included (Decision 2015/495/EC). Recently, the new EU Directive proposal for urban wastewater treatment (2022/0345) set a list of 16 substances, including DC stayed, that classified them into three categories based on ease of their removal. The analysis of removal of DC by using bed filtration with two different adsorbents was analyzed by a model that considers convection and adsorption/desorption, which was extended by accounting for degradation during filtration. The sorbents used were a granular activated carbon (GAC) and an enzyme-based complex. The validity of the model was demonstrated. In the particular case of the enzyme-based complex, the removal of DC is initially due mostly to adsorption and hardly degradation. The model yields in parallel to the experimental results an increase of the concentration of emerging DC with time for a range of times, but the model predicts attainment of a steady state which is reached earlier in the case of a larger degradation constant and in the case of a longer filter. The analysis of the filtration data with the model enabled to determine parameters for generating predictions for other sets of operational conditions. This enables to determine the capacity of the filters for economic estimates.

4.05.P-Mo344 Assessment of Novel Constructed Wetland Configurations for Preventing Groundwater Pollution from Contaminants of Emerging Concern. A Bench-Scale Study

Clara Laguna Marín[1] *and Victor Matamoros*[2]*, (1)Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Spain, (2)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Nature-based solutions, such as constructed wetlands, have shown to be effective and sustainable technologies to remove contaminants of emerging concern (CEC) from wastewater, becoming feasible measures to prevent groundwater pollution. In consequence, interest has grown in finding new configurations and materials to increase their efficiency. Within the context of UPWATER project, this study assessed the effectiveness of novel constructed wetland designs on CEC mitigation during groundwater recharge with secondary treated wastewater.Configurations tested included: floating root mats (FRM) with: *Cyperus alternifolius*, *Cyperus alternifolius* with biochar and control pools, and horizontal flow constructed wetlands (HFCW) where *Phragmites australis* performance was tested in three filling materials: biochar, coke, and sand. Experiments were fed with secondary treated wastewater spiked at an environmentally relevant concentration (5 μg/L) with the 10 most relevant pollutants in groundwater bodies (benzotriazole, bisphenol A, carbamazepine, diclofenac, gemfibrozil, iopamidol, lamotrigine, methyl benzotriazole, sucralose, and valsartan).

Among FRM configurations, best removals were achieved in the *Cyperus* system with biochar, ranging from 41% for iopamidol to 99 % for gemfibrozil (82% on average) for Hydraulic Loading Rate (HLR) 12 mm/day and ranging from 23% for sucralose to 99 % for gemfibrozil (72% on average) for HLR 24 mm/day. Configurations with only *Cyperus* obtained an average of 62% and 58% with HLR 12 and 24 mm/day respectively, whilst control setups gave an average of 50% and 34% with HLR 12 and 24 mm/day. Among HFCW configurations, biochar stood out as the most effective material, achieving an average of 98% and 97% removal efficiency for HLR 50 and 100 mm/day, with significantly higher removals for 7 out of 10 pollutants compared to other treatments. Coke resulted in removal average of 59 and 45 % and sand of 60 and 52% for HLR 50 and 100 mm/day respectively. The addition of ZVI did not result in better removal efficiencies, on average.These results underscore the significance of the filling material choice in the design of constructed wetlands for CEC removal from wastewater, with biochar offering the most effective solution, they prove the effectiveness of plant presence and the importance of HLR choice. Thus, these experiments highlight the viability of nature-based solutions as a promising measure for preventing groundwater pollution.

4.05.P-Mo345 Nature-Based Solutions to Reduce Antibiotics, Antimicrobial Resistance Genes and Risk Assessment Approach

Edward Jair Pastor López[1], *Monica Escola Casas*[2], *Dominik Hellman Sr.*[3], *Jochen Müller Sr.*[3] *and Victor Matamoros*[4], *(1)Institute of Environmental Assessment and Water Research - Spanish National Research Council (IDAEA-CSIC), Spain, (2)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Microbial Genetics and Bioinformatics, Karlsruhe Institute of Technology (KIT), Germany, (4)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Climate change and high water demand generated by human population growth and the continuous expansion of industry and agricultural activities reduce the quality and quantity of available freshwater years. In recent years, antibiotics (AB) have become the primary concern due to the increased concentration in aquatic environments. ABs are able to reach the aquatic stream via wastewater treatment plant (WWTP) discharge and livestock manure application. Furthermore, antimicrobial-resistant bacteria (ARB) and antimicrobial resistance genes (ARGs) are also present in wastewater and may pose a rising risk to aquatic ecosystems and human health concerns due to the reuse of this water.

In this study, 12 conventional wastewater quality parameters and 22 ABs for 9 different categories (beta-lactam, trimethoprim, fluoroquinolones, ionophore, lincosamides, macrolides, rifamycin, sulfonamides and tetracyclines) were monitored in the seasonal performance (summer and winter) on 2 different CW configurations (Surface Flow (SFCW) and Horizontal Flow (HFCWs)) in terms of improvement of general water quality parameters and reduction of ABs, ARGs and risk assessments.

NBSs were able to reduce the release of nutrients (N and P) into the aquatic environment better than the conventional TWWTP reference. 12 out of the 22 ABs were detected with a concentration ranging from 5 to 1,218 $ng \cdot L^{-1}$. Azithromycin (AZI) was the most abundant AB with a concentration level above 400 ng·L-1. A moderate to high attenuation capacity for ABs was performed by NBSs (74% to 88% for both seasons on average) than conventional T-WWTP (34% for both seasons on average). Moreover, preliminary results showed a reduction of ARG in NBSs (intl1 and sul1) by 99% and less than 90% for TWWTP. Regarding risk assessments, ecotoxicological and potential bacterial selection risks (PMRS) were estimated at influent and effluent points for each treatment. Results indicated a high accumulative risk ranging from 4.7 to 70.1 at influent points. NBSs were able to minimize the risks (61 to 87% for both seasons on average) more than conventional TWWTP technology (<20% for both seasons on average). Nevertheless, only SFCW was able to reduce the cumulative risk for PMRS below 1 during the warm ($\Sigma RQs = 0.8$) and the cold periods ($\Sigma RQs = 0.8$).

In conclusion, this study shows that NBS can be employed as a tertiary treatment technology to improve water quality parameters and to reduce ABs, ARGs and risks in aquatic ecosystems.

4.05.P-Mo346 Cost-Benefit Analysis of Innovative Microplastic Filtration System

Javier Delgado Gallardo[1], *Jan Puhar*[2], *Kostja Klabjan*[3], *Annamaria Vujanović*[2] *and* ***Milica Velimirovic***[1], *(1)Flemish Institute for Technological Research (VITO), Belgium, (2)University of Maribor, Faculty of Chemistry and Chemical Engineering, Slovenia, (3)CleraOne, Slovenia*

Approximately 35% of microplastics released to oceans globally originate from washing synthetic textiles. Therefore, there is a growing need for effective removal technologies to facilitate the reuse of greywater and effectively preventing the discharge of microplastics. In this study the comprehensive cost-benefit analysis (CBA) of innovative filtration system with membrane pores as small as 0.1 microns designed specifically for the removal of microplastics from wastewater sources is performed. This innovative microplastics filtration system maintains low pressure while allowing high water permeability and the flow and finally a sustainable wastewater treatment system. This innovation allows for the comprehensive removal of fibers or particles ranging from 5 mm to 0.10 microns in a single automated process, conserving 70% more energy. The CBA analysis included different factors such as the initial capital investment for filter installation, operational and maintenance costs, as well as the potential benefits derived from reduced environmental impact and improved water quality. Environmental benefits are assessed through the estimation of microplastic removal efficiency and subsequent positive impacts on aquatic ecosystems. This cost-benefit analysis contributes valuable insights into the economic viability of microplastic removal filters, providing a foundation for informed decision-making by policymakers, environmental agencies, and stakeholders involved in water management. The results aim to guide the development of sustainable strategies for mitigating the impact of microplastic pollution on water ecosystems, human health, and the global environment.

4.05.P-Mo347 At-source hospital wastewater treatment to eliminate harmful pharmaceuticals: a novel immobilised approach using UV-LED activated photocatalytic nanomaterials

Manuel-Thomas Valdivia[1]*, Mark A. Taggart*[2]*, Sabolc Pap*[2]*, Alistair Kean*[1] *and Ian Megson*[1]*, (1)Life Sciences Innovation Centre, University of the Highlands and Islands, United Kingdom, (2)Environmental Research Institute, University of the Highlands and Islands, United Kingdom*

After excretion by hospital patients, drug concentrations in hospital wastewater are very low (mostly in the ng L^{-1} concentration range). Nevertheless, drugs released from hospitals pose an increasing risk to the aquatic environment and to human health, as ecotoxic hospital drugs and their metabolites accumulate in food chains. In addition, accumulation of hospital-derived antibiotics in the environment contributes to the growing problem of antimicrobial resistance. Current conventional wastewater treatment still fails to effectively eliminate most persistent hospital drugs and research into novel, sustainable and economical treatment technologies is urgently needed to eliminate the complex mixture of toxic drug residues in hospital wastewater.

Immobilised photocatalysis, using economical UV-A LEDs and light-activated metallic nanomaterials may provide a sustainable, reusable at-source hospital wastewater treatment solution for the oxidation and elimination of toxic hospital-derived drugs. At bench-scale, high-temperature calcination of photocatalysts onto spherical supports, such as glass beads, is mostly used to incorporate photocatalysts onto solid (porous) structures. However, the use of spherical support materials in fast-flowing hospital wastewater can cause unwanted hydrodynamic effects. In this study, planar borosilicate support materials were functionalised with an effective photocatalytic nanomaterial thin-film and tested in a novel UV-light fixed-bed reactor.

A wide band gap 3.37eV UV-light active photocatalytic metallic nanomaterial, zinc oxide (ZnO) and, by way of a negative control, narrow band gap 1.24 eV UV-light inactive, copper (II) oxide (CuO), were covalently functionalized and thin-film coated onto a borosilicate glass support by means of silanization using 3-aminopropyltriethoxysilane (APTES). Widely applicable borosilicate is a promising support matrix for photocatalytic applications in novel continuous flow treatment settings, such as for the effective oxidation and elimination of hospital drugs from fast-flowing wastewater. Furthermore, economical 365nm UV-A LEDs provide a cost-effective low energy alternative to conventional xenon light bulbs.

This novel immobilised photocatalytic treatment design has demonstrated tremendous effectiveness to oxidise and eliminate various toxic hospital drugs in fast-flowing simulated wastewater, by means of UV-light activated synthesis of reactive oxygen species (ROS) on the catalyst surface.

4.05.P-Mo348 Leaching experiments in columns systems to study the potential use of organic wastes as organic amendments to reduce groundwater pollution.

Raquel Rojas[1]*, José Morillo*[2]*, José Usero*[2]*,* ***María Llana-Ruíz-Cabello***[1]*, Sara Maisanaba*[1]*, Consuelo Alvarez-Herrera*[1] *and Guillermo Repetto*[1]*, (1)Universidad Pablo de Olavide de Sevilla, Spain, (2)Universidad de Sevilla, Spain*

The use of pesticides in agriculture is necessary for large-scale food production and to keep populations supplied. However, its intensive use is a source of pollution in the different environmental compartments. The addition of organic matter to soils could help to control the migration of soils into groundwater, as organic matter has been shown to be able to adsorb them. In this work, the potential use of several low-cost organic wastes (chicken manure - CM, rice husk - RH, composted urban solid waste – CRSU and residues from cotton gins – CG) was studied as soil amendments using leaching columns at laboratory scale. Hand packed columns were constructed from soil and soil amended with 10% of the cited organic wastes. Pesticides of different physico-chemical characteristics (Atrazine-AT, chlorfenvinphos-CF, chlorpyrifos-CP, simazine-SM and trifluralin-TF) were applied at the beginning of the experiment and columns were subjected to a simulated rain till pesticide concentration in the leachate remained constant. Pesticides were extracted and analyzed by Stir Bar Sorptive Extraction and analyzed by Gas Chromatography coupled with Mass Spectrometry. Relative and cumulative breakthrough curves (BTC) were constructed from pesticide detected each day in aqueous leachate. In general, the day of elution was delayed by amending the soil, with a few exceptions where it was brought forward or had no effect. Sorption of the organophosphate CF, improved with all studied organic residues, both in BTC and cumulative curves. The cumulative curves showed that the addition of the proposed organic residues improves the retention of the pesticide CF by up to 2.5 times. CG doubles the adsorption capacity of the soil and CM is good to retain the herbicide SM. The addition of organic residues does not appear to have any effect on soil holding capacity for the low-water solubility pesticides CP and TF. Results showed that specific organic waste incorporation in soil could reduce the leaching of pesticides.

4.05.P-Mo349 Contribution of earthworms and plants to remediation of contaminated shooting range soil

Gintare Sujetoviene[1]*, Auksė Daukšytė*[2] *and Diana Miškelytė*[2]*, (1)Vytautas Magnus University, Kaunas, Lithuania, (2)Vytautas Magnus University, Lithuania*

Shooting sites are a major concern due to high levels of pollution. As ecosystem engineers, earthworms can help maintain soil structure, improve soil quality, and alter the availability of heavy metals. Therefore, it can be used as in phytoremediation processes. Plants and earthworms were exposed to different levels of soil contamination. Our aim was to evaluate the role of earthworms and plants in soil metal availability and their influence on plant metal uptake at different heavy metal concentrations in soil. The results show that earthworms and plants changed the level of metals in the contaminated soil after exposure. Reproduction was more affected by contamination than worm survival or weight change. Metal accumulation in plants depended on the metal element under consideration and the presence of earthworms. These findings revealed that earthworm activity can alter the availability of heavy metals to plants in contaminated soil.

4.05.P-Mo350 Evaluation of the Improvement in Urban Runoff Water Quality After Passing Through Sustainable Urban Drainage Systems (SUDS)

Ainhoa Lekuona-Orkaizagirre[1], *Ainara Gredilla-Altonaga*[2], *Maite Meaurio-Arrate*[1], *Eneko Madrazo-Uribeetxebarria*[3], *Jose Antonio Carrero*[1] *and Maddi Garmendia-Antin*[3], *(1)Applied Chemistry, University of the Basque Country (UPV/EHU), Spain, (2)Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (3)Energy Engineering, University of the Basque Country (UPV/EHU), Spain*

When rain falls on a natural landscape, it infiltrates into the soil, evaporates, is absorbed by plants and part of it reaches streams and rivers. These stages of the water cycle can be prevented when land is altered by urban development, due to the fact that there is less permeable ground available for infiltration. When rain falls on impermeable surfaces, more surface water runoff is generated, which can cause floods, water pollution and erosion problems. Climate change predictions show it is likely that heavy rainfall and flooding will become more frequent, so, it is important an effective management of surface water runoff. In this context, Sustainable Urban Drainage Systems (SUDS) have been designed to maintain and protect the natural water cycle, to support the management of flood risk and to manage the quality of the runoff to prevent pollution. Among these systems, permeable pavements allow rainwater to infiltrate through the soil and stormwater tanks can store the runoff water for its later use with another purpose, such as for irrigation or cleaning activities.

The study presented here is located in Legazpi, a town of the north of Spain which participated in a project called LIFE Good Local Adapt. The goal of this project is to develop sustainable solutions to adapt the city’s neighbourhoods to extreme weather events and its consequent floods. With this aim, permeable pavements were installed in one of the parkings of the town of Legazpi, which were connected to a stormwater tank. The objective of this study was to evaluate the influence of SUDS on the quality of urban runoff and for this purpose, several physicochemical parameters (pH, turbidity, conductivity, dissolved oxygen) and the content of anions, metals, metalloids and Polycyclic Aromatic Hydrocarbons (PAHs) were determined in urban waters. The water before entering the permeable pavements, after passing through the permeable pavements and the water stored in the stormwater tank was taken at the beginning of different rainy events. Therefore, urban waters were compared before and after passing through the SUDS. Results show a decrease in the turbidity of the waters after passing through the permeable pavements and a reduction of the concentration of some metals, such as iron and copper. Despite this improvement, the water storing in the tank results in a possible accumulation of some elements, such as chlorides or lithium.

4.05.P-Mo351 Evaluation of the Influence of Hydrodynamic Separators on the Quality of Urban Runoff

Ainhoa Lekuona-Orkaizagirre[1], *Ainara Gredilla-Altonaga*[2], *Maite Meaurio-Arrate*[1], *Eneko Madrazo-Uribeetxebarria*[3], *Jose Antonio Carrero*[1] *and Maddi Garmendia-Antin*[3], *(1)Applied Chemistry, University of the Basque Country (UPV/EHU), Spain, (2)Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (3)Energy Engineering, University of the Basque Country (UPV/EHU), Spain*

Anthropic sources and soil or rock degradation form a very important matrix: the sediment that can be found in urban areas. These urban sediments accumulate different types of pollutants, until they are pulled by urban runoff. Urbanization implies an increase in the waterproofing of the land surface, which increases the volume of urban runoff and the speed at which this moves through the urban surface, favoring the drag of urban sediments, and thus, its contaminants. Sustainable Urban Drainage Systems (SUDS) have been implemented with the aim of preventing floods and protecting and improving the quality of urban runoff, mitigating the impact that pollutants of the urban sediment produce on the discharge point into the natural channels. Hydrocyclones or hydrodinamic separators can be clasified as treatment systems that are designed for the physical removal of the sediment of urban runoff by gravity, moving the water in a centrifugal manner from the inlet to the outlet.

The main objective of this study was to evaluate the influence of hydrocyclones on the quality of urban runoff in different sites and rainy events. Water samples were collected at the inlet and outlet of five hydrocyclones located in San Sebastian, a city located on the Cantabrian coast, in northern Spain. Three hydrocyclones (H1, H2, H3) are located in an industrial polygon of the city, one in a residential area (H4) and another in a residential and touristic area next to the port (H5). Comparing the inlet and outlet water of the hydrocyclones, it was not observed a general trend of decreasing contaminant content. Turbidity was generally related to the content of metals and metalloids but not to anions and it generally decreased in H1, H2 and H4, but not in H3 and H5. Comparing the sites, the waters of H1 and H2 had higher content of Zn and H4 contained more sulphates and nitrates. Samples of May contained more contaminants than in November and this difference could be related to the precipitation of the previous days: the rainfall accumulated in 7 days before the samplings was 0.3 mm and 57.6 mm, respectively. So far, it has been observed that the amount of rainfall in the previos days influenced the contaminant content and that the inlet and output results varied according to the hydrocyclone, the sampling day and the contaminant. Further samplings are required in order to understand better the functioning of these systems.

4.05.P-Mo352 Assessment of the Influence of Permeable Pavements on Urban Runoff Quality: a Case Study in San Sebastian (Spain)

Ainhoa Lekuona-Orkaizagirre[1], *Ainara Gredilla-Altonaga*[2], *Maite Meaurio-Arrate*[1], *Eneko Madrazo-Uribeetxebarria*[3], *Jose Antonio Carrero*[1] *and Maddi Garmendia-Antin*[3], *(1)Applied Chemistry, University of the Basque Country (UPV/EHU), Spain, (2)Analytical Chemistry, University of the Basque Country (UPV/EHU), Spain, (3)Energy Engineering, University of the*

Basque Country (UPV/EHU), Spain
In recent decades, the urbanization of cities has caused an increase in surface waterproofing, which has modified the natural water cycle, preventing, between other things, the infiltration of surface waters to the ground. This fact increases significantly the volume of urban runoff and the speed at which this move through the urban surface, favoring the drag of urban sediments. Sustainable Urban Drainage Systems (SUDS) have been implemented with the aim of preventing floods and protecting and improving the quality of urban runoff. This way, they can mitigate the impact that pollutants present on the urban sediment can produce on the discharge point into the natural channels. Permeable Pavements are a type of SUDS that favor the infiltration of urban runoff and PICP (Permeable Interlocking Concrete Pavement) and PA (Pervious Asphalt) are among the most employed structures. In PICP urban runoff is infiltrated through the joints between blocks and in PA through a porous material. Since runoff water is infiltrated through the pavement pores, a filtration process is generated, which can improve the quality of the infiltrated water.

The objective of this study was to evaluate the influence of permeable pavements on the quality of urban runoff. The study site is a parking located in a residential district of San Sebastian (north of Spain) and includes two types of permeable pavements: PICP and PA. In addition, the area offers the oportunity to compare the runoff before and after passing through the permeable pavements, since it includes a sump with three channels, on which water that comes directly from the surface and water that has passed through each of the permeable pavements is differentiated. For the evaluation of the influence of permeable pavements on the quality of urban runoff, several physicochemical parameters were measured in the water collected from each of the three channels mentioned: turbidity with a turbidimeter and pH, conductivity and dissolved oxygen using a portable series meter. Then, anions were determined by Ion Chromatography (IC) and metals and metalloids by an Inductively Coupled Mass Spectrometer (ICP-MS). Results showed a decrease in the content of some metals (such as Fe, Ba and Mn) after passing through the SUDS, and a clear difference was detected in the turbidity of the surface waters (39 FNU) and the waters that passed through the two types of permeable pavements (1.6 FNU).

4.05.P-Mo353 Bacteria Responsible for Disruption of Bentonite Barrier in Hazardous Waste Landfill
Kristyna Markova[1]*, Katerina Bobcikova*[2]*, Jan Rohovec*[3]*, Jakub Riha*[4]*, Karel Sosna*[5] *and Alena Sevcu*[6]*, (1)Technical University of Liberec, Czech Republic, (2)Technical University Liberec, Czech Republic, (3)Institute of Geology of the Czech Academy of Sciences, Czech Republic, (4)Technical University Liberec, Institute for Nanomaterials, Advanced Technology and Innovation, Czech Republic, (5)SG Geotechnika, Czech Republic, (6)Technical University of Liberec, Institute for Nanomaterials, Advanced Technology and Innovation, Czech Republic*
Although the number of landfills will decrease in the some waste, especially toxic waste, including incinerator fly ash, will still be landfilled. The structural elements of landfills often include sealing geosynthetic clay (bentonite) layers to protect the environment against toxic leachates. The extreme chemical properties of hazardous landfill leachate together with the high activity of microorganisms affect the bentonite mineralogy and isolation properties. As an example, montmorillonite with high swelling capacity can be replaced by non-swelling kaolinite and illite. This can lead to the leakage of toxic substances into subsoil and groundwater. Our study aims to determine the bacterial populations proliferating in the bentonite saturated with hazardous waste landfill leachate and affecting bentonite isolation properties.

Freshly collected landfill leachate from the hazardous waste landfill was transported to the laboratory and mixed with bentonite. Mixtures were airtight and incubated at 50 °C for three months in a self-developed anaerobic atmosphere. Vessels containing bentonite mixed with tap water and sterilized (Gamma irradiated) landfill leachate were added to the same heated box and served as controls. At the end of the incubation, samples were collected for DNA extraction and tests of chemical, geo-mechanical and hydro-dynamical properties of bentonite. Extracted DNA samples were used for qPCR and DNA sequencing analyses to compare the abundance and composition of bacterial communities in bentonite mixtures.

Most bentonite samples had higher bacterial abundance after the incubation than at the beginning. Bentonite mixed with the landfill leachate contained high amounts of acetogenic, iron-reducing, and sulphate-reducing bacteria. Some bacteria were present in the landfill leachate, but their abundance decreased during incubation, e.g., halophilic *Halocella* and *Marinebacterium*. On the contrary, others increased during incubation, such as the halophilic *Marinococcaceae*, *Sinibacillus* and *Oceanobacillus*. The most abundant taxon within the community were bacteria from the *Limnochordaceae*, which ferment organic substrate. Particularly sulphate, sulphite and iron-reducing bacteria from the landfill leachate contributed to the disruption of the bentonite layer.

The authors acknowledge the assistance provided by the project No. FW03010349 supported by TAČR.

4.05.P-Mo354 Enhancing hospital wastewater treatment: evaluating the combined efficacy of a Moving Bed Biofilm Reactor (MBBR) and nanofiltration to mitigate effluent risks.
van Xuan Nguyen[1]*, Florian Chapeau*[2]*, Claire Albasi*[3]*, Muhammad Eshamuddin*[4]*, Laury Gauthier*[5]*, Jerome Silvestre*[4]*, Maïalen Barret*[1]*, Eric Pinelli*[1]*, Lauris Evariste*[5] *and Florence Mouchet*[1]*, (1)UMR5245 CNRS-UT3-INPT Laboratoire Ecologie Fonctionnelle et Environnement, France, (2)University of Toulouse III - Paul Sabatier, France, (3)UniversitÈ de Toulouse INPT, France, (4)Université de Toulouse INPT, France, (5)UMR5245 CNRS-UT3-INPT laboratoire Ecologie Fonctionnelle et Environnement, France*

Hospital wastewater contain potentially harmful molecules, which pose environmental and health hazards. Traditional wastewater treatment methods are not effective in the elimination of some micropollutants such as pharmaceuticals, personal care products, and other toxic substances. This study investigates the use of a Moving Bed Biofilm Reactor (MBBR) combined with nanofiltration to effectively reduce contaminant release and effluents ecotoxic potential. A non-targeted LC-MS-MS analysis was carried out to monitor the effluent contaminant composition and treatment process efficiency. Thus, 1235 molecules were detected in the influent and 349 after treatment. Among the molecules identified based on the highest reliability score, 71 and 34 were identified in the influent and treated effluent respectively. On the remaining molecules, 50% exhibit a relative reduction rate exceeding 75%, indicating the effectiveness of this hybrid system. Two standardized assays were carried out to determine efficiency on the effluent toxicity: an acute test with *Daphnia magna* on raw effluent and a (geno)toxicity test with *Xenopus laevis* using dilutions representative of WWTP environmental releases. The acute toxicity test showed treatment efficiency, leading to a reduction of *D. magna* mortality induced by influent exposure. In *X. laevis*, no genotoxicity of the matrix was demonstrated whatever the condition. However, a significant reduction of erythrocytes mitosis was observed even at the most diluted concentration of effluent (1/300). Significant growth inhibition was observed for the untreated effluent diluted at 1/10, while not after exposure to diluted effluent (1/10). No impact on growth was observed at 1/300 dilution, either before or after treatment. Analysis of gut microbial diversity using 16s RNA sequencing showed significant changes in microbial population, suggesting potential physiological impacts on organisms. Overall, the hybrid MBBR/nanofiltration system effectively lowers micropollutants in hospital effluents and reduces ecotoxicity. Yet, ecotoxicological assays show residual toxicity to *Daphnia m*. and sublethal effects on *Xenopus l*., highlighting the necessity of integrating chemical and ecotoxicological evaluations for a comprehensive assessment of the environmental impact of treated hospital effluents.

4.05.P-Mo355 Reduction of Eco-toxicity of Biodegradation of the Antidepressant Citalopram by Co-metabolically Stimulated Polishing Moving Bed Biofilm Reactors

*Chuanzhou Liang[1] and **Kai Bester**[2], (1)Aarhus University, Denmark, (2)Environmental Science, Aarhus University, Denmark*

Citalopram is one of the most utilized antidepressants around the world. Citalopram and its transformation products (TPs) are frequently detected as in natural water due to the inefficient wastewater treatments for them. Polishing moving bed biofilm reactors (MBBRs) were able to remove citalopram efficiently according to previously studies, however the TPs and their eco-toxicity were not comprehensively evaluated.

This study investigated the biotransformation efficiency and pathways of citalopram by polishing MBBRs in a laboratory batch experiment. Through target and non-target analysis by HPLC-HRMS, the transformation rate and TPs of citalopram were comprehensively analyzed. The eco-toxicity of TPs was predicted using ECOSAR.

Of the 19 TPs, 7 were de-novo identified. These included quaternary amines, alkenes and conjugate TPs. Notably, dosing simple carbon source,i.e, acetate as a co-metabolically stimulation did not only increase the reaction rates of citalopram, but largely varied the transformation pathways. The nitrile hydrolysis (up to 43%) was the major pathway under carbon-limited condition, whereas amide hydrolysis and *N*-oxidation became the main pathways under carbon-rich condition. Moreover, carbon stimulation indicated towards formation of less toxic metabolites, i.e., carboxylic acid, *N*-oxide and ester TPs of citalopram, while the carbon-limited condition resulted in the more toxic carboxamide, *N*-desmethyl and alkene TPs. Therefore, this study proved that a co-metabolic stimulation by dosing simple carbon source to polishing biofilm could lead to a more efficient reduction the eco-toxicity of citalopram TPs than the constant carbon starvation condition.

4.05.P-Mo356 Sustainable support liquid membranes based on deep eutectic solvents for the removal of contaminants of emerging concern from WWTPs effluents

***Jose O. Fernandes**, Rui Lapa, Eulália Mendes, Lúcia Saraiva and Sara Cunha, LAQV-REQUIMTE, Portugal*

Contaminants of emerging concern (CECs) such as UV-filters, pharmaceuticals and pesticide residues in both wastewater treatment plants (WWTP) effluents and surface waters are associated with the increasing urbanization and limited removal efficiency of CECs by WWTP and represent a great threat to the environment and human health. Despite the availability of some treatment technologies, e.g., membranes bioreactors and ozonation to remove CECs the majorities of these treatments are expensive and their application limited.

Deep eutectic solvents are biodegradable solvents that have been used to efficiently extraction of CECs from the sample medium. The immobilization of organic solvents in membranes permits the separation of large amounts of contaminants with low consumption amount of solvent. However, most of this solvent are toxic an present low stability which constrained its industrial application. Therefore, in this work, we will present the main objective of the CLEANH2O project, which aims to provide a sustainable and cost-effective technology using a supported liquid membrane based on deep eutectic solvents for the removal of relevant CECs from WWTP.

4.05.P-Mo358 Unraveling Mercury Stable Isotope Ratio Fractionation from Mine Waste to Fish

***Michael Pribil**, JoAnn M Holloway, Danny Rutherford, Johanna Kraus, PhD and Ben N McGee, U.S. Geological Survey (USGS)*

Elevated levels of mercury (Hg) are frequently found at locations adjacent to and downstream of legacy mercury mines. Persistent mercury impact from legacy mines continue to present risk to the environment. Understanding of the source pathways of Hg methylation (MeHg) is critical in evaluating and minimizing Hg impact to ecosystems. Our study area was the

Stibnite Mining District located near the headwaters of the East Fork South Fork Salmon River in central Idaho, USA. Cinnabar Mine drains into Cinnabar Creek, a steep and narrow mountainous drainage system ranging in elevation from mountain peaks at 8900 ft. down to 6200 ft. at the Cinnabar Creek confluence with Sugar Creek. The study area is remote with minimal contribution from other anthropogenic sources of Hg allowing for a detailed Hg source pathway assessment. Samples were collected from three sampling sites downstream of the Cinnabar Mine area and two baseline sampling sites located above the Cinnabar Creek and Sugar Creek confluence on Sugar Creek. We measured Hg concentration and isotopic composition for biological (bull trout, spiders and macroinvertebrates), calcine and sediment samples. Scanning electron microscope (SEM) imaging of seston material identified absorbed sub-micron and micron sized cinnabar and calcine particles suggesting that other samples collected from the impacted streams may also contain absorbed inorganic Hg (IHg). Fish, spider and adult macroinvertebrates contained predominantly MeHg, whereas larval macroinvertebrates collected from the impacted streams containing mostly absorbed IHg. Initial interpretation of the data identified the need for determining $\delta^{202}Hg_{(MeHg)}$ in addition to $\delta^{202}Hg_{(T)}$. The $\delta^{202}Hg_{(MeHg)}$ was calculated by applying a mass balance formula using MeHg and $Hg_{(T)}$ concentrations as well as $\delta^{202}Hg_{(T)}$. The $\delta^{202}Hg_{(MeHg)}$ for samples collected at the three sample sites downstream of the mine area resulted in very negative $\delta^{202}Hg$. A possible source of the very negative $\delta^{202}Hg$ determined for the MeHg is gaseous Hg flux originating from large calcine waste piles. In-lab gaseous Hg flux experiments were conducted on waste calcines collected from the Cinnabar Mine area and resulted in similar negative $\delta^{202}Hg$ similar to that determined for the MeHg in the samples. These results suggest that in this region a primary source pathway of Hg to the food web is likely gaseous Hg flux evolving from waste calcine piles.

4.05.P-Mo359 Effects of pH and Competing Ions on the Sorption of Oxyanion-Forming Contaminants onto Lake Sediments

***Mirsya Ekarina Mulyani**, University of Leeds, Leeds, United Kingdom*

Oxyanions such as chromate, arsenate, vanadate, selenate, molybdate, and antimonate are often present both naturally in the environment and as a result of anthropogenic activities. Mining activities, the burning of fossil fuel, and municipal waste are contributing towards the increasing release of these oxyanions.

Despite the numerous studies in the sorption behaviour of these oxyanions, they are usually studied in a single element system with pure mineral as the sorbate. However, studies on sorption of oxyanion mixture onto natural samples are limited. This study simulates a pollution event involving these oxyanions in freshwater lakes through laboratory experiments.

We investigate the sorption of chromate, arsenate, vanadate, selenate, molybdate, and antimonate onto lake sediments using batch sorption method. A mixture of contaminant spikes containing those mentioned above were added to sediment and water sample taken from Loch Leven, Kinghorn Loch, and Loch Fitty in Scotland (UK) then shaken for about 48 hours at ambient temperature. The three lakes have different contamination history with varying mineralogical composition.

Two variables are included for the study: pH and competing ions. All contaminants are more mobile in alkaline conditions ($pH>7$) and less mobile in acidic conditions ($pH<7$). In the presence of phosphate ($pH\approx8$), both arsenate and vanadate are more mobile with the increase in phosphate concentration, while there is a slight increase in the sorption of antimonate. For selenate and molybdate, very low sorption is observed at pH 8, with no observed change despite the increasing phosphate concentration. No change is observed in chromate sorption with the addition of phosphate, but there is a trend of increased mobility with the addition of carbonate. For other oxyanions, the addition of carbonate does not seem to affect their sorption. Sulfate addition has little to no effect to the sorption of oxyanions.

In conclusion, the sorption of oxyanions in the sediment-water interface is affected by the pH and available competing ions in the environment. The presence of competing ions has different effect towards the sorption of oxyanion-forming contaminants. However, the behaviour of these contaminants are quite similar despite the different characteristics of the lake sediments. This study provides more insight into a real-life scenario where pollution events usually contain mixtures of contaminants rather than a single element.

4.05.P-Mo360 Assessing the relevance of bauxite residue amendments with gypsum and organic wastes for phytomanagement of Bauxite Residue from Hydro-Alunorte, Brazil

***Gabrielle Dublet-Adli**[1], Mehdi Movahed Aagre[2], Yuuki Silveira Miura[3], Santiago Quinteros[1], Vittoria Capobianco[1], Jan Mulder[4], Caroline Berge Hansen[1], Hogne Stubhaug[5], Ploy Chutigan[4] and Gudny Okkenhaug[1], (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Trondheim Municipality, (3)Boston Metal do Brazil, (4)Norwegian University of Life Sciences (NMBU), Norway, (5)Asplan Viak, Norway*

Bauxite residue is a highly alkaline, saline, and sodic tailing of alumina refineries with little re-use potential and is mainly dry-stacked in land disposal areas. Erosion caused by wind and rain imposes the risk of hydrosphere and lithosphere contamination. In situ revegetation of the ameliorated residue is the most effective strategy for mitigating the environmental risks. The study presented aimed to assess revegetation solutions for bauxite residues from the Hydro-Alunorte refinery in Brazil, based on technosol construction using local waste materials. Column experiments were used to assess the success of soil amendments for limiting the concentrations of alkaline, saline and metal(loid) compounds in soil water. The effect of the soil amendment solution on revegetation success was assessed by focusing on the root development. Image analysis techniques were performed on micro-computed tomography (μCT) scans from 5 samples that were amended by different compositions of gypsum and local organic waste. After manual segmentation of roots from the mixtures, they were quantitatively analysed for number and depth of roots, root volume density, root area ratio, and porosity of the soil. After two weeks of growth and out of 30 seeds, up to 21 roots with average depth of 10 mm were observed across all samples; and after four weeks up to 50 roots with average depth of 12mm. Porosity values across all samples averaged into 64% before plantation, 54% after two weeks, and 37% after 4 weeks of growth. Samples with 10% gypsum and no organic amendment showed most dense root development, with clearly different root densities compared with samples with either acai or food waste. Samples with 5% gypsum had very poor to no growth. Root descriptors were correlated with certain chemical parameters such as dissolved organic carbon, electrical conductivity, alkalinity, and calcium concentration in the leachates. It was concluded that image analysis based on µCT is an effective method to analyse the roots in bauxite residue and that root growth is closely related to chemistry of the ameliorated residue. This work also showed that reuse of local waste fractions is a promising strategy for constructing technosols supporting vegetation for phytomanagement of bauxite residues.

4.05.P-Mo361 How do Physicochemical Factors and Suspended Particulate Matter Impact the Metal Content of River Water in a Tropical Environment (New Caledonia)?

Chloé Dubernet[1]*, Aurélie Barats*[2]*, Christophe Renac*[2]*, Peggy Gunkel-Grillon*[3]*, Sylvain Gallet*[2]*, André Mexias*[4]*, Lucas Gomes*[4]*, Charlotte Hurel*[5]*, Marion Alberola*[6]*, Isabelle Desriaux*[3]*, Monika Lemestre*[3]*, Sylvie Russet*[3]*, Maximilien Mathian*[3]*, France Pattier*[3]*, Clément Buzet*[2] *and Cordélia Diart*[7]*, (1)Côte d'Azur University, Nice, France, (2)Université Côte d'Azur, Géoazur, IRD, CNRS, Observatoire de la Côte d'Azur, France, (3)Université de Nouvelle-Calédonie, Institut des Sciences Exactes Appliquées, France, (4)Federal University of Rio Grande do Sul (UFRGS), Brazil, (5)Université Côte d'Azur, Institut de Physique de Nice, France, (6)Université Côte d'Azur, Département de Chimie, France, (7)Direction Départementale des Territoires de Haute Savoie, France*

In New Caledonia, 61% of the sources of drinking water arise from surface water whilst 24% originate from ultramafic massifs. In these massifs, natural weathering and anthropogenic activities, (mining, fires and invasive species), enhance soil erosion and promote the production of suspended particulate matter (SPM) rich in metals (Ni, Co, Cr) into local rivers. This study examines the river water quality downstream of ultramafic massifs, with a specific focus on the role played by SPM in their water quality. Fine fractions (<100 µm) of soils from mines and river sediments were studied because they are considered representative of SPM. Their mineralogy was characterized by X-Rays Diffraction. The samples were mineralized using acid digestion assisted with microwaves to determine their metal content. Sequential extractions were then performed on these solid samples using an adapted BCR protocol to investigate the potential transfer of metals from SPM to the dissolved phase of water during changes of physicochemical conditions (T, pH, Eh…). Mineralized samples and extracts were analyzed by ICP-AES (Cr, Fe) and ICP-MS (Ni, Mn, Co, As). Soils and sediments are mainly composed by serpentines, quartz and Fe or Mn oxides/hydroxides. They contain significant concentrations of Fe, Mn, Ni, Co and Cr (few $g.kg^{-1}$), exceeding the available Ni, Co, Cr quality guidelines of Europe and North America. Sequential extractions underline first that Mn and Co can be transferred from SPM to the dissolved phase of water under reductive conditions (around 37% in sediments, 60% in soils). This process is suggested to be associated to the dissolution of Fe and Mn oxides/hydroxides. Secondly, Fe, As, Cr, Ni, Mn and Co are demonstrated to be strongly retained in the solid phases, most likely in Si-rich mineral phases such as serpentine and quartz. However, whilst metals are released to a limited extent from solid samples to the water (e.g. an average of 12% of the total Ni content in the first 3 steps of sequential extractions), due to the high metal content of the bulk sediment (an average Ni concentration of 7.1 $g.kg^{-1}$), solid/liquid metal transfers cannot be ignored. Changes in physicochemical conditions (pH, Eh) can lead to Ni and Cr levels in water approaching the WHO's guidelines, which may pose a health issue. This study emphasizes the fundamental importance of SPM in assessing water quality and will assist in establishing appropriate water guidelines in New Caledonia.

4.06.A Hazards, Risks, and Management of Soil Ecosystems for Sustainable and Environmental Conservation

4.06.A.T-01 Influence of soil properties in lower tier tests. Is an assessment factor based uniquely on Organic Carbon sufficiently protective?

Tiago Natal da Luz[1,2]*, Daniela Alves*[1]*, Leticia Scopel*[1]*, Sara Leston*[3]*, Stephan Jänsch*[4]*, Peter Craig*[5]*, Jörg Römbke*[4]*, Bjoern Scholz-Starke, PhD*[6]*, Pia Kotschik*[7]*, Silvia Pieper*[7]*, Susanne Walter-Rohde*[7] *and José Paulo Sousa*[8]*, (1)CloverStrategy Lda, Portugal, (2)Dep Life Sciences, University of Coimbra, Portugal, (3)CFE - Centre for Functional Ecology, Portugal, (4)ECT Oekotoxikologie GmbH, Germany, (5)Dept Of Mathematical Sciences, Durham University, United Kingdom, (6)darwin statistics, Germany, (7)German Environment Agency (UBA), Germany, (8)University of Coimbra, Centre for Functional Ecology, Portugal*

Environmental risk assessment (ERA) of plant protection products (PPPs) in the European Union (EU) does not consider all relevant uncertainties. Critical sources of uncertainties are not included in the currently applied assessment factor (AF) of five, which is used to extrapolate observed effects on single species in the laboratory to expected effects on other species and communities in the field. Several uncertainties are closely related with the properties of test soils (OECD artificial soil or natural soil) in relation to the range of natural soils in the geographical area subjected to the risk assessment. In fact, the risk for soil organisms exposed to chemicals is assessed in the first step based on laboratory tests performed in OECD artificial soil according to the EU Terrestrial Guidance Document. However, OECD artificial soil strongly diverges in its composition from natural soils. Sorption, bioavailability, and the resulting toxicity to non-target organisms depend on the characteristics of the test chemicals and the properties of the respective soil and will, therefore, be different in soils with different properties. In addition, non-target species with different routes of exposure to chemicals will reveal different sensitivities to them. A set of

laboratory experiments was carried out using a targeted combination of five soils (one artificial soil and four natural soils), two test species (*Eisenia andrei* and *Folsomia candida*) and six test substances (insecticides of Cyantraniliprole and Sulfoxaflor, fungicides of Fluazinam and Prochloraz, a herbicide of Prosulfocarb and the chemical metabolite 1,2,4-Triazole) to fill knowledge gaps on uncertainties that have not been adequately addressed by the data available in regulatory databases and the literature. The relationship between the ecotoxicological endpoints for each test substance and the properties of the test soils was evaluated by constraint multivariate analyses (i.e., through Redundancy Analyses) using the EC10 and EC50 values estimated in the laboratory reproduction tests. The results showed that using artificial soil in ecotoxicity testing with soil invertebrates was insufficiently protective, if the current assessment factor of 5 is used. Moreover, analysis of inter-soil variation suggested that any correction factor based solely on organic matter or organic carbon content has limited capability to explain the variation of effects on non-target soil organisms between different soils.

4.06.A.T-02 The Influence of Soil Organic Matter Content on the Toxicity of Pesticides to Soil Invertebrates

Bart Gerrit van Hall[1]*, Christopher Sweeney, PhD*[2]*, Melanie Bottoms*[3] *and Cornelis A.M. van Gestel*[4]*, (1)Vrije University Amsterdam, Netherlands, (2)Syngenta Ltd, Bracknell, Berkshire, United Kingdom, (3)Syngenta, United Kingdom, (4)Amsterdam Institute for Life and Environment (A-LIFE), Vrije University Amsterdam, Netherlands*

To account for potential differences in bioavailability (and toxicity) due to different soil organic matter (SOM) contents in natural and artificial soil (AS), in the current European environmental risk assessment (ERA) a correction factor (CF) of 2 is applied to toxicity endpoints for lipophilic pesticides (i.e. log Kow>2) generated from laboratory toxicity tests on soil invertebrates. This CF is based on 14-day earthworm toxicity tests focusing on mortality, and therefore its applicability to other soil invertebrates and toxicity endpoints is questionable. To improve the ecological relevance of ERA approaches, a better understanding of how soil organic matter (SOM) content influences other toxicity endpoints and other soil invertebrates is needed. In the current study, the influence of SOM content on pesticide toxicity to earthworms (*Eisenia andrei*), springtails (*Folsomia candida*), and enchytraeids (*Enchytraeus crypticus*) was investigated. Animals were exposed to five (moderately) persistent pesticides differing in lipophilicity (log Kow 0.6 - 4.7) in four soils (three artificial soils, one natural soil) with different SOM contents (2.5 - 10%), using survival and reproduction as endpoints. The data were used to determine LC50, EC50, and EC10 values, and the relationships between toxicity endpoints and SOM content were analysed through linear regression analysis. The linear regression equations were used to calculate the toxicity in soils containing 10.0% and 5.0% SOM content, and the ratios between these values were used to assess the suitability of the current CF of 2. The results show that pesticide toxicity differed significantly between soils. LC50s and EC50s for all pesticides strongly correlated with SOM content in AS ($r2 > 0.82$), with pesticide toxicity decreasing with increasing SOM content. In almost all cases, the observed ratios between model-estimated toxicity in the two soils exceeded the CF of 2. Overall, the influence of SOM content on pesticide toxicity differed between pesticides, endpoints, and test organisms, and no clear relationship between toxicity-SOM relationships and lipophilicity was observed. This shows that the CF of 2 is based on incorrect assumptions regarding the relationships between pesticide lipophilicity, SOM content and toxicity and, therefore, may not be appropriate.

4.06.A.T-03 Effect or no effect? The normal operating range of the abundance of soil organisms in ecotoxicological field studies

Agnes Schimera[1]*, Jörg Hanisch*[2]*, Michael Thomas Marx*[3]*, Frank Staab*[4]*, Zhenglei Gao*[5]*, Lijuan Yan*[6]*, Pernille Thorbek*[7] *and Gregor Ernst*[8]*, (1)ADAMA Deutschland GmbH, Germany, (2)Rifcon GmbH, Germany, (3)Bayer AG, (4)BASF SE, Germany, (5)Data Science, Bayer AG, Germany, (6)BASF Services Europe GmbH, Germany, (7)Apd/EE, BASF plc, United Kingdom, (8)Environmental Safety, Bayer AG - Crop Science Division, Germany*

For the registration of PPPs in the EU, ecotoxicological risk assessments for soil organisms are required. Within a tiered approach, laboratory-derived effects on single species are compared to a modelled soil exposure value. In case a risk is indicated, field studies can be required, focusing on recovery of non-target soil organisms within one year after application of the respective product. Although ISO guideline 11268-3 adapted with literature data is used to conduct field studies on earthworms, no OECD test guidelines exists. In additon to lack of guidance for collembola, high natural variability of species abundance may lead to discussions on biological relevance and statistical significance, with a preprogramed high uncertainty from a regulatory perspective.

Aim of the project was to compile data from EU soil organism field studies to investigate what can be a biologically relevant test item effect, and how to investigate its statistical signfiicance. Therefore, abundance data from 13 collembola field studies from Central Europe was collected. The taxa to focus on were selected by dominance classification according to Engelmann (1978). The normal operating ranges (NORs) were derived based on the mean abundance (individuals/m²) for each taxon per sampling point and study as the percentage by which the abundance deviates from the mean control value for a given taxon at one observation point, which can include a certain percentile range (e.g., NOR90 includes all values between the 5^{th} and 95^{th} percentile; NOR80 all between the 10^{th} and 90^{th} percentile). The abundance data for test item treatment groups from a given field study were compared to the respective NOR of a taxon and further with the statistical outcome based on different methods like Dunnett, Williams, or the relatively new Closure Principle Computational Approach Test.

Our investigation shows that a high variability in abundance in ecotoxicological field studies is often observand and not uncommon from a biological perspecive, but it can be challenging regarding interpretation of potential test item effects. We introduce the NOR concept as a valuable tool to help interpret the results, and to put the outcome of statistical analysis in a population-relevant context. However, with regards to the high complexity of the data, a field study should be the last step in the RA and not the only ecotoxicological refinement option. Therefore, intermediate tier testing options need to be developed.

4.06.A.T-04 Intermediate Tier Risk Assessment of Plant Protection Products for Soil Invertebrates - Where do we stand?

***Gregor Ernst**, Environmental Safety, Bayer AG - Crop Science Division, Germany*

The conservativeness of the Tier 1 risk assessment of pesticides for soil invertebrates is expected to increase as the upcoming guidance for estimating PECsoil will lead to higher exposure estimates and higher failure rates. Further, a new guideline for higher tier studies (earthworm field test) is under development on OECD level, which is expected to lead to an increasing complexity in the higher tier risk assessment. A risk assessment framework should be protective, internally consistent, and cost efficient. However, the upcoming changes described above lead to a situation in which more substances will trigger into a more complex higher tier assessment. Intermediate tier approaches are currently lacking in the European risk assessment framework for soil invertebrates, yet urgently needed. Different intermediate tier options (natural soil testing, non-standard species testing, assessing recovery in laboratory tests, and multi-species tests) were discussed on a workshop in March 2022 in which it was concluded that further work on standardization and risk assessment calibration is needed. Therefore, case studies for Collembola were compiled to quantify the relationships between the endpoints of the different study types. The presented case studies allow 1) to compare the recovery pattern of different taxa seen in field studies with those that are predicted from *Folsomia candida* multi-generation studies, and 2) to assess the conservativeness of different intermediate tier risk assessment approaches. The case studies indicate that the recovery predicted in the multi-generation studies with *F. candida* is well in line with the recovery pattern of the sensitive taxa in the field studies. The protectiveness of the proposed intermediate tier approaches is well demonstrated for the available case studies. Reducing the uncertainty in the risk assessment by providing additional experimental evidence must be acknowledged with clearly lower assessment factors (compared to Tier 1) to achieve a cost effective and consistent tiered risk assessment framework.

4.06.A.T-05 Bioaccumulation and mixture toxicity effects of organic pollutants are highly dependent on soil type and test species

***Jonas Fischer**[1], Tobias Frische[2], Urs Dippon-Deissler[3] and Juliane Filser[1], (1)University of Bremen, Germany, (2)Section „Soil Protection Measures“, German Environment Agency (UBA), Germany, (3)German Environment Agency (UBA), Germany*

Soils are mostly contaminated by a mixture of numerous pollutants which enter the environment either by direct (e.g. agriculture) or indirect pathways (e.g. atmospheric deposition). In chemical risk assessment, only single substances in standard soils are tested. However, the uptake and toxicity of substances can be supported by their co-contaminants in a positive (synergistic), additive or a negative way (antagonistic), and also by the properties of the test soils, e.g. clay and organic content.

In this study, the soil invertebrates *Folsomia candida* and *Enchytraeus crypticus* were exposed to chemical mixtures consisting out of two agrochemicals, the fungicide fluazinam and the trisiloxan-based wetting agent Break-Thru S301, and two ubiquitary pollutants, the PAH fluoranthene and the plastic softener DEHP. Substances were applied in binary, ternary and quaternary mixtures with a toxicity of 1 or 2 Toxic Units. The animals were exposed in a 28-day standard reproduction test in which survival and dry weight of the adults were also assessed as well as their bioaccumulation of the substances. Three different field test soils were used: a sandy soil (S), a sandy-organic soil (SO), and a loamy soil (L).

Overall, the chemical mixture was most toxic in the S soil and more toxic to *F. candida* than *E. crypticus*. For *F. candida*, tests with the wetting agent had to be excluded as the high impact on the surface tension skewed results of the reproduction test evaluated by flotation method. However, the remaining data clearly showed that the mixture toxicity effect was additive in S and SO soil, while in L soil it was clearly antagonistic. Bioaccumulation of fluoranthene was clearly highest in S soil and massively increased by the presence of DEHP, followed by SO, while in L soil fluoranthene bioaccumulation completely disappeared in the ternary mixture. For *E. crypticus*, however, the quaternary mixture acted additively in L soil, but antagonistically in S and SO soil.

The study aims to link absolute toxicity of the substances and mixture toxicity effects to tissue and pore water concentrations which are currently assessed. Overall, the results show the clear impact of the test soils and species on bioaccumulation and the manifestation of mixture toxicity effects. Furthermore, it supports the common practice to choose concentration addition as the default or worst-case model for chemical mixtures in the soil environment.

4.06.B Hazards, Risks, and Management of Soil Ecosystems for Sustainable and Environmental Conservation

4.06.B.T-01 Turning Recovered Street Cleansing Wastes into a Circular Economy Soil Product – A Seasonal Monitoring of Harmful Substances

***Daniel Niepsch**, Manchester Metropolitan University, United Kingdom*

Street sweeping is a routine maintenance operation that collects residues consisting of diverse materials, including litter, grit, leaves, glass, bituminous macadam, paper and plastics and thus may contain potentially harmful elements (PHEs), such as heavy metals and organic compounds (e.g. total petroleum hydrocarbons, TPHs). Currently, street cleansing residues are treated as waste and have to be disposed of at suitable facilities, e.g. landfill or incineration. However, treatment of street cleansing residues can ensure reclamation (and use) of gravels/aggregates and sands. Finer materials (i.e. silt and clays) are currently disposed of, but have the potential to be used as soil amendments in structural soils and/or as growing media. Due to the decline in soil resources, such material could provide essential qualities in supporting plant life, by also reducing the need for "virgin material" (i.e. dug-up and transported to site) and being used close to its source. Road sweepings are often perceived of as contaminated, however, relatively little is known about the physico-chemical properties of reclaimed street sweeping material, how this varies with time, and what the associated environmental and human health risks are.

This study aims to provide a temporal (over a 12-months period) physico-chemical characterisation of treated and recovered street sweepings (using internationally recognised standard procedures, e.g. British Standards Institution procedures). Our results show consistent physico-chemical properties of the recovered material throughout the study's period, with metal/elemental concentrations and TPH concentrations, present at concentrations below screening values for use in a public open space. This demonstrates potential capability and suitability for the reclaimed material's to be used as a soil and/or soil amendment for urban green infrastructure, that may provide a 'circular' alternative to 'virgin' material and prevent unnecessary landfilling of a useful resource.

4.06.B.T-02 Methodology and Tools to Promote the Reuse of Excavated Soils in France

***Noémie Dubrac**, Samuel Coussy and Virginie Vincenti, French Geological Survey (BRGM), France*

Each year in France, nearly 130 million tons of soil are excavated for infrastructure and development projects. A major portion of this waste is still stored in landfills, whereas they could be used as backfill material or reused as topsoil in many development projects. However, land developers and local authorities consider it risky to reuse these materials, because of the lack of traceability over the flow of excavated soil and because of the lack of soil quality control.

To address these issues, the French government set an ambitious target in 2015 to reuse 70% of construction waste as part of the Energy Transition Law for Green Growth (LTECV) and asked the French Geological Survey (BRGM) to develop a methodology and tools to promote the excavated soil circular economy.

The methodology developed in 2013 and updated since then aims to facilitate, encourage and supervise the reuse of excavated soil while preserving human health and the environment. The last changes, which should be published in the beginning of 2024, will allow soil reuse on surface with different threshold values depending on the site use. For some compounds, bioaccessibility tests will be recommended to better estimate transfers from soils to humans. Additional studies are still permitted if the excavated soil's quality exceed the threshold values.

This new methodology based on the future use of the site needs to have an efficient traceability to fulfill recent mandatory obligations but also to fulfill environnement and human health issues in case of a change of use.

The BRGM developed for the Ministry of the Environment the TERRASS application, a public tool that aims to help public works actors manage excavated soil and make traceability easier. It allows producers and receivers to connect together for soil exchange, and to ensure the traceability of soil flows at different scales thanks to the emission of soils follow-up forms. Since January 2023, the TERRASS application is connected to the French National Register of Soil and Sediments (RNDTS) making it easier to fill in the mandatory declarations established as part of the AGEC law (anti-waste for a circular economy): all soil flows with a volume greater than 500 m^3 must be declared by the producer, sorting/transit facility, and receiver.

The new methodology and regulatory requirements should encourage actors to improve traceability and enhance the circular economy of excavated soil.

4.06.B.T-03 Functional versus compositional tests in the risk assessment of the impacts of chemicals on the soil microbiome

***Christopher Sweeney, PhD**[1], Melanie Bottoms[2] and Rishabh Kaushik[2], (1)Syngenta Ltd, Bracknell, Berkshire, United Kingdom, (2)Syngenta, United Kingdom*

In Europe the OECD 216 Soil Nitrogen Transformation Test is used to conduct the risk assessment for the exposure of the soil microbiome to plant protection products. However, this study system has come under criticism for a lack of sensitivity, which has led to calls to further develop the suite of tests available for assessing the risk of PPPs to the soil microbiome, such as the integration of tests of microbial community composition as measured via amplicon sequencing. The proposed use of amplicon sequencing within a standardised regulatory test system brings with it significant challenges, such as the complexities of collapsing data on 1000s of microbial taxa into a single endpoint. Furthermore, it has yet to be established whether the use of more complex, compositional metrics to study the microbiome would provide additional protection to the soil microbiome above and beyond the current functional approaches implemented in OECD 216. Dose response soil nitrogen transformation tests were conducted as per the OECD 216 guideline and at the end of the study period, soils were sampled, and bacterial communities characterised via 16S rRNA amplicon sequencing. Traditional functional endpoints were calculated and compared to a variety of compositional endpoints generated based on microbial diversity, microbial dissimilarity to the control and threshold indicator analysis. Endpoints generated from the compositional data ranged from approximately 5 times lower to 20 times higher than those calculated using the traditional functional endpoints from the OECD 216 guideline. The endpoints from the compositional analysis spanned an approximately 100-fold range, showcasing a high level of variability between methods of endpoint calculation. Our data show that functional endpoints based on soil nitrogen transformation are in many cases more or at least equally sensitive as endpoints generated from compositional data. Moreover, we found that certain compositional endpoints, such as microbial community diversity and dissimilarity to the control could not consistently detect significant effects that were reported from the functional OECD 216 endpoints. It is our conclusion that amplicon sequencing data does not provide data that would provide additional protection to the soil microbiome above and beyond the current functional approaches implemented in OECD 216. OECD 216 studies may be more sensitive than current opinion suggests.

4.06.B.T-04 Disaggregation behavior in the terrestrial isopod Porcellionides pruinosus as a new ecotoxicological endpoint for assessing infochemical disrupting activity

Lorenzo Federico[1]*, Gianna Serafino Monti*[2]*, Susana Loureiro*[3] *and Sara Villa*[4]*, (1)Applied Science And Technology (DISAT), Department of Applied Science And Technology (DISAT), Italy, (2)University of Milano-Bicocca, Italy, (3)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal, (4)Dept Earth and Environmental Sciences, University of Milano-Bicocca, Italy*

Among rapid ecotoxicological tests for screening soil quality, avoidance behavior tests on gregarious edaphic species, such as *Porcellionides pruinosu*s, are widely used. However, the effect of soil contamination on the adaptive aggregation ability has not yet been investigated. This research aimed to develop a new ecotoxicological endpoint related to the disaggregation effect for investigating the infochemical disruption at the population level during the avoidance test. This new endpoint was evaluated using tire particles and benzothiazole as preliminary reference substances. As a measure of disaggregation, the Disaggregation Index (*DI*) and the Disaggregation Groups (*DG*) are presented to quantify the effect of contaminants on the aggregation behavior. The disruption of aggregation in a group of ten individuals is evaluated alongside the sub-lethal avoidance test after 48 hours. The extent of disaggregation is measured by the number of subgroups formed. The *DI* and *DG* indexes span from 0 to 1, representing respectively the highest degree of aggregation and disaggregation achieved during the test. Our findings reveal that all woodlice successfully passed the avoidance test validation but failed to exhibit a gregarious behavior, indicating a fragmentation within the population. These results propose combining avoidance behavior with disaggregation in individuals of *P. pruinosus*. The concentration observed to induce alteration in gregariousness is in the range of the sublethal effects inducing avoidance. Considering both aspects can produce more accurate and robust environmental risk assessment results.

4.06.B.T-05 Importance of Heat Stress in the Risk Assessment of Pesticides for Soil Arthropods

Micha Wehrli[1]*, Stine Slotsbo*[2]*, Inge S. Fomsgaard*[3]*, Bente B. Laursen*[3] *and Martin Holmstrup*[2]*, (1)Department of Biological and Environmental Sciences, University of Gothenburg, Göteborg, Sweden, (2)Department of Ecoscience, Aarhus University, Denmark, (3)Department of Agroecology, Aarhus University, Denmark*

The pressure from anthropogenic pollution of soils, such as agricultural pesticides, is currently addressed in pro- and retrospective risk assessments as outlined in the Regulation (EC) No 1107/2009. The framework for prospective ecological risk assessment is mainly based on hazard assessments from laboratory tests in which environmental conditions are maintained at optimum for the organism in focus. Given that environmental factors (e.g., temperature) can influence the toxicokinetics and toxicodynamics of chemicals, we propose that laboratory-based hazard assessment should include important abiotic factors.

Human-caused climate change is already affecting many weather and climate extremes in every region across the globe. The global rise in temperatures poses a significant threat to soil-dwelling organisms, unsettling the delicate balance of ecosystems. Nature is directly affected by the rising mean temperature and the ubiquitously projected increased frequency and intensity of heat waves. Recent studies highlighted alterations of uptake and elimination of toxicants in soil invertebrates due to temperature induced variation in metabolic rates and diffusivity. Nevertheless, our understanding of the repercussions of high temperature on the performance of soil arthropods, especially regarding sub-optimal high temperatures and their influence on pesticide uptake and effects, remains largely unexplored.

Here, we aim to address this lack of knowledge with a testing approach, combining a commonly used springtail (*Folsomia candida*) reproduction test with incubation at a range of non-optimum high temperatures. As our test compound we used the widely used fungicide, fluazinam. The test also included analysis of internal concentration as well as metabolites of fluazinam. Concentrations of fluazinam and its metabolites in spiked soil and in springtail bodies were analysed using a newly developed LC-MS/MS method. Preliminary results revealed that high environmentally realistic temperatures hamper detoxification processes in *F. candida*. Furthermore, we found an increase of metabolites over time, and with the increase of temperature, indicating that detoxification processes are significantly influenced by high temperature as reported by others. In the ongoing work, we investigate the interaction between sub-optimal temperature and fluazinam effects using a full factorial test design.

4.06.P Hazards, Risks, and Management of Soil Ecosystems for Sustainable and Environmental Conservation

4.06.P-We328 Predicting Earthworm Toxicity Endpoints in Non-Standard Soils: Risk Assessment Concept and Model Validation

Amund N. Løvik[1], Melanie Bottoms[2], Tania Alvarez[2], ***Nika Galic[3]*** *and Roman Ashauer[1], (1)Syngenta Crop Protection, Switzerland, (2)Syngenta, United Kingdom, (3)Syngenta AG, Switzerland*
Earthworm risk assessment for plant protection products (PPP) in Europe is normally based on toxicity tests performed in artificial test soils with either 5% or 10% organic matter (OM). Soil characteristics, in particular organic matter content, influence the bioavailability of chemicals, and one would therefore expect different levels of toxicity in natural soils. Here we present a concept for predicting toxicity endpoints in untested soils using the results of a toxicity test (EC_{50} or LC_{50}) in a standard soil containing 10% OM and a previously published empirical model. The model predicts the uptake and elimination rate constants of a one-compartment toxicokinetic model based on earthworm species properties (lipid content and specific surface area), topological polar surface area of the molecule, and the organic matter content of the soil. We evaluate the accuracy of the model in predicting EC_{50} and $LC_{50,}$ using previously published toxicity data on 22 organic compounds that were tested in multiple soils with different organic matter content. The model showed high accuracy with 87% of predictions within a factor of 2 of the observations. The predictions are overall conservative, tending towards somewhat lower endpoints than those empirically determined in non-standard test soils. Based on the observed accuracy, we conclude that the model is suitable for predicting toxicity endpoints in untested soils. Incorporating such an approach into the ecological risk assessment for earthworms in Europe allows an increased level of ecological realism and provides an opportunity to refine the PPP risk assessment according to the soil properties of concern.

4.06.P-We329 Novel Strategy to Assess the Risk of Sequential Application of Tank Mixtures to Non-Target Soil Organisms

Fernanda de Santo[1]*, Tiago Natal da Luz[2], Julia Carina Niemeyer[3] and José Paulo Sousa[4], (1)University of Coimbra, Portugal, (2)CloverStrategy Lda, Portugal, (3)Federal University of Santa Catarina (UFSC), Brazil, (4)University of Coimbra, Centre for Functional Ecology, Portugal*
Mixing two or more plant protection products within the sprayer equipment's tank (tank mixtures; TMs) is a cost-effective method, but has been neglected by European Union’s legal directives. Moreover, most ecotoxicological studies on PPP mixtures have evaluated only the impact of binary combinations on non-target soil organisms, failing to mirror real-world application scenarios, besides using only one test organism. Aiming to contribute to filling this gap, the present study proposes a novel strategy to evaluate the risk of a sequential application of TM to non-target soil invertebrates. The adequacy of the proposed strategy was evaluated by the comparison of the effects on the reproduction of non-target species to the single application of TMs with the cumulative effects on reproduction of the same species over sequential applications of the same TMs, as it occurs in a real scenario usually adopted in soybean crops. Reproduction tests were carried out using the species *Eisenia andrei*, *Folsomia candida* and *Hypoaspis aculeifer*following ISO and OECD guidelines. A natural soil collected in an agricultural field was used as test soil. Ranges of increasing concentrations of TMs usually applied in soybean crops were used in ecotoxicological tests. Test concentrations of TMs were based on toxic units estimated with effect data obtained from the literature. Test treatments were prepared from a stock solution with the mixture of products in a proportion related to their individual recommended doses. The sequential experiment followed field application sequences, including microbial inoculation for degradation. Results showed varying sensitivities among organisms in response to different TMs. For sequential applications, earthworms showed the highest sensitivity in TM1+TM2, while predatory mites after the application of TM3. In contrast, single applications showed different patterns, with collembolans been the most sensitive organism in TM2, TM3, and TM4, while *E. andrei* was the least sensitive for TM1, TM2 and TM3, and *H. aculeifer* for TM4. Data produced show that in a real sequential application scenario there is a cumulative effect of the PPP applications that considerably increases the risk of PPPs to non-target soil organisms. The strategy proposed in the present study seems to allow an adequate assessment of the cumulative effect of PPP applications and therfore, has potential to be considered in ecological risk assessment of PPPs in the future.

4.06.P-We330 Why do we neglect key drivers for soil health in environmental risk assessment? – A plea for the use of nematodes as bioindicators

Sebastian Hoss[1]*, Nicola Reiff[1] and Walter Traunspurger[2], (1)Ecossa, Germany, (2)Bielefeld University, Germany*
Nematodes constitute the most abundant animal phylum on earth, with up to 10 million organisms inhabiting one square meter of soil. Due to their high taxonomic and functional diversity, they occupy all trophic levels in soil food webs, making them key drivers for soil health. Although plant parasitic nematodes are among the most severe threats for agriculture, their free-living species are essential for the maintenance of important soil functions, such as nutrient cycling. In the meanwhile, standardized and innovative methods with a high level of preciseness are available to assess effects of chemicals on nematodes (ISO 10872, small scale microcosms). Moreover, due to their high densities, nematodes offer many advantages in field studies (easy sampling, small sample volumes, statistical power, etc.). Although also EFSA already mentioned nematodes as key drivers of soil functioning (EFSA 2017, EFSA Journal, 15(2), 225; https://doi.org/10.2903/j. efsa.2017.4690), this organism group is still not adequately represented as bioindicators in the risk assessment of soil contaminants, such as plant protection products. This can mainly be explained by two assumptions: (1) Nematodes are not sensitive to toxic chemicals, such as pesticides. (2) Nematodes are a challenging organism group in terms of taxonomic identification, due to their small size and morphological similarity, resulting in a low number of experts and, thus, hampering the use as bioindicators. With this presentation, we want to bring light in the discussion about nematodes in environmental risk assessment and to get rid of some tenacious myths about the low suitability of nematodes as bioindicators. As there are simply too few studies on effects of chemicals (especially pesticides) on soil nematodes, a valid comparison of sensitivities to other soil organisms, such as springtails and earthworms is not possible. However, using standardized tools, such as the soil toxicity test with *Caenorhabditis elegans*(ISO 10872), or

innovative microcosm tests, it could be revealed that nematodes are comparatively sensitive to certain compound classes, such as fungicides. Moreover, in the light of innovative techniques of DNA-based taxonomy, the argument of morphological challenges with nematodes has to be put into a new perspective. More studies, including available innovative tools, are urgently needed for reliably evaluate the suitability of nematodes as bioindicators of soil health.

4.06.P-We331 Targeting Validity Criteria in Natural Soil Testing as Intermediate-Tier Approach with Earthworms, Soil Mites and Springtails

Eva Aderjan[1]*, Eiko Wagenhoff*[2] *and Andreas Duffner*[1]*, (1)Eurofins Scientific, Germany, (2)Terrestrial Ecotoxicology Lab, Eurofins Agroscience Services Ecotox GmbH, Germany*

Natural soil laboratory testing as an intermediate-tier option for soil organisms would be a valuable supplementation for the current environmental risk assessment because there is a vast gap between laboratory testing in artificial soil and complex field studies. Major technical challenges for natural soil testing are the selection of suitable soils regarding representativity and the achievement of control validity criteria to obtain reliable results.

The influence of the soil parameters soil moisture, pH, sand, silt, clay and organic matter on the validity criteria number of juveniles and mortality was investigated for *Eisenia fetida, Hypoaspis aculeifer and Folsomia candida* following the guidelines OECD 222, OECD 226 and OECD 232. The influence of different moisture levels on number of juveniles and mortality was investigated by testing a range of soil water potentials in OECD artificial soil and a natural soil for each species from nearly water saturation (pF 1.3 / -2 kPa) to permanent wilting point of plants (pF 4.2 / -1.5 MPa). In separate testings, the influence of the remaining soil parameters was tested with all three species in four natural soils covering a wide range of soil properties representative for soils under agricultural use, using a soil water potential within the ecological optimum of the respective species.

The results show that the guideline validity criteria for artificial soil are also achievable in typical agricultural soils. Soil parameters like pH, texture or organic matter content play a subordinate role in explaining differences in control performance. The dominating factor influencing control reproduction of earthworms and springtails is not the water content itself, but the soil water potential (negative pore water pressure) that determines the bioavailable water.

Laboratory testing with natural soils according to the current guidelines is feasible with some technical adaptions. Natural soil testing will help reducing uncertainties in bioavailability of substances in comparison to OECD artificial soil, providing a more realistic scenario.

4.06.P-We332 Molecular-ecological Studies on Bile Acid Degrading Bacteria in Soil for Assessment of Plant Protection Products

Antonia Bruder[1,2]*, Julio Cesar Coutiño-Montes*[2]*, Karsten Schlich*[1]*, Cecilia Andrea Diaz Navarrete*[1] *and Bodo Philipp*[2,3]*, (1)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Institute of Molecular Microbiology and Biotechnology, University of Münster, Germany, (3)Environmental Microbiology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

One of the important functions of microorganisms in soil is the metabolic transformation of organic material. This function can be affected by the introduction of chemicals such as plant protection products (PPP) into the environment and may thus have a negative impact on the fitness of soil organisms. The metabolic capacity of soil bacteria has, so far, been mainly determined by the sum parameter nitrification. However, these tests do not provide information on changes in microbial communities occurring after the introduction of such substances into soil. There is an evident knowledge gap between the function and the structure of microbial soil communities. To close this knowledge gap, specific carbon and energy sources that are used as substrates by defined taxa only, could be used to correlate metabolic activity with the structure of the microbial soil community. In this respect, bile acids might serve as appropriate substrates. Bile acids can be used by a limited number of bacterial genera such as *Comamonas*, *Pseudomonas* or *Rhodococcus*. Therefore, microbial metabolism of bile acids might be established as an alternative way to evaluate the metabolic capacity of soil samples in response to the introduction of chemicals.

During the first stage of the project, the abundance of bile acid degrading bacteria from soil spiked with bile acids was analyzed with colony forming units (CFU). The degradation of bile acids was analyzed with HPLC-MS measurements. Additionally, amplicon sequencing of the genes encoding the 16S rRNA was conducted to analyze the microbiome. In a second step, the effect of the PPP propamocarb and thiram was evaluated in a soil test. Soil samples were taken and incubated with bile acids. By comparing soils with and without PPP, we will evaluate if a reduced bile acid degradation correlates with reduced bacterial abundance (CFU and qPCR) of the specific bile acid degrading taxa.

Based on the available data that the genera *Comamonas* and *Pseudomonas* belong to the few known bile-acid degrading taxa, their increased abundance in bile-acid containing soils supports the suitability to consider this metabolic trait for linking metabolic capacity to the structure of bacterial soil communities. By adding PPP to the soil, ongoing tests will reveal wheter the function of bile acid degradation is influenced and wheter this influence is reflected by the structure of the microbial community in the soil.

4.06.P-We333 Effects of Heavy Metals from Artisanal Gold Mining and Pesticides on Farmland Soil Quality and Earthworm Biodiversity in Batouri, East Cameroon

Patricia Bi Asanga Fai*[1,2] *and Joan Anyikeng Nkemasong*[1]*, (1)Coltech, University of Bamenda, Cameroon, (2)Department of Animal Biology, University of Dschang, Cameroon

Batouri gold deposits in the East Region of Cameroon have long been subjected to Artisanal and Small-scale Mining (ASM) activities resulting in pollution, land degradation and deforestation. The progressive loss of agricultural land to mining activities necessitates action to preserve the soil quality of remaining farmlands for continued productivity. Earthworms are a major component of soil fauna communities and are highly susceptible to pollutants. Their number and diversity are an important indicator of soil quality. This research set out to assess the effects of heavy metals from Artisanal and Small-scale Gold Mining (ASGM) and pesticides use on soil quality and earthworm diversity in farmlands in the Batouri gold mining district. Surface soil samples were collected from 6 farmlands located at varying distances (5m to 1765m) from mining sites and analyzed for physicochemical characteristics, Cd, Cu, Fe, and Hg. Questionnaires were used to determine pesticides use by farmers. Earthworm diversity and abundance were assessed using quadrats. Results showed that the Hg concentrations at all sites exceeded the European Environment Agency guideline in agricultural soils leading to extremely high soil contamination factor ($23.6 \leq Cf \leq 114$) and potential ecological risk ($944 \leq Er \leq 4575$). Hg contributed between 96% and 99.6% to the overall potential ecological risk index (RI). The geo-accumulation index (Igeo) indicated that anthropogenic activities was the source of Hg enrichment in the soil. It also indicated low to moderate Cu pollution from anthropogenic sources, most likely from pesticides. 8 earthworm species from the three major ecological categories were identified (3 epigeic, 4 anecic and 1 endogeic species). Earthworm abundance followed the order Endogeic > anecic > epigeic species. Principal Component Analysis showed a positive association of earthworm abundance with the % organic matter, % silt, Cu concentration and the distance away from the mining locations while the Cf, Er and Igeo for Hg were negatively correlated to the earthworm abundance. ASGM is therefore causing widespread Hg pollution in Batouri and significantly affecting the soil quality and earthworm abundance in farmland soils. In addition, the use of pesticides containing Cu may be causing moderate soil pollution. There is therefore the need for risk assessment and management of Hg and Cu in farmland soils in Batouri to prevent ecological and human health effects.

4.06.P-We334 Ecotoxicological characterization of nano-biochar obtained by ball-milling

Monika Stefania Raczkiewicz*[1]*, Aleksandra Bogusz*[2] *and Patryk Oleszczuk*[1]*, (1)Department of Radiochemistry and Environmental Chemistry, Maria Curie-Skłodowska University, Poland, (2)Institute of Environmental Protection National Research Institute, Poland

Biochar has garnered extensive research attention due to its potential applications in agriculture, soil improvement, and contaminated area remediation. Its capacity to enhance soil fertility, water and nutrient retention, and positive impact on soil microorganisms make it a promising agricultural tool. However, concerns about the safety of biochar application persist, as it can contain both organic (e.g., PAHs) and inorganic contaminants (e.g., heavy metals).

Recent focus has shifted to nano-biochars (n-BCs), produced by ball milling bulk biochars (b-BCs). This method, considered eco-friendly, cost-effective, and reliable, offers advantages such as fine powder production and suitability for milling toxic materials. N-BCs, being produced from waste materials, have a reduced environmental footprint and show potential for diverse applications, making them efficient and adaptable.

The study aimed to assess the influence of n-BCs (<100 nm) and their bulk counterparts, prepared from various feedstocks and pyrolysis conditions, on PAH content and distribution. Ecotoxicological tests with Aliivibrio fischeri, Folsomia candida, and Daphnia magna evaluated potential environmental risks.

Ball milling's impact on biochar particle size significantly affected PAH content. After ball milling, the total content of Σ16 PAHs in selected n-BCs decreased by 10.8% to 59.2%. Similarly, freely dissolved Σ16 PAHs in n-BCs decreased from 10.1% to 65.1%. Changes in the contribution of Ctotal and Cfree PAHs based on the number of rings were also observed in all n-BCs.

Ecotoxicological tests revealed higher toxicity to A. fischeri for n-BCs compared to b-BCs, with toxicity increasing over time. In contrast, F. candida and D. magna tests showed no mortality or immobilization but inhibited reproduction in both b-BCs and n-BCs.

In conclusion, the study highlights the impact of ball milling on n-BCs' properties, influencing PAH content and ecotoxicological effects. N-BCs show promise, but careful consideration of their environmental impact and potential risks is necessary for widespread applications.

4.06.P-We335 An agricultural systems' perspective on soil and biodiversity: Learnings from a set of field trials with soil health and climate balance in a broader sustainability context

Christian Bogen*[1]*, Florian Ballhaus*[2]*, Andrea Rossbach*[2] *and Julia Köbele*[3]*, (1)EMEA Public Affairs, Science & Sustainability, Bayer AG - Crop Science Division, Germany, (2)Tier3 Solutions GmbH, Germany, (3)Bayer AG - Crop Science Division, Germany

To guide and implement long-term improvements at the interface between agriculture, soil health and biodiversity, the use of suitable metrics and a perspective on sustainability performance can be decisive, ensuring economic, ecological and social viability of the proposed systems.

In the case of this work a broader sustainability setup was chosen for field trials with the aim to create a more comprehensive perspective on agricultural production and its various challenges for farmers, including potential trade-offs and unintended consequences. Among other parameters, specific focus was set on a number of soil health metrics in different production systems to learn more about the interaction between soil organic carbon, nutrient balance, earthworm abundance, greenhouse gas emissions at the interface to impacts on yield, crop rotation and production costs. Above-ground carabid populations were investigated as a proxy for biodiversity for both the in-field and off-field area.

Results from the first two years have been presented at the previous SETAC and this work aims to complement and draw conclusions on key learnings and how to approach these themes in the future.

To increase the sustainability of agriculture a transparent perspective on performance and trade-offs is required. Such a perspective will be decisive to not only enable realistic reference frames and protection goals for the ecotoxicological assessment of plant protection products but also to create a broader perspective for life cycle assessments and practical improvement of sustainability performance at farm level. The next steps would be to explore how to minimize the trade-offs and therefore increase the sustainability of the applied practices and enable upscaling.

4.06.P-We336 Co-occurrence of Di-2-ethylhexyl phthalate (DEHP) and Titanium Dioxide Nanoparticles (nTiO2) in Soil Aggravates Ecotoxicity Associated with Disrupted Energy Budget in Nematode Caenorhabditis elegans

Yu-Hsuan Kuo[1]*, Chun Ming How*[2] *and Vivian Hsiu-Chuan Liao*[2]*, (1)Department of Bioenvironmental Systems Engineering, National Taiwan University, Taipei, Taiwan (China), (2)Department of Bioenvironmental Systems Engineering, National Taiwan University, Taiwan*

Emerging contaminants, such as the plasticizer di(2-ethylhexyl) phthalate (DEHP) and nanomaterial titanium dioxide nanoparticles (nTiO_2), pose potential threats to soil-dwelling communities. Understanding the singular and joint toxicities of these contaminants is crucial for predicting their environmental impact. We investigated the effects of DEHP and nTiO_2 on the soil nematode *Caenorhabditis elegans* (*C. elegans*), using concentrations ranging from 1 to 100 mg/kg. Our results indicate that both DEHP and nTiO_2 individually caused significant reproductive impairments in *C. elegans*, with the lowest observed adverse effect levels (LOAELs) of 100 and 1 mg/kg, respectively. For combined exposure, the effects of 1 mg/kg DEHP and nTiO_2 (1, 10, and 100 mg/kg) were examined. We found that combined exposure to DEHP and nTiO_2 resulted in aggravated toxicity, revealing LOAELs of 100 and 1 mg/kg nTiO_2 for growth and reproduction, respectively. To unravel the physiological modes of action (pMoAs), we employed a dynamic energy budget (DEB) model. The model allowed us to derive predicted no-effect concentrations and elucidate the heightened reproductive costs associated with individual DEHP or nTiO_2 exposure. The results indicate that the combined presence of DEHP and nTiO_2 increased the cost of growth and reproduction. Considering that energy budgets are linked to energy status, we assessed adenosine triphosphate (ATP) levels in *C. elegans*. Singular exposure to DEHP (1 mg/kg) or nTiO_2 (100 mg/kg) decreased ATP levels. Notably, combined exposure synergistically exacerbated the impact on ATP levels, suggesting a lower energy threshold for joint exposure. Furthermore, mitochondrial damage and reactive oxygen species (ROS) levels were also evaluated. While singular nTiO_2 exposure increased worms with mitochondrial damage, co-exposure to DEHP and nTiO_2 further heightened damage by 200%. Additionally, the combined exposure significantly elevated ROS levels. Our study highlights that joint exposure to DEHP and nTiO_2 results in heightened toxicity in soil. Furthermore, we propose an adverse outcome pathway involving disruption of energy allocations, linking molecular events to declines in organismal propagation and, potentially, population decline. This research contributes valuable insights into the complex interactions of soil co-contaminants and their impact on soil-dwelling organisms.

4.06.P-We337 Field Study with Carbendazim in Brazil to Evaluate Effects on Local Earthworm Community

Julia Carina Niemeyer[1]*, Tiago Natal da Luz*[2,3]*, José Paulo Sousa*[4]*, Marie Bartz*[4,5]*, Ulrich Menke, Dr.*[6]*, Emerson Franco*[7] *and Gregor Ernst*[6]*, (1)Federal University of Santa Catarina (UFSC), Brazil, (2)CloverStrategy Lda, Portugal, (3)Dep Life Sciences, University of Coimbra, Portugal, (4)University of Coimbra, Centre for Functional Ecology, Portugal, (5)Municipal Center for Culture and Development, Organic Farming - Agriculture and Organic Production Partnership, Centre for Organic and Regenerative Agriculture, Portugal, (6)Environmental Safety, Bayer AG - Crop Science Division, Germany, (7)Bayer AG - Crop Science Division, Brazil*

Risk associated to the application of plant protection products (PPPs) in soil invertebrates is usually defined by considering its toxicity to standard species as surrogate/representative of specific key organism groups. Previous studies have reported that local earthworm species may be more sensitive to specific PPPs than the standard species *Eisenia andrei/fetida*. Because of that, countries outside Europe, such as Brazil, have highlighted the necessity and the interest of adapting the ecological risk assessment (ERA) of PPPs to their reality (i.e. taking into account local species). However, data regarding the effect of PPPs on earthworm local communities in countries of Latin America (LA) are scarce and the high local endemism of earthworm species and the restricted number of species with broad distribution in countries like Brazil have made the adaptability of soil ERA difficult to achieve. Therefore, field studies are needed to check sensitivity of natural earthworm communities under local environmental conditions. These data are crucial to understand at which point, data from European field studies can be used in ERA of LA countries. Moreover, local field studies will help in identifying possible technical limitations (e.g. population densities and seasonal abundances may condition the definition of adequate sampling dates), to calibrate lower tier risk assessment and to validate effect models for LA scenarios. Therefore, a field study was conducted in a grassland area in Santa Catarina State, Brazil, aiming to 1) compare the sensitivity of earthworm field populations with those from European studies; 2) calibrate Brazilian lower tier risk assessment. A commercial formulation of Carbendazim was used as test substance and a randomized block design with three carbendazim doses (0.32, 1.8 and 10 kg a.s./ha) plus a control was followed. Six earthworm species belonging to four families (Glossoscolecidae, Ocnerodrilidae, Megascolecidae and Lumbricidae) were identified in the pre-sampling and showed a higher earthworm density compared to the sampling after 1 month. A heterogeneous distribution of earthworms was found, independently of the application rates. Samplings evidenced that earthworms density is highly influenced by soil moisture and recent rain events. Data from samplings before and 1, 6 and 12 months after Carbendazim application will be presented and discussed and technical limitations will be pointed out.

4.06.P-We338 "Evaluation of soil enzyme activities in abandoned mine area"
***Haemi Kim**, Tae-Yang Lee, Dokyung Kim and Youn-Joo An, Konkuk University, Korea, Republic of (South)*
As commonly known, mining sites were highly contaminated of heavy metals. Soil enzymes play a major role in the cycling process of soil and plant. Also, it can be used as an indicators of soil condition. In this study, the soil enzyme activity of contaminated soil was assessed. Three heavy metal contaminated site (S1 – S3) were selected, including reference site soil (R). Five types of soil enzyme activity were evaluated such as acid phosphatase activity (ASA), arylsulfatase activity (ASA), ß-glucosidase activity (ßGA), fluorescein diacetate hydrolase activity (FDA), and Protease activity (PRT), using 1 g of each site soils. The total heavy metal content was higher in the order of site 1 (S1), site 2 (S2), site 3 (S3) and R. Site 1 soil showed a significant decrease in the activity of all types of soil enzymes. As a result, heavy metals contents can inhibit the soil enzyme activities such as acid phosphatase activity, arylsulfatase activity, ß-glucosidase activity, fluorescein diacetate hydrolase activity and protease activities. Soil conditions are related to microorganisms and soil interactions, therefore evaluation of soil enzyme activity can provide a major information. *Acknowledgement-This work was supported by Korea Environment Industry & Technology Institute (KEITI) funded by Korea Ministry of Environment (MOE) 2022002450002(RS-2022-KE002074).*

4.06.P-We339 From invasion to solution: Optimizing a Sargasso Biochar Strategy for Chlordecone Sequestration that not alter Caribbean Soil Quality
***Perrine Stephan**[1], Séverine Piutti[2], Matthieu Delannoy[1], Sarra Gaspard[3], Guido Rychen[1] and Claire Soligot[1], (1)Urafpa, Université de Lorraine, France, (2)Lae, Université de Lorraine, France, (3)Covachim M2E, Université des Antilles, France*
The use of biochar's (BC) as a rehabilitation tool for polluted soils is increasingly being studied, especially in the case of the Caribbean chlordecone (CLD) crisis. BC have the ability to sequester pollutants but may also have an impact on soil fertility, especially on the microbial communities, biological fertility keystone. The effect of BC on soil microorganisms is very diverse and remain incompletely investigated. The impact of BC on soil seems to be the most impactful during the maturation period of the soil-BC mixture. This phase allows the BC to interact with the pollutant without external competition granting an optimal sequestration. This phase, varies from one study to another, especially du to BC and soil diversity. So, it is necessary to determine the optimal maturation time for each case.

This study aims was to pinpoint the optimal maturation period of Sargasso (invasive algae) BC for efficient CLD sequestration in Caribbean soils and to elude its impact on microbial communities' structure. For this, CLD assays and 16S rDNA quantification in 2 contaminated soils (Andosol and Nitisol) amended or not with 2% of Sargasso BC were carried out during 5 months.

For Andosol 50% reduction of CLD were reached after 24 hours and seems to reach a 90% plateau reduction after 29 days. For Nitisol, at 24 hours the CLD reduction was up to 37% and 50% of CLD reduction was reached at 5 months. The difference between the two soils may be explained by the large difference in initial soil contamination (Andosol: 1.85 mg/kg, Nitisol: 7.99 mg/kg). A high CLD concentration implies a possible BC surface saturation as well fewer CLD-BC bonds, contributing to a slowdown of sequestration. Andosol is known as a matrix strongly sequestering CLD, so it would have been logical to obtain shorter ripening times for Nitisol. So, these results highlight the strong correlation between the optimal maturation time and the initial level of contamination. Preliminary measurements on the samples were made to visualize the evolution of bacteria abundance in soil revealed by 16S rDNA copy number. No statistically differences were measured between the control and the BC treatment at each kinetic time. These results tend to demonstrate that for Caribbean soil the Sargasso BC does not alter bacteria abundance. Within this framework, additional analyses are underway aiming to effect of BC amendment on the structure and diversity of bacterial communities by metabarcoding approach.

4.06.P-We340 Can the land use affect the risk for inducing antibiotic resistance by heavy metals?
***Carla Cruz Paredes**[1], Qinmei Zhong[2], Vanesa Santás-Miguel[3] and Johannes Rousk[4], (1)Roskilde University (RUC), Denmark, (2)Southwest Minzu University, China, (3)Soil Science and Agricultural Chemistry, University of Vigo, Spain, (4)Biology, Lund University, Sweden*
The ongoing spread of antibiotic resistance is a global challenge for human health. Soils, due to their high microbial diversity, act as an important reservoir of microbial resistance to antibiotics. There is growing concern that heavy metals (HM) can co-select for antibiotic resistance in soil. This study aimed to investigate microbial tolerance to HM and antibiotics in different land uses and the sensitivity of antibiotic resistance induction to further contamination. Agricultural and forest soils with varying levels of HM contamination were sampled and analyzed. Replicated microcosms were set up and spiked with Cu or tetracycline, or used as a control. Microbial biomass, respiration, growth, community composition, and tolerance to Cu and

tetracycline were measured over several weeks. The results showed that bacterial tolerance to Cu and tetracycline varied among different land uses. Bacterial Cu tolerance was highest in contaminated forest soil, intermediate in pristine forest soil, and lowest in agricultural soils. On the other hand, tetracycline tolerance was highest in agricultural soils, intermediate in pristine forest soils, and lowest in contaminated forest soils. This suggests that bacterial tolerance to antibiotics was linked to land use rather than only the HM pollution level. The inducibility of bacterial Cu tolerance was higher in pristine forest soil compared to contaminated forest soil, potentially due to differences in initial levels of microbial species diversity. Additionally, the development of tetracycline tolerance in agricultural soil may be limited by microbial biodiversity. The speciation of tetracycline, influenced by the pH of the medium, was found to be more toxic to bacteria in contaminated forest soils compared to pristine soils. Overall, our study highlights the complexity of microbial tolerance to HM and antibiotics in different ecosystems and the need for further research in this area.

4.06.P-We341 Assessment of pesticide mixtures on soil organisms: challenges for non-standard endpoints
*Camilla Drocco[1,2], Marion Devers-Lamrani[3], Fabrice Martin-Laurent[3], Aymé Spor[3] and **Anja Coors**[2], (1)INRA, Germany, (2)ECT Oekotoxikologie GmbH, Germany, (3)Agroécologie, INRAE, Institut Agro, Univ. Bourgogne, France*
Agricultural application of pesticides often occurs as combination of several products, either together in a tank mixture or in a series by applying similar or different products to the same crop during a vegetation period. The consideration of mixture effects in the environmental risk assessment has repeatedly been called for in the last decades, and it has been demonstrated frequently that existing prediction models such as Concentration Addition (CA) as well as Independent Action (IA) would be fit for purpose in many cases. These cases include e.g. the effects of a mixture of substances applied together and to be assessed for acute effects in a standard test organisms. However, the assessment of mixture effects with regard to non-standard or higher-tier endpoints, such as soil microbial community composition and/or long-term effects in field studies, are still lacking guidance and supporting evidence. Similarly, potential mixture effects of serial applications, in field or laboratory studies, are rarely investigated and difficult to assess with the available mixture toxicity models. Here, we combine the experience gained in several studies with soil microorganism communities and soil invertebrates as well as evidence from the literature to discuss the possibilities of a meaningful mixture assessment for these complicated, but realistic mixture scenarios.

4.06.P-We342 Ecotoxicity of the monoterpene eugenol on soil microbial communities
*Natalia Ferrando Lázaro[1], Guillermo Lorca[1], **María Rosa Pino Otín**[1], Diego Ballestero[1], Eva Terrado[2] and Elisa Langa[1], (1)Universidad San Jorge, Spain, (2)Universidad de Zaragoza, Spain*
Terpenoids, a diverse class of natural compounds found in plants and some microorganisms, play pivotal roles in various biological processes. Among them, eugenol stands out, known for the wide-ranging pharmacological activities, exhibits potent anti-inflammatory, antiseptic, and antimicrobial properties. Due to its increasing use, an environmental toxicity assessment is warranted.

This work evaluates the ecotoxicity of eugenol on soil microbial communities obtained from an uncontaminated crop field in Zaragoza, Spain, at different doses (0,1, 10, 100, and 1000 µg/mL). The overall ability of natural ecosystems to break down 31 typical carbon sources was indicated by the Average Well Colour Development (AWCD), which was determined by Biolog EcoPlates® analysis. At 0,1, 10, and 100 µg/mL, the results showed a steady decrease in AWCD and metabolite intake, leading to complete growth inhibition at 1000 µg/mL. Interestingly, there was a decreased capacity to metabolize carbon sources, most notably carbohydrates and polymers.

As a result, this study shows that an increase in eugenol consumption could have an impact on the environment. These findings improve our knowledge of how eugenol affects soil community structures, providing valuable insights for proactive environmental management strategies.

4.06.P-We343 Intermediate Tier Testing Alternatives for Ground Invertebrates – A Granular Insecticide Case Study
***Ricardo Petersen**[1], Mariana Vieira Rato[2] and Stephanie Fritz[3], (1)ERM International Group Limited, United Kingdom, (2)ERM International Group Limited, Portugal, (3)R&ra, Sumitomo Chemical Co. Ltd., Japan*
Soil organisms such as beetles or collembolans represent some of the most abundant communities in agricultural fields and surrounding areas and are non-target organisms of concern in terms of potential exposure to plant protection products (PPPs). While the standard risk assessment for non-target arthropods includes various intermediate testing options – extended laboratory studies with fresh/aged residues – the risk assessment for PPPs for soil macro- and meso-fauna is based on Tier 1 tests and, when unacceptable risks are identified, higher tier testing consisting only of field studies is required. Therefore, as there is a lack of intermediate levels from standard lab tests to full field effect studies, achieving more realistic exposure conditions in laboratory tests is deemed a necessary and practical step providing additional information in refined risk assessments of certain PPPs.

In this case, an alternative design was developed for two soil organisms exposed to a granular insecticide formulation: the rove beetle *Alleochara billineata* exposed to fresh and aged residues (Grimm *et al*., 2000) and the collembola *Folsomia candida* (OECD 232) exposed to fresh residues. In the standard method, a test item is mixed within the soil substrate homogeneously, while the alternative method simulates the intended field application of the product *i.e*. as granules are to be applied in the field at 4 cm deep furrows, the test design was adapted to create a layer of granules at 4 cm depth in the test units. While this design doesn't fully mimic the field application in furrows, it represents a worst-case approach where organisms can avoid the granules in the majority of the arena.

For *A. billineata* a standard aged residue study (granules mixed within soil homogeneously) resulted in 90% mortality at 159 days aged residues (application rate – 1.39 kg a.s./ha), while the modified study design (granules buried 4 cm deep), resulted in 2.1% mortality with fresh residues (application rate – 1.16 kg a.s./ha).

For *F. candida*, the modified exposure design with granules buried 4 cm deep resulted in a reduction in reproduction of 9.6% and 28% at 1xGAP (10 kg PPP/ha) and 5xGAP (50 kg PPP/ha), respectively.

This technique enabled organisms to avoid direct granule exposure, demonstrating more realistic effects when mimicking field application. The alternative study design may form the basis for intermediate tier testing for ground invertebrates when assessing granular formulations.

4.06.P-We344 A multispecies test system as tool for an intermediate test system in soil ecotoxicology and risk assessment

Michael Thomas Marx*, Gregor Ernst, Andreas Richter, Olaf Wüstner and Ulrich Menke, Dr., Environmental Safety, Bayer AG - Crop Science Division, Germany*

For the registration of PPPs in the EU, a tiered ecotoxicological risk assessment (RA) for soil organisms is required. In the recent framework endpoints obtained from standardized Tier 1 laboratory studies exposed in artificial soil are compared to a modelled predicted environmental concentration. As higher Tier only the performance of a field study is foreseen, where potential effects on soil organism communities are evaluated over one year. This knowledge gap between Tier 1 laboratory studies and the field study can be filled with results from intermediate tier test systems. A laboratory multi species test design could be a valuable methodological approach for such an intermediate tier test system.

We designed a laboratory multispecies test design with different settings to answer relevant questions concerning inter- and intraspecific competition, feasibility and reliability of the test system and the results. The basic test design is adapted from the recent OECD guidelines (OECD 226 and OECD 232) for testing single soil arthropod species. The test medium is a defaunated natural agricultural soil, where different combinations of soil taxa were added. The tested collembolan species were *Proistoma minuta*, *Sinella curviseta* and *Folsomia candida*. As predator the gamasid mite *Hypoaspis aculeifer* was included. Further included species are *Panagrellus redivivus* (Nematoda) and *Enchytraeus albidus* (Enchytraeidae). Beside different controls, boric acid and chlorpyrifos-methyl were tested as chemical stressors.

The test design can be used to draw conclusions about direct toxic effects of the chemical stressors, effects based on competition for food resources as well as predatory effects. The statistical outcome of the test results and adaptations of the test system to obtain better results are also discussed.

4.06.P-We345 Representativeness of Standard Species of Microarthropods for Pesticides Risk Assessment in Brazil

Julia Carina Niemeyer*[1], Gabriel Queiroz[2], Simone B da Fontoura[3], Fabrielle P dos Reis[1], Victoria S do Nascimento[4], Maria E Ossowski[1], Gabriel F M Faria[5], Tayanna F Pimentel[6], Laiara M Moreira[1] and Vanessa Menezes-Oliveira[6], (1)Federal University of Santa Catarina (UFSC), Brazil, (2)Departamento de Entomologia, Museu Nacional/UFRJ, Brazil, (3)Programa de Pós-Graduação em Ecossistemas Agrícolas e Naturais (PPGEAN), Universidade Federal de Santa Catarina (UFSC), Brazil, (4)Programa de Pós-graduação em Ciências Florestais e Ambientais, Universidade Federal do Tocantins (UFT), Brazil, (5)Curso de Engenharia Agronômica, Universidade Estadual de Tocantins (Unitins), Brazil, (6)Programa de Pós-Graduação em Biodiversidade, Ecologia e Conservação (PPGBEC), Universidade Federal do Tocantins (UFT), Brazil*

Microarthropod species have been used as bioindicators of soil quality, being very sensitive to abiotic and biotic changes in ecosystems, as well as to soil contamination. Although these organisms represent a small proportion of soil biomass and respiration, they have a crucial role in nutrient cycling and microbiological regulation in soil ecosystems. To improve the pesticide risk assessment in Brazil, this work aimed: 1) to list the representative collembola and predatory mite species from Brazilian agricultural areas; 2) to compare the sensitivity of the standard species of collembola, *Folsomia candida,* and the predatory mite *Hypoaspis aculeifer*, with alternative species, in ecotoxicity tests with natural and artificial soil. To achieve the first objective, a literature review was performed. The most common sub-order was Entomobryomorpha, with emphasis on the Entomobryidae and Isotomidae families (50% of all). Although *F. candida* was not found in Brazil, the genus was present in agricultural fields. The literature review showed that *F. candida* is very sensitive to different pesticides, but there is a lack of data for comparisons among species. To achieve the second objective, ecotoxicity tests were performed with the standard species *F. candida* and *H. aculeifer*, and the alternative collembola species *Proisotoma minuta* and *Sinella curviseta*, in one natural tropical soil (Oxisol) and one tropical artificial soil (TAS), to answer the questions: a) Are the results from the sensitivity of *F. candida* and *H. aculeifer* enough to protect other species?; b) Are the pesticide effects in artificial soil similar to that in Oxisol? For this purpose, the active ingredients (a.i.) from the two most commercialized pesticides in Brazil were evaluated, imidacloprid and mancozeb. Reproduction tests followed the ISO 11267, with adaptations for the alternative species (e.g., 20 organisms per replicate for species with sexual reproduction). NOEC and EC values were compared among species and soils for each a.i. Results indicated that *F. candida* is potentially enough sensitive to protect other Collembola species and that, depending on the species, protection values obtained with natural soil can be more restrictive than those obtained with artificial soil. Additional studies with other microarthropod species and their exposure are of crucial importance to better understand the reliability of extrapolating results obtained with *F. candida* to protect other species.

4.06.P-We346 Compatibility of commercial bacterial consortium of plant biostimulant with copper-based pesticides
*Sara Cristiana Lopes Peixoto[1], **Marija Prodana**[1], Rui G. Morgado[1], Luís Tavares[2] and Susana Loureiro[3], (1)CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal*
Plant-biostimulants based on beneficial microorganisms (mPB) are currently being developed to boost crop productivity mainly by increasing nutrient efficiency in soil, representing an environmentally friendly alternative to conventional agrochemicals. Several reports have indicated that these nature-based products increase the ability of plants to grow under adverse environmental conditions, such as drought and low temperatures. However, studies reporting the compatibility of these microbial-based biostimulants with agrochemicals commonly used in agriculture are scarce and not fully understood. To address this knowledge gap, our study aimed to investigate whether commercial microbial based-biostimulants containing a consortium of bacteria, namely *Azospirillum brasilense* and *Pseudomonas fluorescens*, could lead to synergistic, antagonistic, or neutral effects on plant performance and soil functioning when applied in combination with conventional and nano-copper agrochemicals. For this, inhibition of biostimulant activity was tested in the presence of agrochemicals, using microdilution assays and enumeration of colony-forming bacteria. The inhibition assays were established using three doses of microbial biostimulants (3×10^6 (recommended dose); 6×10^6; and 3×10^7 cell/ml), exposed to a wide range of concentrations of three formulations of commercial pesticides with active ingredients of copper sulfate, copper oxychloride, and copper hydroxide, and one nano-based pesticide (nCuO): 0 to 30 mg[Cu]/ml. A pot experiment was conducted using a natural soil inoculated with microbial biostimulant, in the presence of *Medicago sativa L.* and exposed to copper-based agrochemicals, for 28 days, to validate the compatibility of these products. As a result, microbial-based biostimulants were susceptible to conventional- and nano-pesticides in a dose-dependent manner, in which the highest inhibition rate was observed in the highest concentrations of copper. The preliminary results from soil pot experiments suggested that the microbial biostimulant stimulates plant growth, dependent on the copper concentration tested. Thus, this study emphasizes the potential use of this bacterial consortium of plant-biostimulants in conventional agricultural systems. Furthermore, this data can also be considered a baseline for an in-depth investigation of the functional recovery of degraded soils affected by intensive agricultural practices.

4.06.P-We347 Integrating Terrestrial Model Ecosystems into Soil Risk Assessment – A Tier 3 Refinement Option
***Hanna Samantha Schuster**[1], Johanna Oellers[2], Ellie Welch[1], Abdul Abu[1], Zoe Leanne Parker-Crosse[1], Nadine S Taylor[1] and Monika Hammers-Wirtz[2], (1)Cambridge Environmental Assessments (CEA), United Kingdom, (2)gaiac Research Institute, Germany*
Soil dwellers are an essential part of healthy soils that support ecosystem functions and services such as nutrient cycling essential for ensuring crop growth (EFSA 2017). In the European Union (EU), there is the requirement to assess and understand the risk of plant protection products (PPP) to soil dwelling organisms. The current risk assessment for soil organisms compares the NOEC (No Observed Effect Concentration) and/or EC10/20 (Effect Concentration with a 10% / 20% effect) to the maximum Predicted Environmental Concentration in the soil (PECsoil) calculated according to FOCUS (FOCUS 1997).

The proposed introduction of a new exposure assessment procedure for in-field soil organisms is expected to impact the current risk acceptability of many PPPs. Specifically, Tier 1 and 2 of the EFSA (2017) exposure assessment procedure uses the Persistence in Soil Analytical Model (PERSAM), which integrates European scale environmental and agronomic data for calculation of PECsoil values for the three EU Regulatory Zones and Individual Member States. Therefore, existing PECsoil values (FOCUS) are subject to change, and it is also likely that the new PECsoil values (PERSAM) will be higher than current ecotoxicological endpoints, causing PPP risk assessments to fail.

Where a compound fails the risk assessment at Tier 1 of the ecotoxicological risk assessment, field studies are often the only option for endpoint refinement. Intermediate tiers such as extended laboratory studies (Tier 2: non-standard species, exposure refinement, modelling) and soil mesocosm studies (Tier 3) to address issues in the risk assessment are rarely conducted. This lack of regulatory accepted interim tiers necessitates an increased need for the development of robust intermediate tier options to close this growing gap in soil risk assessment. Terrestrial Model Ecosystems (TMEs), where soil cores taken from a pasture or meadow to ensure sufficient abundance and biodiversity for reliable outcomes, have been shown to be a robust testing system, however, they have yet to be incorporated into soil risk assessments. As soil risk assessments aim to protect in-field soil dwellers, TMEs represent a worst-case scenario and results can be regarded as protective of in-field organisms, in a similar concept to aquatic mesocosms representing edge-of-field systems.

Here we aim to present ideas and concepts on how to use TMEs as a refinement option at Tier 3 for the effects on soil dwelling organisms.

4.06.P-We348 Ecotoxicity of commercial nanopesticide to the soil model Enchytraeus crypticus (Oligochaeta): from standard tests to long(er)-term effects assessment

*Susana I.L. Gomes[1], Sekerani B Chidiamassamba[1], Janeck J Scott-Fordsmand[2] and **Monica Amorim**[1], (1)Biology, Department of Biology & CESAM, University of Aveiro, Portugal, (2)Department of Ecoscience, Aarhus University, Denmark*

Nanopesticides hold the promise of being more environmentally sustainable alternatives to conventional pesticides due to their increased effectiveness and targeted delivery, allowing the reduction of application rates, hence increasing agricultural productivity in a more sustainable way. However, given its novelty, the environmental risk assessment of these advanced materials is mostly absent, particularly concerning non-target organism. Among those, soil living invertebrates are in the first line of exposure from pesticides application and their run-offs. Thus, the aim of the present study was to investigate the toxicity of a commercial insecticide, with reported nanofeatures - Karate Zeon®, and compare it to the active substance lambda-cyhalothrin, for the soil model invertebrate species *Enchytraeus crypticus* (Oligochaeta). Effects were assessed in LUFA 2.2 soil, covering various endpoints and life-stages, beyond the standard, from short- to long(er)-term exposures. Four test types were performed (endpoints:days): avoidance test (avoidance behaviour: 2 days), OECD standard reproduction test (survival, reproduction plus adults' size: 28days) and its extension (total number organisms: 56 days), and Full Life Cycle (FLC) test (hatching and juveniles' size: 13 days; survival, reproduction and adults' size: 46 days). Results showed that enchytraeids did not avoid Karate Zeon® nor the active substance lambda-cyhalothrin, which could be due to neurotoxicity. Karate Zeon® was equally toxic to the active substance lambda-cyhalothrin in *E. crypticus* and there was no indication that toxicity would increase in prolonged exposure (based on the 56d results). FLCt results indicated that juvenile life stage was the most sensitive life stage to both Karate Zeon® and lambda-cyhalothrin exposure, resulting in an increased toxicity for the survival of adult animals that were exposed from the cocoon stage (as opposed to the exposure during adult stage alone). The similar toxicity between Karate Zeon® and lambda-cyhalothrin shows that, if given at a lower application rate, the nanopesticide could still theoretically pose lower risks to the enchytraeid population and hence it would represent an improved benefit to substitute to an advanced material. We here show the potential of novel approaches to test methods, beyond the standard, where the longer-term exposure and additional endpoints represent remarkable added value to the interpretation.

4.06.P-We349 “FORESEE”: A Spatial and Temporal Explicit (DEB-)TKTD Model for Earthworms

***Natalie Carmen Dallmann**[1], Kim Rakel, MSc Ecotoxicology RWTH University[1], André Gergs[2], Gregor Ernst[2] and Vanessa Roeben[2], (1)gaiac - Research Institute for Ecosystem Analysis and Assessment, Germany, (2)Bayer AG - Crop Science Division, Germany*

Earthworms represent an important factor for soil health as they are main contributors to nutrient availability in soil and influence the soil structure due to their burrowing behavior. For these ecosystem services, they are used in risk assessment of plant protection products as non-target organisms. To reduce the need of laborious field studies and to be able to predict the behavior or population dynamics of different earthworm species based on different weather and/or exposure scenarios, Johnston et al. introduced two independent individual based earthworm models in 2014 and 2018, the “EEEworm”, for *Aporrectodea caliginosa* and *Lumbricus terrestris*, respectively.

With the development of the dynamic energy budget model (DEB) and extension of the AddmyPet-database in the past years, the possibility was provided to convert the previous earthworm models into the generic earthworm model “FORESEE” with the individual development of the worms based on DEB theory. Moreover, to add to realism, species-dependent movement due to moisture and food gradients calibrated to lab experiments as presented in Gergs et al. 2022 was newly integrated into the model.

To evaluate the performance of the new model, we will use the case studies applied by Johnston et al. 2014 & 2018 and compare the predictions of FORESEE and the previous work of Johnston et al. on which FORESEE is based on.

4.06.P-We350 Long-term nanoplastics exposure affects soil carbon dioxide emission and microbial carbon metabolism in agricultural soil

***Chi-Wei Huang**[1] and Vivian Hsiu-Chuan Liao[2], (1)Department of Marine Environmental Engineering, National Kaohsiung University of Science and Technology, Taiwan, (2)Department of Bioenvironmental Systems Engineering, National Taiwan University, Taiwan*

Nanoplastics (NPs), arising from physical breakdown or chemical degradation of plastic pollutants, can accumulate in soil through sludge application and landfill. With the escalating production and disposal of plastic, the environmental concentration of NPs is likely to increase, posing potential risks to soil ecosystems. However, the harmful effects of NPs on the soil function and carbon metabolism remain much unclear. In this study, we investigated the impacts of NPs on agricultural soil and its microbial community. Our findings showed that, following a 56-d incubation, the NPs-treated soil exhibited higher total organic carbon compared to the control. At day 56, the activities of extracellular enzymes, glucosidase, and xylosidase were significantly inhibited in the NPs-treated soil. Moreover, carbon dioxide (CO_2) emission was found to notably decrease in soil in the presence of NPs after 56 days. We also observed a significant decrease in the abundance of the most prevalent bacterial species in the soil samples (*Bradyrhizobium* sp.). In addition, the genes associated with carbon metabolism were altered by the presence of NPs. Our study indicates that long-term exposure to NPs (56 days) hinders carbon metabolism and reduces CO_2 emissions in the agricultural soil samples, potentially linked to the diminished abundance of *Bradyrhizobium* sp.

4.06.P-We351 Ecotoxicological effects of roadside soils on earthworms - the role of pollution variation with distance and habitat type

Gintare Sujetoviene[1]*, Jurate Zaltauskaite*[2] *and Agnieszka Babczyńska*[3]*, (1)Vytautas Magnus University, Kaunas, Lithuania, (2)Vytautas Magnus University, Lithuania, (3)University of Silesia in Katowice*

Earthworms are one of the animals with the largest biomass in soil, playing critical roles in improving the permeability, water retention of the soil and improving soil quality. As a model organism, earthworms are more sensitive to pollutants than other soil organisms. The aim of the study was to evaluate the toxicity of contaminated highway soil to earthworm *Dendrobaena veneta*. The study sites – forest and meadow are located near the highway in Poland. Soil from the study sites was collected at different distances from the highway of the non-forest (meadow) site. The negative impact of soil collected ant non-forest site to earthworms' survival increased with the distance from the traffic line. The effect of contaminated soil was dependent on the distance from the road. In the soil collected 25 m from the traffic line, mortality was insignificant and no change in mortality was detected with increasing exposure time, while at 50 m from the traffic line, a significant lethal effect was detected from the first weeks of exposure and increased with increasing exposure for time. The effect of contaminated soil on earthworm weight depended on habitat type. The lowest weight loss was in the soil collected at the traffic line in the non-forest site. Weight loss decreased with increasing distance from the traffic line, with significantly lower weights compared to soil-exposed earthworms collected 25 m from the traffic line.

4.06.P-We352 Long-chain Hydrocarbon-Degrading Bacterial Communities in Long-Term Polluted Soil in Ogoniland, Niger Delta

Professor Chioma Blaise Chikere, PhD[1]*, Ramganesh Selvarajan*[2] *and Kevin Mearns*[3]*, (1)Department of Microbiology, UNIPORT; CAES - UNISA, Nigeria, (2)College of Agriculture and Environmental Sciences, UNISA Science Campus, South Africa, (3)Environmental Sciences, University of South Africa, South Africa*

This study is the first to identify long-chain n-alkane degrading genes in a Niger Delta soil microbiome severely impacted by oil pollution. Soil samples were collected from different depths, namely surface level (SPS) and one meter below the surface (SPSS), along with an unpolluted control sample (UPS) from a site approximately 1 km away. Physicochemical attributes, soil microbiome, and isolated bacterial cultures were characterized through standardized analytical methods, Illumina MiSeq and Sanger sequencing. Isolates were further screened for *almA* and *ladA* genes, which encode enzymes essential for hydrocarbon degradation. The study employed various enrichment media, including Hexadecane (HDX), Paraffin oil (POL), paraffin wax (PWX), and heavy bonny crude oil (HCO), and assessed degradation capabilities using the 2, 6-dichlorophenol indophenol (DCPIP) redox indicator. Total petroleum hydrocarbons (TPH) and polycyclic aromatic hydrocarbons (PAHs) were substantially higher in polluted soils. A range of bacterial species, including *Marinomonas* and *Pseudomonas*, exhibited significant hydrocarbon degradation capabilities. Only *Marinomonas* possessed the *almA* gene. Targeted amplicon analysis identified *Koribacteraceae*, *Rhizobiaceae*, and *Streptococcaceae* as core bacterial families in polluted soils. Alpha diversity metrics revealed higher microbial diversity at the surface soil compared to subsurface and highlighted the richest diversity in the unpolluted soil. The findings suggest that indigenous bacterial communities in the polluted site have the potential for long-chain hydrocarbon degradation, offering promising avenues for bioremediation strategies.

4.06.P-We353 Effects of Temperature and Moisture on the Ecotoxicity of Metal-Based Fungicides Towards Earthworms

Hussain Kaka[1]*, Prosper Ashibudike Opute*[2] *and Mark Maboeta*[3]*, (1)North-West University, South Africa, (2)University of Benin, Nigeria, (3)Zoology, North-West University, South Africa*

The aim of this study was to determine if varying soil moisture contents and different temperatures will influence the toxicity of single and binary mixtures of the fungicides, copper oxychloride and mancozeb, (in different concentrations) towards earthworms (*Eisenia andrei*) as bioindicators of soil quality. Tests were done using artificial soil in accordance with the OECD guidelines under two different temperatures *viz.* 20°C and 25°C and two different moisture contents *viz.* 30% and 50%. The concentrations for copper oxychloride (CuOx) were 200, 500 and 1000 mg/kg and mancozeb (MnZn) 44, 850 and 1250 mg/kg in single and binary mixtures. Endpoints measured included metal analyses, comet assays (DNA analysis) and soil enzymatic analyses. DNA damage increased as the concentrations of the treatments increased. Significant differences ($p<0.05$) were found between the different temperatures and soil moistures although the different experiments produced different results. Body metal analysis test corresponded with the comet assay test wherein there was an increase in body metal concentration as the concentrations of the treatments increased ($p<0.05$). Significant differences ($p<0.05$) were found in the copper and manganese concentrations although no significant differences were found in the zinc concentrations. Soil enzymatic analysis indicated significant differences in the alkaline phosphatase and glucosidase tests for the single and binary (copper oxychloride and mancozeb) treatments and at the 25°C 50% exposure it was the most significant. It is evident that fluctuating temperatures and soil moistures had varying effects on the single and binary mixtures of copper oxychloride and mancozeb. It was concluded that varying temperatures and soil moistures would have a significantly different result on the effects of metal-based fungicides towards earthworms.

Keywords: Alkaline phosphatase; Body metal analysis: Climate change; comet assay; Copper oxychloride; *Eisenia andrei;* Glucosidase; Mancozeb; Moisture; Temperature

4.06.P-We354 Heat Waves Decrease the Avoidance of Folsomia candida to the Fungicide Fontelis 20 SC

Sara Sophie Coordes*, Juliane Filser and Borbála Szabó, University of Bremen, Germany*

With increased mean temperature, heat waves, drought, cold snaps and extreme rain, climatic extremes cause severe changes in the environment and challenge biodiversity both above and below ground. Since the soil fauna is an important pillar in most soil ecosystem services, studying the effects of climate-induced stressors on these is essential. Extreme climate events can presumably also alter the effects of plant protection products on soil organisms. Hence, our focus is on the effects caused by the interaction of heat waves, drought, and agrochemicals in the model organism *Folsomia candida* (Collembola).

Here, our test substance is Fontelis 20 SC, a frequently used fungicide in the EU. The active ingredient penthiopyrad has not yet been tested on soil fauna and has limited data on its toxicity to other organisms. Thus, we studied the single and combined effects of heat waves, drought, and Fontelis 20 SC on the avoidance behaviour of *F. candida* (ISO 17512-2:2011). Based on observations in other tests with heat waves, we hypothesized that heat and drought change the avoidance behaviour towards Fontelis 20 SC compared to standard conditions.

Our treatment groups were one of three concentrations of Fontelis SC (750, 187.5, and 46.875 mg penthiopyrad/ kg dry soil) on one side, offered against clean soil, and a control group with clean soil on both sides. These concentrations were combined with the following 4 environments: Standard temperature (20 °C) with 50% and 35% of water holding capacity (WHC); heatwave (24 °C for 24 h then 28 °C for 48 h) with 50% and 35% WHC. We introduced twenty animals into each jar, with ten replicates for each treatment. We analysed the avoidance in each environment by a paired t-test and the combined effects of all stressors on the avoidance with a generalized linear model.

First results suggest that Fontelis 20 SC induces avoidance in high concentrations and preferential behaviour in low concentrations in *F. candida*, while the heat wave prevents overall movement. This suggests grave consequences for Collembola in contaminated sites during heat waves. In conclusion, this study highlights the importance of integrating climate change into ecotoxicological studies, not only as a potential stressor but also as a synergistic stressor in combination with agrochemicals.

4.06.P-We355 Natural Soil Testing in the OECD 226 Soil Mite Reproduction Test using Dimethoate

***Eva Aderjan*[1]**, *Navjot Kaur[2], Eiko Wagenhoff[3] and Andreas Duffner[1], (1)Eurofins Scientific, Germany, (2)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (3)Terrestrial Ecotoxicology Lab, Eurofins Agroscience Services Ecotox GmbH, Germany*

Soil pollution is a global issue that must be effectively addressed using appropriate risk assessment methodologies. Current laboratory testing for ecotoxicological risk assessment (ERA) of plant protection products (PPP) for non-target soil organisms using OECD artificial soil does not reflect the high variation in chemical-physical soil properties found in natural agroecosystems. Using natural soils for laboratory testing as an intermediate-tier option for soil organisms would be a valuable supplementation for the ERA.

Soil mites are regarded as crucial biological markers to evaluate possible effects of PPP, because as predators they add a new trophic level to the community of soil arthropods. However, for the OECD test species *H. aculeifer*, the usage of natural soils in laboratory testings are not adequately investigated, yet.

Four typical agricultural soils were compared to OECD artificial soil following OECD 226, to investigate if specific soil parameters have an influence on *H. aculeifer* lethal and reproduction toxicity of dimethoate.

We found that all tested soils were suitable for *H.aculeifer.* In case of biodegradable dimethoate, soil microbial biomass - the total mass of soil microbial degraders - was beside clay and organic matter one of the main explanatory factors for different toxicities between the tested soils. OECD artificial soil ranged among the soils with higher toxicity and lowest EC50 (3.75 (3.51-4.00) mg/kg sdw) and the lowest toxicity and highest EC50 (9.52 (8.10-11.19) mg/kg sdw) was found in a loamy soil with high microbial biomass.

4.06.P-We356 Ecotoxicological effects of sugarcane vinasse in natura and biogested in methanogenic reactor on the reproduction of Enchytraeus crypticus

***Mayara Caroline Felipe*[1]**, *Aline Bernegossi[2], Bárbara Franco Vieira[3], Marcelo Zaiat[4] and Cornelis A.M. van Gestel[5], (1)Hydraulics and Sanitation, University of São Paulo (USP), Brazil, (2)University of São Paulo (USP), Brazil, (3)Hidraulic and Sanitation, University of São Paulo (USP), Brazil, (4)São Carlos School of Engineering, University of São Paulo (USP), Brazil, (5)Amsterdam Institute for Life and Environment (A-LIFE), Vrije Universiteit Amsterdam, Netherlands*

Vinasse is a subproduct of the sugar or ethanol industry that has been applied in crops as a fertilizer, thus preventing the high contamination of direct discharge in water bodies. Although fertilizer use is considered a circular economy aggregating value to this subproduct, it is important to understand if the continued recycling of vinasse as a fertilizer is also safe and sustainable for the soil environment. This study evaluated if sugarcane vinasse causes any adverse effect on an important soil model organism, the potworm Enchytraeus crypticus. The tests were carried out for 21 days of duration using sugarcane vinasse in natura (collected from a large-scale sugar and ethanol plant located in Pradópolis in the State of São Paulo, Brazil) and sugarcane vinasse biodigested (effluent of a lab-scale (2.1L) methanogenic anaerobic structured bed reactor (AnSTBR) from the Biologic Process Laboratory (LPB) in a methanogenic reactor) and LUFA 2.2 soil, and were exposed to six vinasse concentrations (0.23, 0.92, 3.59, 14.38, 57.50 and 230 ml/kg dry soil, the highest concentration corresponding with the recommended field dose). The concentration of vinasse did not affect the survival or reproduction of the enchytraeids ($p = 0.273$ and 0.489, Two Way ANOVA, factor A). The type of vinasse (in natura or biodigested) did significantly impact the ecotoxicological response ($p < 0.05$, Two-Way ANOVA, factor B), with higher survival and reproduction in the exposures to biodigested sugarcane vinasse. Such an increase was, however, also observed in the controls. Our results indicate that in natura sugarcane vinasse can alter the chemical characteristics of the soil but has a low impact on the life cycle of E. crypticus. It is recommended to expand the understanding of the potential effects of the continued use of sugarcane vinasse for other species or soil organism, and also to assess its effects on aquatic organisms considering the potential runoff occurring in the field.

4.06.P-We357 Abundance of frequently found soil organisms (Collembola) in ecotoxicological field studies in Central Europe and determination of their normal operating range – part 1

***Agnes Schimera**[1], Jörg Hanisch[2], Gregor Ernst[3], Zhenglei Gao[4], Michael Thomas Marx[5], Frank Staab[6], Pernille Thorbek[7] and Lijuan Yan[8], (1)ADAMA Deutschland GmbH, Germany, (2)Rifcon GmbH, Germany, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany, (4)Data Science, Bayer AG, Germany, (5)Bayer AG, (6)BASF SE, Germany, (7)Apd/EE, BASF plc, United Kingdom, (8)BASF Services Europe GmbH, Germany*

For the registration of PPPs in the EU, an ecotoxicological risk assessment (RA) for soil organisms is required. In that context, field studies are conducted if a potential risk to non-target soil organisms cannot be excluded. They focus on recovery of earthworms or Collembola within one year after application of the respective product on grassland or arable soil. However, no official OECD Test Guidelines have been adopted for such field studies; ISO guideline 11268-3 adapted with literature data is used to conduct field studies on earthworms. Collembola field studies are generally conducted following these recommendations, yet there is a lack of guidance for evaluation and interpretation of results. Especially where a high natural variability of abundance of respective taxa is observed, this may lead to discussions on biological relevance and statistical significance, with a preprogramed high uncertainty on the outcome from a regulatory perspective.

We analysed and reviewed historical control data to investigate natural variability in Collembola populations in field studies conducted on grassland or arable soil in Central Europe. Frequently occurring species per study were selected based on the dominance classification of Engelmann from 1975. Variability in species abundance for selected taxa was investigated within one study, and across different studies, and the normal operating range (NOR) was determined. Due to the lack of a specific NOR definition for soil organisms in the literature, we propose to define it as the percentage by which the abundance deviates from the mean control value for a given taxon at one observation point, which can include a certain percentile range (e.g., all values between the 5th and 95th percentile).

Based on this evaluation, abundance of a species in treated samples can be compared with the NOR of the control for a specific study. The results shall support data interpretation of field studies and help to distinguish between natural variability and biologically relevant test item effects.

In the first part of this poster, the frequently found species in soil cores and pitfall traps of the available soil and grassland studies are presented. Based on our investigation, *Parisotoma notabilis* and *Protaphorura armata* are frequently found in soil cores of arable soil studies, while *Lepidocyrtus cyaneus* and *Isotoma viridis* are more prominent in grassland studies.

4.06.P-We358 Abundance of frequently found soil organisms (Collembola) in ecotoxicological field studies in Central Europe and determination of their normal operating range – part 2

***Agnes Schimera**[1], Jörg Hanisch[2], Gregor Ernst[3], Zhenglei Gao[4], Michael Thomas Marx[5], Frank Staab[6], Pernille Thorbek[7] and Lijuan Yan[8], (1)ADAMA Deutschland GmbH, Germany, (2)Rifcon GmbH, Germany, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany, (4)Data Science, Bayer AG, Germany, (5)Bayer AG, Germany, (6)BASF SE, Germany, (7)Apd/EE, BASF plc, United Kingdom, (8)BASF Services Europe GmbH, Germany*

For the registration of PPPs in the EU, an ecotoxicological risk assessment (RA) for soil organisms is required. In that context, field studies are conducted if a potential risk to non-target soil organisms cannot be excluded. They focus on recovery of earthworms or Collembola within one year after application of the respective product on grassland or arable soil. However, no official OECD Test Guidelines have been adopted for such field studies; ISO guideline 11268-3 adapted with literature data is used to conduct field studies on earthworms. Collembola field studies are generally conducted following these recommendations, yet there is a lack of guidance for evaluation and interpretation of results. Especially where a high natural variability of abundance of respective taxa is observed, this may lead to discussions on biological relevance and statistical significance, with a preprogramed high uncertainty on the outcome from a regulatory perspective.

We analysed and reviewed historical control data to investigate natural variability in Collembola populations in field studies conducted on grassland or arable soil in Central Europe. Frequently occurring species per study were selected based on the dominance classification of Engelmann from 1975. Variability in species abundance for selected taxa was investigated within one study, and across different studies, and the normal operating range (NOR) was determined. Due to the lack of a specific NOR definition for soil organisms in the literature, we propose to define it as the percentage by which the abundance deviates from the mean control value for a given taxon at one observation point, which can include a certain percentile range (e.g., all values between the 5th and 95th percentile).

Based on this evaluation, abundance of a species in treated samples can be compared with the NOR of the control for a specific study. The results shall support data interpretation of field studies and help to distinguish between natural variability and biologically relevant test item effects.

In the second part of this poster, the derived NORs of selected frequently found species from individual studies are presented, and compared with other studies where these species occur. Data shows that an overall NOR for a certain species and season cannot be derived; the NOR should be determined for each species and study individually. For a clear definition of the NOR, specific protection goals are required.

4.06.P-We359 Misfortunes never come singly: Interplay of temperature and soil moisture on toxicity of Cu contamination in springtails, Folsomia candida

Jian Ge[1], *Stine Slotsbo*[1], *Jesper Givskov Sørensen*[2], *Christian Frølund Damgaard*[1], *Alex Robinson*[3], *Emily Eagles*[3], *David Spurgeon*[3] *and Martin Holmstrup*[1], *(1)Department of Ecoscience, Aarhus University, Denmark, (2)Department of Biology, Aarhus University, Denmark, (3)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*

Ecotoxicologists have been endeavouring to incorporate important climatic stressors into environmental risk assessment (ERA) of anthropogenic contaminants. Temperature has been widely studied and recognised as one of the most important climatic factors influencing chemical effects on ectotherms. For soil-living arthropods, soil moisture has also been reported as a critical environmental factor not only for their survival, growth and reproduction but also for how they respond to simultaneous existence of contaminants. In this study, we conducted a full factorial experiment investigating the effects of temperature, soil moisture and Cu contamination on a typical soil arthropod, *Folsomia candida*. We hypothesize that the interplay of suboptimal temperatures and moisture conditions increases Cu bioaccumulation and consequently reduces physiological performance of springtails *F. candida*. Soils contaminated with three copper levels (approx. 40, 400 and 1500 mg/kg dry weight soil) were collected from a former timber preservation industry at Hygum, Denmark. Age-synchronized springtails (12-14 d; ten individuals per replicate) were exposed to the three exposure levels in Hygum soil and distributed to combinations of 5 temperatures (5, 10, 20, 24 and 28 °C) and 6 soil moisture levels (soil water potential: -3, -5, -10, -40, -70 and -100 kPa) with 5 replicates. After a 28-day exposure, adult springtails were weighed, and the numbers of adults and juveniles were counted to calculate survival, growth of adults and reproduction. The internal Cu concentration of springtails was measured using Inductively Coupled Plasma Mass Spectrometry. This research demonstrated synergistic interactions between suboptimal temperature, drought and Cu contamination reducing the survival, growth and reproduction of springtails, which shed new light on the role of multiple climatic stressors on soil arthropods under heavy metal contamination. Our findings also call for consideration of climatic stressors in existing ERA policies.

4.06.P-We360 Evaluating the Effect of Carbendazim on Soil Fauna Feeding Activity through a Bait-lamina Test

Higor Eisten Francisconi Lorin[1], *Ulrich Menke, Dr.*[2], *Gregor Ernst*[2], *Tiago Natal da Luz*[3], *Fabrielle P dos Reis*[4], *Laiara M Moreira*[4], *Luiz P P M Stiebler*[5], *Rafael Eguchi Cristófoli*[4], *Erick Dal Molin Pilati*[4], *Thomas M Kinupp*[4] *and Julia Carina Niemeyer*[4], *(1)Federal University of Santa Catarina (UFSC), Florianópolis, Brazil, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany, (3)CloverStrategy Lda, Portugal, (4)Federal University of Santa Catarina (UFSC), Brazil, (5)Programa de Pós-Graduação em Ecossistemas Agrícolas e Naturais (PPGEAN), Universidade Federal de Santa Catarina (UFSC), Brazil*

This study investigated the effects of the application of a fungicidal formulation with Carbendazim as active substance on the feeding activity of soil fauna using the Bait-lamina test following the procedures described in ISO 18311. A field test was conducted in a natural grassland and pasture area in Santa Catarina State, Brazil, in Nitisol with no history of pesticide application in the last 10 years. A Randomized Block Design (RBD) comprising three Carbendazim doses (0.32, 1.8 and 10 kg a.s./ha) plus a control (only sprayed with water) was followed adopting the recommendations of ISO 11268-3 for earthworm field test. Twenty-four bait-lamina sticks (i.e. 3 groups of 8 bait-lamina) were introduced in each plot 33, 188, and 365 days after fungicide application and left in the field each for 15 days. After this period, the percentage of bait consumption was estimated in each plot and at the three sampling times. The percentage of consumptions were compared between treatments by a repeated measures ANOVA followed by Dunnett test ($p<0.05$) for comparisons with control. In the 33-days sampling, significant differences were observed in the feeding activity between test treatments. The 0.32 and 1.8 kg a.s./ha treatments showed significantly higher consumptions compared to control, with mean consumptions of 62.5%, 52.1% and 33.8%, respectively for 0.32, 1.8 kg a.s./ha and control treatments. On the other hand, the highest dose of 10 kg a.s./ha showed a consumption of 38.7%, which was not significantly different from control. The significantly higher consumption found in bait-lamina of 0.32 and 1.8 kg a.s./kg treatments could be related to direct and/or indirect effects of an increase of microbial activity resulting from the degradation of Carbendazim molecules, which most likely does not happen at excessively high doses as 10 kg a.s./kg. At 188- and 365-days samplings, no significant differences were detected in consumptions of bait-lamina between treatments compared to control. These results suggest that Carbendazim does not negatively affect feeding activity of soil fauna in this soil type. However, measured actual soil concentrations of Carbendazim (residue analysis is ongoing) and the comparison of bait-lamina consumption data with soil fauna community measurements (in terms of diversity and abundances) would be desirable to confirm the non-effect of Carbendazim we found through bait-lamina.

4.06.P-We361 Sustainable agriculture strategies in the face of Climate Change: Biosolid compost and trace elements impact on soil and crops

Jose Antonio Mediano-Guisado[1], *Maria Teresa Domínguez*[2], *Engracia Madejón*[1], *Laura Lozano De Sosa*[1] *and Paula*

Madejón Rodriguez[3], (1)Soilplant, Institute of Natural Resources and Agrobiology of Seville, Spanish National Research Council (IRNAS-CSIC), Spain, (2)Cristalografía, Mineralogía y Química Agrícola, Universidad de Sevilla, Spain, (3)Soilplant, Institute of Natural Resources and Agrobiology of Seville (IRNAS-CSIC), Spain
Increasing soil organic carbon stocks can strengthen resilience of rainfed Mediterranean crops against shifting rainfall patterns. Biosolid compost (BC) offers an affordable and broadly available solution for these agricultural soils, yet its use may unintentionally amass trace elements (TE) in the soil. Long-term field studies have revealed notable TE buildup in the soil due to repeated compost applications. For this purpose, bioavailable fractions of harmful TE should be considered, given that these fractions are easily uptaken by plants and can be transported by drainage water. Additionally, numerous uncertainties exist concerning the dynamics of TE within BC under climate change conditions. Thus, changes in soil hydrology could accelerate or reduce the release and lixiviation of TE from soils. This research aims to understand TE inputs through compost, their behavior under drought conditions, and their impact on crop accumulation. A factorial experiment with 6 plots (6 × 50 m) was established under Mediterranean conditions. Each plot was divided into two subplots; half receiving no amendment (control) and the others treated with 50 T/ha of BC. Rainout shelters simulated reduced rainfall were established at each subplot. A crop rotation of legumes and wheat was selected. Analysis of the compost complied with regional legislation for TE content. Soil samples taken immediately after compost addition (November 2022, T=0) and before crop harvest in April 2023 (T=1) exhibited significantly higher total TE content in amended soils at T=0. The lower pH in amended soil heightened TE availability, a trend sustained for some TE (As, Cd, Cu, and Ni) at T=1, although at very low levels (μg kg-1), despite pH adjustment. After 5 months of study, reduced rainfall at T=1 did nut notably affect TE availability. Crop shoot TE levels (*Vicia faba*) across all treatments remained within normal ranges without signs of phytotoxicity. Continuous monitoring is necessary, as excessive compost application over time could escalate TE availability, potentially impacting crops in the long run.

4.06.P-We362 Sustainable waste management: The impact of olive pomace-derived Entomofertilizer on soil health
***Amid Mostafaie**[1], José Nereu Pinto[1], Ana Eduardo Rodrigues[2], Inês Bento Cruz[3], Marija Prodana[1], Sara Cristiana Lopes Peixoto[1], Ana Rita R. Silva[1], Daniel Murta[4], Ivã G. Lopes[5], Diogo N. Cardoso[1] and Susana Loureiro[6], (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)Department of Biology & CESAM-Centre for Environmental and Marine Studies, University of Aveiro, Portugal, (3)Department of Biology, University of Aveiro, Portugal, (4)Ingredient Odyssey S.A. - EntoGreen, Portugal, (5)Department of Biosystems and Technology, Swedish University of Agricultural Sciences (SLU), Sweden, (6)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal*
Integrating olive pomace into insect-based substrates presents a novel approach to addressing waste management challenges in the olive oil industry while increasing the sustainability of the use of insects for food and feed. The dual benefits of this approach, effective waste management and the production of high-quality and sustainable protein, align with global efforts towards a circular bioeconomy and sustainable food systems, making it a highly relevant topic in environmental and agricultural research.

Hermetia illucens (black soldier fly BSF) can use various organic substrates and produce frass, which is proposed as a valuable entomofertilizer. The efficacy of olive pomace-based entomofertilizer OP-BSF_{frass}, particularly its non-phytotoxic nature despite being derived from olive pomace, has been demonstrated in plant growth assays. However, further research is necessary to understand better its impact on soil microbiota and related functions.

This study aims to evaluate the effects of frass on soil quality parameters by looking at microbial community responses to the presence of (OP-BSF_{frass}) using soil functional parameters related to enzymatic activities (urease, β-glucosidase, aryl sulfatase, dehydrogenase, phosphatases-acidic and alkaline) and community-level physiological profiling (CLPP). OP-BSF_{frass} was added to Lufa 2.2 standard soil in different concentrations (from 0.3 to 9.6 %w/w) and incubated at 20°C for sixty two days. Results demonstrated that soil enzymatic activity increases in a dose-dependent manner with the concentration of OP-$BSF_{frass,}$ stimulating β-glucosidase, urease, alkaline phosphatase, and at the lowest concentration of frass, aryl sulphatase, and acidic phosphatase. Also, a significant decrease in the activity of acidic phosphatase, aryl-sulphatase, and dehydrogenase was observed in the highest concentrations of OP-BSF_{frass} (4.8%, 9.6%). The CLLP was analyzed using the average-well color development (AWCD) index, demonstrating a significant increase in the carbon-utilization pattern in microbial communities present in OP-BSF_{frass} treatments compared to the control soil. Overall, the results reveal that the moderate application of OP-BSF_{frass} stimulates the nutrient cycling and the metabolic activity of microbial communities, potentially due to the nutritional decomposition of the frass. The promising results of this entomofertilizer, derived from waste-fed *H. illucens*, are crucial in advancing sustainable waste management.

4.06.P-We363 Soil fertilization with a novel Zn fertilizer: The effects of Zn-Al-NO3 layered double hydroxide on soil biological and chemical properties and maize development
***Catarina Correia de Lemos Malheiro**[1], Amadeu M.V.M. Soares[2], Rui G. Morgado[3] and Susana Loureiro[4], (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)CESAM - Department of Biology, University of Aveiro, Portugal, (3)CESAM and Department of Biology, University of Aveiro, Portugal, (4)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal*
Zinc is an essential micronutrient that is vital in several plant physiological functions. When its supply is inadequate, the development of plants can be adversely impacted. To overcome this problem, especially in Zn-deficient soils, fertilizers containing Zn are applied. Still, their (over)application has been associated with harmful consequences to the environment,

such as soil degradation, through runoff causing water eutrophication, among others. In this sense, it is critical to develop novel Zn fertilizers to sustain crop production and quality, while maintaining the health of ecosystems. Layered double hydroxides (LDHs) are multifunctional nanomaterials whose potential for agricultural application as an alternative to Zn fertilizers has been progressively explored. Yet, to ensure sustainability, it is extremely important to understand their behaviour, fate, and toxicity in ecosystems. In this context, the aim of the present study was to evaluate the potential of Zn-Al-NO_3 LDH as an alternative Zn fertilizer, at relevant concentrations for agronomic applications. Zinc sulphate was tested as a conventional fertilizer. This integrated assessment lasted 19 days and combined the evaluation of plant performance and Zn bioaccumulation in maize (*Zea mays*), with soil quality indicators and Zn fate assessments. The ecotoxicological assessment evaluated the seed emergence and growth of maize and the functionality of soil microbial communities, through the activity of soil enzymes. Additionally, the bioavailability and accumulation of Zn in maize root and shoot tissues and the contents of Zn and nitrate in leachates were characterized. Applying Zn-Al-NO_3 LDH to soil slightly increased the shoot length and biomass of maize and the content of Zn in the plant roots. Soil enzymatic activities were influenced by both Zn-Al-NO_3 LDH concentrations in soil and incubation time, in an enzyme-specific response. The activity of soil enzymes increased over time in all treatments, except for urease. The soil treatment with Zn-Al-NO_3 LDH did not change the concentration of Zn in the DTPA-fraction and in leachates, the content of nitrates increased with the Zn-Al-NO_3 LDH increasing concentrations. Overall, our work shows that Zn-Al-NO_3 LDH can be an effective alternative to conventional fertilizers.

4.06.P-We364 From waste to resource: Exploring the use of Black Soldier Fly entomofertilizers to replace mineral fertilizers in agriculture practices

Ana Eduardo Rodrigues[1]*, Inês Bento Cruz*[1]*, José Nereu Pinto*[2]*, Amid Mostafaie*[3]*, Marija Prodana*[3]*, Ana Rita R. Silva*[2]*, Rui G. Morgado*[3]*, Sara Cristiana Lopes Peixoto*[3]*, Diogo N. Cardoso*[3] *and Susana Loureiro*[4]*, (1)Department of Biology, CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)CESAM & Department of Biology, University of Aveiro, Portugal, (3)CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (4)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal*

The interest in sustainable agriculture increased the exploration of new organic fertilizers, such as insect frass, a by-product of insect farming constituted by the leftover fecal matter. This study explores sustainable alternatives to traditional mineral fertilizers by assessing the efficacy of *Hermetia illucens* (black soldier fly) larvae frass, in agricultural applications. The effects of frass from different sources was tested in a soil pot experiment with *Brassica rapa*, where it was tested: (1) a reference frass produced by the insect digestion of agricultural leftovers and (2) a frass produced from the insect digestion of olive pomace, a residue from the olive oil industry known for its phytotoxic properties. We aim to assess the potential of both frasses to complement or replace conventional mineral fertilizer, NPK (nitrogen, phosphorus, potassium). Experimental treatments include NPK alone, each frass alone (at relevant application rates based on nitrogen content), and in combinations of each frass and NPK (at different proportions). The experimental control group consists of the natural LUFA 2.2 soil, the same soil used in the treatments, but without adding fertilizers. With this experimental setup, we selected plant performance and soil functional parameter endpoints for the efficacy of test treatments. Germination, biomass (growth, weight) and productivity endpoints (seeds, pods) of *B. rapa* under these different fertilization regimes were assessed following OECD 208 and ISO 22030-2011 guidelines, also ensuring the safety of using olive pomace-derived frass. Enzymatic activities (urease, β-glucosidase, aryl sulfatase, dehydrogenase, and both acidic and alkaline phosphatases) were measured to assess the impact of the treatments on soil biochemical properties and nutrient cycling. Our results suggest that both frasses stimulate plant growth, potentially offering a viable strategy to reduce the dependence on mineral fertilizers. Olive pomace frass does not exhibit phytotoxic effects on *B. rapa*, indicating the bioconversion process's effectiveness and providing input in using insects in waste management. Furthermore, soil enzymatic activity results reveal a positive influence of frass treatments on soil health, with positive implications for more environmentally friendly and resource-efficient farming methods.

4.06.P-We365 Ecotoxicological Evaluation of Drilling Cuttings from Oil Wells for Organomineral Fertilizer Development: Predicting Impacts on Forest Ecosystems

Fabrielle P dos Reis[1]*, Laiara M Moreira*[1]*, Higor Eisten Francisconi Lorin*[2]*, Roberta Schmidt*[1]*, Thomas M Kinupp*[1]*, Rafael Eguchi Cristófoli*[1]*, Erick Dal Molin Pilati*[1]*, Heraldo N de Souza*[3]*, Everaldo Zonta*[4] *and* ***Julia Carina Niemeyer***[1]*, (1)Federal University of Santa Catarina (UFSC), Brazil, (2)Federal University of Santa Catarina (UFSC), Florianópolis, Brazil, (3)Centro de Pesquisa e Desenvolvimento Leopoldo Américo Miguez de Mello (CENPES), Brazil, (4)Programa de Pós-Graduação em Agronomia, Universidade Federal Rural do Rio de Janeiro (UFRRJ), Brazil*

The oil industry holds significant importance for the Brazilian economy, being a major contributor to non-renewable energy raw materials. However, it also generates substantial waste, including liquid, solid, and gaseous residues with significant pollutant potential. Among these, gravel from oil well drilling stands out due to its pollution potential and large volume. Research and studies have focused on this waste due to its chemical components such as K, Ca, P, Mg, Fe, among others, making it potentially useful in non-food agricultural sectors, forestry, and the restoration of degraded areas as organomineral fertilizer. However, its use is limited due to high sodium (Na) content, which can be ecotoxic to plants and soil invertebrates. As a strategy, gravel from oil wells was treated to reduce Na content. This study aimed to evaluate the ecotoxicity of gravel from post-salt and pre-salt oil well drilling after treatment, analyzing its potential for organomineral fertilizer production and recommending its use in forest areas. Two ecotoxicity tests were conducted with treated gravel from pre-salt and post-salt layers. The first assay, based on ABNT NBR/ISO 11269-2 and adapted by Silva (2019), assessed growth and biomass with the tree species *Mimosa scabrella*. Different concentrations (0.25% to 5%) of pre-salt and post-salt gravel in Tropical Artificial

Soil (SAT) were tested, evaluating aerial and root length, as well as dry mass. The second test, a multispecies test used Tropical Artificial Soil with gravel concentrations (0.25% to 5%) to assess the response of two test organisms, *Folsomia candida* and *Enchytraeus crypticus*. It examined if contaminants affected soil fauna feeding activity and tested organism reproduction. Data were analyzed by comparing treatments to the control (no gravel addition) using Analysis of Variance (ANOVA) followed by Dunnett's test ($p<0.05$) or Kruskal-Wallis test followed by Dunn's test. Overall, results showed no ecotoxicity associated with the waste for tree species germination and initial development. In the multispecies test, different concentrations of treated gravel did not adversely affect the feeding activity or reproduction of test organisms. Concentrations ranging from 0.25% (equivalent to 6.5 tons/ha) to 5% (equivalent to 130 tons/ha) demonstrate potential for use as organomineral fertilizer, especially in forest planting and degraded area restoration scenarios.

4.06.P-We366 A Spatiotemporally Explicit Modeling Approach for Exposure and Risk Assessment of Off-field Soil Organisms

Christopher M Holmes[1]*, Thorsten Schad*[2]*, Sascha Bub*[3]*, Magnus Wang*[4]*, Klaus Hammel*[2] *and Gregor Ernst*[5]*, (1)Applied Analysis Solutions, LLC, (2)Bayer AG - Crop Science Division, Germany, (3)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (4)WSC Scientific GmbH, Germany, (5)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Natural and semi-natural habitats of soil living organisms in cultivated landscapes can be subject to unintended exposure by active substances of pesticides used in adjacent fields. Spray-drift deposition and runoff are considered major exposure routes into such off-field areas. In this work we develop a model (xOffFieldSoil) and associated scenarios to estimate exposure of off-field soil habitats at flexible levels of realism (https://github.com/xlandscape/xOffFieldSoilRisk). The modular approach consists of components each addressing a specific aspect of exposure processes, e.g., pesticide use, drift deposition, runoff generation and filtering, and PECsoil estimation. The approach is spatiotemporally explicit and operates at scales ranging from local edge-of-field to large landscapes. The outcome can be aggregated and presented as comprehensible endpoints to the risk assessor, considering ecologically relevant dimensions and scales for species protection. The approach also assesses the effect of mitigation options, e.g., field margins, in-field buffers, or drift-reducing technology. Presented scenarios start with a schematic edge-of-field situation and extend to real-world landscapes of up to 5 km x 5 km. A case study was conducted for two active substances of different environmental fate characteristics. Results are presented as a collection of percentiles over time and space, as contour plots and as maps. The results show that exposure patterns of off-field soil organisms are of a complex nature due to spatial and temporal variabilities combined with landscape structure and event-based processes. Our concepts and preliminary analysis demonstrate that more realistic exposure data can be meaningfully consolidated to serve in standard-tier risk assessments. The real-world landscape-scale scenarios indicate risk hot-spots which support the identification of efficient risk mitigation. As a next step, the spatiotemporally explicit exposure data can be directly coupled to ecological effect models (e.g., for earthworms or collembola) to conduct risk assessments at biological entity levels.

4.07 Legacy of War: Environmental Contamination, Ecotoxicity and Human Health Concerns of Explosives and Chemical Warfare Agents

4.07.T-01 Disposal of ammunition from World War One (1914 -1918) on the western front by Open-Burning. The fingerprint of 100-year old forgotten contaminations

Daniel Hubé*, French Geological Survey (BRGM), France*

During the World War One, ammunition was used on an unprecedented scale. When hostilities ceased, huge ammunition dumps remained as fired unexploded ordnances. There was an urgent need to dispose of 2.5 to 3 million tons of hazardous ammunition during the interwar period. More than 200 old ammunition destruction sites have been identified in France. New methods for safely breaking down projectiles, including Open-Burning (OB), were subsequently developed and operated, causing severe contaminations of topsoil and likely contributing to the contamination of groundwater by perchlorate and nitroaromatics compounds (NAC) on a regional scale. However, few studies (often fragmentary) are available on this topic. Recent research was carried out on 9 abandoned burning-grounds in France and Belgium to fingerprint the contamination and assess risks to land and groundwater use. Because the possible presence of warfare material and extremely high concentrations of hazardous compounds, special methods have been developed to safely sample OB residues and soils. Metals, NAC, chemical warfare agents and theirs by-products, chlorinated and brominates dioxins (PCDD/F, PBDD/F) were analyzed. Parts of munitions have also been collected to be characterized by EOD experts. No vegetation grows at some OB locations due to extreme contamination by heavy metals (Zn: 10 to 100 g /kg DM, As: 2 to 110 g/kg DM) and PCDD/F (1,000 to 4,000,000 ng/kg DM). Isomer distribution patterns indicate that PCDF were the preferred products of burning when primary precursors are chlorinated diphenylarsenical compounds, while ∑PCDF equal ∑PCDD when monoaromatic compounds and/or sulfur mustard (dichlorodiethyl sulfide) was decomposed. There are some historical and geoscientifical evidences that the fires were out of control with temperature ranging from ca. 300 °C to up to 1,500 °C, over PCDD/F pyrolysis temperature. PCDD/F formation in OB fires may drastically increase when temperature decreased in the presence of precursors mass excess. Inorganic arsenical compounds were associated with organic As by-products where arsenical shells loaded with the sternutator diphenylchlorarsine were open-burned. The fingerprint of contamination is to be linked with the composition of the ammunition being destroyed, and the manner to operated burnings, giving i) valuable historical information that is missing in archive records, and ii) data how to assess OB sites in order to protect public health and environment.

4.07.T-02 Monitoring environmental contamination from relic munitions in the Baltic Sea using lab-based methods and novel fieldable instrumentation

***Aaron J Beck**, Kenneth Arinaitwe, Mario Esposito, Björn Raupers, Martha Gledhill, Jens Greinert and Eric P. Achterberg, GEOMAR Helmholtz Center for Ocean Research Kiel, Germany*

The environmental contamination from relic munitions (i.e., the explosive chemicals TNT, RDX, and DNB) has been mapped throughout German waters of the Baltic Sea on a near-annual basis since 2018. This monitoring relies on highly sensitive and selective methods using solid-phase preconcentration, liquid chromatography, and high-resolution mass spectrometry. Observed patterns show clear hotspots of contaminant release from particular munitions dumpsites, which has been confirmed by visual verification of exposed explosives at these sites. Spatial distributions indicate that the type of chemical contamination varies among dumpsites, likely due to sorting of munition types during demilitarization dumping activities. Interannual variability evident for e.g., TNT at the major dumpsite Kolberger Heide, suggests that chemical release is not constant over time, and that regular monitoring is necessary to evaluate environmental risk. However, lab-based methods are extremely time- and effort-intensive, making such monitoring challenging. A new lab-in-a-box system, the Xplotector, has been developed for automated, shipboard analysis of munition chemicals at the sub-ng/L level in seawater. The southwest Baltic Sea and Danish straits were successfully mapped in October 2023, and showed TNT levels generally less than 1 ng/L. Low TNT concentrations were also detected directly above piles of apparently intact munition objects, whereas concentrations increased by many orders of magnitude near corroded munitions. These real-time analysis capabilities allow responsive sampling during monitoring, and greatly speed data acquisition for mapping. Advances in automated analysis of organic contaminants have the potential to revolutionize chemical monitoring for example during munitions clearance or extreme weather events.

4.07.T-03 Life-History Effects of Munition-Related Chemicals in the Copepod Nitocra spinipes: Single Chemicals and a Mixture

***João Barbosa**, Colin Janssen and Jana Asselman, Blue Growth Research Lab, Ghent University (UGent), Belgium*

The extensive disposal of munition, including conventional explosives and chemical warfare agents, in global coastal and off-shore sites post-World Wars I and II has led to concerns about environmental contamination. Due to decades of exposure to seawater, munition shells are anticipated to be highly corroded, releasing toxic chemicals into the environment. *Nitocra spinipes*, a copepod benthic species inhabiting these coastal areas, is crucial for connecting microphytobenthos to higher trophic levels in marine systems. Despite escalating environmental concerns, the toxic potential of dumped munition and their degradation products remains largely unknown.

This study provides insight into the impact of seven munition-related chemicals, i.e. thiodiglycol, 1,4-dithiane, 1,4-oxathiane, TNT, tetryl, 1,3-DNB and picric acid, and a mixture on the life cycle of *Nitocra spinipes*, while mimicking as closely as possible the North Sea environmental conditions. Internationally accepted guidelines were used to assess the impact on larval development, focusing on pre-adult mortality and larval development ratio (ISO 18220), and reproductive endpoints, namely inter-brood time and brood size (ENV/JM/MONO(2014)17). Despite conservatively chosen concentration ranges, all munition-related chemicals significantly impacted larval development endpoints. Notably, 1,4-dithiane affected developmental endpoints yet at environmentally unrealistic concentrations, while tetryl emerged as the most toxic E&RC, showing significant effects at environmentally relevant concentrations. The chemical mixture led to severe pre-adult mortality at lower concentrations (in the range of low µg/L) than individual chemicals, indicating synergistic interactions. Reproduction test results generally exhibited non-monotonic concentration-response patterns, with large intra-concentration variability. Exceptionally, tetryl caused significant delays in inter-brood time, and picric acid reduced brood size, suggesting particular concern in scenarios of chronic exposure.

The study demonstrates the effects of the tested munition-related chemicals on two key indicators of population ecology, with potential implications for the marine food chain. The high pre-adult mortality observed from exposure to the chemical mixture and the reported sub-lethal effects underscore the need for more chronic studies involving different species to comprehensively understand the impact of munition dumpsites on marine ecosystems.

4.07.T-04 How Contaminated is our Fish with Munition Chemicals from World War Relics

***Edmund Maser**, Tobias Bünning and Jennifer Strehse, Institute of Toxicology and Pharmacology for Natural Scientists, University Medical School Schleswig-Holstein, Germany*

Seas worldwide are threatened by an emerging source of pollution: millions of tons of all kinds of warfare materials were dumped after World Wars I and II. The global amount of unexploded ordnances (UXO) is hard to quantify. However, after more than 70 years the metal shells of these munitions are corroding, such that energetic compounds (EC) leak out, distribute in the marine environment and contaminate surrounding sediment and water. In addition, EC are absorbed by aquatic organisms and pose a threat to both the marine ecosphere and human seafood consumers.

EC like TNT are known for their toxicity and potential carcinogenicity. Therefore, persistent contamination of the marine ecosystem may cause adverse effects to marine life, and directly affect human health via entry into the marine food chain. To date, little is known about the bioavailability, accumulation, distribution, metabolism, detoxification, excretion, and *in vivo* toxic properties of EC from sea-dumped munitions.

In the present study, sediment and fish were examined in defined areas of the North Sea (Lower Saxony) to determine whether EC transfer to fish living in these regions. Of special interest was to infer if EC are present in the edible part (fillet) of the fish and if this endangers the human seafood consumer. Sediment and fish (*Limanda limanda*; dab) samples werde collected, processed and analyzed for the presence of diffent EC by gas and liquid chromatography coupled with mass spectrometry.

In the sediments EC were found in trace concentrations of approx. 1 ng/kg dried sediment. Next, a total of 33 fillet and bile samples were examined for different EC. All fish bile samples were positive for EC detection. Mean concentrations ranged below the one-digit ng/ml for TNT and its metabolites. EC residues could also be measured in the fillet of the flatfish. While TNT metabolites were below 1 ng/g of dry weight, TNT itself was found in concentrations of around 2 to 4 ng/g dry weight. This is interesting, because, as was the case for fish bile, higher concentrations of the TNT metabolites were to expected in the fish fillet, rather than parent TNT. Therefore, we hypothesize an absorption of EC into fish fillet other than per diet.

We conclude 1) EC from corroding World War munitions transfer into marine biota; 2) EC appear in the fish fillet and might therefore endanger human seafood consumers; 3) TNT obviously enters fish through an additional route, e.g. by gills, in addition to diet.

4.07.P Legacy of War: Environmental Contamination, Ecotoxicity and Human Health Concerns of Explosives and Chemical Warfare Agents

4.07.P-Tu386 Munitions at Sea: Making ecotoxicological sense out of a littered seafloor – spatial and temporal considerations

***Guilherme R. Lotufo*[1]*, Gunther H. Rosen[2], Edmund Maser[3] and Jennifer Strehse[3], (1)U.S. Army Engineer Research and Development Center, (2)Naval Information Warfare Center (NIWC) Pacific, (3)Institute of Toxicology and Pharmacology for Natural Scientists, University Medical School Schleswig-Holstein, Germany*

Underwater unexploded ordnance and discarded military conventional munitions, collectively referred to as underwater military munitions (UWMM), present challenges due to both explosive blast (safety) considerations and potential ecological and human health impacts resulting from the release of munitions constituents (MC) to the aquatic environment. UWMM have the potential to corrode, breach, and leak MC into aquatic environments. When undissolved MCs still contained within a munition enters the aquatic environment, they are not immediately released; environmental releases only occur after the munition is breached by corrosion or mechanical breakage. Breaching can occur either through explosion, mechanical breakup on impact or through corrosion. Historically, large quantities of munitions have been disposed of in the oceans and in large lakes. Despite the large mass of MC present within UWMM at some sites, exposure measurements and estimates have shown that MC is typically present below the limit of detection or at low concentrations (e.g., single digit µg/L). Site characterization efforts at coastal sites have revealed relatively small areas with high concentrations associated with point sources of release with the contamination decreasing orders of magnitude at short distances (e.g., 1 m). As a result of the heterogenous distribution of contamination, the majority of the organisms living at UWMMs sites are likely unaffected by MC present in the water column and sediment, but sessile or low motility organisms, including corals and larval fish, living in those areas of localized higher MC concentrations may be adversely impacted. Potential ecological risk to biota at well-investigated UWMM sites, as well as approaches for site characterization and risk management for UWMM sites will be discussed.

4.07.P-Tu387 Depuration Kinetics of TNT and its Metabolites in lab Exposed Blue Mussels (Mytilus edulis, L.)

***Matthias Brenner*[1]*, Romina Marietta Schuster[2], Franziska Isabell Binder Mrs.[3], Tobias Bünning[4], Jennifer Strehse[4] and Edmund Maser[4], (1)Alfred Wegener Institute for Polar and Marine Research, Bremerhaven, Germany, (2)Ecological Chemistry, University of Bremen, Germany, (3)Ecological Chemistry, Alfred Wegener Institute Helmholtz-Center for Polar and Marine Research, Germany, (4)Institute of Toxicology and Pharmacology for Natural Scientists, University Medical School Schleswig-Holstein, Germany*

Explosive chemicals released by dumped warfare material pose a threat to the marine environment and can enter the marine food web. These chemicals are toxic and are suspected to be carcinogenic, mutagenic and have also genotoxic effects. 2,4,6-Trinitrotoluene (TNT) is one of the most used explosives in munitions and therefore of special interest. To test the potential uptake, bio-concentration or bio-accumulation, and metabolism or depuration of TNT in marine organisms two lab exposure experiments were conducted using common blue mussels (*Mytilus edulis*). Mussels were exposed to different TNT concentrations for a specific period of time. The first experiment ran for a total of 120 hours, with 48 hours of exposure to different TNT concentrations (0 mg/L, 0.625 mg/L, 1.25 mg/L and 2.5 mg/L) followed by a 72 hours recovery phase in clean artificial seawater. Mussel sampling took place during the recovery phase.

The second experiment was performed as follow up to the first experiment and was conducted over 36 hours, with 24 hours of exposure and 12 hours of recovery. Water and mussel samples were taken during exposure and recovery phase with a higher sampling resolution within the first hours of the recovery phase.

GC-MS/MS was used to determine the mussel tissue and water concentration of TNT and its metabolites 2-amino-4,6-dinitrotoluol (2-ADNT), 4-amino-2,6-dinitrotoluol (4-ADNT) and 2,4-diamino-6-nitrotoluene (2,4-DANT).

Results of the first experiment showed a rapid decrease in TNT and metabolite concentrations in mussel tissues over time. Overall, 57 to 76 % of the detected concentration was metabolised within the first four hours after the exposure. Analysis of samples of the second experiment verified the results from the first experiment showing clear linear digression of the two ADNTs within the first four hours of the recovery phase and a more or less complete metabolism of the parent compound TNT.

In summary, uptake of TNT in relation to the exposure concentration could be proven and first insights concerning the metabolism and depuration velocity could be shown.

4.07.P-Tu388 Screening Concentrations for Ecotoxicological Assessment of Soils Contaminated with Explosives Residues

Roman Kuperman[1]*, Guilherme R. Lotufo*[2]*, Michael Simini*[1] *and Emily Stricklin*[3]*, (1)U.S. Army DEVCOM Chemical Biological Center, (2)U.S. Army Engineer Research and Development Center, (3)Excet, Inc*

Many sites associated with ongoing operations in Eastern Europe and the Middle East, as well as those that involve munition manufacturing, disposal, testing, and training contain elevated levels of explosives, propellants, and related energetic materials (EM) in soil. We conducted definitive toxicity studies with terrestrial plants and soil invertebrates to establish receptor-specific toxicity benchmarks for nitrogen-based organic energetics RDX (hexahydro-1,3,5-trinitro-1,3,5,-triazine), HMX (octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine), TNT (2,4,6-trinitrotoluene), TNB (1,3,5-trinitrobenzene), 2,4-DNT (2,4-dinitrotoluene), NG (1,2,3-trinitroglycerine), DNAN (2,4-dinitroanisole), and NTO (3-nitro-1,2,4-triazol-5-one), each weathered-and-aged up to three months in Sassafras or Teller sandy loam soils. Toxicity benchmarks were derived using the EC20 level of the EM effects on plant growth or soil invertebrate reproduction measurement endpoints determined from standardized toxicity tests. Soil screening concentrations for an EM-receptor pairing were calculated as the geometric mean of EC20 toxicity benchmarks determined from the individual studies. Toxicity benchmarks determined in these studies have filled the data gaps in current knowledge of the potential ecological risks of release of EM compounds into soil and can be used to develop risk-based approaches to assessing exposure risks and developing remedial goals for contaminated soils.

4.07.P-Tu389 Calculation of the dynamics of special unexploded ordnance (UXO) for rapid recovery and avoidance of toxic environmental contamination

Daniel Klembt[1]*, Peter Menzel*[2]*, Mirko Rummelhagen*[2]*, Richard Whitehouse*[3] *and Sebastian Escobar*[3]*, (1)Corvus Works, Germany, (2)Corvus Works UG, Germany, (3)HR Wallingford, United Kingdom*

Unexploded Ordnance Devices (UXO) and Discarded Military Munitions (DMMs) pose a persistent and alarming threat in coastal regions, primarily due to their exposure to environmental forces like saltwater corrosion, wave dynamics, currents, and shifting seabed sediments. This threat extends beyond human safety to encompass the environment, with a specific concern regarding the release of toxic substances.

These remnants of war continue to pose a latent threat to human life, particularly in areas where offshore construction activities occur. Extensive surveys are conducted to locate, identify, and clear these hazardous objects as needed. However, the danger persists even after clearance operations. The possibility of these objects being mobilised by currents or waves, whether in cleared areas or those left undisturbed, remains a critical concern.

To assess the potential for object mobilisation, it is essential to calculate the critical loads required to displace UXO from their stable positions within the sediment bed. These loads depend on factors such as hydrodynamic and hydrostatic forces, friction, gravity, and inertia.

This study employs a comprehensive approach to analyse the underlying forces. Hydrodynamic forces are rigorously examined using a combination of analytical methods and numerical simulations. The determination of the dimensionless coefficients is done by wind tunnel experiments. The study also establishes the complex relationships between the dimensionless coefficients for lift, drag and additional mass, considering the Reynolds number and burial depth.

The study uses model simulations based on fluid mechanics to quantify the forces acting on these objects through the interaction of waves and currents. For this purpose, critical flow velocities and wave conditions required for the mobilisation of various objects are determined and these results are compared with existing environmental conditions, especially in the Fort Pierce region in Florida, USA.

This research and its outcomes provide the means to forecast the underwater path of UXO situated on the seabed. Such predictive capabilities can profoundly reduce the substantial hazards posed to human safety and mitigate the environmental risks associated with the release of toxic substances. Additionally, this information can be leveraged to enhance the efficiency of surveys, thereby expediting offshore construction projects and markedly enhancing the safety of coastal areas.

4.07.P-Tu390 Heritage of war - a multi-biomarker approach to investigate the effects of sunken war wrecks on common dab (Limanda limanda) in the North Sea

Romina Marietta Schuster[1]*, Franziska Isabell Binder Mrs.*[2] *and Matthias Brenner*[3]*, (1)Ecological Chemistry, University of*

Bremen, Germany, (2)Ecological Chemistry, Alfred Wegener Institute Helmholtz-Center for Polar and Marine Research, Germany, (3)Alfred Wegener Institute for Polar and Marine Research, Bremerhaven, Germany
Today, the North Sea is the final resting place for hundreds of shipwrecks from the two world wars. Many of these ships were still partially or fully loaded with munitions at the time of their sinking. The increasing corrosion of munition shells in the saline environment leads to an increased leakage of chemical substances into the marine ecosystem posing risks to marine organisms. A large amount of the chemicals preserved in the munitions are toxic and classified as CMR substances (carcinogenic, mutagenic, toxic for reproduction). Particularly, the 2,4,6 - trinitrotoluene (TNT) is of great concern here, since it has been the most commonly used explosive during the world wars. The accumulation in the tissue of various organisms has been proven in previous studies, but the knowledge about the biological effects of TNT on marine organisms is still limited.

To investigate the biological effects of World War munition on marine organisms, field studies were conducted on three selected wrecks (SMS Ariadne, SMS Mainz, UC30) from the First World War in the southern North Sea, as well as from a suitable reference area. Therefore, non-migratory dabs (*Limanda limanda*) were caught as close as possible to the wreck sites and investigated using a multi-biomarker approach. The dabs were first examined for obvious alterations in the liver before being dissected for subsequent assessment of relevant tissues.

The results show that dabs fished near the wrecks react negatively to the elevated TNT concentration in the water. The percentage of dabs with liver alteration is significantly increased in the fish caught at the wreck sites compared to the dabs from the reference area. Similarly, those results can also be mirrored at the cellular level. Elevated TNT concentrations in the water lead to the accumulation of metabolic end products in the liver tissue and alter the activity of enzymes involved in the anti-ox-defense system.

These results correlate with the TNT concentrations detected in the water and therefore suggest a negative impact of the explosive compounds still left on war wrecks on marine organisms.

4.07.P-Tu391 Bacterial Clues of Shipwreck TNT Pollution in the North Sea

Wyona Schütte[1]*, Josefien Van Landuyt*[2]*, Jennifer Strehse*[3]*, Tobias Bünning*[3]*, Sven Van Haelst*[1]*, Koen Parmentier*[4]*, Edmund Maser*[3]*, Nico Boon*[2] *and Maarten De Rijcke*[1]*, (1)Flanders Marine Institute (VLIZ), Belgium, (2)Center for Microbial Ecology and Technology (CMET), Ghent University, Belgium, (3)Institute of Toxicology and Pharmacology for Natural Scientists, University Medical School Schleswig-Holstein, Germany, (4)Institute of Natural Sciences, Ecosystems Physico-Chemistry (ECOCHEM), Belgium*
Almost 300 shipwrecks are found in the Belgian part of the North Sea. At the time of sinking, many were armed and fully or partially loaded with ammunition. One of the most important substances in this context is 2,4,6-trinitrotoluene (TNT). Commonly used as an explosive for military applications, TNT is equally known for its toxicity as well as its potentially mutagenic and carcinogenic properties. Corrosion ultimately results in the leakage of dissolved explosives from lost munitions in shipwrecks, causing the surrounding sediments to be contaminated by TNT and related organic compounds. Marine biota like fish and shellfish bioaccumulate these compounds, thereby creating a risk to human seafood consumers. By analysing changes in the marine microbial community in the presence of TNT and its metabolites, we aim to identify bacterial taxa that can serve as indicators for pollution of dissolved explosives from shipwrecks.

This study investigates the link between dissolved explosives and the microbial fingerprint in sediments next to a WWII destroyer. This wreck still has semi armour-piercing shells on board, which are leaking low levels of TNT into the surrounding sediments. Samples were taken by divers at 10-meter increments away from the wreck and were analysed for their concentrations of dissolved explosives using gas chromatography combined with mass spectrometry (GC-MS). Next, 16S rRNA gene long-read nanopore sequencing will be explored as a rapid, cheap tool to map the microbial composition of sediment samples. Previous studies show a sensitive shift in microbial fingerprints in the presence of aromatic pollutants. Here, we expect to find changes in the microbial community, potentially towards TNT-degrading taxa, in samples with higher concentrations of dissolved explosives.

4.07.P-Tu392 Spatial Distribution of WWII Legacy Munition Compounds in the Baltic Sea.

*Kenneth Arinaitwe, Siao Jean Khoo, Björn Raupers, **Aaron J Beck**, Martha Gledhill, Jens Greinert and Eric P. Achterberg, GEOMAR Helmholtz Center for Ocean Research Kiel, Germany*
After about eight decades in the sea, WWII legacy dumped munitions are at different stages of corrosion and continue to leak chemicals into the water column and sediment. Rise in demand for renewable energy, conservation of biodiversity and reduced risk of human exposure to munition compounds (MCs), to mention but a few, necessitate assessment of the current status of dumpsites, exploration of cleanup options and prioritization of sites for cleanup. To this end, mapping of the MC pollution in the Baltic Sea, particularly in the German Waters, is ongoing. Water and sediment samples are collected and analysed for MCs using an Ultra High-Performance Liquid Chromatograph coupled to a High-Resolution Mass Spectrometer. Water samples collected in October 2022 show the major hotspots of current TNT release to be in the Kolberger Heide – Falshöft sections (reaching 10 ng L^{-1}) whereas the Lübeck Bay is a major hot spot for DNB and RDX emissions (reaching 75 ng L^{-1} at a site off Haffkrug and 37 ng L^{-1} at a site off Neustadt, respectively). Transformation products of TNT, 2-ADNT and 4-ADNT were detected in all water samples, the highest concentrations being observed at Kolberger Heide (1.4 and 3.4 ng L^{-1},

respectively). A more detailed discussion of the spatial distribution of key MCs and transformation products of TNT measured in the entire stretch of the German waters, and along the Little Belt – Aarhus –Great Belt - Femer Belt section of the Danish waters of the Baltic Sea, will be presented.

4.07.P-Tu393 Biological effects of munition left on war wrecks on the health of blue mussels (Mytilus edulis, L.) in the North Sea

Romina Marietta Schuster[1]*, Franziska Isabell Binder Mrs.*[2] *and Matthias Brenner*[3]*, (1)Ecological Chemistry, University of Bremen, Germany, (2)Ecological Chemistry, Alfred Wegener Institute Helmholtz-Center for Polar and Marine Research, Germany, (3)Alfred Wegener Institute for Polar and Marine Research, Bremerhaven, Germany*

The North Sea was the scene of many naval battles during both World Wars in which a large number of military ships, civilian merchants, and cargo vessels sank. Many of those ships were still partially or fully loaded with munition at the time of their sinking. However, only rough estimates about the remaining quantities of munition on these wrecks can be made. After decades in the marine environment, munition shells are corroding and start leaking chemicals of their explosive cargo into the marine environment. As the main component of most munitions, 2,4,6 trinitrotoluene (TNT) is of great importance here. Next to its ability to explode, TNT is also known for its toxicity and for being carcinogenic and mutagenic.

To test for leaked explosives in the surrounding waters, sediments and biota field studies were conducted on three wreck sites in the North Sea. Water analysis shows different TNT concentrations at the wrecks. The measured concentration of explosives is subsequently correlated with potential health impairments in exposed blue mussels. These mussels were exposed for several weeks in steel cages on or near the three wreck sites. Three to four cages with blue mussels were placed at different locations on each of the wrecks. At the end of the exposure time mussels were retrieved and examined for mortality, subsequently dissected and analyzed in the lab for biomarker responses according to a multi-biomarker approach.

The first results show differing water concentrations of dissolved TNT around the wreck sites ranging from low ng/L of dissolved TNT at SMS Mainz up to the µg/L and mg/L levels at UC30 and KW58. Furthermore, they show that higher TNT concentrations at the wrecks trigger biological responses in the mussels. Elevated TNT concentrations lead to increased activities of enzymes involved in the anti-ox-defense system and to higher accumulations of metabolic end-products in cells of the digestive tissues of the mussels, as a response to the presence of organic pollutants, suggesting a negative impact of TNT dissolved in the water on the exposed mussels.

4.07.P-Tu394 Ecotoxicological risk of World War relic munitions in the sea after low and high order blast in place operations

Tobias Bünning[1]*, Jennifer Strehse*[1]*, Edmund Maser*[1]*, Katrine J Andresen*[2] *and Ole R Clausen*[2]*, (1)Institute of Toxicology and Pharmacology for Natural Scientists, University Medical School Schleswig-Holstein, Germany, (2)Aarhus University, Denmark*

Submerged munitions from both World Wars (WW) are present in marine waters across the globe and are threatening human activities in the oceans, including fisheries and shipping or the construction of pipelines and offshore facilities. Several studies have shown that TNT and its metabolites are carcinogenic and exhibit acute and chronic toxic effects in a wide range of marine organisms.

Remotely controlled high-order blast-in-place (BiP) operations are used by navies worldwide to clear underwater munitions. This involves detonating the explosives in the mine with an external explosive charge. The resulting shock waves pose a serious threat to marine mammals such as harbor seals and harbor porpoises as high sound pressure and explosion-related shock waves can lead to severe injuries and hearing impairment in marine mammals in great distances from the detonation site. Low-order BiP operations are being discussed as a marine mammal-friendly alternative. With this form of remediation, not all of the explosive material is detonated, which minimizes the shock wave.

Previous studies have proven that after underwater high-order BiP detonations, toxic energetic compounds (EC) such as TNT will not completely combust, but rather distribute within the marine ecosphere. It is therefore to be expected that even larger quantities of EC will be released during low-order BiP operations.

Two British MK I-IV ground mines were chosen for detonation using high-order (Mine Mike) and low-order (Mine Golf) BiP operations. Water and sediment samples were taken at 0, 0.5 and 1 m in all four directions prior to and in 0, 1m and 5 m in the right direction immediately after the respective BiP operation by Danish Royal Navy divers. Samples were extracted in the lab and analysed by sensitive GC-MS/MS and LC-MS/MS technology for their concentrations of the EC 1,3-DNB, 2,4-DNT, TNT, and its metabolites 2- and 4-ADNT.

Our study provides unequivocal evidences that BiP operations in general lead to a significant increase of contamination of the marine environment and ecotoxicological risk with toxic EC. Although the noise emission and shock wave are considerably lower with low-order BiP operations, they result in a several thousand-fold higher burden on the marine environment. For this reason, we explicitly criticize both types of BiP operations because of the resulting environmental hazards, which can ultimately even endanger human seafood consumers.

4.07.P-Tu395 Demonstration of a Commercially Available Passive Sampler for Monitoring of Munitions Constituents at an Underwater Naval Training Range

*Gunther H. Rosen[1], **Guilherme R. Lotufo**[2] and Jason B. Belden[3], (1)Naval Information Warfare Center (NIWC) Pacific, (2)U.S. Army Engineer Research and Development Center, (3)Oklahoma State University*

As a result of military activities, discarded military munitions and unexploded ordnance are present in underwater environments, which has resulted in the release of munitions constituents (MC) including the high explosives 2,4,6-trinitrotoluene (TNT) and hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX), to the water column and adjacent sediments. This paper focuses on the environmental characterization of exposure (i.e. aqueous concentrations) of these constituents in an underwater embayment having relatively high densities of underwater unexploded ordnance (UXO), specifically the Vieques Naval Training Range at Bahia Salina del Sur (Vieques, Puerto Rico, USA). Following multiple calibration efforts, in situ passive sampling using polar organic chemical integrative samplers (POCIS) was employed for the detection and quantification of MC in water adjacent to potentially leaking munitions. Laboratory calibration and field demonstration of HLB POCIS (alongside grab sampling) verified that passive sampling was a useful tool towards the estimation of time averaged water concentrations for MC including TNT, RDX, and their primary degradation products at the site. POCIS-derived and averaged grab water samples agreed within a factor of 3. When detected, MC concentrations were observed at ultra-trace concentrations (as low as 4 ng/L for RDX), except 30 cm from one General Purpose bomb where the TNT concentration was 5.3 µg/L, indicating that low level contamination existed at the site on a localized scale despite the relatively high density of munitions, similar to previously reported results for other munitions sites around the world. More specifically, POCIS was able to detect MC at levels substantially lower than achievable using typical grab sampling methods, allowing for improved characterization of MC in comparison to grab sampling at underwater sites where very low concentrations (ng/L) or fluctuation in concentrations are expected to occur.

4.08.A Marine and Coastal Pollution: Detection, Monitoring, Assessment, Regulation, and Management

4.08.A.T-01 Evolving Chemical Assessment for Use in the Marine Environment

***Claire Phillips**[1], Sylvia Blake[2], Nicola Geary[1], James Brown[1], Carl Clarke[1], Nathan Read[1], Malgorzata Wilczynska[1] and Anna Sypniewska-Huk[1], (1)Centre for Environment Fisheries and Aquaculture Sciences (Cefas), United Kingdom, (2)Advice and Assessment, Centre for Environment Fisheries and Aquaculture Sciences (Cefas), United Kingdom*

Introduction

The aquatic environment is subject to multiple chemical inputs. Chemicals are discharged in offshore oil and gas exploration, many are also used in offshore renewables and form shipping, riverine inputs and aquaculture chemicals. Chemical regulation varies between different sectors and geographic regions and present a significant regulatory challenge and pose difficult questions. For example, how do we control the use and discharge of chemicals and what sort of methods can we use to model risk and fate? Are there any data gaps? Where are the highest areas of concern and uncertainty? A major source of uncertainty is the hazard assessment of unknown variable chemicals or biological substances (UVCBs) which are ubiquitous in our daily lives, in materials and chemicals that are used and discharged. Questions have been raised regarding the suitability of test protocols to help identity environmental hazard concerning UVCBs and reaction mixtures, and whether assessment factors could be applied to reduce uncertainty, especially with mixtures. Many chemicals appear to be readily biodegradable but many are not. While increasing the handling and solubility they also enhance biodegradation by masking persistence. In addition, once any solvent enters the aquatic environment it is diluted and dispersed with smaller more mobile molecules being stripped out of the mixture leaving amorphous solids such as gels and polymer dispersions. There are rightly concerns regarding plastic pollution but on contrast there is less concern raised about other polymers which could lead to the build up of residues in the environment.

Discussion: One way of taking into account masking of persistence is the use of solvent correction calculations. This has been demonstrated on a simple rhodamine B dye and acetic acid as a solvent and could apply to mixtures where excess chemicals are present. There are additional issues that need to be addressed, e.g. whether mixture effects are important and whether assessment factors can be applied to identify safe use of products or substances, and whether this could be applied to UVCBs and reaction mixtures where the toxicity of individual components may be known? How can we obtain chronic information without increasing animal testing? There are guidelines available that can help address the need for chronic data, but further work is needed for regulators to understand the New Approach Methodologies (NAMs) endpoints to be able to apply them.

4.08.A.T-02 Chemicals in OWF Coatings and their Leaching into the Marine Environment

***Lisbet Sorensen**[1], Elena Hengstmann[2], Andy Booth, PhD[1], Pablo Zapata Corella[3], Torben Kirchgeorg[4], Simone Hasenbein[4], Bavo De Witte[5], David Vanavermaete[6], Marianne Molid[1] and Javier Castro-Jiménez, PhD[7], (1)SINTEF Ocean, Norway, (2)BSH, (3)IFREMER, (4)German Federal Maritime and Hydrographic Agency (BSH), Germany, (5)Marine Research, Institute for Agriculture and Fisheries Research (ILVO), Belgium, (6)ILVO, (7)Chemical Contamination of Marine Ecosystems, IFREMER, France*

Turbine coatings used for corrosion protection on offshore wind farms (OWFs) are in direct contact with the surrounding seawater, while leading edge erosion of the rotor blades can result in the formation and release of coating particles to the marine environment. Both of these exposure routes present an opportunity for additive chemicals and non-intentionally added substances (NIAS) to leach from the coating materials into the seawater, where they can be bioavailable to marine organisms.

In the current study, chemicals reported used in coatings were reviewed and a standard operating procedure for laboratory investigation of chemicals leaching from paints and coatings commonly used at North Sea OWFs into seawater was developed and applied.

Data from the literature review was compiled, listing known chemicals, as well as available chemical and hazard information, and classifying all chemicals according to the emission source/s. The primary focus was on organic substances potentially emitted by coatings, but the list also includes chemicals released from other sources within OWFs like sacrificial, firefighting foams or operational fluids. Different groups of chemicals (e.g. phenolic compounds, diisocyanates, heavy metals, poly- and perfluorinated compounds) were identified and prioritized for further analysis.

To investigate the leaching of chemicals from OWF coatings, stainless steel coupons sandblasted and painted via air spray using the two most applied commercial paints, with different combinations of layers, primers and top coats. The coupons were subjected to a 7-day leaching study in seawater under low turbulence conditions at 12 °C. Leachate extracts were analysed using a non-target screening method using two-dimensional gas chromatography coupled with mass spectrometry to tentatively identify the chemicals leaching.

The results indicated some matches between reported chemicals in the literature and those chemicals found in experimental seawater leachates. Some of the chemicals expected to be in the coatings were not observed in leachates, possibly because they are not readily water-soluble in the conditions tested (and therefore not expected to be bioavailable in the marine environment) or because they were not amenable for GC-MS analysis. Further work still needs to address the sources of chemicals found in leachates that are ranked as potentially hazardous, but which are currently unreported and thus not subject to environmental risk assessments.

4.08.A.T-03 The Underestimated Problem with Discharge Water from Exhaust Gas Cleaning Systems of Seagoing Ships

Martina Fenske, PhD[1]*, Annika Krutwa*[2]*, Octavio Marin-Enriquez*[2]*, Marcus Lukas*[3] *and Denise Spira*[1]*, (1)Federal Institute of Hydrology (BfG), Germany, (2)Federal Maritime and Hydrographic Agency (BSH), Germany, (3)German Environment Agency (UBA), Germany*

The introduction of the global limit of 0.50% (m/m) of sulphur emission in 2020, accelerated the number of exhaust gas cleaning systems (EGCS or scrubbers) installed on seagoing ships. Whereas the sulphur bill tackles airborne SO_x emissions, the operation of scrubbers produces highly toxic wash water, which is released into the marine environment. The present project aimed to assess whether the current discharge criteria of the "2021 EGCS Guidelines" (IMO resolution MEPC.340(77) sufficiently safeguard the protection of the marine environment, based on an ecotoxicological evaluation. Thus, a sampling campaign was conducted on four ships with scrubber hybrid systems and the water samples then chemically and ecotoxicologically analysed. The EGCSs were sampled at several stages of the scrubbing process under normal operating conditions in both operation modes, open-loop (OL) and closed-loop (CL). For the ecotoxicological assessment, a combination of whole effluent toxicity (WET) tests on three marine species (*Aliivibrio fisheri*, *Phaeodactylum tricornutum*, *Acartia tonsa)* and two specific tests for mutagenic (Ames fluctuation test) and dioxin-like effects (YDS - recombinant yeast dioxin screen) was applied. Additionally, fish embryo acute toxicity tests (FET/OECD 236) were included as a non-animal test with a vertebrate species. The WET results showed much higher toxicity of the CL discharge samples (all categorised extremely toxic) than of the OL discharge samples (practically non-toxic to considerably toxic). The highest sensitivity was shown by the copepods, followed by the marine algae. The dioxin-like effects in the YDS were also higher for the CL than the OL discharge samples. The result pattern of the CL samples showed some coherence with the oil content and the 16 EPA PAH concentrations. The Ames tests with the strains TA98, TA100, YG1041 and YG1042, with and without metabolic activation, showed mutagenic potency in all discharge samples. However, OL discharge samples were less mutagenic than CL discharge samples. The undiluted CL discharge water samples of the ships S2 and S4 also caused over 50 % mortality (48 h) and reduced hatching rates of ^{3}85 % in the FET. Given these ecotoxicity results, we consider the release of scrubber discharge water from both operation modes into the sea to be of high concern. The effluent is acidic and contains persistent, bioaccumulative and toxic pollutants (PAHs, heavy metals, etc.) which may cause long-term effects.

4.08.A.T-04 Sulphate sensitivity of aquatic organisms in northern Baltic Sea coastal brackish water explored by toxicity tests and species sensitivity distribution

Xiaoxuan Hu[1]*, Juha S. Karjalainen*[2]*, Matti T. Leppänen*[3]*, Kari K. Lehtonen*[3]*, Johanna Järvistö*[3]*, Anna K Karjalainen*[4]*, Ossi Tonteri*[3]*, Mikko Mäkinen*[2]*, Evita Strode*[5]*, Hoi Shing Lo*[6]*, Hansika Sarathchandra*[2] *and Natalja Kolesova*[7]*, (1)Biological and Environmental Science, University of Jyväskylä, Finland, (2)Department of Biological and Environmental Science, University of Jyväskylä, Finland, (3)Finnish Environment Institute (SYKE), Finland, (4)Envineer Ltd, Finland, (5)Latvian Institute of Aquatic Ecology, Latvia, (6)Department of Environmental Science, Stockholm University, Sweden, (7)Tallinn University of Technology, Estonia*

Sulphate is a naturally occurring major ion ubiquitously found in natural environments. Major anthropogenic sources of sulphate include runoff from agricultural lands on acid sulphate soils, effluents from industrial activities, as well as mining and municipal wastewaters. Chronic sublethal effects of sulphate on freshwater aquatic organisms have been explored and observed in many toxicity tests, and the development of sulphate environmental quality standard in freshwater has gained more attention recently. However, the effects of sulphate on the brackish water biota are poorly known and experimental data from biotests are largely missing. We conducted chronic sulphate toxicity tests on species from northern coastal Baltic Sea areas and used Species Sensitivity Distribution (SSD) modeling to derive the 5th percentile hazardous concentration (HC5) that would protect 95% of the species in the brackish water ecosystem where sulphate concentrations range between 100 to 500 mg/L. Chronic sulphate toxicity varied notably between the species tested. The most sensitive species tested were whitefish *Coregonus lavaretus* and common water moss *Fontinalis antipyretica*. This study provides important preliminary understanding on sulphate sensitivity in brackish water and more toxicity tests are needed to include possibly sensitive species not included in this study.

4.08.A.T-05 Toxicity Variations in Produced Water: A Study on Danish Offshore Oil Fields

Neri Bonciani, MA, PhD[1]*, Steven Brooks*[2]*, Sebastian Kuehr*[2]*, Matteo Ottaviani*[3] *and Karen Feilberg*[4]*, (1)Danish Offshore Technology Centre, Denmark, (2)Norwegian Institute for Water Research (NIVA), Norway, (3)Technical University of Denmark (DTU), Denmark, (4)DTU Offshore, Technical University of Denmark (DTU), Denmark*

In the oil and gas sector, including carbon capture and storage, produced water (PW) is a significant byproduct. Denmark's offshore oil production annually discharges about 30 million cubic meters of PW, a complex mixture of hydrocarbons, suspended solids, metals, and production chemicals, into the sea. Current regulations, mainly focusing on oil-in-water content, do not fully address the variability in PW's composition, which can harm marine life. The challenge in regulating PW lies in its diverse constituents and the reliance on limited or unclear data for environmental assessments.

This study designed a sampling protocol for offshore personnel to evaluate the toxicity variations in PW from different Danish North Sea oilfields. The research involved 48-hour acute toxicity tests on the copepod *Tisbe battagliai* and *Crassostrea gigas* (oyster) embryos using various dilutions of PW samples. The study examined the toxicity effects of suspended particulate matter (SPM), bivalent cations, and volatile compounds employing filtration, EDTA chelation, and nitrogen wash as intermediate treatments, respectively.

Results showed significant variability in PW toxicity across different fields and sampling times, indicating challenges in developing effective regulations. Factors like SPM, volatiles, and toxic elements (Cu and Zn) notably influenced organisms' responses, with variations even within samples from the same field.

In conclusion, the study emphasizes the complexity of regulating PW due to its variable toxicity. As the oil and gas industry evolves, monitoring PW's composition and eco-toxic effects becomes crucial. The Danish Underground Consortium aims for "zero harmful discharge" by 2050, highlighting the need for comprehensive PW monitoring and regulation in subsurface operations.

Acknowledgment - The authors kindly acknowledge the Danish Underground Consortium (TotalEnergies E&P Denmark, BlueNord & Nordsøfonden) for providing data, and real PW samples and granting permission to publish this work. This research has received funding from the Danish Offshore Technology Centre (DTU Offshore) under the Produced Water Management program.

4.08.B Marine and Coastal Pollution: Detection, Monitoring, Assessment, Regulation, and Management

4.08.B.T-01 Impacts of the UV Filters Octinoxate and Octocrylene on Symbiodinium sp.: A Symbiotic Microalgae in Corals

Ana Catarina Almeida[1] *and Adam Lillicrap*[2]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)Norwegian Institute for Water Research (NIVA), Oslo, Norway*

The widespread use of ultraviolet (UV) filters in sunscreens and personal care products has raised concerns due to their adverse effects on aquatic organisms. This study investigated the specific toxicity of two UV filters, octinoxate, and octocrylene, known for their potential harm to coral reefs. The focus is on *Symbiodinium* sp., a photosynthetic dinoflagellate crucial for the symbiotic relationship with corals, contributing to nutrient acquisition and coral reef structure.

Exposure of exponentially growing *Symbiodinium* sp. to octinoxate and octocrylene revealed significant toxicity. Octinoxate proved three orders of magnitude more toxic than octocrylene, emphasizing the differential impact of these UV filters. The study utilized a comprehensive set of sub-lethal endpoints analyzed through flow cytometry, including cell viability, pigments content, cell size, complexity, metabolic activity, reactive oxygen species production, and membrane potentials.

For octocrylene, sub-lethal effects included increased cell complexity, lipid peroxidation, and altered membrane potential. At higher concentrations, decreased cell viability and metabolic activity indicated severe membrane depolarization. Octinoxate, even at lower concentrations, affected cell size, complexity, viability, and metabolic activity, with an increase in lipid peroxidation levels. The results underscore the potential for structural changes in cellular components.

The study's findings emphasize the importance of an early warning system to protect *Symbiodinium* sp. within coral reef ecosystems. The differential toxicity of UV filters warrants careful consideration in formulating effective conservation strategies. Flow cytometry emerges as a valuable diagnostic tool for detecting sub-lethal effects, providing insights into the health of *Symbiodinium* sp. and, by extension, the resilience of coral reef ecosystems. Overall, this study contributes valuable insights into the specific impacts of UV filters on a key component of coral reef ecosystems and advocates for proactive measures to safeguard these vital environments.

4.08.B.T-02 Effect-based Water Quality Diagnosis to Improve Coral Reef Resilience and Recovery

Milo Leon de Baat, PhD, *Freshwater and Marine Ecology, University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Netherlands*

In the marine environment, and in particular on coral reefs, the presence of complex mixtures of pollutants and especially their effects are still poorly understood. Coral reefs are exposed to low-level and at times highly variable toxic pollutant mixtures, and passive sampling is particularly fit for these conditions as it allows for the *in-situ* concentration of analytes and the integration of extended periods. Target chemical analyses overlook unknown chemicals and are unable to integrate the toxic effects of complex mixtures. Effect-based methods (EBM) can overcome these limitations by providing a risk-scaled assessment of the mixture toxicity elicited by all known and unknown bioactive chemicals in a sample. Hence, the combination of passive sampling and EBM is particularly fit to monitor the complex low-level mixtures of chemicals that can threaten the health of coral reefs and help prioritize sites that are suitable for coral conservation and restoration efforts. However, although this has been developed for freshwater systems, an approach to monitoring chemical pollution in coral reef ecosystems using passive sampling and EBM is currently not available. Here, we present the results of a pilot and follow-up study, in which polar organic chemical integrative samplers (POCIS) were exposed at multiple inland bays and coral reef sites on the island of Curaçao in the Southern Caribbean. POCIS extracts were exposed to a battery of bioassays to determine the toxic pressure at the locations, and bioassay responses were compared to effect-based trigger values to identify potential ecotoxicological risks. Extracts from the bays consistently elicited higher bioassay responses than those from their adjacent reef sites, confirming the expected dilution of pollution as it is transported from land onto the reefs. This was also reflected in the cumulative ecotoxicological risk quotients for each of the locations. Chemical target and non-target analyses of the POCIS extracts were included in the follow-up study to provide insight into the link between toxicity and the occurrence of pollutants and their sources. Effect-based water quality assessment shows great promise for the identification of local chemical stressors that threaten the health of coral reefs. Further development of these methods is needed to inform local stakeholders and help them control local stressors to improve the resilience and recovery of these valuable ecosystems.

4.08.B.T-03 Mapping Coastal Chemical Contamination in Different Environmental Matrices Across the Galapagos Archipelago

Georgie Savage[1]*, Katie Deakin*[1]*, Jen Jones*[2]*, Ildiko Kriston*[3]*, David Santillo*[3]*, Alistair Boxall*[4]*, Tamara Susan Galloway*[1] *and Ceri Lewis*[1]*, (1)Biosciences, University of Exeter, United Kingdom, (2)Galapagos Conservation Trust, United Kingdom, (3)Greenpeace Research Laboratories, United Kingdom, (4)University of York, United Kingdom*

As a developing island province, the Galapagos Archipelago is at the forefront of the Anthropocene footprint, with its population influx, urbanisation, reliance on fossil fuels, growing tourism, fishing and agricultural industries cumulatively contributing to increasing pollutant input at the coastal interface. Subsequently, despite its geographical isolation ~1000 km off the coast off South America in the eastern Pacific Ocean, the Galapagos Marine Reserve (133,000 km^2 encompassing the islands) is at risk from oil, plastic, pesticides, persistent organic pollutants and heavy metal contamination; such contaminants threaten to overwhelm the adaptive capacity and resilience of these fragile island ecosystems and the unique biodiversity they support. Here we characterise and quantify coastal chemical contamination in different environmental matrices at the archipelago scale. Surface seawater and benthic sediment samples were collected in triplicate using grab techniques from eleven coastal sites around the three main inhabited Galapagos Islands (San Cristobal, Santa Cruz and Isabella). Novel passive samplers (Markes ‘HiSorb’ probes) – steel probes coated with PDMS solid phase – were also deployed at each site for a period of 1–3 weeks to further understand the temporal variability of contamination and evaluate their potential use as rapid assessment monitoring tools. HPLC-MS analysis revealed carbendazim and diuron to be the most frequently detected pesticides and found at the highest concentrations (43.75% and 37.5% of samples; 24.6 ng/L and 24.9 ng/L, respectively). Proximity to urbanisation and point-sources appeared to influence levels of pesticide contamination, with enclosed brackish waterbodies exhibiting the highest concentrations. Initial forensic GC-MS screening of compounds bound to HiSorb probes has identified medium-to-long chain hydrocarbons, chemical ingredients associated with sunscreen products and residues of the widely used insect repellent DEET. This investigation provides valuable baseline data on chemical contamination across the Galapagos Archipelago to inform future management and mitigation strategies by the Galapagos National Park. Over the next decade, a complex trade-off between urbanisation and conservation must be carefully navigated to ensure the preservation of this UNESCO World Heritage Site in this evolving chemical landscape.

4.08.B.T-04 Microplastics as Toxicant Vectors: Comparisons with Natural Particles in a Marine Trophic Web

Estefanía Pereira Pinto M.S.[1]*, Estefanía Paredes Rosendo*[1]*, Juan Santos-Echeandía*[2] *and Juan Bellas*[2]*, (1)University of Vigo, Spain, (2)Vigo Oceanographic Center of the Spanish Oceanographic Institute, Spanish National Research Center (IEO-CSIC), Spain*

Microplastics (MPs, 1 µm - 5 mm) are a major aquatic environmental issue, linked to various effects on marine organisms. MPs pose risks beyond direct impacts, as they can transport environmental pollutants. While trophic transfer of MPs has been demonstrated, the fate of pollutant-loaded MPs in the food chain remains underexplored. Additionally, organic particles present in marine environments like microalgae (MA) can also act as pollutant carriers, making it crucial to compare the roles of MPs and MA in transporting highly bioaccumulative and toxic pollutants, such as mercury (Hg). Therefore, a three-level model trophic chain based on phytoplankton (*Rhodomonas lens*), copepods (*Acartia tonsa*) and fish (*Scophthalmus maximus*), was chosen to study the individual and combined effects of Hg, high-density polyethylene MPs and MA in *S. maximus* larvae (16-31 days post-hatching). Over 15 days, larvae were fed 1,000 adult *A. tonsa*/day from each condition: (1) Filtered seawater control; (2) 4 µg Hg/L waterborne Hg (WBHg), (3) 3,000 part/mL oxidized MPs (Ox MPs), (4) 3,000 part/mL and 4 µg Hg/L (Ox MPs+Hg), and (5) 3,000 part/mL and 4 µg Hg/L. Hg-loaded *R. lens* (MA+Hg). Each test group had four replicates, each containing 30,000 *R. lens*/mL. No statistically significant differences were observed among experimental conditions in survival rate, total length, Fulton's condition index, and copepod consumption by larvae at the end of the experiment. Larvae exposed to Ox MPs+Hg and WBHg exhibited similar bioaccumulation levels over the exposure period, being significantly different from larvae exposed to MA+Hg and control after 3 and 7 days of exposure. After 7 days, MA+Hg treatment showed significantly higher acetylcholinesterase activity than Ox MPs and WBHg. At day 3, larvae exposed to Ox MPs exhibited higher GST activity than all other conditions except MA+Hg. However, by day 7, Ox MPs showed significantly decreased GST activity compared to control and MA+Hg. No significant differences in GRx activity were observed at 3 and 15 days across conditions, but after 7 days, larvae exposed to MA+Hg exhibited a significant increase compared to Ox MPs and WBHg. MPs transported Hg in the studied trophic chain as larvae exposed to Ox MPs+Hg showed bioaccumulative and toxic effects comparable to WBHg. MA may prevent Hg bioaccumulation, while inducing an adaptive response against oxidative stress. These results emphasize the need for comprehensive environmental health management.

4.08.B.T-05 Antibiotic Occurrence and Distribution in a Coastal Areas with Aquaculture Activity.

Santiago Nicolás Otaiza González[1]*, Jose Maria Castano-Ortiz*[1]*, Ismael Lozano, Lic.*[2]*, Gian Luna*[3]*, Grazia Quero Dr*[4]*, Massaccesi Naomi*[4] *and Sara Rodriguez-Mozaz*[5]*, (1)Catalan Institute for Water Research (ICRA), Spain, (2)IBBEA, Conicet-UBA, Argentina, (3)National Reseach Council of Italy, Italy, (4)Institute for Marine Biological Resources and Biotechnology, National Research Council (IRBIM-CNR), Italy, (5)University of Girona (UdG), Spain*

The presence of antibiotics (AB) in the environment can be originated from both human and veterinary sources and can pose a risk to non-target species and to contribute to the spread of antibiotic resistance. AB can permeate surface waters, coastal regions, and groundwater, and can disrupt aquatic ecosystems and eventually impact human health. Aquaculture, a crucial source of fish for human consumption, raises concerns due to how environmental pollution affects this industry. This study aims at investigating antibiotic occurrence in coastal marine environment and in aquaculture facilities located in such areas (mariculture).

Conducted in Porto Venere, Liguria, Italy, at a commercial "antibiotic-free" aquaculture plant, the study encompasses two sampling campaigns in summer 2022 and winter 2023. Sampling sites, selected along a putative pollution gradient, include a negative control sample (CASTAGNA), four fish cages within the aquaculture plant, an intermediate site (PONTILE), and a semi-submerged channel (CANALE) influenced by urban discharges and tidal variations.

Water samples underwent filtration and pre-concentration using solid-phase extraction (Oasis HLB cartridges). Sediments were processed using a QUEChERS methodology and fish fillets and benthic biota were analyzed using zirconium beads beating. A comprehensive range of 27 AB and four human metabolites, classified into 10 distinct chemical groups, were monitored using LC-MS/MS. Environmental risk assessment was conducted in water and sediments by calculating risk quotients (RQ) categorized as no risk ($RQ < 0.1$), moderate risk ($0.1 < RQ < 1$), and high risk ($RQ > 1$).

Results indicate sulfonamides and macrolides as the most abundant AB in mariculture seawater, with higher concentrations in winter. Sediment samples revealed a diverse AB presence, with ofloxacin recording the highest concentration. Fish and biota analysis identified specific AB. Despite the aquaculture farm being antibiotic-free, the presence of AB suggests potential external sources and anthropogenic contamination.

Risk assessment outlines moderate and high risks for certain AB in seawater and sediments, emphasizing potential threats to the marine environment. These findings underscore the need for ongoing monitoring and mitigation efforts to protect marine ecosystems and maintain the integrity of aquaculture practices.

4.08.P Marine and Coastal Pollution: Detection, Monitoring, Assessment, Regulation, and Management

4.08.P-Mo362 Contaminants of Emerging Concern in the Marine Environment: An Integrated Effects Assessment Approach (CONTRAST)

Steven Brooks[1]*, Samantha Eslava Martins, PhD*[2]*, Bavo De Witte*[3]*, Juan Bellas*[4]*, Ketil Hylland*[5,6]*, Aourell Mauffret*[7]*, Joachim Sturve*[8]*, Ed Temperley*[9]*, Jonathan Barber*[10]*, Marina Lipizer*[11]*, Christos Tsabaris*[12] *and Adam Lillicrap*[2]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (3)Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Belgium, (4)Vigo Oceanographic Center of the Spanish Oceanographic Institute, Spanish National Research Center (IEO-CSIC), Spain, (5)University of Oslo (UiO), Norway, (6)Institute of Marine Research, Norway, (7)IFREMER, France, (8)University of Gothenburg, Sweden, (9)SHIRE creative, United Kingdom, (10)Centre for Environment Fisheries and Aquaculture Sciences (Cefas), United Kingdom, (11)National Institute of Oceanography and Applied Geophysics, Italy, (12)Hellenic Centre for Marine Research, Greece*

The Horizon Europe project, CONTRAST that started in January 2024, will develop an integrated assessment and effect-based monitoring framework (IAF) to measure the impacts of contaminants of emerging concern (CECs) on the marine environment, which will contribute to the assessment of Good Environmental/ Ecological Status for application in EU policy (i.e., MSFD/WFD). The IAF will involve chemical measurements together with biological effects endpoints that will be optimised to detect the presence and degree of effect of CECs in the marine environment. CONTRAST will identify the CECs that pose the greatest threat to marine life by using chemical prioritisation schemes to inform which of the CECs should be measured in the environment. Additionally, which CECs to target in the laboratory experiments, where the effects on biological systems and marine biodiversity will be assessed. A combination of *in silico*, *in vitro* and *in vivo* bioassays together with omics will be used to determine the mechanisms of toxicity of selected CECs. This will provide important information on how CECs may interact with marine organisms at environmentally relevant concentrations and inform which biological effects tools should be used in the IAF to cover the range of toxicity mechanisms that CECs produce. CONTRAST will address this by optimising existing and developing new biomarkers, so that the IAF includes biomarker tools to cover the most relevant mechanism of toxicity produced by CECs. A series of European-wide case studies will be used to test the suitability of the IAF to measure the effects of chemicals including CECs on indicator species and biodiversity. The knowledge gained from field testing and laboratory studies will form the basis for guidance documents and policy briefs on the best practices for performing an IAF on CECs in the marine environment and help to provide the necessary protection of marine ecosystems. Furthermore, the interactions of climate change drivers on CECs will be evaluated including effects on CECs distribution, circulation, fate, bioavailability, and toxicity to marine life. CONTRAST is funded by the European Commission within the Horizon Program.

4.08.P-Mo363 Baltic Sea Biological Effects Activity Cluster: Joint Regional Activities for an Improved Assessment of Chemical Pollution in the Marine Environment

Kari K. Lehtonen[1]*, Natalja Kolesova*[2]*, Elena Gorokhova*[3]*, Joachim Sturve*[4]*, Owen Rowe*[5]*, Ivan Kuprijanov*[2]*, Ksenia Pazdro*[6]*, Milda Stankeviciute*[7]*, Ieva Barda*[8]*, Evita Strode*[8]*, Roque Gastón Alurralde*[3]*, Raisa Turja*[1] *and Zhanna M. Tairova*[9]*, (1)Finnish Environment Institute (SYKE), Finland, (2)Tallinn University of Technology, Estonia, (3)Department of Environmental Science, Stockholm University, Sweden, (4)Biological and Environmental Sciences, University of Gothenburg, Sweden, (5)Baltic Marine Environment Protection Commission HELCOM, Finland, (6)Institute of Oceanology Polish Academy of Sciences, Poland, (7)Nature Research Centre, Lithuania, (8)Latvian Institute of Aquatic Ecology, Latvia, (9)Department of Ecoscience, Aarhus University, Denmark*

Chemical pollution impacts the health of marine biota, key functions of the ecosystem, and biodiversity. The current environmental monitoring and assessment approach is focused on chemical and ecological measurements, while linking biological effects to chemical exposure, has been challenging. Although the contaminant assessment using single compounds is of utmost importance for environmental quality standards, taken alone it does not ensure compliance with Descriptor 8 of the Marine Strategy Framework Directive, which is a key requirement for achieving Good Environmental Status in marine ecosystems. It is currently well acknowledged that the monitoring of chemical concentrations alone is not sufficient to protect populations since considering only a tiny number of substances while a myriad of others is left unnoticed. In addition, the hazards related to contaminant mixtures remain undetected. Examining biological effects provides an understanding of the impact of the multiple mixed effects of contaminants on marine biota. Recently, the Helsinki Commission (HELCOM) sub-team focusing on biological effects of hazardous substances (EG Haz BE) has been seeking to develop and support the implementation of effect-based methods (EBM) in the integrated chemical-biological monitoring and assessment frameworks for the Baltic Sea region. These efforts resulted in developing a regional platform for EBM using support for several joint activities. From the Baltic Sea viewpoint, this cluster of new activities involving the HELCOM EG Haz BE as the core group has significant potential to improve monitoring and assessment strategies and to increase understanding of the importance of EBM in current monitoring programmes. The cluster of activities establishes direct contact with different types of stakeholders to evaluate their needs and barriers in addressing mixed effects of contaminants. The scene will thus be set for recommendations on harmonised procedures to be implemented at municipal, national, or regional levels with the aim of establishing foundations for a long-term practical approach to addressing the pollution impact on the Baltic Sea ecosystem.

4.08.P-Mo364 "Socioeconomic Dynamics of Sunscreen Pollution from Coastal Tourism: A Comprehensive Assessment of Beachgoer Habits and Preferences in Southern Spain"

Cristina Pallero[1]*, Jose Luis Oviedo*[1]*,* ***Antonio Tovar-Sánchez***[1]*, Araceli Rodríguez-Romero*[2] *and Carlos Moreno*[3]*, (1)Department of Ecology and Coastal Management, Institute of Marine Sciences of Andalusia, Spanish National Research Council (ICMAN-CSIC), Spain, (2)Department of Analytical Chemistry, Faculty of Marine and Environmental Sciences, Marine Research Institute (INMAR), University of Cadiz, Spain, (3)Department of Analytical Chemistry, Faculty of Marine and Environmental Sciences, University of Cádiz, Spain*

To address the challenges of marine and coastal pollution, it is essential to gain an understanding of the pressures, and impacts associated with the activities we aim to manage. In the context of coastal tourism, an understanding of the effects on marine ecosystems become paramount for formulating sustainability objectives. A pertinent example is the case of sunscreens. Coastal pollution attributed to sunscreen has emerged as a significant environmental concern, prompting the need for comprehensive strategies. While most studies have followed an experimental approach in controlled environments to analyze the effects, there is still a considerable lack of works that have considered the use patterns of these products on beaches to assess sunscreen pollution. The delineation of interrelationships and socio-economic dynamics (encompass the description of user behavior and their perceptions of resultant issues) provide the necessary context for assess both the current and potential impacts of sunscreen-related pollution.

In this work, we designed and applied a survey of beachgoers to analyze their habits, sunscreen consumption, input to coastal waters, and willingness to pay for eco-labeled alternatives. The study focuses on two urban beaches in the highly popular tourist destination of southern Spain: La Caleta in Cadiz (n=205) and La Bajadilla in Malaga (n=198). Our findings revealed significant disparities between the two case studies, both in terms of the percentage of beachgoers using sunscreen (97.1% and 89.4% respectively) and the volume of sunscreen used (7.9 and 11.9 ml per application and person respectively). While these amounts were below the recommended maximums, they surpass estimates from theoretical studies. This result in a total sunscreen input into coastal waters of 76.3 and 109.3 ml per user during the summer season in La Caleta and La Bajadilla, respectively. On a per-person basis, respondents' average willingness to pay was 11.5€/250ml and 14.2€/250ml, respectively. Despite the incipient perception of the problem, the results indicated a positive inclination towards eco-labeled alternatives.

The divergent outcomes from two ostensibly similar beaches underscore the necessity for a more thorough and on-site characterization of beachgoers and their habits to advance our understanding of the potential impact of sunscreens on marine ecosystems, facilitating effective and sustainable tourism management.

4.08.P-Mo365 Characterization of scrubber water discharges from ships using advanced suspect and target screening strategies

***Meritxell Gros**[1], Elisa García[1], Georgios Gkotsis[2], Maria-Christina Nika[3], Ida-Maja Hassellöv[4], Kent Salo[4], Anna Lunde Hermansson[5], Jana Moldanova[6], Leonidas Ntziachristos[7], Andreas Gondikas[8], Erik Ytreberg[4], Nikolaos S. Thomaidis[3], Martin Hassellöv[9] and Mira Petrovic[1], (1)Catalan Institute for Water Research (ICRA), Spain, (2)Chemistry, National and Kapodistrian University of Athens, Greece, (3)National and Kapodistrian University of Athens, Greece, (4)Chalmers University of Technology, Sweden, (5)Mechanics and Maritime Sciences, Chalmers University of Technology, Sweden, (6)Swedish Environmental Research Institute (IVL), Sweden, (7)Aristotle University of Thessaloniki, Greece, (8)Creative Nano, (9)University of Gothenburg, Sweden*

While shipping is acknowledged as an energy-efficient transport mode, ship engine combustion produces pollutants like particulate matter, carbon dioxide (CO_2), nitrogen and sulphur oxides (NOx, SOx) that are emitted to the atmosphere. Currently, many shipping companies have installed exhaust gas cleaning systems, also known as scrubbers, on their vessels, to comply with the restrictions set by the International Maritime Organization (IMO) concerning SOx emissions. During the scrubbing process, the exhaust gas is driven through a fine spray of water which readily dissolves SOx so that levels are sufficiently reduced in air emissions. However, the waste stream generated, known as scrubber water, contains a mixture of contaminants that are directly discharged into the marine environment. Despite the widespread adoption of scrubbers, there is limited information on the chemical composition and environmental risks associated with scrubber water discharges. Previous research has identified polycyclic aromatic hydrocarbons (PAHs) and metals as prevalent pollutants in scrubber waters, with alkylated PAH derivatives anticipated to be present at higher concentrations than their parent compounds. To address this gap, in this study a suspect screening based on gas chromatography coupled to high-resolution mass spectrometry (GC-HRMS) was used to identify the most relevant PAHs and alkyl-PAHs in scrubber waters. Subsequently, a target method was developed based on headspace solid-phase microextraction (HS-SPME) coupled to GC and tandem mass spectrometry, to identify PAHs and alkyl derivatives in scrubber waters from an on-board case study in a container ship, sailing from the North Sea to the Eastern Mediterranean, with the aim to pinpoint key substances acting as markers for scrubber water contamination in marine ecosystems. The suspect screening successfully identified 7 PAHs and 12 alkyl homologues. The most prevalent were naphthalene, phenanthrene and fluorene derivatives covering from one to four (C1-C4) degrees of alkylation. Notably, methyl (C1) derivatives were particularly prominent among identified alkyl homologues. In the results from the on-board sampling campaign, sea waters showed minimal detection of target compounds while scrubber waters exhibited high concentrations, particularly for naphthalene, phenanthrene and their alkylated derivatives, emphasizing the environmental significance of these compounds in scrubber water discharges.

4.08.P-Mo366 Quantitative estimation of drivers for ecotoxicological effects of scrubber water discharge to the marine environment

*Juliette Perrier, Anders Baun and **Lars Skjolding**, DTU Sustain, Technical University of Denmark (DTU), Denmark*

Global trade is heavily reliant on ocean shipping with around 90% of traded goods being shipped in the maritime sector. The sector is predicted to triple by 2050. While the Nordic Region are front runners in efforts to reduce the environmental impact of maritime activities in line with Sustainable Development Goals such as SDG 12 and 14, there is still grounds to be covered with regards to identifying significant contributors to ecotoxicological effects of discharges related to technologies set to reduce the maritime emission of SO_x e.g. scrubber technology. Discharges from both open and closed scrubber systems emit substances of environmental concern such as polycyclic aromatic hydrocarbons (PAH), oil residues and heavy metals. With increasing number of vessels equipped with scrubber technology the concern increases. The inherently complex nature of the mixture makes it challenging to quantitatively assess the individual contribution to the overall toxicity, making targeted actions to minimize environmental impact difficult for both operators and regulators (e.g. OSPAR and IMO). For complex industrial discharges the US-EPA developed Toxicity Identification Evaluation (TIE). The approach utilizes a series of physical and chemical process operations allowing a step-wise evaluation of the residual toxicity following each step. Hereby, identifying fractions that contribute/dominate the toxicity (e.g. metals, volatile compounds, non-polar or polar organic compounds. The approach has so far not been applied to scrubber water. The poster will present results on 1) the utilization the TIE approach to identify main contributors to the whole effluent toxicity 2) evaluation of pH on the bioavailability of contributors identified 3) evaluate dilution need and the potential reductions (based on TIE) required to comply with current guidelines inside/outside of emission control areas according to IMO's MEPC. The overall goal is to create a scientific basis for targeted approaches to minimize the environmental impact of scrubber water discharges and the feasibility of reaching current targets of MSFD and evaluating this end-of-pipe technology in a broader context of emerging concepts such as the Safe-and-sustainable-by-Design.

4.08.P-Mo367 Generating inputs for the calibration of oil spill effects models: Filling data gaps for marine and freshwater species of importance and application of oil spill biomonitoring system

Bjørn Henrik Hansen[1], *Benjamin Patrick de Jourdan*[2], *Deborah P. French-McCay*[3], *Thomas Parkerton*[4], *Ben Speers-Roesch*[5], *Raymond Nepstad*[6], *Lisbet Sorensen*[6], *Julia Farkas*[6], *Liv-Guri Faksness*[7] *and Danielle Philibert*[2], *(1)SINTEF, Norway, (2)Huntsman Marine Science Center, Canada, (3)RPS Ocean Science, (4)ExxonMobil Biomedical Sciences, Inc., (5)University of New Brunswick, (6)SINTEF Ocean, Norway, (7)Climate and Environment, SINTEF Ocean, Norway*

Through the program Multi-Partner Research Initiative (MPRI), Natural Resources Canada has funded a 4-year project focussed on testing, evaluating, adjusting, coupling, and validating a combination of existing models (oil solubility model, target lipid model (TLM), PETROTOX, and SIMAP) to predict potential environmental impacts of spilled oil. We will address key knowledge gaps related to complex interactions of confounding abiotic (photomodification) and biotic (species sensitivity) variables using a combination of high-resolution chemical analyses, state-of-the-art ecotoxicological applications and oil spill fate and effects models. We will utilize existing and acquire new data on detailed oil chemistry and ecotoxicology considering important abiotic and biotic variables. Comprehensive high-resolution chemistry data (GC×GC-FID) on crude oils (fresh and weathered) will be used to assign hydrocarbon blocks and predict toxicity using existing models, which will be validated with targeted experiments using whole oils. We will focus primarily on sensitive life stages of aquatic species to benchmark against existing datasets applied in oil spill models. Already existing data sets on oil high-resolution chemistry and ecotoxicity testing (*Skeletonema pseudocostatum*, and *Calanus finmarchicus*) for >20 oils and data with single PACs for several marine species will be expanded with data on additional freshwater and marine species and will include sublethal endpoints including physiological performance (e.g., metabolic rate and cardiac output) and biomarkers of exposure in lumpfish (*Cyclopterus lumpus*). The lumpfish biomarkers will be validated in a mesocosm and field exposure, using a newly SINTEF-developed technology for housing lumpfish embryos for in-situ exposure and effects assessment. Through this project, this technology will be intercalibrated and further developed for the use in the event of future accidental or intentional research-related oil spills in the marine environment. In total, this project will provide the basis for improved reliability of risk, impact, and damage assessment models, as well as NEBA-based decision making, in the event of oil spills in sensitive marine and freshwater environments.

4.08.P-Mo368 Risks of Environmental Impacts of Accidental Spills of Ammonia to the Marine Environment

Bjørn Henrik Hansen[1], *Julia Farkas*[2], *Marta Bucelli*[3] *and Raymond Nepstad*[2], *(1)SINTEF, Norway, (2)SINTEF Ocean, Norway, (3)Gas Technology, SINTEF Energy, Norway*

Regulations for fuel usage in maritime traffic by MARPOL are setting global standards that aims at reducing air pollution, reducing carbon emissions, and increasing energy efficiency. However, in the event of an accidental acute spill, how does conventional fuel oils compare to green ammonia in terms of potential environmental impact? We explored this challenge by a combination of an experimental ecotoxicology and a modelling approach. First, we assessed the acute and sub-lethal toxicity of fuel oils and ammonia to Atlantic cod (*Gadus morhua*) embryos. Atlantic cod embryos were exposed for 4 days starting 3 days after hatch, and after exposure, the embryos were transferred to clean sea water until 3 days post hatch. Survival and hatching were monitored daily, and at the end of the experiment, larvae were imaged for assessing larvae morphometry and potential deformations. Second, we simulated acute spills of the fuels using the Dose-related Risk and Effects Assessment Model (DREAM) and the Oil Spill Contingency and Response model (OSCAR) to predict spreading and estimate the risk of toxicity to pelagic marine organisms. Ammonia caused acute toxicity to cod embryos; however, no indications of delayed toxicity were observed. No additional mortality was observed during the recovery period, and the surviving larvae displayed no deformations. Fish exposed to petrogenic fuel oils, however, displayed both acute toxicity as well as clear signs of deformations. DREAM and OSCAR simulations suggests that most of the ammonia reached the surface and evaporated, but some spreading of ammonia as ammonium generated a plume which displayed concentrations exceeding predicted no-effect concentrations (PNEC). Spills of marine gas oil, very low sulphur fuel oil and heavy fuel oil behaved differently. MGO, like ammonia, spread in the water column, however, substantial fractions also evaporated, biodegraded, surfaced, and reached shorelines. Most of the heavy fuel oil and very low sulphur fuel oil, however, ended up on the surface and were carried by waves and to shorelines, and very little of the mass ended up in the water column. The MGO had a lower PNEC than ammonia, so the total volumes of water containing concentrations exceeding the PNEC was higher for MGO than ammonia. For the VLSFO and HFO, insignificant volumes of water exceeded PNEC, due to the fate outcomes discussed above.

4.08.P-Mo369 Risk-based Approach for Regulation of Marine Pollution

Kirit Wadhia, *Environmental, NOV Inc, United Kingdom*

It is apparent that regulations worldwide exist for management of marine pollution dealing with different industry sectors. There is diaparity between the different frameworks employed and even within. Criteria for different sectors require particular and specific considerations. Concern of marine pollution impinges on the change pertaining to physical, chemical, and biological state of the water bodies and coastal areas. The 1982 UN Convention on the Law of the Sea defined marine pollution as: "the introduction by man, directly or indirectly, of substances or energy into the marine environment … which results or is likely to result in such deleterious effects as harm to living resources and marine life." (UNCLOS, 1982). The most significant threat is the potential impact on marine wildlife and ecosystems. Chemical pollution in general can emanate from a range of sources including crude oil and other petroleum products, antifoulants, pesticides, pharmaceuticals and personal care products. In context of the petroleum sector industrial discharge (i.e. produced water) containing chemicals from anthropogenic and natural sources is of primary concern. The offshore oil and gas industry thematic strategy (Offshore Strategy) sets the objective of preventing and eliminating pollution and taking the necessary measures to protect the OSPAR maritime area against the adverse effects of offshore activities so as to safeguard human health, conserve marine ecosystems and, when practicable, restore marine areas which have been adversely affected. Risk assessment involves evaluation taking into consideration the potential direct and indirect consequences. It involves comparison of the exposure of the ecosystem to chemicals of pertinence & concern with the sensitivity of the ecosystem for these chemical through the specific exposure-route. Perspective pertaining to the regulatory framework with insight of developments, considerations and progress concerning risk-based approach for the management of produced water discharges is the focus of this conveyance.

Reference: UNCLOS. (1982). United Nations Convention on the Law of the Sea. Available at: https://www.un.org/Depts/los/convention_agreements/texts/unclos/UNCLOS-TOC.htm

4.08.P-Mo370 A New IOGP Report on Fate and Effects of Naturally Occurring Substances in Produced Water

Megan Griffiths, MSc[1], *Chesney Swansborough*[2], *Emma Pemberton*[1], *Mathijs Smit, PhD*[3], *Kevin Cailleaud*[4], *Christopher Prosser*[5] *and Ezzaini Ramli*[6], *(1)Ricardo, United Kingdom, (2)Ricardo Energy & Environment, United Kingdom, (3)Shell Global Solutions International BV, Netherlands, (4)TOTALENERGIES, France, (5)ExxonMobil, (6)International association of oil and gas producers (IOGP), Belgium*

Produced water, generated during the production of oil and gas from offshore wells, is the largest continuous operational waste stream discharged to sea by the offshore oil and gas industry. Produced water contains a complex mixture of dissolved and particulate organic and inorganic substances including naturally occurring substances (NOS) from geological formations such as hydrocarbons, metals, and chemicals intentionally added during production processes. Some components of produced water have hazardous properties including environmental persistence, toxicity, potential for endocrine activity, and potential to bioaccumulate in marine organisms. Consequently, produced water discharges are heavily regulated.

The International Association of Oil and Gas Producers (IOGP) has previously published technical reports describing the fate and effects of NOS in produced water. However, in the two decades since publication, the scientific understanding of the fate and effects of NOS in produced water has expanded considerably. In order to produce an up-to-date Report, a structured review of evidence in the scientific literature was performed, and an overview of the composition, fate, and effects of NOS in produced water has been produced. The poster presents the main conclusions of the Report, describing the constituents present as NOS in produced water, their fate and effects considering both substance-based and whole effluent testing, and field-based monitoring and surveillance activities. It is envisaged the work will inform relevant practitioners of the environmental risks from produced water discharges to the marine environment.

4.08.P-Mo371 Analysis of emerging contaminants in ship greywater through liquid chromatography and a wide scope target high resolution mass spectrometry screening method

Elisa García[1], *Ruben Gil-Solsona*[2], *Elisa Mikkolainen*[3], *Mia Hitty*[3], *Sara Rodriguez-Mozaz*[4], *Erik Ytreberg*[5], *Pablo Gago Ferrero*[2], *Mira Petrovic*[1] *and* ***Meritxell Gros***[1], *(1)Catalan Institute for Water Research (ICRA), Spain, (2)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Baltic Sea Action Group, (4)University of Girona (UdG), Spain, (5)Chalmers University of Technology, Sweden*

Shipping has long been recognized as an energy-efficient transport medium for moving freight. However, the increase of maritime traffic has led to the continuous discharge of substantial volumes of wastewater into the marine environment, posing potential threats to vulnerable ecosystems. Greywaters, among the various ship-released wastewaters, constitutes a significant portion of the total volume of water produced. Currently, the release of greywater from ships lacks comprehensive regulation in numerous sea regions. Moreover, these discharges may contain a diverse array of chemical contaminants, including pharmaceuticals and personal care products, and their composition may be influenced by on-board activities. Since ship greywaters are more concentrated than land-based wastewaters, it is of outmost importance to perform a comprehensive chemical characterization of greywaters emitted from ships to fully assess the potential environmental and human health risks associated with their discharge to the marine environment. This study focused on using the benefits of wide scope target screening by high-resolution mass spectrometry (HRMS), using an Orbitrap Exploris^{TM} 120 instrument, for the holistic characterization of ship greywaters. Samples were provided by the BSAG, who collected greywaters from cargo ships docked at Helsinki port in Finland, as part of the Horizon 2020 EMERGE project (Grant agreement ID: 874990). The methodology employed encompassed information for more than 700 compounds, including the exact mass of precursor and fragment ions and their retention time, allowing for the identification of contaminants in the samples. With this holistic approach, 88 compounds were tentatively identified, with 44 fully validated and quantified using analytical standards. A semi-quantification tool was used to estimate the approximate concentration of the remaining 44 substances. The compounds identified spanned various chemical classes, including pharmaceuticals (e.g. antihypertensives, analgesics and antidepressants), stimulants (e.g. caffeine and metabolites), tobacco and food related products, personal care products, UV filters, surfactants, perfluoroalkyl substances, plasticizers and flame retardants, among others. This comprehensive analysis provides valuable insights into the composition of ship greywaters, facilitating a better understating of potential environmental implications and human health risks associated with their discharge

4.08.P-Mo372 Persistent Organic Pollutant Accumulation in Pacific Abyssal Plain Sediments and Biota: Implications on Sources, Transport, and Deep-Sea Mining

Dana Sackett[1]*, Dominique Anderson*[2]*, Theodore Henry*[3]*, Andrew K Sweetman*[4] *and Lance T Yonkos*[5]*, (1)Department of Environmental Science and Technology, University of Maryland, College Park, (2)Institute of Life and Earth Sciences, Heriot-Watt University, United Kingdom, (3)Heriot-Watt University, United Kingdom, (4)Scottish Association for Marine Science, Oban, United Kingdom, (5)Environmental Science & Technology, University of Maryland*

Despite its vast size, ecological, and economic importance, the deep sea is one of the least understood ecosystems on Earth. While much remains to be discovered, researchers have established that the deep sea is being exposed to numerous anthropogenic stressors, one of which is chemical pollution. Persistent organic pollutants (POPs), defined by their persistence in the environment, bioaccumulation, and high toxicity, are continually discharged and transported into the deep sea despite protections under global and regional conventions. Few studies have provided insight into POP transport processes and accumulation in the deep sea and none to our knowledge have examined POPs at the seafloor of the Pacific abyssal plain; an area currently being targeted for deep-sea mining and previously assumed to be too far removed to be affected by POPs. Here, we provide baseline data on POPs in deep-sea fish from a region of the deep abyssal plain targeted for deep-sea mining. All congeners of polychlorinated biphenyls (PCBs), polybrominated diphenyl ethers (PBDEs), and multiple per- and polyfluoroalkyl substances (PFAS) were measured in sediment, fish muscle, and fish liver of a deep-ocean predator and scavenger, *Coryphaenoides sp.*, to provide information on sources, transport, accumulation, and contributions of legacy versus emerging (e.g., unintentional PCBs) POPs. Here, we provide the first evidence of PFAS, PCBs, and PBDEs in sediment and biota in this region of the Pacific abyssal plain. Preliminary results show that PCBs were more evenly distributed over the sampling region, while PBDEs and PFAS had patchy distributions and concentrations. Unintentional PCBs (*e.g.*, PCB 11, a component of pigments) significantly contributed to sediment and muscle tissue concentrations, suggesting unregulated PCB releases are accumulating in the deep Pacific Ocean. PFAS was detected in one sediment sample and all biota at levels as high as those found in freshwater ecosystems. Results suggest that the flux of carrion, organic matter particles and vertically migrating species may present an important transport process for POPs that result in patchy contaminant distributions and differences seen in scavenging biota versus sediment. However, for PCBs, with a longer production duration, sinking particle transport may be a more important driver, with raining particles (*e.g.*, POM and plastics) laden with adsorbed PCBs, resulting in a more uniform distribution across this region.

4.08.P-Mo373 What is in the water? Evaluating patterns of organic chemicals at different depths on a transect across the North Pacific Ocean

Elisa Rojo-Nieto[1]*, Cedric Abele*[1]*, Christoph Rummel*[2]*, Eric Carmona Martinez*[3]*, Jörg Watzke*[1]*, Jörg Ahlheim*[4]*, Martin Krauss*[4] *and Annika Jahnke*[5,6]*, (1)Department of Ecological Chemistry, Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Department of Bioanalytical Ecotoxicology, Helmholtz Centre for Environmental Research (UFZ), Germany, (3)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany, (4)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany, (5)Department of Exposure Science, Helmholtz Centre for Environmental Research (UFZ), Germany, (6)RWTH Aachen University, Institute for Environmental Research, Germany*

We aimed to unravel patterns of organic pollutants in water samples from different depths on a transect across the North Pacific Ocean, from Vancouver to Singapore, in 2019 in the frame of the project Micro-Fate. During leg 268/3 of the German Research Vessel SONNE, 45 large-volume seawater samples (60 L) were collected using two methods. On the one hand, deep waters were grab sampled using the Niskin bottles attached to a CTD-Rosette, with which water from a) the bottom (close to the sea floor, at around 5000 m depth), b) 2500 m depth, c) 300 m depth and d) at the depth of the Chlorophyll maximum, were sampled at 8 stations. On the other hand, surface water was sampled using the ship's rotatory pumps, at the same stations where the CTD-Rosette was deployed and while steaming (7 samples). Each sample was extracted on board using a large-volume SPE (LV-SPE) device, equipped with cartridges filled with Chromabond® HR-X sorbent. To our knowledge, this is the first time that this LV-SPE approach has successfully been applied in an oceanic sampling campaign, and some adjustments and challenges due to the salinity and the movement of the ship needed to be solved *in situ*. After each extraction, 1 L of LC grade water was circulated through the cartridges to remove the salts, and they were kept cold at 4°C on board. After finishing the sampling campaign, the cartridges were shipped cooled to our laboratories, dried using nitrogen, freeze-dried and stored at -20°C until elution. They were eluted with a sequence of solvents, following Schulze et al. [doi.org/10.1016/j.scitotenv.2016.12.140], and the volume was reduced, adjusted to 5000-fold concentrated extracts relative to the initial volume of water. The analysis was carried out using LC-HRMS Orbitrap Q-Exactive, Thermo Fisher, and MzMine and MzQuant were used to evaluate 600 compounds. The preliminary results showed 140-150 potentially quantifiable compounds present in the samples, currently under evaluation according to our established quality assurance/quality control (QA/QC) procedures. Final results will be disclosed at the SETAC Europe 34th Annual Meeting.

4.08.P-Mo374 Effects of Particles from Road Tunnels Construction on Post-Smolts Atlantic Salmon

Samantha Eslava Martins, PhD[1]*, Maria Christou*[2]*, Tania Gomes*[1]*, Ana Catarina Almeida*[2]*, Steven Brooks*[2]*, Maria T. Hultman*[2]*, Simon Rodriguez*[2]*, Joachim Johansen*[2]*, Adam Lillicrap*[1]*, Emelie Forsman*[2]*, Lene Heier*[3] *and Sondre Meland*[2]*, (1)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (2)Norwegian Institute for Water Research (NIVA), Norway, (3)Norwegian Public Roads Administration, Norway*

Suspended solids (SS) in coastal ecosystems may arise from natural or anthropogenic sources, the latter including emission of particles from road construction. When tunnels are constructed in Norway, drilled and blasted bedrocks disposed in nearby

fjords may increase the concentration of particles in suspension as well as associated chemicals. Some fjords are used by salmon as a migration corridor during their life cycle. In this study, the impact of particulates on post-smolts Atlantic salmon (*Salmo salar*) was investigated. Fish (mean weight at test start: 130 ± 14 g) were exposed to fine particles (< 100 µm) from the construction of a tunnel, at nominal concentrations of 4, 40 and 400 mg SS/L for 21 days, followed by 7 days of depuration. A control- and a naturally eroded particles (NEP, 400 mg/L) group, collected at a reference river, were run in parallel. A Recirculating Aquaculture System (RAS) with a dosing system was installed to reduce particle loss due to sedimentation. Analysis to elucidate the effects of these particles at histological, osmoregulatory, immunological and genetic levels are underway, but the preliminary results show that salmon exposed to the highest concentration have reduced growth compared to fish exposed to NEP. In addition, surface and slow swimming behavior, caudal fin deformities, empty intestinal content and inflamed gallbladder were observed in some individuals exposed to the highest concentration. This study will increase knowledge on the sublethal effects resulting from the exposure to particles from tunneling activities on Atlantic salmon and their ability to recover after dumping is ceased, providing results that can support the strategy for tunneling construction particles disposal in water systems. The joint road and rail project Arna-Stanghelle is a collaborative research between the Norwegian Public Roads Administration (main funding), Bane NOR, and NIVA.

4.08.P-Mo375 Metal bioaccumulation, trophic dynamics, and risk of consumption of various marine fish species from the Indian River Lagoon (Florida, USA)

Luana Hainzenreder Bauer[1]*, Douglas Adams*[2]*, Benjamin D Barst*[3]*, Marc Amyot*[4] *and Maikel Rosabal*[5]*, (1)Biological Sciences, University of Québec à Montréal, Canada, (2)Fish & Wildlife Research Institute, (3)Institute of Northern Engineering, University of Alaska Fairbanks, (4)Groupe de recherche interuniversitaire en limnologie (GRIL), University of Montréal, Canada, (5)Groupe interuniversitaire en limnologie et en environnement aquatique (GRIL), University of Québec à Montréal, Canada*

Trace metals bioaccumulation in the marine biota can pose great environmental risk to the aquatic ecosystem once reaching toxic levels. Metal measurements among a variety of marine fish species considering a range of trace elements is a research subject still expanding; namely those focusing on species with dissimilar trophic behaviour. Therefore, this study aims to generate in-depth information on bioaccumulation, trophic dynamics, and risk of consumption by humans using a suite of trace metals considering recreational and economic important fish species (*Sciaenops ocellatus*, *Lutjanus griseus*, *Ariopsis felis*, *Centropomus undecimalis*, *Bairdiella chrysoura*, *Cynoscion nebulosus*, *Archosargus probatocephalus*, and the shark *Sphyrna tiburo*) collected from impacted sites in the estuary Indian River Lagoon (Florida - USA). Notably, trace elements (THg, MeHg, As, Se, Pb, Cd, V, Nd, La, and Ce) known by their significant toxicity are being measured in fish's liver and muscle using inductively coupled plasma mass spectrometry (ICP-MS); and metal concentration in each species will be linked to their trophic dynamics and feeding behavior. Additionally, the processes of biodilution and biomagnification will be evaluated. Differences in total metal concentrations among the fish species selected are observed where biological features (size, age) and ecological behaviour (trophic position and diet sources) may be explanatory factors of these results. Biodilution is observed for most trace metals. Correlating the contamination level of each fish species with their nutritional ecological habits might help to identify which trophic level is most likely to be impacted. By revealing this novel information, we hope to provide original data and tools to strengthen our environmental protection awareness and capabilities, ultimately guiding us toward more informed and effective management practices.

4.08.P-Mo376 Risk assessment of Potential toxic Elements in Marine coastal areas of Campania Region (Southern Italy)

Luisa Parrella[1]*, Simona Schiavo*[2]*, Sara Accardo*[3]*, Maria Rita Montereali*[4]*, Giovanna Armiento*[5] *and* ***Sonia Manzo***[6]*, (1)ENEA PORTICI Research Center, Italy, (2)National Agency for New Technologies, Energy and Sustainable Economic Development (ENEA), Italy, (3)University Parthenope, (4)ENEA Casaccia Research Centre, Italy, (5)ENEA, (6)ENEA CR Portici, Italy*

Addressing cumulative multi-hazards related to pollution of marine coastal areas (MCA) in a climate change perspective is today a real challenge that needs interdisciplinary approach to enhance our ability to protect and preserve ecosystems in the face of complex and interrelated threats.

MCAs are exposed to different anthropogenic impacts (e.g., coastal land use, maritime activities, river inputs) and are sensitive to climate change consequences (e.g., acidification, loss biodiversity, costal erosion, ecc) that can contribute to a deterioration of coastal environmental quality.

An approach of multi-risk assessment was applied to MCAs of Campania Region (Southern Italy), in order to evaluate the risk of diffuse Potential Toxic Elements (PTEs) pollution and their ecotoxicological effects on one or more component ecosystems in a contest of climate change. This study is part of “ISSPA” Project supported by PO FEAMP (Fondo Europeo per gli Affari Marittimi e la Pesca) Campania 2014-2020.

Chemical monitoring data was collected between September - October 2020 and June - July 2021 in 27 stations of Campania coastline. The occurance of PTEs in water (As, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb, U, V e Zn) and sediment (As, Be, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, U, V, Zn, Al e Fe) was investigated and a comparison of potential Ecological Risk Assessemnt (ERA) of mixture of chemicals (As, Cd, Cu, Ni, Zn) and of observed Ecotoxicogical Risk for water and sediemnt was conducted.

Results obtained by overlaying Ecological Risk Assessment with Ecotoxicologiacl Risk Evaluation showed that risk was not attributable only to PTE mixture and that different pollutants could be a role in the observed toxicity. This evaluation will be useful to provide an overview of ecological and acotoxicological risk for this particular coast and a prioritization of coastal stretches for managing diffuse metal pollution.

Also the actual environmental changes need to be considered in the ERA ecotoxicological data selection.

4.08.P-Mo377 Integrated Chemical-Biological Monitoring of Pollution off Main Coastal Cities of Finland Using the Perch (Perca fluviatilis) as the Indicator Species

Ville Aimo Eemeli Junttila, Anu Lastumäki, Rami El Dairi, Katri Siimes, Tanja Kinnunen and ***Kari K. Lehtonen****, Finnish Environment Institute (SYKE), Finland*

In Finland, the regular national monitoring of environmental chemicals in marine coastal waters has been running for a few decades based on tissue concentrations of selected organic compounds measured in the muscle tissue of perch (*Perca fluviatilis*). In 2015, the monitoring programme was supplemented by the inclusion of the biological effect parameter lysosomal membrane stability (LMS), measured from frozen liver tissue sections using the histochemical method. LMS is a widely recommended biomarker for the assessment of cytotoxic effects and indicates non-specific stress, which may be caused by a large variety of chemical contaminants. In this presentation we report the results of monitoring of tissue concentrations of selected organic chemicals such as planar and dioxin-like PCBs, DDTs, dioxins, brominated flame retardants, and mercury, in conjunction with LMS and morphometric indices measured in perch collected yearly during 2015-2022 from five monitoring stations located off the cities of Helsinki, Kotka, Parainen, Pori and Vaasa along the Baltic Sea coast of Finland, known to be under marked anthropogenic influence. Statistical analyses were carried out on the data to detect changes over time at each of the study sites as well as differences between them. Multivariate analyses were performed on the chemical and biological parameters to examine relationships between them. This is the first report of a continuous integrated chemical-biological monitoring of contaminants performed in coastal marine areas of Finland and shows the usefulness of the approach in producing more reliable assessment of the contamination status of the region.

4.08.P-Mo378 Assessment of 6PPD-Quinone Acute Toxicity to San Francisco Bay Delta Fish Species and Sublethal Effects to Salmonids

Jackie Lang[1]*, Louise Cominassi*[1]*, Andrea Chandler*[1]*, Luann Wong*[2]*, Nann Fangue*[1]*, Thomas Michael Young*[1]*, Florian Mauduit*[1]*, Richard Connon*[3] *and Amelie Segarra*[1]*, (1)University of California San Francisco (UC San Francisco), (2)Civil & Environmental Engineering, University of California Davis (UC Davis), (3)Department of Anatomy, Physiology and Cell Biology, School of Veterinary Medicine, University of California San Francisco (UC San Francisco)*

Tire and road wear particles are an inevitable consequence of tire use in automotive traffic and are of particular concern in near-urban ecosystems. A toxic transformation product of a common tire additive, N-(1,3-Dimethylbutyl)-N'-phenyl-p-phenylenediamine-quinone (6PPD-quinone), has been detected in water samples from San Francisco region creeks at concentrations near and above the LC50 for Coho Salmon. The presence of 6PPD-quinone in the San Francisco Bay-Delta region thus presents a potential risk to local aquatic species. This project aims to assess the toxicity of 6PPD-quinone to five species of conservation concern: Coho Salmon, Chinook Salmon, Steelhead, Longfin Smelt, and Delta Smelt. Larvae and juveniles of each species were tested for acute toxicity with ongoing investigations of sublethal toxicity. Sublethal endpoints include behavior, thermal tolerance, and swimming performance to assess potential neurotoxicological and cardio-respiratory effects of 6PPD-quinone exposure. Results suggest interspecies differences in susceptibility, with Coho Salmon and Steelhead showing acute sensitivity at 0.07 and 5.00 µg/L, respectively, while Chinook Salmon, Longfin Smelt, and Delta Smelt are acutely insensitive.Together with acute assay details, we will also present sublethal effects determined through behavioral assessments. Observed erratic behavior in exposed Chinook Salmon and Coho Salmon support the growing weight of evidence that 6PPD-quinone acts as a neurotoxicant. The results from this study will inform ongoing conservation efforts for these critically threatened species.

4.08.P-Mo379 Detection of Tire Rubber Particles from a Football Field in an Urban Estuary

Claudia Halsband[1]*,* ***Elisabeth Støhle Rødland***[2]*, Kristin Galtung*[2] *and Amy Lusher*[2]*, (1)Akvaplan-niva, Norway, (2)Norwegian Institute for Water Research (NIVA), Norway*

Tire particles (TPs) are one of the largest sources of microplastics to coastal systems in Norway, and understanding their fate and impact in the environment is an important prerequisite to implement measures and solutions for environmental challenges from human activities, such as developing more sustainable transport systems in the future as part of the envisioned 'green shift'. Based on recent method development to detect TPs and studies on the uptake and toxicity of TP additives, we here aim at quantifying tire particle pollution pathways in a Norwegian coastal system to evaluate different TP markers in riverine and estuarine sediment samples to elucidate the transport pathways from land to ocean in a gradient from a football field with TP granulate infill via a local creek to an urban estuary in the town of Tromsø, Norway. Samples from the football field and from the estuary were analyzed for TP using pyrolysis gas chromatography mass spectrometry (Pyr-GC/MS) using four different markers and marker combinations for styrene butadiene rubber and butadiene rubber (SBR/BR): M4 (*benzene, α-methylstyrene, ethylstyrene* and *butadiene dimer*) M3 (*α-methylstyrene, ethylstyrene* and *butadiene dimer*), VCH (vinylcyclohexene), and Butadienes (*butadiene dimer*, *SB dimer* and *SBB trimer*). The results show varying marker concentrations in selected tire granulate samples from the football field, where M3 and Butadienes were the most promising candidates for the quantification of rubber in the field samples. The sediment samples showed similar trends for both M3 and

Butadienes, where the mid-river station showed the highest rubber concentrations at roughly an order of magnitude lower concentrations than the rubber granulate on the football field. These preliminary data will serve further refinement of rubber detection methods and guidance for more comprehensive field sampling to distinguish granulate runoff from potential background contamination from local traffic.

4.08.P-Mo380 Assessment of Microplastics in the Sediments around Hywind Scotland Offshore Wind Farm

Andy Booth, PhD[1]*, Stefania Piarulli*[1]*, Lisbet Sorensen*[1]*, Stephan Kubowicz*[2]*, Helene K Vrålstad*[3] *and Kari Mette Murvoll*[3]*, (1)SINTEF Ocean, Norway, (2)SINTEF AS, (3)Equinor*

Leading edge erosion of turbine blades is thought to be a primary source of MP emissions to the marine environment. Leading edge protection (LEP) materials are increasing being used to protect the coatings and reduce damage to the main rotor blade, but might also represent a source of MP emissions. Estimates indicate that up to 200 g of coating material can be lost in this way per turbine per year. Given the higher density of rotor blade coating materials than seawater, released MP are expected to sink to the sediments and accumulate around the OWF infrastructure. Methods for the general extraction, clean up and analysis of thermoplastic MPs from sediments are well established, this has not been completed for OWF coatings. To ensure OWF particles can be reliably identified and quantified, there is a need for chemical fingerprinting and verification of extraction and sample clean up techniques.

Here, we present an approach for the quantification and characterisation of microplastics (>300 µm) in sediments collected from the Hywind Scotland floating OWF in Scotland, with a focus on distinguishing MP derived directly from OWF infrastructure (i.e., rotor blades coatings and LEP) from background levels of conventional thermoplastic MPs (e.g. PE, PP, PS, PET, PVC). Reference materials produced from the different coating layers and LEP material were produced and used to generate library infrared spectra and mass spectra. The reference materials were also used to assess if the density separation ($ZnCl_2$) and filtration approaches used in the pre-processing and purification steps caused damage to the particles. Results suggested the LEP material was unaffected by the sample processing, but fragmentation was observed for the two coating layers studied, leading to an increase in the number of particles and a decrease in weight due to loss of particles <300 µm. Finally, the methods were applied to remove biogenic and mineral particles, isolating MP from the real sediment samples (3 x 100 g of sediment from each of the 15 sampling locations). After isolation, the particles were evaluated using microscopy and a total of 30 candidate MP particles were collected and sent for detailed chemical characterisation by Fourier transform infrared spectroscopy. Twenty of the particles were confirmed to be MP, but none had polymer compositions matching the coating and LEP materials, instead representing common thermoplastics in the form of flakes, films, fragments and filaments.

4.08.P-Mo381 A History of Microplastic Pollution in UK Salt Marshes

Anna Elizabeth Rosevear Gilbert[1]*, Willem Roland Gehrels*[1]*, Mark Hodson*[1]*, Jonathan Brett Sallach*[1]*, Roland Kröger*[1]*, Annette Burden*[2]*, Ed Garrett*[1]*, Martha Koot*[3] *and William Blake*[3]*, (1)University of York, United Kingdom, (2)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (3)University of Plymouth, United Kingdom*

The amount of plastic pollution in the environment has increased exponentially since its mass production began in the 1950s. As the vast majority of plastic cannot biodegrade, it instead tends to degrade slowly by mechanical and chemical processes, producing microplastics (MPs, < 5 mm) that are found in all areas of the globe. There is increasing concern about the potential negative impacts of MPs on the environment. Considerable research has been performed concerning MP pollution in aquatic and coastal environments but the amount of plastic in UK salt marshes is yet to be quantified.

Salt marshes are types of coastal wetland with a unique range of flora and fauna; they provide coastal protection and many other ecosystem services, including sequestering ‘blue’ carbon. Sediment deposited by high tides, as well as growth and decay of plants, allows vertical growth of salt marshes. The sediment deposited may contain pollution such as plastic, so it is possible that these coastal wetlands act as a plastic sink, accumulating MPs over time. However, there are very few studies of MPs in salt marshes, and even fewer that incorporate sediment dating using short-lived radio-isotopes (^{210}Pb, ^{137}Cs, ^{241}Am) to estimate when the plastic pollution entered the environment.

In this study, 29 salt-marsh cores from around the UK coastline were dated using ^{210}Pb, ^{137}Cs and ^{241}Am. Chronologies were constructed using the Bayesian Plum model. A method for the extraction of MPs from these cores and their identification was developed in order to create a history of MP pollution in UK salt marshes, giving insight into the types and quantities of plastics present.

To extract MPs, organic matter in salt marsh sediment was first digested using 30% H_2O_2 in an ice bath, rather than the commonly used method of digesting with 30% H_2O_2 and heating to 70°C. MPs were then extracted from the sediment using density separation with LST FastFloat. This was followed by a combination of Nile Red staining, fluorescence microscopy and Raman spectroscopy to identify the types of plastic present.

This study is the first of its kind conducted on UK salt marshes. The novel extraction methodology will allow a more accurate count of the number of MPs present in sediment. The accurately dated cores will allow a detailed history of MP pollution in salt marshes to be constructed.

4.08.P-Mo382 Microplastic Pollution Along the Mediterranean Coast of Turkey: Impacts on Loggerhead Turtles (Caretta caretta) Nesting Environments and Coastal Ecosystems

Sevda Eryilmaz Soydan*, Fatma Nur Eraslan, Mine Sağdıç Ulusoy, Mansoor Ahamd Bhat and Eftade Emine Gaga, Environmental Engineering, Eskisehir Technical University, Turkey*

Plastic pollution, a global environmental concern, leads to significant amounts of microplastics (MPs) in oceans due to the breakdown of larger plastics worsened by improper disposal practices. The presence of microplastic pollution on beaches, particularly in areas close to the ocean, clearly indicates more significant plastic pollution issues. Due to their high exposure, loggerhead turtles are crucial biomarkers for monitoring plastic pollution in the Mediterranean coastal area. This study aimed to determine the level of microplastic exposure faced by Caretta caretta turtles along their nesting route and hatching. Samples were collected during the morning and night at the same points to observe the effect of wind direction on MP distribution. We characterised microplastics collected from a protected nesting area based on their colour, shape, size, and polymer type. The sand samples were isolated using density separation and oxidation procedures and analysed visually with stereomicroscopy and chemically with Fourier Transform Infrared Spectroscopy. The preliminary results identified 16 types of microplastics, with common types across all samples being Polyethylene (PE), Polypropylene (PP), Cellulose, High-density Polyethylene (HDPE), and Tencel. The region's high urbanisation and increased tourism contribute to the diversity and abundance of MPs. Various plastic types, including polyethylene-vinyl acetate(PEVA), low-density polyethylene(LDPE), and polystyrene(PS), were found in both day and night samples, reflecting their widespread use. The research highlights the concern of MP accumulation on nesting sites in the Mediterranean Sea of Turkey, particularly impacting marine turtles' incubating environment. MPs affect species indirectly in coastal environments and potentially affect marine turtles' nesting success. During subsequent phases of the study, the trajectory of microplastic pollution along the coastline will be determined, and the factors influencing this pattern will be investigated. Further research endeavours may explore the health risk assessment by microplastics on loggerhead turtles by conducting a thorough investigation into the various adsorbed chemicals, additives, and other parameters that may affect the risk assessment to examine how these factors contribute to the endangerment of this species.

Keywords: microplastic, Mediterranean, loggerhead turtles, plastic, pollution.

4.08.P-Mo383 Developing a rapid assessment methodology for mangrove plastic contamination by coupling image analysis and machine learning

Andrea Milena Osorio Baquero[1]*, Lara Pinheiro*[1]*, Henry Moreau-Smith*[2]*, Daniel Clewley*[3]*, Katie Deakin*[1]*, Georgie Savage*[1]*, Juliana Salazar*[4]*, Gustavo A. Dominguez*[4]*, Victor Martinez-Vicente*[3]*, Tamara Susan Galloway*[1] *and Ceri Lewis*[1]*, (1)Biosciences, University of Exeter, United Kingdom, (2)Bioscience, University of Exeter, United Kingdom, (3)Plymouth Marine Laboratory, United Kingdom, (4)Escuela Superior Politecnica del Litoral (ESPOL), Ecuador*

With the global environmental plastic waste burden increasing exponentially, it is urgent to develop rapid methodologies for assessing the plastic contamination of critical ecosystems. This work develops and validates an innovative methodology for identifying macroplastic pollution in mangrove forests, using a machine learning approach. Plastic monitoring is challenging in large, complex areas such as mangroves which are known to be areas of high plastic waste accumulation. Here, we used the You Only Look Once (YOLOv5) object-detection algorithm, to test whether it can detect and categorise macroplastics from video footage collected in more complex mangrove ecosystems. Video transects were collected from 3 different mangrove areas in the Galapagos Islands and 6 in Guayaquil, Ecuador, using low-cost cameras such as GoPros and smartphones. Footage collected over measured transects (ranging from 10 – 570.8 m) labelled using VIAME free software (Video and Image Analytics for Multiple Environments), by annotating the location and category of plastics (*bag*, *bottle, rope*, *packaging* and *ni* - non-identifiable) in 18 videos, totalling 21,881 frames. Labelled data was exported and uploaded to the NERC Earth Observation Data Acquisition and Analysis Service (NEODAAS) MAssive GPU for Earth Observation (MAGEO) system where it was extracted, separated into individual frames, augmented, and formatted for use with YOLOv5. For model training, the frames were split into training, validation, and test sets with different mangroves and filming conditions represented across each. The preliminary test data was 1,825 frames, and the remaining images (20,056) were split into training (80%) and validation (20%) datasets. Initial results using validation data demonstrated YOLOv5 was successful at the detection of *bag* (83%), *packaging* (88%), *rope* (72%), *bottle* (77%) and *ni* (76%). Further analysis will include trialling alternative model and image modifications to increase accuracy. Next steps are to trial modifications in the model and on images to booster accuracy It is expected that this innovative and collaborative rapid assessment tool provides timely data on plastic contamination in large, complex, and difficult to access ecosystems such as mangroves. This will enable future identification of contamination hotspots and inform monitoring and mitigation strategies.

4.08.P-Mo384 Investigations of Microplastics in Surface Water of Tokyo Bay using a Novel Automated Microplastic Sample Preparation System

Yutaka Kameda *and Emiko Fujita, Chiba Institute of Technology, Japan*

Microplastics (MPs) in surface water, including rivers, lakes, and oceans, are increasingly recognized as a parameter for general water quality monitoring in various countries. Currently, numerous research efforts employ pretreatment methods recommended by the National Oceanic and Atmospheric Administration (NOAA). However, these methods are known to be comprehensive, labor-intensive, and time-consuming. As a result, analytical operators require techniques to minimize contamination during pretreatment, maintain the properties of MPs, and ensure the extraction of all MPs from water samples. Additionally, they may need to modify their procedures in specific cases, such as incorporating optional treatments like the Fenton reaction or digestion by sodium hydroxide to analyze MPs in organic-rich water samples. To enable precise analysis of

MPs with high efficiency, particularly for operators with limited experience, a novel automated microplastic sample preparation system (MAP-100, Shimadzu corporation) has been developed in Japan. This system can extract fragment-type MPs larger than 300μm from suspended matter in water samples. The process involves collecting MPs in surface water using nets such as neuston nets. Operators then gather suspended matter, removing matrices larger than 5 mm through sieves. The suspended matter smaller than 5 mm is placed in a small strainer of the system, which can then automatically perform digestion by hydrogen peroxide and density separation by sodium iodide in one continuous tube. In recovery tests, where commercial polyethylene microplastics larger than 500 μm were added to ultrapure water and actual suspended matter from a river, the system demonstrated recovery rates of 99.0% and 93.3%, respectively. We also compared microplastic concentrations, polymer types and their size distributions in Tokyo bay between by using ordinary manual pretreatment and by using MAP-100. The fragment-shaped microplastic concentrations, polymer compositions and size distributions by MAP-100 were comparable to those by manual pretreatment. On the other hand, fabric microplastics by MAP were underestimated because of loss during the automated process. However, Poster will show a revised model of MAP-100 which can measure even fabric microplastics more accurately. Therefore, this device will be a useful automatic tool for the pretreatment process of microplastic analysis for any scientists in the world.

4.08.P-Mo385 Development of Neural Network Models for Distributions of Plastics Patches in the Ocean by Sentinel-2 High-resolution Data

Yutaka Kameda *and Emiko Fujita, Chiba Institute of Technology, Japan*

Microplastics (MPs) are widespread in the surface water of boundless expanses of the ocean. However, MPs range from less than 1μm to 5 mm, and their analytical and sampling methods have not been developed nor integrated globally. Moreover, recent reports suggest that large MPs, such as macro MPs or meso MPs, aggregate in surface layers of the ocean, floating with various debris as big islands or long lines accumulated by tides. It is also known that their distributions in the ocean change dramatically. Though these results indicate that the size and distributions of MPs in the ocean are very complex, it is important to reveal time trends in the geographical distributions of these plastic patches to estimate their ecological risk and control their concentrations. However, it is challenging to monitor their distributions by general grab sampling of MPs samples from the ocean.

In this study, methods for estimating seasonal geographical distributions of plastic patches in the ocean are developed using satellite data and generic models. We used four bands of spectral data from Sentinel-2 satellites, following a previous report by Biermann et al. We also used two indicators, the Floating Debris Index (FDI) and Normalized Difference Vegetation Index (NDVI), to distinguish plastic pixels from others. One strong point in our study is the establishment of a generic model capable of downloading satellite data from websites, easily correcting the data with Atmospheric Correction for OLI lite version 20181210.0 (ACOLITE), and calculating FDI values and NDVI values for each pixel. The model can also classify each pixel into nine materials such as plastic, ships, water, pumice released from volcanoes, sand, clouds, rocks, plants, and woods using the K-nearest neighbor algorithm in Python. However, the accuracy of the K-nearest neighbor algorithm is not high enough, approximately 60%. Further revisions, such as replacing the algorithm with neural network models, are needed. Nevertheless, this novel model will enable all users, including non-experts, to generate geographical distributions of plastic patches in widespread areas such as the Japan Sea, the Mediterranean Sea, the North Atlantic Sea, and other bays and lakes all over the world.

4.08.P-Mo386 The First Volunteer Monitoring Project to Reveal Distributions of Microplastics larger than 1μm in Global Oceans by a Japanese Giant Ship Company

Yutaka Kameda*, Chiba Institute of Technology, Japan*

Microplastics (MPs) are recognized as one of the pollutants with numerous environmental impacts. There are lots of studies of MPs in specific areas of the ocean with different methods and different polymers and sizes. This is the first study of distribution of MPs larger than 1μm in global oceans with a harmonized method. We are investigating the numbers, sizes and polymer types of MPs greater than 20 μm in the global oceans starting from March 2020 and now started monitoring of MPs larger than 1 μm from 2023. Sampling of MPs in the ocean was carried out by 14 volunteer ships with the cooperation of a Japanese shipping company. Two hundred samples had been collected by November 2022. Approximately 1 m^3 of sea water samples at depths of 3 to 14 meters were obtained from the hydrant of the ships. Particulate matters were collected by plankton nets (10 μm mesh) on site. The filtered samples were pretreated by H_2O_2 oxidative digestion and NaI density separation. The MPs polymers were characterized by a spectrum imaging method using micro-Fourier transform infrared spectroscopy. The MPs smaller than 20 μm were measured by a spectrum imaging method using Raman microscope. The observed concentrations of MPs larger than 20 μm ranged from 22 to 4,660 pieces m^{-3} in the ocean. Their geometric mean value was 260 pieces m^{-3}. Remarkably high concentrations exceeding 1,000 pieces m^{-3} were found at Kuroshio Current, California Current, Kamchatka current and North Atlantic Gyre. These results indicated that distribution of MPs was heterogeneous in the oceans. The median diameter of the MPs size distribution was approximately 60 μm. The dominant polymer is polyethylene (PE), polypropylene (PP), polyethylene terephthalate (PET) and polymethyl methacrylate (PMMA). PET was the most dominant fibrous polymer. Interestingly, PMMA was detected predominantly in the Pacific Ocean. There were some PMMA hotspots in Kuroshio Current. Polymer types and shapes may be influenced by land-based input, ocean currents and wave-driven. The PMMA contamination might be unique to Asia. This project will continue several years later and can provide data on MPs abundance to further the understanding of MPs pollution in the ocean, especially Asian sea. This data will also be used to develop numerical models to predict MPs in the global ocean. I hope many collaborators in Asian countries will join the monitoring program and share these valuable data.

4.08.P-Mo387 Development of a Semi-automatic Software to Identify Microplastics from Imaging Data by Micro-Fourier-transform Infrared Spectroscopy

***Yutaka Kameda**, Chiba Institute of Technology, Japan*

Small microplastics (MPs) smaller than 300 μm can be easily detected by the imaging technique of Micro-Fourier-transform infrared reflectance spectroscopy (μFTIR). In my laboratory, Nicolet™ iN™ 10 MX (Thermo Fisher Scientific) is used to analyze microplastics greater than 20 μm in water, sediment, biota, and the atmosphere. OMNIC™ Series Software is also utilized to identify and quantify various polymers from contour diagrams of polymers, which were measured by the FTIR. However, it has been revealed that the "Profiling" feature in the software often misidentifies polymers. Therefore, many scientists have to reidentify each microplastic particle and fiber extracted by the software. This visual inspection always consumes a significant amount of time and effort. To save time and identify microplastics more precisely, a semi-automatic software, YCALOS13, was developed. The software, YCALOS 13 (You Can LOok microplasticS), is a free software based on a macro in Excel. After imaging analysis of microplastic samples by Nicolet™ iN™ 10 MX, the mapping file is converted to CSV format. YCALOS13 can extract only spectra of designed polymers from more than 100,000 spectra data in the mapping file, based on polymer-specific bands, the peak areas, and their shapes, which users can decide in the configuration. It can generate each contour diagram of many target polymers simultaneously after only pushing the start button. Finally, ImageJ software can quantify the number of MPs from the contour diagram of each polymer. We compared the abundances of MPs in river water samples and sea water samples between OMNIC software plus visual inspection and YCALOS13. It was revealed that YCALOS13 could detect concentrations comparable to OMNIC software plus visual inspection. YCALOS13 can be a useful tool to identify various polymers from imaging data from μFTIR. This poster will also introduce a novel software "YCALOS-DE," which can also classify each MPs fragment and fiber by MPs degradation level "age." YCALOS-DE will be a useful tool to identify environmental MPs more accurately and rapidly without professional knowledge and experience.

4.08.P-Mo388 Occurrences of Microplastics larger than 20 microns in Surface Waters at Tokyo Bay

***Yutaka Kameda** and Emiko Fujita, Chiba Institute of Technology, Japan*

A release of microplastics (MPs) from the terrestrial environment via rivers is considered to be one of the sources of MPs observed in the ocean. Especially, their occurrences in the surface water of river mouths and bays are influenced by their input from their watershed. On the other hand, ecosystems in bays are very important for human activities such as fisheries and sightseeing, as well as habitats for a huge amount of wildlife. However, ecological risk assessment of microplastics is remarkably difficult because of a lack of information about MPs concentrations, polymer compositions, and size distributions.

The objective of this study is to reveal the occurrences of microplastics larger than 20 microns in surface water at Tokyo Bay, which is considered one of the most contaminated bays in Japan. Microplastics greater than 20 microns were analyzed using micro-Fourier-transform infrared spectroscopy (micro-FTIR) according to the method established by Kameda et al. Several hundred liters of water samples were passed through plankton nets with a pore size of 10 microns on ships at 10 sites in Tokyo Bay and river mouths in 2023. Suspended samples were digested by hydroperoxide in a 200 mL tall beaker. Pretreatment by enzyme was also conducted. Following digestion, sodium iodide was added to the beaker for density separation. Supernatants were obtained three times, and the pooled supernatants were passed through a hydrophilic PTFE membrane. Microplastics greater than 20 microns on the membrane were measured using the imaging technique of micro-FTIR. The poster will demonstrate the concentrations, polymer compositions, and size distributions of microplastics in the surface water of Tokyo Bay.

4.08.P-Mo389 Occurrences of Microplastics larger than 20 Microns in Sediments at Tokyo Bay

***Yutaka Kameda** and Emiko Fujita, Chiba Institute of Technology, Japan*

Microplastics are ubiquitous in various environmental media, as indicated by previous reports. However, detailed information on their toxicity to human health and other organisms, concentrations, polymer compositions, and size distributions, especially for fine microplastics smaller than several hundred microns, remains limited. MPs have also been observed in the sediment of rivers, bays, and seas, in addition to surface water. The presence of MPs in sediment can provide crucial insights into the environmental behavior of plastics from terrestrial areas to the ocean.

This study focuses on the occurrences of MPs in the sediment of Tokyo Bay, which is considered one of the most contaminated bays in Japan. Initially, an analytical method for MPs greater than 20 microns was established using micro-Fourier-transform infrared spectroscopy (micro-FTIR). Subsequently, ten sediment samples were collected from Tokyo Bay using an Ekman sampler in 2023. The moisture contents of these sediment samples were measured in our laboratory. The dried sediment samples were used for the analysis of MPs.In the analysis process, the dried samples underwent digestion by the Fenton reaction in a 200 mL tall beaker. Following digestion, sodium iodide was added to the beaker for density separation. Supernatants were obtained three times, and the pooled supernatants were passed through a hydrophilic PTFE membrane. Microplastics greater than 20 microns on the membrane were measured using the imaging technique of micro-FTIR. The poster will demonstrate the concentrations, polymer compositions, and size distributions of microplastics in the sediment of Tokyo Bay.

4.08.P-Mo390 Occurrences of Microplastics Larger than 20 Microns in Surface Waters of the Philippines

Emiko Fujita[1], *Apple AJ Langcamon*[2], *Maria Kristina Oquinena Paler*[2], *Yuka Motohashi*[1] *and Yutaka Kameda*[1], *(1)Chiba Institute of Technology, Japan, (2)University of San Carlos, Philippines*

In preparation for the international treaty on the reduction of plastic pollution in 2025, and potentially following the ratification of such a treaty, countries worldwide may need to create emission inventories for plastic and monitor environmental concentrations. Moreover, it is estimated that Asia is home to rivers that contribute significantly to global plastic emissions into the ocean. However, there is a significant lack of information on the current levels of plastic pollution in Asian countries, especially concerning microplastics.

The aim of this study is to reveal occurrences of microplastics larger than 20 microns in surface waters of rivers, coastal areas, and off the coast of the Philippines. Microplastic samples were collected at various sites along the Butuanon River, which is the most contaminated river in Cebu. Microplastics were also collected in coastal areas in the Philippines. Microplastics off the coast areas were sampled using volunteer ships. The sampling was conducted as follows: more than several hundred liters of water samples were passed through plankton nets with a pore size of 10 microns on ships or at all sampling sites. Microplastics greater than 20 microns were analyzed using micro-Fourier-transform infrared spectroscopy (micro-FTIR) according to the method established by Kameda et al. Suspended samples were digested by hydrogen peroxide in a 200 mL tall beaker. Following digestion, sodium iodide was added to the beaker for density separation. Supernatants were obtained three times, and the pooled supernatants were passed through a hydrophilic PTFE membrane. Microplastics greater than 20 microns on the membrane were measured using the imaging technique of micro-FTIR. This poster will demonstrate the concentrations, polymer compositions, and size distributions of microplastics in the surface water of the Philippines. This will be the first study to reveal occurrences of fine microplastics in the Philippines.

4.08.PC Marine and Coastal Pollution: Detection, Monitoring, Assessment, Regulation, and Management

4.09 Microfibre Release From Textiles and Subsequent Pollution: Root Causes, Emission Routes, Effects and Mitigation

4.09.T-01 Unnatural 'Naturals': Sources, Pathways, and Impacts of Textile's Plastic Alternatives

Thomas Stanton[1], *Brett Sallach*[2], *Chimdia KeChi-Okafor*[3], *Elyse Stanes*[4], *Harley Nicholls*[5] *and Deirdre McKay*[6], *(1)Loughborough University, (2)Department of Environment and Geography, University of York, United Kingdom, (3)Northumbria University, United Kingdom, (4)School of Geography and Sustainable Communities, University of Wollongong, Australia, (5)Geography and Environment, Loughborough University, United Kingdom, (6)School of Geography, Geology and the Environment, Keele University, United Kingdom*

Natural textile fibres (e.g., cotton and wool) are widely marketed as biodegradable, greener alternatives to their plastic analogues, which are major source of microplastic pollution worldwide. In 2015, the potential impacts of these fibre types as a 'missing link to chemical pollution' was first suggested. In 2019 the entire environmental textile fibre population was first quantified in an environmental science study, reporting a dominance of natural textile fibres in three UK rivers and atmospheric deposition. Eight years after natural fibres were first proposed as a potentially key particulate pollutant, and four years since their dominance in the natural environment was identified, the scientific community has still not assessed the environmental impacts of one of plastic's most common alternative materials.

This presentation will sumarise a body of work that has investigated natural textile fibre pathways to, fate in, and impacts on freshwater environments. This research includes consideration of the role of hand laundry in textile fibre shedding in the Global South. Informed by ethnographic methodologies and a laundry-independent assessment of the propensity of textiles to shed fibres, we find that the way clothes are made is a key factor in global microfibre shedding. We also explore the movement of different textile fibre types through aquatic environments using an Armfield 10m flume, finding that river characteristics influence the distribution of fibres of all types. The preservation of textile fibres in the lake sediment record is considered using a chemical-free method of textile fibre isolation from aquatic sediments. This approach enabled the extraction of natural textile fibres from a 20cm sediment core dating to at least the 1950s. The majority of fibres isolated from this core were natural, not plastic. Finally this work explores the interactions of chemical pollutants with natural and plastic textile fibres (analysis ongoing).

Findings are considered in the context of sustainable fashion narratives, considering the roles of key groups in efforts to address the problem of textile fibre pollution in the Global North and in the Global South. Concern for the environmental impacts of plastic textile fibres are justified, but replacing these fibres with natural alternatives is inappropriate. These alternatives cannot be used to facilitate business as usual consumption.

4.09.T-02 Accumulation of anthropogenically derived microfibers in a coastal food web and responses in representative zooplankton species

Susanne M Brander, (she, her, hers)[1], *Felix Biefel*[2], *Leigh Torres*[3], *Lisa Hildebrand*[3], *Lauren Miki Kashiwabara*[1], *Juergen Geist*[2], *Julia Parker*[3] *and Richard Connon*[4], *(1)Department of Fisheries, Wildlife, and Conservation Sciences, Oregon State University, (2)School of Life Sciences, Technical University of Munich, Aquatic Systems Biology Unit, Germany, (3)Oregon*

State University, (4)Department of Anatomy, Physiology and Cell Biology, School of Veterinary Medicine, University of California San Francisco (UC San Francisco)

Anthropogenic microfibers are increasingly detected worldwide, and textiles are now considered to be one of the largest sources of microscopic waste in marine, freshwater, and terrestrial ecosystems. Microfibers are now considered to be one of the more toxic particle shapes, given that they are difficult to excrete and may be more easily translocated within biota. Toxicity in organisms may be caused by physical interactions between the fiber and organism and/or by toxic compounds released from the particles. We investigated the presence of synthetic and anthropogenic microfibers in zooplankton (prey) and gray whales (predator) which are part of a critical coastal food web off the West coast of North America. Additionally, we examined microfiber toxicity (200 microns length, 3 MFs per ml) using two synthetic textiles (nylon, polyester) and two anthropogenic textiles (cotton, hemp) in representative model zooplankton (*Americamysis bahia*). Field samples were collected via light trap, lab experiments were conducted with cultured mysids. All digestion and analysis protocols followed standard approaches (e.g. KOH, FTIR). In lab exposed animals, reactive oxygen species and behavior were measured. Three species of common gray whale prey, *A. tridens*, *H. sculpta*, and *N. rayii*, sampled off the Oregon coast, had 4 microparticles per gram of composited digested tissue on average; ¾ of microparticles were microfibers with the majority being identified as either anthropogenic in origin (e.g. cellulosic, wool) or synthetic (e.g. polyester). In the lab, MFs became lodged in the mysid (*A. bahia*) foregut area after 7 days of exposure. Ingestion levels were similar to what had been observed in wild zooplankton of relatively the same size and phylogenetic group. ROS was elevated, especially at high exposure temperatures, and was highest with hemp. In conclusion, average ingestion in wild zooplankton was relatively low, the majority of these particles were microfibers, and a sizeable portion were not synthetic, but anthropogenically modified (e.g. cotton). This is in alignment with other recent studies. In the lab, both synthetic and naturally-derived particles can induce changes in ROS production and to a lesser-extent behavior. By understanding impacts at the base of food webs can we better evaluate potential microfiber impacts on predators and entire ecosystems.

4.09.T-03 Ecotoxicological Effects of Bio-based Microfibres on the Key Soil Detritivore Eisenia fetida

Winnie Courtene-Jones, *Richard D. Handy and Richard C. Thompson, School of Biological and Marine Sciences, University of Plymouth, United Kingdom*

Bio-based plastics are sometimes promoted as less environmentally harmful than their petrochemical-based counterparts. Bio-based fibres are widely used in clothing, sanitary products and wet wipes, and their production is projected to increase over the coming decades. Microfibres can accumulate in soil in substantial quantities through the application of biosolid fertilisers, where they can interact with soil biota. The aim of this study was to compare the ecotoxicity of bio-based (viscose and lyocell) and conventional (polyester) microfibres on the key soil ecosystem engineer, *Eisenia fetida*. In the absence of acute toxicity data, experiments were initially conducted to determine the lethal threshold of each material (0 - 10,000 fibres.mL; 72-hour exposure, OECD TG 207 filter paper method), then a second series of experiments using environmentally relevant concentrations (100 $mg.kg^{-1} \equiv 0.01\%$) examined sub-lethal effects across a suite of endpoints including growth and reproduction (28-days, soil exposure, OECD TG 222). The dose-response and the lethality estimates indicate that the bio-based polymers cause greater mortality than conventional polyester to *E. fetida* (LC_{50}: 50 $mg.L^{-1}$ viscose and 132 $mg.L^{-1}$ lyocell), while polyester only achieved 30% maximum mortality despite increasing concentrations to 1000 $mg.L^{-1}$. Following 28-day exposure to soil contaminated with 100 $mg.kg^{-1}$ fibres, no significant effects on mortality or growth were observed, however adult bioturbation activity varied significantly between timepoints ($F_{(3,383)} = 34.166$, $p < 0.001$) and treatments ($F_{(3,383)} = 12.365$, $p < 0.001$), where activity was higher in the viscose and lyocell treatments than compared to polyester or control groups. The wet weight of juveniles differed significantly between treatments ($F_{(3, 12)} = 7.472$, $p = 0.004$) with lower biomass recorded in the viscose than polyester treatments. Results show that bio-based fibres have the potential to elicit greater toxicological responses than conventional polyester fibres which may have implications on individual fitness, population dynamics, and wider ecosystem function. We emphasise the importance of ecological risk assessment for any materials proposed as plastic alternatives/substitutes.

4.09.T-04 There is much more than Fiber Release during Washing: a Life Cycle-based View on Particle and Fiber Release from Polyester Textiles

***Bernd Nowack**[1]*, *Barbora Pinlova[2], Mangi Gao[2], Yaping Cai[2,3] and Tong Yang[2], (1)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)Empa, Switzerland*

A lot of research has been performed about release of microplastics from polyester textiles, mostly focusing on the release of microplastic fibers (MPF) during washing. However, washing is not the only life-cycle stage where release can occur and MPF are not the only type of material released. The aim of this presentation is to give an overview of a number of studies we performed with polyester textiles. A main conclusion is that a range different types of materials can be released from polyester textiles during all stages of the life cycle: fiber production, washing, abrasion during use and weathering (outdoor use or end of life), both for virgin as well as for recycled polyester. There is a wide variety of different materials released: MPF, fibrils, odd-shaped microplastics and nanoplastics, depending on the release process. While washing mainly releases MPF and a few fibrils formed during the yarn manufacturing, abrasion produces new MPF but also fibrils. Weathering by simulated sunlight is able to produce a high amount of various fiber and particle shapes. A comparison of virgin and recycled polyester fabrics revealed that there are no significant differences between the two in terms of MPF and fibril release during washing and abrasion. Nanoplastics are released both during washing as well as during abrasion. However, a more systematic investigation of the identity of the released nanoplastics revealed that a large fraction of them are actually water-insoluble oligomer particles and not polymeric materials. Overall, the results presented here indicate that fate and effect studies about microplastics released from fabrics need to consider other particles types, shapes and size classes than just the "standard" MPF.

4.09.P Microfibre Release From Textiles and Subsequent Pollution: Root Causes, Emission Routes, Effects and Mitigation

4.09.P-Tu400 Every workout counts? Concentrations of trace elements, anti-microbials and total fluorine in sportswear

Sally Gaw Prof[1], *Brittany Connelly*[1], *Shirley Peter Celestine*[1], *Andrew Chappell*[2], *Bill Trompetter*[3] *and Olga Pantos Dr*[2], *(1)University of Canterbury, New Zealand, (2)ESR, New Zealand, (3)GNS Science, New Zealand*

Clothing fibres are ubiquitous contaminants having been detected from the Antarctic to the Himalayas and in a wide range of environmental matrices, including human lung tissue. Trace elements and organic compounds, many of which are recognised as hazardous, are used in the manufacture of clothing from production of the textile through to post-treatment of garments. There is a paucity of information on the types and quantities of chemicals that may be present in different types of clothing and hence associated with the fibres released during wear, laundering and ultimately disposal of the garment. This lack of information on the chemical burden of fabrics hampers our understanding of the environmental and health risks of fibres released from synthetic textiles. Sportswear is a rapidly growing category of clothing that comprises circa 20% of all clothing sold globally. As sportswear is intended to be worn for exercise, anti-microbial, stain resistant and sweat repelling chemicals may be added to reduce the need for laundering and to enhance the life of the garment. The aim of this project was to characterise the concentrations of trace elements, antimicrobial compounds and total fluorine as a proxy for organofluorine compounds in sportswear to identify priority chemicals that may be associated with fibres released from synthetic textiles.

Twenty-six new items of sportswear were analysed for trace elements, total fluorine and organic antimicrobial compounds. Antimony, chromium, zinc and silver were the trace elements measured at the highest concentrations in sportswear with the concentrations dependent on the fabric type as well as the additives added to impart functionality. Lead and mercury were not detected and nickel was only in 4 garments. Total fluorine concentrations ranged from 6 to 40 mg/ kg and were lower than previously reported values for clothing known to be coated with poly- and perfluoroalkyl substances. Surface contamination from machinery during processing may be a potential additional source of total fluorine in clothing. Three organic anti-microbial compounds were identified and quantified in some of the items; benzotriazole (ND to 18 μg/kg), methylbenzotriazole (ND to 48 μg/kg) and alkyl tri methyl ammonium bromide (ND-20 μg/kg)). Our results indicate that fibres released from clothing are likely to have a high chemical burden and that further research is required to determine the associated environmental and human health risks.

4.09.P-Tu401 Chronic effects of microplastics to Artemia franciscana in benthic system

Lia Kim, *Haemi Kim, Yubeen Song and Youn-Joo An, Konkuk University, Korea, Republic of (South)*

Worldwide contamination of microplastic is a global issue in environmental field. Especially for marine ecosystem, microplastics gradually settle to bottom that crawling organisms in benthic system can be easily exposed to sunk microplastics contaminants. Since *Artemia franciscana* from juvenile stage crawls on the bottom performing feeding activity, this study applied microplastic exposure to *A. franciscana* under benthic condition. This study assessed the chronic effects of polyethylene terephthalate microplastics with 3 fragments (small, medium, large) and two fibers (short or long) by comparing their sizes and shapes, and *A. franciscana* at juvenile stage was exposed to contaminated seawater with sand on the bottom. Through 4 weeks of exposure, mortality, growth, and swimming activity were examined. As results, microplastics increased mortality and small-sized fragments and short-length PET fibers caused growth inhibition with movement alterations. These results indicated that microplastic contamination under benthic system can affect aquatic living organisms depending on the microplastic size and shape. *Acknowledgement-This research was supported by "Risk assessment to prepare standards for protecting marine ecosystem" of Korea institute of Marine Science & Technology Promotion (KIMST) funded by the Ministry of Oceans and Fisheries (KIMST-20220383).*

4.09.P-Tu402 Fabrication and Analysis of Fibrous Microplastics for Toxicity and Testing Assessments

Chaehwa KIM[1,2], *Jun Hyuk Lee*[2,3] *and Tae Hee Kim*[2], *(1)Jeonbuk National University, Jeonju-si, Korea, Republic of, (2)Advanced Textile R&D, Korea Institute of Industrial Technology (KITECH), Korea, Republic of (South), (3)Konkuk University, Korea, Republic of (South)*

Fibrous microplastics, constituting a substantial portion (30~80%) of marine microplastic pollution, are known to be released during the laundry of clothing. These fibers entangle the digestive tracts of marine organisms, causing issues such as ingestion disorders and eventual death. It is estimated that they can have a profound impact on humans through the food chain, with fiber-type microplastics being considered among the most hazardous in the realm of microplastics. Household laundry serves as a well-known primary source of these fibers. When microplastics enter the human body, they can induce particle toxicity, oxidative stress, inflammation, tissue migration, and accumulation. Thus, effective management of microplastics is deemed essential. In this study, micro-sized polymeric fibers were fabricated by shredding various fiber materials to assess the toxicity of fibrous microplastics, utilizing equipment capable of maintaining fiber morphology while adjusting only the length. This process can precisely control the degree of fiber refinement by adjusting the number of shredding. The resulting fibrous microplastic samples, diverse in lengths and characteristics, will play a crucial role in conducting comprehensive assessments of environmental behavior and toxicity, as well as research on the occurrence and mitigation of microplastic pollution.

4.09.P-Tu403 Long term exposure of Lumbriculus variegatus (Oligochaeta) to nylon-6 microfibers

Victor Carrasco Navarro, PhD[1]*, Anna Kukkola*[2] *and Jussi Kukkonen*[1]*, (1)University of Eastern Finland, Finland, (2)University of Birmingham, United Kingdom*

Microplastics (<5 mm) are a complex group of emerging contaminants. Their origin (e.g., custom made MP for certain applications) can play a crucial role in their distribution and toxicity in biota. MP in cosmetics (such as sunscreen and hair spray) is an important source of primary MPs to the environment. However, they are severely understudied for their effects, making investigating their toxicity to aquatic biota essential.

To address this gap, we investigated the chronic effects of nylon-6 fibers (Ø = 14µm, length = 500µm) to the sediment dweller oligochaetes *Lumbriculus variegatus*, a freshwater model species which is present in a wide variety of habitants in most continents.

Experimental vessels (n=3) consisted of natural lake sediment (70g), spiked with the fibers at concentrations of 0.01, 0.1 and 3% of sediment dw and 150mL of artificial freshwater (AFW; 1mM in Ca^{2+} and Mg^{2+}). Additional controls (n=3) without fibers, were also set. Phosphate buffer was added to the AFW after week 1 to maintain stable pH level. Two timepoints was assessed: after 28 days and after 30 weeks as long term experiment. *Urtica spp.* was added to the sediment as an extra food source (0.5% of sediment dw). Ten worms, pre synchronized for reproduction (14d before), were added per replicate. The tests followed existing guidelines (OECD, 2007) and the endpoints monitored were reproduction (number of worms) and biomass (dry weight).

Results after the 28d of exposure indicated no effect in the reproduction and growth of the worms with any of the concentrations of microfibers used. The results of the ongoing 30 week experiment will help us to determine the potential effects of microplastic fibers on wildlife on a long-term basis. Further, a possible reduction in the burrowing patterns of worms has been tentatively observed and will be quantified by photographing the sediments.

Overall, this study highlights the importance of introducing long term exposures in ecotoxicology tests of not just microplastics, but all types of anthropogenic chemicals. This would enhance the environmental significance of existing data.

4.09.P-Tu404 Unravelling the Aging Effects of Disposable Masks into Water Towards the Release of Micro-/Nanoplastics and Fibers

Nina Maria Ainali[1]*, Javier Delgado Gallardo*[2]*, Artem Glukharev*[2]*, Kristof Tirez*[2]*, Dimitrios N. Bikiaris*[3]*, Dimitra A. Lambropoulou*[3] *and Milica Velimirovic*[2]*, (1)Department of Chemistry, Aristotle University of Thessaloniki, Greece, (2)Flemish Institute for Technological Research (VITO), Belgium, (3)Department of Chemistry, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Owing to the excessive usage of disposable plastic face masks (DPFMs) throughout COVID-19 pandemic, their discharge and accumulation in the environment has led to severe pollution issues. Once released in the environment, DPFMs can fragmentate and degrade into smaller particles and fibers after the effect of several environmental stresses (e.g., heat, oxidation, UV irradiation, biofouling, mechanical abrasion) that they can possibly undergo, which can possibly circulate and enter water bodies and food chain, with their effects after their intake for both human and living organisms being still a debatable issue. Since natural weathering is a heterogeneous phenomenon, relatively the slow degradation in natural ecosystems can facilitate the generation of a diverse group of particles with several sizes and morphologies, as well as chemical composition, highlighting the challenges that occur from their discharge. In this light, the aim of the present study is to enlighhten the insights into the analytical techniques that can be facilitated to investigate the release of micro-/nano-particles and fibers from DPFMs after simulated UV aging conditions, investigating their role as a newly established core for plastics pollution. State-of-the-art analytical techniques were employed to accomplish this goal, facilitating a thorough inspection of the particles likely to released from DPFMs matrices. The findings of this study can improve the understanding of the fate of DPFMs in the environment and enlighten the strategies towards plastic waste management.

4.09.P-Tu405 Simulated Degradation of Polyester Fibres Released from Laundry and with Different Manufacturing Steps

Vasiliki Soursou[1]*, Julian Campo*[2]*, Yolanda Pico*[1]*, Richard C. Thompson*[3] *and Francesca De Falco*[4]*, (1)Centro de Investigaciones sobre Desertificación, Universidad de Valencia, Spain, (2)CIDE (CSIC UV GV), Spain, (3)Plymouth University, United Kingdom, (4)School of Biological and Marine Sciences, University of Plymouth, United Kingdom*

The pollution of the environment by plastics has been extensively studied during the last two decades. The laundering of synthetic textiles is one of the main sources of microplastics (MPs) in environmental compartments, such as wastewater, sludge and the ocean. The wide use of polyester (PES) in the textile industry contributes to its release and persistence since it cannot be easily degraded. The fate of these synthetic microfibers depends on different parameters, but their photodegradation due to sunlight exposure is considered one of the most common and effective. Recreating this type of degradation in the lab can be time-consuming and, thus, accelerated protocols may be applied to speed up the degradation process. The release and the degradation of PES fibres before and after washing was studied, using an accelerated hydrolytic degradation protocol proposed by Sarno et al (2021). Three different types of polyester textiles were used: undyed polyester (U-PES), dyed polyester (D-PES), a polyester commercial garment (G-PES). Fibre preparation before degradation was done using three different methods: (1) fibres were manually cut from not washed U-PES and D-PES fabrics, (2) D-PES fabrics were washed under domestic washing conditions (40ºC, non-bio detergent, 1200 spin) and the fibres were collected from the drain pipe by a 1µm pore PP filter; (3) G-PES was also washed and the fibres collected as above. Four sampling times were chosen in order to observe the degradation progress. Analysis of all the fibres before and after the degradation was performed by Scanning Electron Microscopy (SEM), micro- FTIR (uFTIR), Pyrolysis- Gas Chromatography- Mass Spectrometry (Py-GC/MS) and High Pressure Liquid Chromatography- High Resolution Mass Spectrometry (HPLC-HRMS). Degradation of the samples was evident, with color and fibre mass loss increasing throughout the procedure. According to the SEM results, the textile type and the washing process did not affect the morphology of the degradation pattern. Py-GC-MS analyses showed differences in the pyrolyzates of the different types of fibres tested. To the best of our knowledge, this is the first study that simulates degradation in fibres collected after washing, determines the effect of laundering on fibre degradation, and compares two PES fabrics that have been processed and used in distinct ways.

4.09.P-Tu406 Who wore it better? Identifying extractables and leachates from textile microfibres

Amanda Dawson[1], *David J. Beale*[2], *Edward Kerr*[3] *and Cassandra Pegg*[3], *(1)CSIRO, Australia, (2)Environment, CSIRO, Land and Water, Australia, (3)Agriculture and Food, CSIRO, Australia*

Synthetic and semi-synthetic microplastic fibres arising from textiles are extremely abundant within the built environment. Moreover, their proliferation within household dust suggests that inhalation of fibres may be one the most prevalent sources of human exposure. As opposed to microplastics generated from food contact items (e.g., plastic containers), textiles can have a multitude of chemical additives, with varying degrees of inherent toxicity, such as flame retardants, optical brighteners, and water repellents. Identification of leachates from these microplastics is of high importance in terms of risk assessment and regulation. In this study microplastic fibres generated from clothing were leached to determine the chemicals present in several clothing types. These were three synthetic shirts comprising of 100% recycled polyethylene terephthalate (PET) (blue), 100% PET (blue), 100% polyamide (PA) (black) and one shirt comprising 100% cotton (black). Polymer composition was verified using ATR-FTIR. To identify the chemicals present in each shirt, fabric was cut into ~1cm x 0.5cm irregular pieces and 1g of each fabric was sonicated in 100% DCM (1:10 w/v) in glass vials for 1h at ambient temperature (RT). Thereafter, extracts were analysed with an Agilent GCMSD. To identify aqueous leachates, microfibres were generated using a cryogenic mill. Thereafter, microfibres (0.2 g) were leached in filtered MilliQ H_2O (1:10 w/v) for 14d at RT on an orbital shaker in the dark. After 14d, nontarget analysis of the extracts was carried out using X500R Quadrupole Time-of-Flight (QTOF) MS (Sciex). Spectral deconvolution and identification of features was carried out using the NIST17 database (GC) or using MS-Dial, MS-Finder and the R package MSCleanr (LC). An MS-Dial MSP spectral database was used for initial searching, whilst a custom-built database using the NORMAN suspect exchange list, in addition to inbuilt MS-Finder databases was used for in-silico searches.

Unexpectedly, when leached in DCM, the PET shirt contained the most features with 555 tentatively identified chemicals, followed by cotton (466), PA (289) and rPET (250). All four clothing items contained chemicals listed on the NORMAN suspect list, and chemicals identified as Substances of Potential Concern. In terms of aqueous leachates, Cotton contained the most identified features (211) followed by PA (185), rPET (112), and PET (112). This poster will present and compare these results.

4.09.P-Tu407 Textile Features Affecting Fibre Release: A Critical Analysis of Empirical Findings and Evidence

Marina Corte Tedesco, *University of New South Wales (UNSW), Sydney NSW, Australia*

Emissions of textile fibres into the environment are recognized as a potential threat to humans, wildlife, and ecosystems. This emerging contaminant is thought to affect human health when inhaled or ingested. In wildlife, they are reported to cause inflammatory processes, reduce reproduction and growth, and increase mortality rates. While research into environmental contamination and health issues in humans and wildlife is increasing, the understanding of how emissions occur and the impact of manufacturing features on fibre release is still limited.

Several authors have studied the influence of textile parameters (e.g. fibre chemical composition and length, twist and type of yarn, fabric's construction and density, method used for sewing clothes) on fibre release, yet, most publications fail demonstrate clear evidence in their findings. A critical review of this evidence is necessary so advancements can be made to mitigate emissions.

In this research, a systematic method was used for finding the literature regarding microfibre release during domestic washing. A search was conducted on 18/04/2023 on Web of Science and Pro-quest databases, from 2010 to 2023. Results were compared and duplicates removed. Only peer-reviewed articles published in scholarly journals and in English were considered. Abstracts were read and potentially relevant papers, selected. Relevant publications were read in full. References from all selected papers were screened and relevant publications were included in this analysis.

46 publications were initially selected. While many publications perceived textile characteristics as having an impact on fibre emissions, such features were not tested in the described experiments, so papers were excluded. Studies were analysed based on their research aims, ability to control variables that could confound results, use of procedural blanks and controls, and use of suitable statistical methods. 70% of publications failed to demonstrate evidence of their findings.

In conclusion, although research about microfibres released into the environment grows at astonishing rates, there are few studies focused on understanding the mechanisms behind this phenomenon. Many features are perceived as having an impact on fibre shedding, but few studies succeeded in demonstrating the evidence of their findings. Our analysis indicates that the quality of studies must be improved so the root causes of microfibre shedding are identified, and mitigation can occur.

4.09.P-Tu408 Quantification and Characterisation of Microplastic Release from Different Aquaculture Nets Towards Emission Reduction

Stefania Piarulli[1]*, Heidi Moe Føre*[1]*, Nina Bloecher*[1]*, Alessio Gomiero*[2]*, Torstein Kristensen*[3]*, Astrid Lunde*[4]*, Hanne Hjelle Hatlebrekke*[1]*, Lisbet Sorensen*[1] *and Andy Booth, PhD*[1]*, (1)SINTEF Ocean, Norway, (2)Norwegian Research Centre (NORCE), Norway, (3)Scale Aquacolture AS, Norway, (4)Brynsløkken AS, Norway*

The fisheries and aquaculture industries have become increasingly dependent upon large amounts of plastic infrastructure and equipment, which can contribute to the microplastic (MP) emissions to the marine environment. Particularly, net cleaning procedures can cause damage and abrasion of nets, potentially leading to synthetic particles from biocidal coatings and/or fibres being released. This study aims to assess MP release from different nets used in aquaculture and identify easily implementable MP emissions reduction measures using specific combinations of polymers and coatings. A laboratory experiment simulating abrasion damage from *in-situ* net cleaning was performed to quantify and compare MP release from a range of different netting materials, including new and used versions of (Nylon, HDPE, Dyneema, ENTEX) net samples, as well as two coating types used to extend the life of the nets (standard and premium). Nylon net samples from above the sea surface and different depths were also assessed. Abrasion tests were conducted using a Buraschi abrasion simulator system. Triplicate samples of each net and net/coating combination were subjected to abrasion followed by washing and filtration on 500 and 10 µm filters to isolate the 'large MP' and 'small MP' fractions. The collected material was then quantified and physicochemically characterised using a combination of gravimetric measurements, microscope imaging and chemical fingerprinting by pyrolysis GC-MS. The total MP load was determined for each sample and comparisons between the different net and net/coating combinations made. The results indicate that nylon nets release higher quantities of MP compared to HDPE, Dyneema and Entex. Used nylon net samples from above the water surface and at different depths below the water surface exhibited very different particle release masses, suggesting UV exposure and environmental weathering strongly influences the potential for MP release. While the tested two coatings had no effect on the quantity of MP released from Dyneema nets, being comparable to the uncoated net, a significantly higher mass of MP was released from the coated nylon nets, especially with the premium coating. The outcomes of this study indicate that the aquaculture industry can select specific combinations of net materials/polymers and, coatings that can minimise MP release to the marine environment throughout the usable lifetime of the infrastructure.

4.09.P-Tu409 LIFE CASCADE Project: Removal of Microplastics and Other Pollutants from Textile Wastewater

Isabella Gambino[1]*, Manuela Antonelli*[2]*, Enrica Baldini*[3]*, Elisa Bayebane*[4]*, Giovanni Bergna*[5]*, Roberta Bettinetti*[6]*, Lisa Bonciani*[7]*, Beatrice Cantoni*[2]*, Antonio Di Guardo*[6]*, Serena Ducoli*[8]*, Stefania Federici*[8]*, Elisa Gavazza*[9]*, Luigi Longhi*[10]*, Francesca Malpei*[2]*, Daniele Pagani*[11]*, Roberto Riccio*[7]*, Domenico Santoro*[12]*, Augusta Silva*[13]*, Elisa Terzaghi, PhD*[6] *and Alberto Zoccali*[2]*, (1)University of Insubria, Varese, Italy, (2)DICA, Politecnico di Milano, Italy, (3)CTSS, Como, Italy, (4)De Nora, Italy, (5)Lariana Depur, Fino Mornasco CO, Italy, (6)DiSAT, University of Insubria, Italy, (7)Biochemie Lab, Campi Bisenzio FI, Italy, (8)DIMI, University of Brescia and INSTM, Italy, (9)ZDHC, Amsterdam The Netherlands, (10)Como Acqua, Italy, (11)Acquedotto Industriale, Fino Mornasco CO, Italy, (12)Aquasoil, Fasano BR, Italy, (13)CITEVE, Oporto, Portugal*

The emission of some emerging contaminants such as microplastics (MPs) and other micropollutants by the textile sector has drawn considerable attention of the scientific community at global level. Some of these substances were used in many industrial sectors for decades, and therefore are ubiquitous in the environment. MPs represent one of the addressed problems, whose origin is largely connected to the textile production cycle and deterioration of textile products. Another important category is that of poly and per-fluorinated substances (PFAS) are among the most persistent micropollutants and among the most studied by researchers due to their impact on the environment and human health. Developing methods for detecting and sustainably removing these micropollutants is important, since existing wastewater treatment plants are not specifically designed for removing these substances. The EU LIFE CASCADE project (EU Call LIFE-2022-SAP-ENV) aims at developing analytical procedures and wastewater treatment technologies meant to detect and remove two very critical categories of micro and emerging contaminants for the textile sector: MPs and PFAS. The project, coordinated by Centro Tessile Serico Sostenibile (CTSS), involves research laboratories of different universities and organizations (Politecnico di Milano, Università degli Studi dell'Insubria, Università degli Studi di Brescia, AquaSoil, Acquedotto Industriale, Biochemie, CITEVE, COMO ACQUA, De Nora, Lariana Depur, ZDHC) with world-class expertise in the management of pollutants in wastewater (WW). The output of the project includes three layers: standardized and multi-lab validated analytical protocols to detect and quantify PFAS and MP contaminants in heterogeneous textile WW; a modular set of WW treatment units to be installed at factory and municipal treatment plant levels; an orchestrating methodology meant to support the design and implementation of the best combination of treatment modules according to the textile district configuration and WW characteristics. Besides, the exposure and effects of PFAS and MPs on aquatic ecosystem in "natural" conditions and after specific treatments will be elucidated. The project demonstration solutions will be installed and tested in the Como Textile District and lab-scale experiments will also be carried out in cooperation with the Portugal textile district. The poster will illustrate the main features and activities of this four-year project.

4.09.P-Tu410 Influence of the microfiber catcher design on the capture efficiency of microplastic fibers generated during the washing process

***MiYeon Kwon**[1] and Juhea Kim PhD[2], (1)Korea Institute of Industrial Technology (KITECH), Cheonan-si, Korea, Republic of, (2)KITECH*

Fibrous microplastics refer to plastic particles under 5 millimeters in length, and have a length-to-diameter ratio exceeding 3. Particularly, fibrous microplastics generated during the clothing laundering process are emerging as a significant contributor to environmental pollution. They are released into the ocean via laundry wastewater and emitted into the atmosphere by remaining on the clothing surface. Upon discharge into marine environments and the atmosphere, these fibrous microplastics accumulate within organisms, through respiration and ingestion, leading to increased disease incidence and mortality rates due to physical harm and chemical toxicity.

Efforts have been made to mitigate microplastic discharge from household washing machines, introducing devices such as laundry bags and laundry balls to capture microplastics within the drum. These devices effectively capture microplastics from both washing machine wastewater and fabric surfaces, thereby reducing their release into the atmosphere and aquatic systems.

Therefore, this study aims to develop microfiber catcher and investigate how their design affects the efficiency in capturing microfibers. The study considers factors like the number of air meshes, the number and design of the external layer on the efficacy of microfiber capture. The ultimate objective is to develop an optimized disposable fibrous microplastic trap design to aid in resolving environmental pollution caused by microplastics.

4.10.P Progress Into Monitoring and Assessing Risks of Antimicrobials and Antimicrobial Resistance in the Environment

4.10.P-We367 Key Environmental Drivers of Antimicrobial Resistance

***Kiri Rodgers**, Andrew Hursthouse and Fiona Henriquez, University of the West of Scotland (UWS), United Kingdom*

Antimicrobial resistance is a global crisis with over 4.95million associated deaths in 2019 alone. Currently there is a lack of knowledge in what causes its prevalence, particularly as it is becoming clear that the acquisition of AMR is more complex and multifaceted than the misuse of antibiotics.

Our research is focused on the characterisation and correlation of biological, physical, and chemical environmental variables to identify key drivers of AMR. In addition, with no monitoring strategy in place we explore the potential of using different toxicity indices.

By analysis sediment and water samples near to chemical water treatment plants, for geochemical properties; physicochemical chemical organic and inorganic pollutants, as well as carrying out microbiome and metagenomic analysis. In addition, we isolated a model eukaryotic organism; *Acanthamoeba sp.* to extract and compare varying levels of resistance and any changes in the microbiome as a result of geochemical changes. Resistance was determined both through suceptibility testing and metagenomic analysis.

We demonstrated that *Acanthamoeba* harbours different bacteria species and can act as a vector for AMR. Further to this, we demonstrate that the need for biological monitoring in AMR detection is a costly process that is difficult to implement on a routine basis. By correlating existing environmental monitoring processes, e.g. of metals and physicochemical properites, and their associated toxicity indices, we can potentially gain an insight to the prevelance of AMR, meaning a cost effective mitigation strategy can be implemented.

4.10.P-We368 Evaluation of the SELECT Assay as a Method to Facilitate Risk Assessment for Antimicrobial Resistance

***Alejandra Bouzas Monroy**[1], John Wilkinson[2], Ville Friman[3] and Alistair Boxall[4], (1)University of York, York, United Kingdom, (2)Environment and Geography, University of York, United Kingdom, (3)Biology, University of York, United Kingdom, (4)University of York, United Kingdom*

Due to the extensive use of antimicrobials throughout the human, veterinary and agricultural sectors, antimicrobial resistance has become one of the greatest concerns to human health across the world. Though selection for antimicrobial resistance (AMR) has been proven to occur at environmental concentrations of antimicrobials, no standardized experimental method has been designed to determine this. This study aims to evaluate the suitabilility of the 'SELection End points in Communities of bacTeria' (SELECT) method developed by Murray et al. (2020) by: exploring variability in results across test laboratories, different test matrices; and comparing the results of the SELECT assay to other testing approaches such as a Colony Forming Units (CFUs) approach or qPCR. CFUs, qPCR and SELECT assays were carried out to determine the effects of the fifteen antimicrobials (azithromycin, cefotaxime, chloramphenicol, ciprofloxacin, clarithromycin, enrofloxacin, erythromycin, gentamicin, trimethoprim, metronidazole, sulfamethoxazole, sulfadiazine, lincomycin, tetracycline, and tylosin) using wastewater samples obtained from five plants. The SELECT assay showed a small variation between the No Observed Effect Concentrations (NOECs). However, none of the antimicrobials had the same NOEC concentration for all five WWTPs. For the eight compounds studied by Murray et al. (2020), at least one of the WWTPs presented the same NOEC concentration reported within the paper. The CFUs approach showed no statistically significant differences between the control and the antibiotic treated plates for all WWTPs. Utilizing a qPCR method, only two compounds (azithromycin and ciprofloxacin) appeared to cause a significant increase in the prevalence of the intl1 resistance gene in at least one of the WWTPs. When the SELECT method was applied the results indicate a small variation between WWTPs and agree with those determined by Murray et al. (2020), showing the transferability of the assay. Given that no statistically significant difference was found when using CFUs, the optical density readings, taken during the SELECT method, appear to be suitable for assessing the effects of antimicrobials on community growth. Furthermore, apart from azithromycin and ciprofloxacion, the SELECT assay appeared to be protective for resistance selection. Overall, the data suggest that the SELECT method is robust a a potentially useful tool for use in the environmental risk assessment of antimicrobials.

4.10.P-We369 Occurrences of antibiotics in wastewater and runoff of pharmaceutical production sites and their impact on environmental water quality

Ursula Karges[1]*, Pia Springmann*[1]*, Tim aus der Beek*[1]*, Ute Kühnen*[2]*, Malgorzata Debiak*[3] *and Arne Hein*[3]*, (1)IWW Water Centre, Germany, (2)Pharmaceuticals, German Environment Agency (UBA), Germany, (3)German Environment Agency (UBA), Germany*

Antibiotic resistance is increasingly jeopardising the effectiveness of prevention and medical treatment of an increasing number of infectious diseases and is causing a high number of premature deaths worldwide. By now, it is widely recognised that one important contributing factor is the release of production wastewater of antibiotics from the pharmaceutical industry into the environment. Evidently, tackling such point sources through appropriate treatment of production wastewater would be a decisive step towards achieving a substantial reduction in antibiotic pollution and consequently the reduction of occurrences of resistant pathogens. The here presented pilot study addresses the overall feasibility of implementing maximum permitted API concentrations in production wastewater and how to verify compliance. Wastewater from 13 production sites from Europe, India and China has been investigated. The antibiotics tested so far include roxithromycin, ciprofloxacin, moxifloxacin, amoxicillin, cefaclor and levofloxacin. In addition, wherever possible, complementary investigations were carried out in surface waters in the surrounding environment connected to the production sites.

So far, 18 different antibiotics have been detected in concentrations above the respective LOQ, some of them repeatedly and at several sampling locations. Four production sites have shown antibiotic API concentrations exceeding the PNEC - in either the wastewater samples or in the affected environmental samples. These include maximum concentrations ranging from 1 µg/L (tiamulin) up to 500 µg/l (azithromycin). Overall, in the total number of measurements of environmental water samples, more than 50 percent of the antibiotic findings exceeded the PNEC as an ecotoxicologically relevant threshold value, while for other antibiotics detected in the samples such a reliable, scientifically derived effect threshold value was not available at the time.

The results of our pilot study quantify and confirm that wastewater from pharmaceutical production sites is a major contributor to high concentrations of antibiotic APIs in the environment, and hence potential AMR formation. At the same time, this study shows that wastewater treatment genuinely represents an effective opportunity to reduce antibiotic emissions from pharmaceutical production into the environment and thus also to reduce the development of AMR.

4.10.P-We370 Occurrence and Seasonal-Spatial Variation of Emerging Chemicals and Antibiotic Resistance Genes in a Wastewater-Effluent-Dominated Stream

Anna Marizzi del Olmo[1]*, Monica Escola Casas*[2]*, Jessica Subirats Medina*[3] *and Victor Matamoros*[1]*, (1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Department of Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Emerging contaminants (ECs), particularly antibiotics and antibiotic resistance genes (ARGs), have been detected in nearly all surface water bodies. This presents a significant and pertinent challenge, as these contaminants have the potential to foster the development of novel resistances within water and surrounding ecosystems, thereby exacerbating the issue of antibiotic resistance. The prevalence and seasonal variations of these pollutants in surface water bodies, such as rivers affected by wastewater treatment systems (WWTPs) discharge, is crucial for assessing and quantifying the associated impact.

In the frame of the Life-BIODAPH2O project, 4 seasonal monitoring campaigns of the Onyar River (Girona, Spain) were conducted during autumn, winter, spring and summer. 52 ECs and 7 ARGs were analysed from water samples collected upstream, at 4 different points downstream and from the secondary WWTP effluent. ECs were detected with an UHPLC-HRMS instrument and ARGs were detected with hight-capacity quantitative PCR.

30 out of the 52 monitored ECs were detected in the monitored water samples, ranging from 0.5 to 34923 ng/L. Median concentrations of ECs were higher at the WWTP effluents than up- and downstream. Sucralose and Caffeine were detected at

the highest concentration in the WWTP effluents. Most of ECs detected in the WWTP effluent disappeared 4 km downstream with an average attenuation of 79 ± 4%. ARGs were detected at high concentrations in the WWTP effluent and steadily decreased throughout the river (average attenuation= 96%). Int1 and Sul1 were the most abundant ARGs throughout the 4 seasons, followed by tetM, qnrS, *bla*OXA, *bla*CTX and *bla*TEM. A seasonal pattern could be observed between Spring and Autumn.

These findings suggest that in-stream attenuation of ECs, including ARGs through processes such as biodegradation, photodegradation or sorption, represents the most plausible mechanisms for reducing these pollutants. Nevertheless, this data also shows that the studied WWTP has an impact on the river ecosystem that cannot be counterbalanced by natural attenuation processes.

4.10.P-We371 Resistome Profile of the Baltic Benthic Ecosystem

Joeselle Serrana[1,2], *Francisco J. A. Nascimento*[3], *Benoît Dessirier*[4], *Malte Posselt*[5] *and Elias Broman*[3], *(1)Stockholm University Center for Circular and Sustainable Systems, Sweden, (2)Department of Environmental Science, Stockholm University, Stockholm, Sweden, (3)Department of Ecology, Environment, and Plant Sciences, Stockholm University, Sweden, (4)Baltic Sea Centre, Stockholm University, Sweden, (5)Department of Environmental Science, Stockholm University, Sweden*

The release of nutrients, antibiotics, and pollutants into the Baltic Sea ecosystem through various sources, e.g., wastewater discharge and industrial activities, are the major factors contributing to the introduction and spread of antimicrobial resistance in the area. These impacted areas serve as relevant reservoirs of pathogenic bacteria and antimicrobial resistance genes (ARGs) that pose severe public health threats. Hence, environmental monitoring of antimicrobial resistance throughout the Baltic Sea is warranted. It is also necessary to understand the link between its resistance profile and associated genes against various environmental parameters to aid in identifying potentially high-risk environments and prevent resistance from spreading to low-exposure habitats. In this study, we re-analyzed previously published metagenomic data from benthic sediment samples collected from 59 monitoring stations in the Baltic Sea. We characterized the antibiotic resistome profile of benthic ecosystems and investigated its spatial variability between eight regions spanning 1,145 km across the Baltic Sea. We report the presence and potential dissemination of important ARG types in each region, with concerning observations of multidrug resistance being the most abundant and prevalent type for all stations. We also report the influence of physicochemical gradients, i.e., salinity, temperature, water depth, dissolved oxygen, total carbon, and total nitrogen availability, on the diversity and composition of the resistome and its associated genes. The microbial structure and distribution of resistance and associated genes mainly differed between regions along the spatial distance and physicochemical gradients of the Baltic Sea. This observation implies that future environmental changes in dissolved oxygen, salinity, and temperature may influence the resistome profile of these benthic habitats. Our findings indicate that the Baltic Sea resistome is stocked with resistance genes and represents concerning ARG types that require further monitoring. Utilizing metagenomics tools and combining analyses of resistance gene abundance and its association with other genes and microbial communities, we provide a valuable approach for monitoring antimicrobial resistance in the Baltic Sea environment and assessing their potential dispersal and possible risks to other health sectors.

4.10.P-We372 Grazing on freshwater biofilm influences Xenopus laevis larvae microbiota and antimicrobial resistance dynamics in the environment

Alexandre J. Thibodeau, *Florence Mouchet, Xuan Van Nguyen, Eric Pinelli and Maïalen Barret, UMR5245 CNRS-UT3-INPT Laboratoire Ecologie Fonctionnelle et Environnement, France*

Antimicrobial resistance (AMR) is an emerging concern and considered as of the biggest threats to public health by 2050, thus being subject of intensive research into thisfield. It has been largely demonstrated in laboratory exposure that AMR is enhanced by various classes and concentrations of antibiotics.In freshwater ecosystems, antibiotics are rejected by Waste Water Treatment Plant (WWTP) and can impact the microorganisms constituting river biofilms, disturbing their role in primary production, at the basis of the aquatic trophic chain. Knowledge of dynamics of AMR in environment and wildlife as potential hotspots or mitigators are missing. In the present study, the influence of biofilm grazing has been investigated on the dynamics of AMR in two microbial compartments of aquatic ecosystems: the grazed biofilm and the gut microbiota of a model grazer (*Xenopus laevis)*. *Xenopus laevis* larvae were fed during 12 days with two different freshwater biofilms from two different sources near (B) or far (A) from a WWTP discharge. The influence of these two types of biofilms was investigated in terms of dynamics of the intestinal microbiota diversity of these organisms, as well as presence of antibiotic resistance genes (ARGs) by MiSeq sequencing and High-Throughput qPCR approach. After 12 days, the microbial composition of grazed biofilms was significantly influenced by the inoculum composition compared to control (without biofilm inoculation. Significant changes in relative abundances of ARGs were also observed. Xenopus microbiota were significantly influenced with 12 and 26 changing OTUs abundance in larvae who grazed on Biofilm A and B respectively and a significant change in ARGs relative abundance have been observed with more abundance of *ampC/blaDHA* and *aac-iVa* in larvae grazing on biofilm B. These findings may play a role in: 1) dynamics of antibiotic resistance dissemination in environment and the gut microbiota and 2) the physiological response of the animal. This study paves the way to further research on biofilm microbiota and ARGs dynamics under more realistic conditions to better constrain the mechanisms driving antibiotic resistance fate in aquatic ecosystems.

4.10.P-We373 Political demands to produce antibiotics more environmentally sustainable

Arne Hein[1], ***Ursula Karges***[2], *Maxana Baltruweit*[3], *Tim aus der Beek*[2], *Daniela Gildemeister*[4], *Ute Kühnen*[4], *Jens Schönfeld*[1]

and Malgorzata Debiak[1], (1)German Environment Agency (UBA), Germany, (2)IWW Water Centre, Germany, (3)AOK Baden-Württemberg, Germany, (4)Pharmaceuticals, German Environment Agency (UBA), Germany
The supply of antibiotics - whether in human or veterinary medicine - is of outstanding importance to all modern societies. At the same time, industrial production of antibiotics can lead to development and spread of resistant microorganisms through contaminated wastewater. The intention of our work is to extract the main political demands for improving the situation at antibiotic production sites based on practical experiences.

Therefore, the Germany's largest health insurance provider, AOK, has launched a pilot study on sustainable antibiotic supply in collaboration with IWW Water Centre and the German Environment Agency. The contracts with the suppliers of selected antibiotics allowed independent wastewater inspections at the production sites and the obligation to given standards for antibiotic emission. The inspections at ten different productions sites in Asia and Europe included a review of the wastewater treatment technologies used, a joint inspection of the production facility and sampling of production wastewater at the end of the treatment chain. Their measurements of 20 antibiotics show high concentrations in the wastewater and adjacent rivers (see also abstract by Karges et al.). These alarming results pose a danger for the local population and risk for worldwide spread of microbial resistance.

The study shows also positive effects: the knowledge about wastewater treatment increases and improvements were achieved at some production sites. It clearly illustrates mitigation of environmental impact is possible. However, more far-reaching changes than individual supplier contracts are needed to implement such measures globally. The EU could play a pioneering role here. Four main political demands in the field of tension between the three dimensions of sustainability (ecological, social and economic) will be addressed: 1. Inclusion of binding environmental criteria in the EU pharmaceutical legislation; 2. Standardised control systems to compliance during authorisation and ongoing production; 3. Knowledge transfer through partner projects, especially in the Asian region; 4. Shortening supply chains through changes to EU procurement law.

4.10.P-We374 The Antimicrobial Resistance Multi-Stakeholder Partnership Platform: An Inclusive And Collaborative Space For Enhancing Global Governance On AMR And One Health

***Paola Grenni, PhD**[1], Andrea Di Cesare[2], Sabiha Essack[3], Francesca Latronico[4] and Nelea Motriuc[4], (1)Water Research Institute (IRSA), National Research Council (CNR), Italy, (2)National Research Council of Italy, Water Research Institute, Italy, (3)University of KwaZulu-Natal, South Africa, (4)FAO, Italy*
Antimicrobials play a crucial role in preventing and treating infections and diseases in humans, animals and plants. Their over-use is the main driver of antimicrobial resistance (AMR). Poor sanitation, inadequate infection prevention and control practices, and a lack of access to clean water facilitate the treatment-resistant microbe spread. As a result, AMR threatens global health, food safety, food security and economic prosperity, as well as planetary biodiversity and ecosystems.

AMR is a global health and development threat and requires a greater coordination, communication, political leadership, interdisciplinary collaboration in a truly One Health spirit to deliver on the Global Action Plan, National Action Plans on AMR and, ultimately, the 2030 Agenda for Sustainable Development.

The 2016 Political Declaration of the High-level Meeting of the United Nations General Assembly (UNGA) on AMR was a milestone for promoting an ad hoc inter-agency coordination group (IACG), which produced a report ‘No time to wait: Securing the future from drug-resistant infections’. The report recommended the establishment of thee global governance structure on AMR along with y the One Health Global Leaders’ Group on AMR (GLG), the Independent Panel on Evidence for Action against AMR (IPEA) and the AMR Multi-Stakeholder Partnership Platform. The latter is a Quadripartite (FAO, UNEP, WHO, WOAH) collaboration on AMR and One Health launched in November 2022 by the Quadripartite.

The AMR Multi-Stakeholder Partnership Platform is a global, inclusive and collaborative platform which aims to catalyse a global movement for action against antimicrobial resistance (AMR) by fostering cooperation between a diverse range of stakeholders at all levels across the One Health spectrum.

On 15-16 November 2023, just before the World AMR Awareness Week, the Inaugural Plenary Assembly of the Platform took place in person and online at FAO headquarters. More than 130 member delegates from different countries and stakeholder groups (governments, financial institutions, civil society organizations, academic and research organizations, private sector) meet for the first time, while presenting their proposals for joint Action Groups, discussing Platform’s collective governance and priorities for the future, such as the UNGA High-Level Meeting on AMR next Sept. 2024, that will be a historic opportunity to renew political momentum and commitment for antibiotic resistance.

4.10.P-We375 Are On-Site Sewage Facilities Contributing to the Spread of Antimicrobial Resistance?

***Valentina Ugolini**[1], Harold Flores Quintana[1], Jessica Subirats Medina[2], Pia Rapp[3], Catarina Dunge[3], Elin Ulinder[4], Lutz Ahrens[1] and Foon Yin Lai[1], (1)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (2)Department of Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Oskarshamn Municipality, Sweden, (4)Department of Biorefinery and Energy, Research Institute of Sweden (RISE), Sweden*

Wastewater is a major reservoir of antimicrobial resistance (AMR) contaminants, both chemicals and antibiotic resistance genes (ARGs). While research often focuses on municipal wastewater treatment plants, on-site sewage facilities (OSSFs) are widely overlooked regarding the occurrence, fate and transport of antimicrobial contaminants. In Sweden, 15% of the households is using OSSFs. As the OSSF effluent can be discharged via soil infiltration to groundwater, an important source for drinking water, water quality assessment is needed.

This study aims to investigate the dissemination of antimicrobial contaminants from OSSFs to groundwater environments, and the related risks of AMR development.

The studied OSSF system serves 300 population equivalents, and samples were collected at the inlet and outlet of the septic tank, and after treatment with aerated ponds over different seasons. Groundwater samples were also obtained beneath infiltration sites and downstream, with upstream samples as reference. Samples were analyzed for antimicrobial chemicals, sewage markers, ARGs, mobile genetic elements (MGEs) and integrons using (SPE)-LC-MS/MS and high throughput qPCR.

Compared to the nearby municipal treatment plant, antimicrobial chemicals were less frequently found and at lower concentrations in the OSSF, attributed to the absence of connections to hospitals or manufacturing industries. Preliminary results show higher relative abundance of specific ARGs associated with aminoglycosides, multidrugs, phenicols, quinolones, tetracyclines and vancomycin resistance, as well as class 1 integrons and MGEs, in the effluent wastewater compared to the influent. ARGs related to aminoglycosides and tetracyclines are additionally found in downstream groundwater but are absent in the upstream samples. Even at non-detectable concentrations of chemicals, microbial selection for AMR can occur, allowing for the proliferation and spread of resistance genes. We will further evaluate removal efficiencies, seasonal correlations between antimicrobial chemicals and ARGs, and the relationship between ARGs and MGEs/integrons, shedding light on the mobility of resistance genes. Risk assessments using predicted no-effect concentrations for quantified antimicrobial chemicals will also be conducted.

Our initial findings suggest that OSSFs may contribute to AMR development and dissemination, highlighting the importance of monitoring these systems as potential AMR sources in the future.

4.10.P-We376 Case study to examine environmentally relevant amoxicillin concentrations in production wastewater - before and after wastewater treatment improvements
Ursula Karges[1]*, Pia Springmann*[1]*, Tim aus der Beek*[1]*, Arne Hein*[2]*, Malgorzata Debiak*[2] *and Ute Kühnen*[3]*, (1)IWW Water Centre, Germany, (2)German Environment Agency (UBA), Germany, (3)Pharmaceuticals, German Environment Agency (UBA), Germany*
Antimicrobial resistance endangers the effective prevention and medical treatment of an ever-increasing number of infections and leads to a high number of premature deaths worldwide. Tackling point sources of antibiotic releases into the environment such as the discharge of wastewater from pharmaceutical production through appropriate treatment would be a decisive step towards significantly reducing antibiotic pollution and ist consequences.

This is where our pilot study comes in and deals with the feasibility of implementing the maximum permissible concentrations in production wastewater and verifying compliance. Since September 2021, we inspected the wastewater from production facilities whose antibiotics are also marketed in Europe. The companies concerned had committed to comply with a Predicted No Effect Concentration for certain target antibiotics in the production wastewater. In cases where the limits were exceeded, manufacturers were instructed to improve their treatment processes. These improvements were then verified by means of repeated wastewater analyses.

Decisive for achieving an effective opportunity to reduce antibiotic emissions into the environment is ensuring that wastewater treatment is very much tailored to the APIs under consideration, including testing for such APIs. This pilot study led to a growing awareness among producers of the environmental and human health impacts of antibiotic releases. Survey results prompted changes, intensified monitoring and strengthened mitigation measures tailored to the specific situation of manufacturing facilities.

The example presented illustrates the increased benefit of an adapted water treatment system with regard to antibiotic contamination from production wastewater. Wastewater from an inspected site was analysed for amoxicillin concentration. During the initial sampling, wastewater treatment at this site consisted of a tank with a pH of 7-8 to break up ring structures. An amoxicillin concentration of 10 µg/L was detected in the production wastewater, which corresponds to 40 times the threshold value of 0.25 µg/L. As a result, the treatment was adapted by choosing a larger tank, an extended retention time and an optimised pH setting. Amoxicillin could no longer be detected in a follow-up analysis.

4.10.P-We377 Plastics as a Potential Vector for Spread of Antimicrobial Resistance and Pathogens From Wastewater Discharge in the Marine Environment – the PlastiSpread Project
Sigrid Hakvåg[1]*, Gunhild Hageskal*[2]*, Sunniva Hoel*[3]*, Ioannis S Boziaris*[4]*, Andy Booth, PhD*[1]*, Julia Farkas*[1]*, Anne Tøndervik*[2]*, Terkel Hansen*[2]*, Foteini F Parlapani*[4] *and Anita N Jakobsen*[3]*, (1)SINTEF Ocean, Norway, (2)SINTEF AS, (3)NTNU, Norway,*

(4)University of Thessaly
Antimicrobial resistance (AMR) and marine plastic pollution are both major environmental and global health concerns. However, there is limited knowledge concerning the occurrence of pathogens and antibiotic resistant bacteria (ARB) in wastewater (WW) effluents from urban areas and in the coastal marine environments into which they are discharged. Furthermore, the potential role of plastics as a vector for the transmission of pathogens, ARB, and antibiotic resistant genes (ARG) throughout the marine environment is poorly understood. The PlastiSpread project studies the role of the microbial community in biofilms associated with marine plastics, and how they are influenced by variations in urban WW discharges. Furthermore, the potential role of marine (micro)plastic litter to act as a reservoir and vector for the development and spread of AMR and pathogenic bacteria in marine environments and into the human food chain is evaluated.

By combining field- and lab-scale plastic model systems, the influence of WW effluent composition and polymer type (PE, PS and PVC), on the bacterial community composition in plastic-associated biofilms will be investigated in relation to other materials (wood, glass). The occurrence of potential pathogens, ARBs and ARGs will also be studied. The laboratory experiments will utilise microplastic forms of each material (300-500 µm) and will be performed both in Norway and Greece. As Greece has among the highest consumption of antibiotics in Europe, such complementary studies will allow investigation into how and to what degree the antibiotic consumption will influence the occurrence of ARB and ARGs in local effluent WW. The field model system will contain plates (10 x 5 cm) of each selected material, which will be placed at exposed and non-exposed sites in the Trondheim Fjord, Norway. Marine bivalve molluscs will be used as indicators for exploring effects on marine organisms present at the same sites. Laboratory experiments will be performed to determine the process of horizontal gene transfer of ARGs from WW to susceptible plastic associated biofilm bacteria.

The knowledge obtained in the PlastiSpread project will have a long-term impact on WW legislation and requirements for how the WW treatment plants design their treatment processes. The project will increase our understanding of marine plastic litter as a vector for pathogens and ARB in the marine environment.

4.10.P-We378 Occurrence of Antibiotic Resistant Bacteria (ARB) and Antibiotic Resistance Genes (ARG) in Water from the Middle Tagus River: Seasonal Variability

***Cristina de los Reyes Ramos**[1], María Rodríguez Pérez[2], Beatriz Larraz Iribas[3], María de los LLanos Palop Herreros[4], Rosa C. Rodríguez Martín-Doimeadios[4] and Susana Seseña Prieto[4], (1)Analytical Chemistry and Food Technology, University of Castilla-La Mancha (UCLM), Spain, (2)Inorganic and Organic Chemistry, and Biochemistry, Castilla La Mancha University (UCLM), Spain, (3)Applied Economics, Castilla La Mancha University (UCLM), Spain, (4)Analytical Chemistry and Food Technology, Castilla La Mancha University (UCLM), Spain*
The Tagus River is the longest river in Spain and around 7 million people live along its course, with 80% of them doing it in its middle section. Unfortunately, overpopulation and related wastewater treatment plants, many different industries, and agricultural and livestock activities are also concentrated in this central area.

The presence of ARB and antibiotic resistance genes ARG in natural ecosystems as rivers, is associated with different anthropogenic activities being the agriculture, the pharmaceutical industry, and the wastewater treatment plant the main contributors for these contaminants.

Data related to the presence of ARB and ARG in Tagus River are very scarce, and that is why we set out to carry out the monitoring of these contaminants in the middle Tagus River basin.

Samples of water were collected from 19 sites that had been selected attending to the closeness with livestock and agricultural farms, pharmaceutical industries, and wastewater treatment plants. Four samplings were carried out seasonally during 2022 and 2023. The presence in the water of bacteria resistant to the antibiotics ampicillin, doxycycline, sulfamethoxazole, and ciprofloxacin was quantified by filtering through 0.45 um filter membranes and subsequent incubation of the filters on Tryptone Soy Agar (TSA) plates containing the corresponding antibiotics. For ARG analysis quantitative PCR (q-PCR) reactions were carried out. It has been analyzed genes that code for resistance to tetracyclines (*tetA, tetB*); sulfonamides (*sul1, sul2*); fluoroquinolones (*qnrB, qnrS, qnrA*); β-lactamase from gram-negative bacteria (*blaTEM*); next-generation carbapenem antibiotics (*blaKPC*); vancomycin (*vanA*); colistin (*mcr-1*) and methicillin (*mecA*), as well as the presence of the integron responsible for the accumulation and dissemination of cassettes containing genes for resistance to cephalosporins, carbapenems and quinolones (*int1*).

Results from this study have displayed statistically significant differences in the content of ARB and ARG for the samples of water taken both from different seasons and different sites and between the antibiotics tested. ARB concentration was significantly higher in the summer water samples, what has been related to the weather conditions and the lower river flow both increasing the antibiotic concentration in the water. In addition, a significant increase in the ARG content has been observed in samples of water taken from sites where anthropogenic activity was higher.

4.10.P-We379 Ecosystem-Level Assessment of The Fate and Effects of Benzalkonium Chloride in In-Lake Mesocosms

***Jose Luis Rodriguez Gil**[1], Markus Brinkmann[2], Carolyn Currie[3], Jose Luis Rodriguez Gil[4], Mark L. Hanson[3], Fiona*

Henriquez[5], Vince Palace[1], Charles Knapp[6], Lauren Timlick[1], Karen A. Kidd, PhD[4] and Chris Weisener[7], (1)Experimental Lakes Area (IISD-ELA), Canada, (2)Toxicology Centre, University of Saskatchewan, Canada, (3)University of Manitoba, Canada, (4)McMaster University, Canada, (5)University of the West of Scotland (UWS), United Kingdom, (6)University of Strathclyde, United Kingdom, (7)University of Windsor, Canada
Benzalkonium Chloride mixtures (BACs, or ADBACs), are some of the most common quaternary ammonium compounds used as active ingredients in sanitizing and disinfecting products, including those recommended for preventing the spread of COVID-19 and other viruses. As a result, their use and presence in the environment have increased over the past few years. Their ecosystem-level effects, however, are still poorly understood, particularly in the lower trophic levels which might be more sensitive to their antimicrobial nature. This study presents the results of an 80-day, in-lake mesocosm study aimed at assessing the fate and ecological-level effects of BAC mixtures. Eight ~5,000L open-bottom enclosures were installed in a boreal lake at the IISD-Experimental Lakes Area (Ontario, Canada). Three enclosures were untreated controls while the remaining 5 represented treatments with 20, 112, 632, 3,557, and 20,000 ng/L of a BAC mixture cantered around the C12 and C14 homologs. To simulate a continuous inflow, like what would be expected in the real world, the enclosures were re-spiked weekly to maintain the target exposures. The water-column dissipation half-life of the BAC mixture was estimated at ~5 days, with shorter-chain homologs remaining in the water column longer than longer-chain ones. Sediment concentrations increased throughout the study with preferential accumulation of longer-chain BACs. Treatment effects were clear in the lower-trophic levels with periphyton (measured as chlorophyll) showing concentration-dependent decreases with a NOEC at the nominal 632 treatment level and an almost 100% inhibition at the highest treatment. Ecosystem metabolism (assessed through dissolved oxygen data) was also impacted at the highest treatment level. Analysis of the bacterial resistome in the upper few cm of sediment suggests BAC exposure increases 1) the richness (number of resistance genes detected) and 2) the concentrations of genes, both in a concentration-dependent manner. This was evident for the BAC resistance genes and the genetic elements that promote the presence and dissemination of other resistance (e.g., antibiotic) genes. Maximum measured concentrations for BACs in the environment have been reported at ~2,000 ng/L, a value above those where effects start being apparent in this study, indicating that current levels of BACs in the environment may pose a risk in the higher centiles of the exposure distribution.

4.10.P-We380 "Azole Pesticides and Their Role in Antimicrobial Resistance: Case for Aspergillus fumigatus"
***Diletta Scaccabarozzi**[1], Isabella Sanseverino[1], Marcos Cuesta Sanz[2], Elena Porcel-Rodriguez[3], Livia Gomez Cortes[1], Dimitar Marinov[4], Bas Zwaan[5], Raquel Sabino[6] and Teresa Lettieri[1], (1)European Commission - Joint Research Centre (JRC), Italy, (2)European Commission, Joint Research Centre (JRC), (3)Piksel S.r.l., Italy, (4)ARHS Developments S.A., Luxembourg, (5)Department of Plant Science, Laboratory of Genetics, Wageningen University & Research, Netherlands, (6)Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Portugal*
AMR is global threat, and the environment role, including the climate change, is still under investigation. Recently, fungal pathogens and their resistance attracted more attention because of serious concern. Among the fungi, *Aspergillus fumigatus* (*A. fumigatus*), which natural habitat is soil, is responsible for invasive disease and chronic infections in immunocompromised patients.

For the aspergillosis treatment, one of the larger used substance of the pharmaceuticals is the azole molecule. The azoles are also used as pesticides and biocides to prevent and control plant diseases. Additionally, azoles are widely used in animals and in household and personal care products such as soaps and shampoo.

In recent years, increase of resistant *A. fumigatus* has been observed raising high concern since growing evidences would suggest that *A. fumigatus* acquires resistance when exposed to azoles in the environment. Indeed, azole resistant *A. fumigatus* isolates have been found in patients not previously treated with azole-based pharmaceuticals.

The close correlation between environment and human urges for an action since the environment could be a reservoir of resistant fungi due to the constant environmental exposure to the azoles. Furthermore, the climate change could exacerbate this problem as increasing global temperatures can promote the pathogens’ survival.

The aim of this study was to investigate if *A. fumigatus* is resistant to a selected panel of sixteen azole fungicides. To do so, the wild type *A.fumigatus* and the most common mutant TR_{34}/L98H were exposed to the azole substances and the Minimal Inhibitory Concentration (MIC) was determined. MIC test provides information concerning the susceptibility or resistance of the fungi to the antifungal agent.

Furthermore, soils samples were analyzed for the presence of the *A. fumigatus* and MIC analysis upon exposure to the sixteen azole fungicides were tested. In order to understand the mutations that could cause the resistance, Sanger sequencing for colonies isolated from the soil samples were performed.

In conclusions, the MIC analysis to determine the susceptibility or resistance should be taken into the chemical risk management to prevent and mitigate the spreading of fungal resistance to humans.

4.10.PC Progress Into Monitoring and Assessing Risks of Antimicrobials and Antimicrobial Resistance in the Environment

4.11 Protecting Innovation in Plant Protection: Low-risk Pesticides, Precision Applications, and Considerations on Risk Assessment

4.11.T-01 Nano-enabled strategies to enhance biological nitrogen fixation
Jason C. White[1]*, Peng Zhang*[2]*, Iseult Lynch*[3]*, Christy Haynes*[4] *and Yukui Rui*[5]*, (1)Connecticut Agricultural Experiment Station, (2)University of Birmingham, United Kingdom, (3)School of Geography, Earth and Environmental Sciences, University of Birmingham, United Kingdom, (4)University of Minnesota, (5)China Agricultural University, China*
Synthetic nitrogen fertilizers are widely used to supplement soil fertility, despite their low delivery and use efficiency. This contributes significantly to greenhouse gas emissions, ammonia volatilization and loss of reactive nitrogen into the water from land. Reducing nitrogen fertilizer application is critical to mitigating food insecurity and global warming. Enhanced biological nitrogen fixation (BNF) in crops offers an opportunity to reduce nitrogen fertilizer use and increase yields. The results from two studies investigating nanoscale micronutrients (NiO, MoS_2) important to nitrogen fixation will be presented. A full life cycle study was conducted to compare soil-applied NiO nanoparticles (n-NiO), NiO bulk (b-NiO), and NiSO4 at 10−200 mg kg−1 on soybean. n-NiO at 50 mg kg−1 significantly promoted seed yield, fatty acid and starch contents by 39, 28 and 19%, respectively. The increased yield and nutrition were attributed beneficial impacts on photosynthesis, mineral homeostasis, phytohormones, and nitrogen metabolism. Single particle inductively coupled plasma mass spectrometry (sp-ICP-MS) confirmed that the majority of the Ni in seeds is in ionic form, with only 28−34% as n-NiO. Separately, low dose (10 mg/kg) MoS_2 NPs enhanced soybean BNF and grain yield by 30%, compared with conventional molybdate fertilizer. MoS_2 NPs can more sustainably release Mo, which is then used for nitrogenase synthesis and molybdenum-based enzymes that subsequently enhance BNF. Sulfur is also released sustainably and incorporated into biomolecule synthesis, particularly in thiol-containing antioxidants that protected the nodules from reactive oxygen species damage and delay aging, maintaining BNF function for a longer term. These studies demonstrate that nanotechnology can sustainably enhance BNF and crop yield and to combat global food insecurity.

4.11.T-02 Bacillus strains as biological tools in agriculture - Lets take a look at the soil microbiome and famers practice
Sebastian Hartmann-Wittulsky*, Bayer AG*
Treatments with living *Bacillus* bacteria, such as *Bacillus subtilis* or *Bacillus amyloliquefaciens*, are widely used in agriculture as part of sustainable farming strategies. These bacteria can be found in plant protection products (PPPs), biofertilizers or biostimulants. They benefit crops in several ways when present in soil leading to an increased productivity in agriculture. As biocontrol agents they are antagonistic against plant pathogens by releasing antimicrobial compounds and trigger defense mechanisms via Induced Systemic Resistance (ISR). Research on biofertilizers and biostimulants has shown that *Bacillus* strains can help plants to tolerate abiotic stress and improve nutrient uptake either directly or indirectly. Furthermore, such bacteria are well known to produce certain phytohormones to modulate plant root growth making them for instance more susceptible to colonization by microbes and increased nutrient uptake. However, is an agricultural soil treatment with living *Bacillus* bacteria impacting existing soil microbiomes short-term or even long-term? What is the value of such treatments for farmers and the environment? It is well known that commercially available *Bacillus* strain do have certain capacities to influence soil microbiomes, e.g. due to the release of antimicrobial compounds, resource competition, biofilm formation, impact on soil processes, and the modification of root exudates. With this presentation we are going to summaries two recent microbiome studies performed in different crops treated with living *Bacillus* bacteria. In both studies microbiomes were analyzed using next generation sequencing (NGS) and high throughput sequencing (HTS) technology coupled to bioinformatics. To connect this to the bigger picture, we will further shed some light on the direct benefits to farmers when using living microbes in their cropping system and how this can lead to a reduced need for synthetic PPPs. Examples of disease management strategies in certain crops including treatments with *Bacillus amyloliquefaciens* strain QST713 will be presented. Such biological PPPs are a tool to support sustainable farming approaches by reducing old synthetic PPPs, but are not sufficient to fully replace classical chemicals to ensure high profitable cropping.

4.11.T-03 Precision application of pesticides in agriculture: role and contribution of the European Precision Application Task Force
Anne Alix[1]*,* ***Jonas Schartner***[2]*, Bernhard Gottesbueren*[3]*, Peter Hloben*[4]*, Patrick Pagani*[5]*, Corne Kempenaar*[6] *and Anne Steenbergh*[7]*, (1)Corteva Agriscience, United Kingdom, (2)Federal Office of Consumer Protection and Food Safety (BVL), Germany, (3)Make-Sense consulting, Germany, (4)CEMA, (5)Copa COGECA, (6)Wageningen University & Research (WUR), Netherlands, (7)Board for the Authorisation of Plant Protection Products and Biocides (Ctgb), Netherlands*
Agricultural practices in Europe are seeing a significant evolution towards precision technologies, evolution triggered by both the fast technical developments in digital sciences and farming equipment. The Farm to Fork and Biodiversity strategies of the European Green Deal and the objectives set for all components of sustainable food systems are accelerating this technology evolution. Precision applications are part of this evolution, and stakeholders agree on the urgent need to link the new technologies in use in crop protection to the regulatory context. The European Precision Application Task Force (EUPAF) was created in June 2023, with the objective to provide a scientific platform to gather expertise in precision applications and risk mitigation measures, and engage a dialog between experts in the development of precision application equipment, farmers, regulatory scientists and risk assessors from both the public and private research sector. EUPAF counts 77 experts from 40

organizations and 14 countries. The Task Force is working on an inventory of current equipment, spraying and/or application practice and technique in use, for arable and permanent crops and use this inventory to define classes or categories of use reduction, and risk reduction, enabled by the equipment and practice.

On the basis of the inventory, the experts are developing a harmonized description of the use categories to use into regulatory dossiers for plant protection products. The description should include the aim of the treatment, a precise description of the area treated and proposal on how to best express in the GAP table information on the type of equipment, any necessary recommendation regarding the performance and efficacy of the treatment, additional agronomic advice for e.g. in terms of resistance management, and the category of use reduction / risk reduction.

For each use category, the description enables to evaluate to what extent the use will lead to significant changes in a particular area of the risk assessment, through a significant modification of the exposure and provide first recommendations as to how the exposure assessment can be adapted. The talk will present the general approach and the current results of the EUPAF.

4.11.T-04 Modelling the Reduction Effect of Spot Applications on Pesticide Runoff Losses from Fields with a PRZM-VFSMOD Coupling and a 2D Probabilistic Framework

*Stefan Reichenberger[1], Robin Sur[2], Jorge Olivares-Rivas[3] and **Rafael Muñoz-Carpena**[4], (1)knoell France SAS, France, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany, (3)knoell Germany GmbH, Germany, (4)University of Florida*

Field “spot treatments” of agrochemicals through smart agricultural solutions can significantly reduce agrochemical application in the field. This localized chemical application with high resolution (small spot footprint, <1x1 m) can reduce off-field drift and surface runoff impacts to adjacent water bodies.

While quantification of drift reduction is advancing, very limited work exists for the quantification of potential pesticide runoff reduction from this smart agricultural practice in the regulatory context.

For the case of runoff reduction, small application footprint technologies mean that a very small part of the field becomes a source of pesticide runoff during a subsequent rainfall-runoff event. Particularly for crops with dense surface cover (e.g. cereals), the rest of the untreated field can act as a sink for dissolved and adsorbed pesticides before exiting the field. Part of the difficulty in quantifying the potential reduction of pesticide runoff stems from the pseudo-random pattern of spot applications in the field during each crop season and across years during long-term regulatory assessments.

A new 2D mechanistic-probabilistic modeling framework, SPOTRUN, was developed that considers i) sources: upslope pesticide runoff generation from the spot treatments around the field; ii) sinks: infiltration, sedimentation and pesticide trapping on downslope segments (after spots) of the field with vegetation, iii) variable conditions of the field vegetation during the crop phenology and the effects on runoff and sedimentation, iv) size of spots and percentage of field area treated. v) long-term exposure calculations (PECsw). In a first step, a pseudo-random application pattern on the field isgenerated based on spot size and treated area fraction. The field is then divided into strips in slope direction with the same width as the treated spots. These strips are subsequently simulated with a coupled PRZM-VFSMOD modelling system, which can deal with complex sequences of treated spots (sources, simulated with PRZM) and untreated areas (sinks, simulated with VFSMOD) along the flow path. For each rainfall event in the scenario (e.g. FOCUSsw), the edge-of-the-field runoff hydrographs and associated sediment and pesticide loads are summed up and fed into a TOXSWA metamodel. Different realizations of the pseudo-random application allow to construct a probability distribution of PECsw for each event and thus identify realistic worst-case application patterns.

4.11.P Protecting Innovation in Plant Protection: Low-risk Pesticides, Precision Applications, and Considerations on Risk Assessment

4.11.P-Tu411 How to Improve the Risk Assessment for Low-Risk Pesticides

***Gertie Arts Mrs., PhD** and Héloïse Thouément, Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands*

Increasing the number of low-risk pesticides is considered as an important step forward to a more sustainable agriculture. Active substances regulated under Regulation (EC) No 1107/2009 are only categorized as low-risk if they meet specific additional criteria. Currently no synthetic chemical, but only naturally occurring active substances (covered here by the general term “biopesticides”) are classified as low-risk. Here, the results of a literature review will be presented on the risk assessment for biopesticides covered by the pesticide Regulation (EC) No 1107/2009. This review includes the following topics: which guidance documents apply, what problems are encountered with the authorization of these substances, which research questions are still open and what can be learned from other regulations to achieve a more targeted risk assessment. The substances considered here include microorganisms (which contain organisms such as bacteria, algae, protozoa, viruses, fungi, baculoviruses); naturally occurring substances including botanicals (plant extracts) and e.g. salt/minerals, blood, chitin; semiochemicals (pheromones i.e. substances that are excreted by an organism and influence the behavior of other organisms). Regulation (EC) No 1107/2009 has recently been adapted for micro-organisms (Part B of the regulation) by including focused uniform principles and data requirements for microbial pesticides. However, such an approach has not been implemented for other biopesticides, which are regulated under Part A of the same regulation together with the synthetic chemical pesticides. The lack of specific risk assessment approaches for biopesticides hinders their approval. Moreover, biopesticides registered as low-risk have a clear position in Integrated Pest Management (IPM) approaches as introduced by the 2009 Sustainable Use Directive. However, despite the potential function of low-risk pesticides mainly as fungicides and insecticides, low-risk pesticides are currently mostly allowed for use in specialty crops and viticulture, with only 20 % of them being applicable in cereals. To improve the risk assessment of low-risk pesticides, we recommend to develop focused risk assessment approaches for biopesticides starting with a problem formulation.

4.11.P-Tu412 Addressing Current Challenges in the Risk Assessment of Low-Risk Pesticides

***Bruno Guimarães**[1], Anja Coors[2], Andrea van der Veen[2], João Godinho[3], Justus Wesseler[3], Kutay Cingiz[3], Michael Werner[1] and Stefania Loutseti[1], (1)Syngenta Crop Protection AG, (2)ECT Oekotoxikologie GmbH, Germany, (3)Agriculture Economics and Rural Policy Group, Wageningen University*

Potential low-risk pesticides (LRPs) of natural origin are gaining popularity, particularly in response to the European Green Deal. Yet, their data requirements within the authorisation process in the European Union (EU) are largely similar to those of synthetic pesticides, which may hinder the market entry of potential LRPs. Tailored guidance has already been developed for some groups of potential LRPs and the EU-funded project RATION (grant agreement N° 101084163) set out to significantly contribute to improving the risk assessment procedures for potential LPRs of natural origin. Within RATION, as a very first step an overview was prepared on pertinent regulatory and guidance documents related to the authorisation of microorganisms, plant extracts, pheromones and other semiochemicals, as well as ds-RNA and microbiome solutions as plant protection products.

The publicly available “EU Pesticide Database” was analysed with regards to the number of approved and non-approved active substances of various groups, i.e., microorganisms, semiochemicals, plant extracts, substances from non-plant sources, inorganics, and synthetic organic molecules. The first encountered problem here was that the database barely differentiates between these categories. In addition, the whole terminology surrounding LRPs of natural origin is suffering from ambiguity. It was observed that from all these groups, some compounds were approved as low risk active substances and some were not. The date of approval influenced this status as the criteria for ‘low risk’ were not in place when all of the currently approved active substances were evaluated. A more detailed on-going analysis aims to identify the challenges in their data requirements and support the development of further guidance and an improved risk assessment strategy. The comparison of the regulatory frameworks for potential LRPs in the EU and the United States (US) was another aspect of the present study, which was addressed at a general level and detailed by two case study examples, one plant extract and one microorganism.

The results will be used for identifying the differences in approval by product and length in time. This has important implications for the decisions of companies to invest into these products. Research has shown that the uncertainty with respect to the time length as well as the related costs has a substantial effect on the investment decision.

4.11.P-Tu413 Crop protection by RNA interference – a horizon scanning of approaches to inform risk assessment

*Kirsten Germing[1], Udo Hommen[1], Kerstin Derz[1], Andreas Schiermeyer[1], **Elke Eilebrecht**[2] and Sebastian Eilebrecht[3], (1)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (3)Ecotoxicogenomics, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

RNA interference (RNAi)-based crop protection aims to inhibit the expression of specific essential genes in target organisms by uptake of double-stranded (ds)RNA and subsequent degradation of target gene mRNA. Due to their biological nature and the relative instability of RNA molecules, RNAi applications are assumed to be less harmful for the environment compared to conventional plant protection products (PPPs). While RNAi-based plant protection was initially limited to genetically modified crops producing dsRNA, the development of exogenous technologies like RNAi sprays has increased in recent years. Due to its assumed beneficial properties, RNAi technology receives increasing attention in the development of PPPs.

A literature research was performed using established literature databases as well as patent databases to identify the current state of RNAi developments and applications in plant protection. RNAi applications were categorized based on the following criteria: 1) treated crop species, 2) target pest species, 3) target gene function, 4) type of application and 5) biomanufacturing readiness level.

More than 180 publications have been evaluated. A great variety across treated crops, targeted pest species and functions as well as application types was found. The current state of development of these applications mainly includes the identification of suitable target functions in pest species as well as testing the functionality of these applications in pest-host systems in laboratory studies. In total, RNAi applications for more than 30 different pest species were identified. Most pest species belonged to the insect orders Lepidoptera, Hemiptera and Coleoptera, besides which also applications targeting fungi and viruses were found. The main targeted biological functions in insects were cell cycle/cell integrity and development whereas in fungi, the cell cycle/cell integrity and pathogenesis mechanisms were targeted mostly.

Concluding, RNAi applications were identified to be an upcoming topic in plant protection. Because of the high number of targeted pest species as well as the variety of application types, which differed from common plant protection approaches in some extent, RNAi applications have an increasing relevance for environmental risk assessment. The present literature review is intended as a horizon scanning project to identify current needs and aims for the development of a suitable risk assessment strategy for RNAi based crop protection.

4.11.P-Tu414 A new class of active substances: dsRNA-based pesticides for Plant Protection – a regulatory perspective
Jonas Schartner[1]*, Achim Gathmann*[1] *and Dominik Klinkenbuss*[2]*, (1)Federal Office of Consumer Protection and Food Safety (BVL), Germany, (2)Department of Plant Protection Products, Unit Environment, Federal Office of Consumer Protection and Food Safety (BVL), Germany*

RNA interference (RNAi) is a natural process with important defence and regulatory functions in animals, plants and fungi. Mode of action is a gene silencing mechanism capable of reducing or switching-off the expression of individual genes. Sprayable dsRNA-based plant protection products are in the pipeline aiming at different targets such as flea beetles in oil seed rape, fusarium diseases in barley, or weed control to overcome resistant weeds. It is expected that these products, which should be much more specific regarding target organisms than conventional pesticides and less persistent in the environment, will be used in the field in the near future. In that case, RNAi constitutes a new mode of action that is not completely covered by the current authorisation process, that mainly focuses on chemical compounds. While the characteristics of dsRNA as active ingredient might ease the assessment of some risk areas, for others there is a need for adaptions of existing or the development of new risk assessment tools. The risk assessment might also be challenged by new formulations aiming for the prevention of rapid degradation of dsRNA after product application. Therefore, these type of products generate new demands on the approval as active substance laid down in the regulation (EC) No 1107/2009 and also in the data requirements under regulation (EU) No 283/2013. The presentation will shed light on the authorisation process in the EU and where further research and data are needed. Furthermore, it will highlight important aspects regarding scientific challenges, considerations and the current status for risk assessment and risk management for this new type of plant protection product.

4.11.P-Tu416 Toxicity of the Bioherbicide Pelargonic Acid Varies for Different Primary Producers
Judith Epping *and Paul van den Brink, Wageningen University & Research (WUR), Netherlands*
Biopesticides are considered a possible replacement for currently used synthetic pesticides. Since they are based on naturally occurring substances such as plant extracts, they are frequently considered less harmful to the environment and, therefore, also called low risk pesticides. One example is pelargonic acid, a plant-derived broadband herbicide. Aquatic primary producers, including algae, and rooted and floating macrophytes, essential in maintaining freshwater ecosystem functions, are non-target organisms to this bioherbicide. So far, reported toxicity values of aquatic primary producers vary substantially. The objective of this research is to shine light into the toxicity of analytical grade pelargonic acid to standard and non-standard test species of rooted (*Myriophyllum spicatum*, *Elodea nuttallii*) and floating macrophytes (*Lemna minor*, *Salvinia minima* (to be conducted)) and algae (to be conducted). Five concentrations in the range of 9.4 mg L^{-1} to 150 mg L^{-1} were tested under optimal growth conditions, closely following OECD guidelines 201 “Freshwater algae growth inhibition test”, 221 “*Lemna* sp. growth inhibition test” and 239 “*Myriophyllum spicatum* toxicity test”. Growth variables including dry weight (all), shoot growth (rooted macrophytes) and coverage (floating), as well as pH and oxygen concentrations were evaluated. Preliminary results show substantial differences in species sensitivity with *L. minor* being most sensitive with significant coverage reduction at 9.4 mg L^{-1}. Both rooted macrophytes showed higher tolerance with shoot growth and oxygen concentrations significantly declining at concentrations of 37.5 mg L^{-1} and higher. Dry weight was a less sensitive endpoint than coverage or shoot growth. Experiments will be continued in the coming months with two algae species (to be determined) and *Salvinia minima* as a non-standard floating macrophyte. These results are essential to understand environmental implications of the usage of plant-derived pesticides and will lead to a more precise risk assessment in the future.

4.11.P-Tu417 Evaluation of The Environmental Benefit and Impact of Nitrapyrin
Andrew Woods[1]*, Marian Dinicica*[2]*, Andrew Chadwick*[2]*, Martin Tilbrook*[2]*,* ***Ricardo Petersen***[3]*, Apostolos Koutsaftis*[4]*, Sian Ellis*[5] *and John Marton*[6]*, (1)Ecotoxicology, ERM Regulatory Services Limited, United Kingdom, (2)ERM Regulatory Services Limited, United Kingdom, (3)ERM International Group Limited, United Kingdom, (4)ERM Regulatory Services Limited, Netherlands, (5)Corteva Agriscience, United Kingdom, (6)Corteva Agriscience*
In light of the recent EU policy developments towards reducing the use and risk from pesticides it is identified that there is a need to also examine the environmental benefits and potential challenges of other chemicals used in agriculture such as fertilizers. Nitrapyrin, a widely used nitrification inhibitor, plays a crucial role in enhancing nitrogen use efficiency while improving crop yield.

Nitrapyrin can reduce nitrogen losses through leaching and denitrification. By retaining bioavailable nutrients like nitrogen within the agricultural system, nitrapyrin supports crop yield while reducing the need for additional nitrogen fertilizers, improving economic gains for farmers. Additionally, the reduced nitrogen runoff helps protect aquatic ecosystems, preventing eutrophication and maintaining water quality.

Nitrapyrin has a history of safe use since its introduction in the 1970s and has an EPA Green Chemistry Award for its environmental and economic benefits. Under EU Regulations nitrapyrin is registered as a fertilizer product, which requires a minimal environmental dataset. However, to fully evaluate the potential environmental benefit and potential impact from the use of this product, a literature review (with no chronological limits or restrictions in research areas) has been conducted based on EFSA guidance requirements for plant protection products. Key areas identified in the search covered the impact on soil microbial composition, nitrogen transformation including greenhouse gas production and potential exposure and effects to terrestrial non-target organisms.

The focus of this poster presentation is to provide a thorough overview of the key findings on the research on nitrapyrin, relating to its environmental impacts while demonstrating that its use as a fertilizer in agriculture is beneficial towards maintaining high yield sustainable, agricultural ecosystems.

4.11.P-Tu418 Biomarkers for Phosphine Resistance in Tribolium castaneum: Based on Transcriptomics and Machine Learning approach for Rapid Identification

***Donghyeon Kim**, Chaeeun Kim and Sung-Eun Lee, Department of Applied Biosciences, Kyungpook National University, Korea, Republic of (South)*

Methyl bromide, a substance once used globally to control stored-grain pests during quarantine processes, was regulated due to its classification as an ozone-depleting substance under the Montreal Protocol. As a result, phosphine (PH_3) has emerged as a primary alternative fumigant for stored-grain pest control. However, continuous phosphine usage has led to the development of resistant pest populations, causing significant economic losses. Identifying phosphine-resistant pests is crucial to mitigate these losses. The traditional method, FAO test, is time-consuming, and an alternative mutation analysis targeting the dihydrolipoamide dehydrogenase (DLD) gene can only identify strong phosphine resistance at levels 50-100 times higher. In our preliminary research, we used adult *Aus10* (PH_3-Susceptible, S) and *Aus07* (PH_3-Resistant, R) strains of *Tribolium castaneum* for transcriptomics, resulting in the identification of 16 genes with significant expression differences. Subsequently, we quantified their mRNA expression levels using RT-qPCR during the life cycle stages, including adult, pupa, prepupa, lateral larva, and early larva stages, according to the 2^{-ddCt} method. In addition, machine learning was employed to select three genes according to fold-changes and *p*-values from RT-qPCR data, effectively distinguishing between the two strains at all stages. Validation experiments were conducted with RT-qPCR. Finally, an assessment into the expression levels of these three genes was conducted using the wild strains collected from several grain warehouses in South Korea to confirm their susceptibility and resistance to PH_3 in consistent with FAO test. This study proposes a novel and rapid method for identifying phosphine resistance in various life cycle stages of *T. castaneum*.

4.11.P-Tu419 Environmental Evaluation of the Biostimulant Methylobacterium symbioticum

***Claudia Vaj**[1], Kursten Anderson[2] and Sian Ellis[3], (1)Corteva Agriscience, Italy, (2)Corteva Agriscience, (3)Corteva Agriscience, United Kingdom*

In light of EU policy developments towards reducing the dependency on chemicals and fertilizers in agriculture, biostimulants are recognized to provide a sustainable alternative to improve plant nutrient use efficiency, tolerance to abiotic stress and increasing crop quality and yield. The EU Fertiliser Product Regulation (FPR) has recently been amended to include biostimulants. This allows a transparent assessment of the efficacy and to examine the environmental benefits and potential challenges of their use.

The bacteria species, *Methylobacterium symbioticium* SB23 is a naturally occurring bacteria biostimulant used to increase nutrient efficiency, uptake and availability.

The strain has been assessed according to the FPR to address potential plant pathogenicity and to provide a detailed assessment of the origin and natural occurrence of the *Methylobacterium* genus. To further expand on the environmental benefits and impacts of the genus, a literature review search was conducted in accordance with EFSA's guidance for the submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009 (EFSA, 2011).

The focus of this poster presentation is to provide a thorough overview of the key findings on evaluation of *Methylobacterium symbioticum* relating to its environmental impacts for use as a biostimulant.

4.11.P-Tu420 Challenges of Paraffin Oil in Aquatic Risk Assessment: A Call for Situation-based Higher-Tier Testing

***Louise Wipfler**[1], Bastian H. Polst[1], Wim Beltman[1], Olivier Langevoort[2], Gertie Arts Mrs., PhD[1] and Pauline Iris Adriaanse[1], (1)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands, (2)Dutch Board for the Authorisation of Plant Protection Products and Biocides (Ctgb), Netherlands*

Paraffin and other oils are used as insecticides, offering a potential means to reduce the reliance on synthetic organic pesticides in agriculture. Presently, several products containing paraffin oil as an active ingredient are approved in the EU/Netherlands under the current risk assessment framework. However, the complex and varying composition of these type of oils (alkanes from C15 to C30), and their insolubility in water, pose challenges that are not adequately addressed by the current regulatory risk assessment methods. These challenges include direct and indirect effects of an oil layer on the water surface or dispersed oil drops for aquatic organisms. As such, a refined approach to the risk assessment of paraffin oil in aquatic systems is needed. Our research seeks to underscore the limitations of current assessment methods and shed light on the intricate exposure and effects of paraffin oil in aquatic environments, advocating for a novel approach to environmental risk assessment.

We identified two distinct exposure situations as relevant for aquatic organisms covering the major route of exposure through drift deposition after a spray application in a nearby field. In the first situation, an oil layer forms on the water's surface, directly impacting organisms that live attached to the water surface and indirectly affecting all organisms in the water column due to the limitation of oxygen exchange with the atmosphere. In the second situation, the oil is dispersed within the water column (e.g. due to wind dispersing the oil layer), primarily affecting organisms that reside in the water column and could come into direct contact with the oil drops, e.g. filter feeders.

Fate models are currently not developed to simulate oil layers. In order to be pragmatic and make a consistent link between exposure and effects in the assessment, we propose to use higher-tier effect testing methods, i.e. mesocosm studies, to assess the effects posed by paraffin oil and other mineral oils to aquatic organisms for both exposure situations. These situations should be assessed through realistic worst-case test setups with regard to the exposure and the composition of the aquatic ecosystem. Our proposal integrates the exposure and effects assessment within two higher-tier test situations and links functional and taxonomic groups to specific exposure routes, in this way addressing the complexity of paraffin oil's behaviour in aquatic ecosystems in a pragmatic approach.

4.11.P-Tu421 Soil Specific Outcomes in the OECD 216 Nitrogen Transformation Test

Christopher Sweeney, PhD[1]*, Melanie Bottoms*[2] *and Lennart Schulz*[3]*, (1)Syngenta Ltd, Bracknell, Berkshire, United Kingdom, (2)Syngenta, United Kingdom, (3)BioChem agrar GmbH, Germany*

The OECD 216 test guideline investigates the impact of agrochemicals on soil nitrogen transformation, however, it has come under criticism for a perceived lack of . To explore reasons behind this, we conducted an extensive evaluation of 465 previously conducted OECD 216 studies. In doing so, we discover that test outcomes may be dependent on the soil in which the study was conducted. We identified two contrasting outcomes within the control, non-treated samples: the "rise" response, characterized by consistent increases in nitrate concentrations throughout the test period, and the "dip" response, characterized by an initial decline in nitrate concentration between days 0-7, followed by a subsequent net-generation of nitrate between days 7-28. We suggest the lack of consistency in response between control samples from standardized and internationally recognized test guidelines is problematic and concerning. We argue that the dip response undermines the intended functioning of the test system and compromises the ability to draw accurate ecotoxicological inferences from the data. Our hypothesis suggests that the dip response may be a result of conducting the study in low nitrogen content soils. To explore this, we conducted experiments using ammonium sulphate as an immediately available inorganic nitrogen source, replacing the guideline-mandated complex organic nitrogen source: lucerne meal. Our results indicate that the dip response can be alleviated by this substitution, highlighting the influence of nitrogen availability and accessibility. However, not all low nitrogen soils exhibited the dip response, suggesting the involvement of additional unidentified factors. Based on our findings and real-world regulatory examples, we propose that datasets displaying the dip response should not be considered valid OECD 216 studies. In this case, the influence of soil properties on the performance of the test system precludes an accurate assessment of whether observed impacts are solely driven by the test compound or are instead a product of the soil used. To address this issue, we suggest incorporating techniques to account for soil-specific responses into the conduct and interpretation of OECD 216 studies. These proposed amendments aim to enhance the reliability and robustness of the study system, ultimately increasing confidence in the ecotoxicological conclusions derived from OECD 216 datasets.

4.11.P-Tu422 Non-Target Arthropods (NTA): What Influences their Sensitivity to Pesticides in the Field/Landscape?

Melanie Hagen-Kissling[1]*, Livia De Felici*[2]*, Julia Friman*[2] *and Bogdan Dehelean*[2]*, (1)Eurofins Scientific, Niefern-Öschelbronn, Germany, (2)Eurofins-MITOX B.V., Netherlands*

Higher tier NTA studies measure the responses of local communities to the exposure of a plant protection product in highly complex natural systems in contrast to lower tier lab studies, where experiments are conducted under predefined conditions. These natural systems are complex, and NTA communities are shaped by biotic and abiotic factors, which increase the variability in the system. Consequently, several factors could influence the response of the arthropods to the pesticide exposure. Habitat structure and condition (e.g., vegetation cover), abiotic factors (e.g., temperature, humidity), exposure routes and the biology of the arthropods (e.g., habitat preference, feeding strategy) could affect such differences in response.

In our experiments, we see species belonging to the same arthropod families responding differently to the treatment with plant protection products, which cannot be explained by the arthropods' physiology, only. For example, springtail species spending relatively more time within the soil, might be less affected by the overspray of a plant protection product compared to species, which live mostly above soil.

Here, we investigate, if the differences observed in the effect of the application of plant protection products on closely related taxa is correlated with abiotic factors (e.g., temperature, humidity), habitat structure, life history traits (e.g., resource use, dispersal, habitat preference), or the interaction with other arthropods (e.g., prey suppressing one another's abundance through competition for enemy-free space). Incorporating this additional information about ecology and behavior of the arthropods could lead to a more holistic approach to risk assessment.

4.11.P-Tu423 Bat Activity in Arable Farmland: Assessing Potential Risks from Plant Protection Products

***Charles Hazlerigg**[1], Amy C. Brooks, MBiolSci, PhD, IBERA Certified Environmental Risk Assessor[2] and Mark Whittingham[3], (1)Enviresearch Ltd., United Kingdom, (2)Cambridge Environmental Assessments (CEA), United Kingdom, (3)Newcastle University, United Kingdom*

Bats are commonly present in farmland, feeding on insects, and may therefore be exposed to residues of Plant Protection Products (PPPs) via dermal contact, inhalation and consumption of prey and contaminated water. A review by the European Food Safety Authority (EFSA) in 2019 found that the potential risk to bats from the use of PPPs in the EU is not covered in the current risk assessment. In order to develop a risk assessment methodology for bats, essential ecological knowledge in how they use the farm landscape is required. The aim of this study, was to explore how bat activity varied with changes in cropping at different growth stages throughout the year.

Six passive bat detectors were mounted at different sites within Cockle Park Farm, a research farm at Newcastle University in NE England. Each detector was fitted with a directional microphone and situated at the edge of a field, with the microphone directed into that field. The cropping at each site differed, including winter wheat, spring barley, peas, permanent grassland, woodland edge (control) and farm buildings. The detectors were left out for 1 week every month from May 2022 to October 2023 (18 months). During this time, the crops grew, were harvested and new (different) crops were sown at each site. The bat echolocation recordings were analysed using the BTOPipeline auto-classifier, with additional manual validation for all calls identified as being from uncommon species and 1% for all calls identified as being from common species. Additionally, potential confounding variables (e.g., temperature, wind, rain) were recorded at the farm meteorological station and used in the data analysis.

Initial analysis indicates up to 10 species of bat present in the summer season, associated with the highest activity levels (number of recordings). Into autumn, bat activity declined as expected with a move to torpor, but also species diversity declined with implications for choosing which to make focal species in a risk assessment context depending on the proposed application timing. Data analysis is still ongoing, but further results and conclusions on the differences in bat activity with cropping and growth stage, as well as in relation to environmental variables, will also be presented.

4.11.P-Tu424 Herbicide prioritization and risk reduction in perennial crops

***Zisis Vryzas**[1], Paraskevas Parlakidis[2] and George Adamidis[2], (1)School of Agriculture, Aristotle University of Thessaloniki, Greece, (2)Democritus University of Thrace, Greece*

The non-targeted, non-needed, and repeated applications of the same, few herbicides registered in perennial crops had resulted in reduced efficacy, development of herbicide-resistant weed biotypes and increased risk to agroecosystem compartments and human health. Preferential flow and other herbicide leaching mechanisms, runoff, enhanced biodegradation, other herbicide dissipation processes and the increased numbers of herbicide-resistant weeds forced farmers to increase the application doses, and the overall production cost. Moreover, herbicides are among the most frequently detected pollutants in environmental samples, including surface- and ground-water bodies. The disturbances exerted by repeated agricultural practices in perennial crops are a major factor influencing weed biodiversity and population dynamics. Weed density in an agroecosystem and the various soil-climatic conditions and cultivation practices are factors affecting the frequency of herbicide application making the decision support system particularly complicated. In this study, we have created an intelligent herbicide prioritization and application system that will support the decision for the application of herbicides in a targeted, timely manner with great precision, and improved agricultural practice (quantitatively, qualitatively and from an environmental point of view) while the required amounts of herbicides will be reduced, contributing to the Green Deal and Farm-to-Fork objectives and agroecosystem sustainability. The proposed risk reduction scheme is based on the hierarchy of the herbicides registered in perennial crops. Potential low risk herbicides in terms of environmental fate, resistance development and hazard assessment were also included in the priority. Based on herbicide physicochemical properties and their environmental fate, herbicide resistance classification and weed flora biodiversity indices a matrix-based fit-for-purpose scheme was established for perennial crops. The proposed scheme contributes to reduced environmental contamination and delays herbicide-resistance development.

4.11.P-Tu425 Reduction of Pesticide Risk using Optimal Volume Rate Tools and Spray Drift Reduction Techniques

*Cruz Garcerá Figueroa[1], Patricia Chueca[2], Paolo Marucco[3] and **Marco Grella**[3], (1)Centro de Agroingeniería, Instituto Valenciano de Investigaciones Agrarias, Spain, (2)Instituto Valenciano de Investigaciones Agrarias, Spain, (3)Department of Agricultural, Forest and Food Sciences (DiSAFA), University of Turin (UNITO), Italy*

During the application of plant protection products (PPP) part of them is lost to the environment and can harm nearby residents, bystanders, flora and fauna. With the aim of reducing risks associated with PPP applications in two important Mediterranean vertical crops, citrus and vineyards, the LIFE PERFECT project “Pesticide Reduction using Friendly and Environmentally Controlled Technologies” (ref. LIFE17/ENV/ES/000205) was carried out foccussing in two aspects 1) the use of Optimal Volume Rate Tools (OVRA), CitrusVol for citrus developed by IVIA and Dosaviña UPC for vineyards developed by, based on the adjustment of the spray volume rate to the treatment characteristics (vegetation; orchard; pest or disease:

PPP); and 2) the use of spray drift reducing technologies (SDRT) such as low drift nozzles, air deflectors, together with the calibration and proper adjustment of the sprayers, adapting the spray profile to the target vegetation.

The objective of this study was to determine ground losses and spray drift during PPP applications in citrus and vines, and to evaluate the effect of the optimization of the application, based on the spray volume rate adjustment, fine-tuning of equipment configuration, and use of low drift nozzles.

Results showed that in citrus, while CitrusVol recommended a volume rate 48% lower than that conventionally used, its combination with the SDRT reduced airborne drift by 81% and ground losses by 86%. Considering together all losses in citrus, they accounted for 27% of the PPP applied in the conventional treatment, while this number decreased until 5% in the optimized treatment, which is 81% lower. In the case of vineyards, the optimization in average reduced the volume rate by 27%, airborne drift by 64% and ground losses by 50%. Thus, in this case total losses accounted for 12% of the PPP applied in the conventional treatment, while this number decreased until 6% in the optimized treatment, which is 50% lower

In conclusion, since environmental risks posed by the application of PPP depend directly and proportionally on the amount of PPP used and PPP losses, this work demonstrates the joined effect of 1) volume rate adjustment through the use of developed OVRA tools, 2) use of low drift nozzles, and 3) spray cloud adjustment, on the environmental risk reduction. Therefore, a more sustainable application of PPP is achieved from the environmental point of view.

4.11.P-Tu426 How much an adequate spray volume can contribute to the pesticide use reduction?
***Marco Grella**[1], Cruz Garcerá Figueroa[2], Eric Mozzanini[3], Fabrizio Gioelli[3], Emilio Gil[4], Paolo Balsari[3], Paolo Marucco[1] and Patricia Chueca[5], (1)Department of Agricultural, Forest and Food Sciences (DiSAFA), University of Turin (UNITO), Italy, (2)Centro de Agroingeniería, Instituto Valenciano de Investigaciones Agrarias, Spain, (3)University of Turin (UNITO), Italy, (4)Universitat Politècnica de Catalunya (UPC), Spain, (5)Instituto Valenciano de Investigaciones Agrarias, Spain*
The optimization of spray application through a proper setting of the already in-use sprayers can be the most effective strategy to comply with the Green Deal strategy requirements. In this sense, the DSS can help farmers to define the adequate spray application rate according to crop type and canopy characteristics. The aim of this work was to quantify the potential PPP reductions achieved in citrus and vineyard, along two growing seasons, thanks to the use of Citrusvol and Dosaviña® DSS, respectively. The canopy characteristics, at the time of applications, were measured and used as inputs for DSS to define (as output) the adequate spray application rate. Then, the DSS-based application rates were compared to those used by farmers (reference), and the PPP use reduction was calculated. Results underline that higher volume were always applied in citrus compared to vineyard. With respect to vineyard case, the PPP reductions achieved were more constant in citrus due to the less pronounced canopy variation throughout the season. In general, the PPP use reduction were higher than 30% in citrus, and 45% in vineyard. These percentages were similar across the two-year considered. In conclusion, the DSS resulted an effective tool to reduce PPP use, and therefore, chemical inputs in agriculture. Thus, DSS can consistently contribute to comply with the Geen Deal PPP reduction goal.

4.11.P-Tu427 Precision application of pesticides - Possibilities and challenges from a regulatory perspective
***Balthasar Smith**, Jonas Schartner and Achim Gathmann, Federal Office of Consumer Protection and Food Safety (BVL), Germany*
There is no good reason and no real need for a "business as usual" approach to plant protection. Everyone involved has a special responsibility to support the process towards a more sustainable use of plant protection products in their area. The possibilities for making the use of plant protection products more efficient are better than ever these days. The extent to which plant protection products are used can be completely redefined. However, careful consideration must be given to how risk assessment and risk management interact. The right questions need to be asked. The potentially lower inputs into the environment resulting from the partial area application must be set against an understanding of the exposure pathways, the available data and the uncertainties of the models used. This understanding must also be applied to the risk reduction measures and the consideration of precision application techniques within the framework of toolboxes for combinable measures.

The presentation will illustrate the perspective of a regulator within the framework of the EU-wide harmonized approval procedures for plant protection products in accordance with Regulation (EC) 1107/2009. The focus is on the requirements for risk reduction measures with regard to practicability, effectiveness and controllability.

4.11.P-Tu428 Smart Stewardship in Digital Farming: GIS-Supported Advice for Reducing Groundwater Vulnerability Risks through Optimized Use of Plant Protection Products
***Sebastian Multsch**, Garcia Lucas, Folkert Bauer, Bernd Hartmann and Volker Laabs, BASF SE, Germany*
The rising demand for sustainable and efficient farming practices has led to the development of innovative tools that integrate GIS and digital farming. One such tool is the Groundwater Vulnerability Tool, a Spatial Decision Support System (sDSS) that advises farmers on optimizing herbicide use while minimizing groundwater contamination using Germany as an example.

The sDSS tool builds on the methodologies described in the FOCUS Groundwater guidelines which define the regulatory requirements for assessing the leaching potential of pesticide active substances and their metabolites to groundwater. Leaching needs to be assessed in nine different pedoclimatic scenarios that combine environmental conditions and farming practices which represent the 80th spatial percentile of arable area in the EU. The 80th temporal percentile of the predictions is compared to the limit value for active substances in groundwater (0.1 µg/L) to evaluate the leaching risk.

The sDSS assesses groundwater vulnerability and provides farming advice by simulating leaching masses of active substances and metabolites into the soil using the FOCUS PEARL simulation model. This is done based on long-term climate data, soil maps, groundwater levels, and application patterns. The groundwater vulnerability is calculated based on the number of years with leaching masses exceeding a quality threshold. A regression model is derived between precipitation and vulnerability for each representative soil based on the numerical simulations to create a map with spatially explicit application recommendations. Additional features like potentially drained areas and water protection zones can be added as overlays.

A first validation of predicted leaching masses was conducted by comparing them to predictions for the FOCUS GW scenarios. The Hamburg scenario resulted in the highest leaching mass followed by Kremsmuenster and Châteaudun. The results of the spatial simulation are in the same range with an upper bound of leaching mass close to the results of the Hamburg scenario. The sDSS tool provides an overall similar level of protected as required to comply with the EU legislation 1107/2007, but with a higher spatial resolution and regional specific environmental information. Hence, this study exemplifies how digital farming tools can assist achieving localized risk management and thus contribute to sustainable agricultural practices.

4.11.P-Tu429 Precision Application of Plant Protection Products: Risk Assessment Approaches and Potential as Risk Mitigation Measure

***Rena Jutta Irene Isemer, PhD*[1]**, *Bernhard Gottesbueren[2], Edgars Felkers[3] and Isabelle Christian[3], (1)Crop Science, Bayer AG, Research Triangle Park, United States, (2)Make-Sense consulting, Germany, (3)Crop Science, Bayer AG, Germany*
Agricultural practices in Europe are evolving towards precision technologies like precision application (PA) of plant protection products that allow farmers to apply only the needed amount of the most suitable product at the right time and location. As stakeholders agree on the need to link the new techniques and equipment to the regulatory context, the European Precision Application task Force (EUPAF) was created in June 2023 with the objective to provide a scientific platform to gather knowledge and expertise in PA techniques as well as new risk assessment approaches and risk mitigation measures. This presentation will provide proposals agreed on by the members of EUPAF representing key stakeholders, including experts from the area of plant protection product providers, application technology providers and regulatory risk assessors.

Based on an inventory of current equipment and application practices, PA use categories will be defined and assessed for their potential for product use reduction. For each PA use category, the description allows evaluating to what extent the use would lead to changes in a particular area of the risk assessment (*e.g*., for operators, bystanders, consumers, non-target organisms) through a modification of the exposure and proposing adapted exposure assessment scenarios to be used in the risk assessment.

A reduction of risk would not be equal for all exposure and risk areas. Specific evaluations are necessary to determine the extent and applicability of the different PA techniques with regards to the different risk assessment and mitigation areas. In a first step, it should be assessed if the use category leads to no/medium/substantial change to the risk assessment assuming current regulatory environment and currently available data as well as future developments accounting for field-specific and application-specific (digital) assessments including control options that allow for documentation of applications. Many PA methods result in non-uniform applications in the treated area and the heterogenous exposure on the field would allow differentiated risk diagnosis and management for the field scale compared to simple worst-case assumptions. A conversion factor for each use category ("if use category j is used, reduce risk by factor k in risk assessment area l") will be considered for each risk assessment area.

4.11.P-Tu430 Integrating Precision Application into the Regulatory Environmental Risk Assessment Scheme: A Conceptual Approach

***Patricia González Camarero*[1]**, *Elena Alonso, PhD[2], Clara Vigo Anglada[2] and Ángeles Rico[2], (1)Knoell Iberia S.L., Madrid, Spain, (2)knoell Iberia S.L., Spain*
Precision application is an advanced farming strategy supporting a more efficient and sustainable future for agriculture. There are variety of precision application technologies currently available for the application of Plant Protection Products (PPPs) that, in addition to other agricultural management profits, could reduce the release of chemicals into the environment. However, although these promising methodologies are available and ready to use, their characteristics and benefits are not yet considered for the evaluation and authorization of PPPs under EU Regulation No 1107/2009. Incorporating precision application methodologies into the regulatory framework will help to support the European Commission's Green Deal objective of achieving a more sustainable agriculture.

The objective of this study is to provide useful and effective information that builds up the knowledge to include these methodologies into the EU environmental risk assessment scheme. For that, a literature search on the application technologies currently available in the market and a review of these technologies used in the regulatory dossier has been conducted. The outcome is a general framework summarizing the potential impact of these technologies on exposure calculations and on the effect assessment on non-target organisms considered within the EU evaluation of PPPs. In addition, a conceptual approach that describes different options for integrating the precision application methodologies for the calculation of predicted environmental exposure to organisms and its implication on the effect evaluation is provided. Ecological aspects that should be considered when using precision application are also highlighted. Overall, this work shows the needs for the quantitative adaptation of the EU environmental risk assessment scheme to achieve a harmonized regulatory framework

4.11.P-Tu431 Drift Exposure After Patch Application: Modelling Effects on Lemna

Prakash Srinivasan[1], *Johannes Witt*[2], *Anastasiia Bolekhan*[3] *and Andrew C. Chapple*[1], *(1)Bayer AG, (2)Bayer AG - Crop Science Division, Germany, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Patch application, characterized by targeted and localized pesticide treatments, is becoming more common in agriculture and can significantly reduce pesticide loadings to the field. Adopting patch spraying approaches can also reduce off-field drift, surface runoff, and drainage loadings to adjacent water bodies thus reducing off-field pesticide exposure and environmental impact. The present EU risk assessment required for authorization of plant protection products (PPPs) considers a homogeneously sprayed field as the standard scenario, with the above-mentioned entry pathways into adjacent water bodies. Surface water exposure of PPPs applied in patches could be approximated by reducing the exposure from full field treatment by the percentage of treated area in some cases, for example, for exposure *via* drainage or leaching to groundwater. However, this is not the case for exposure via drift and runoff as exposure in such cases depends on the distance between the treated area and waterbody.

In this case-study, we have investigated the drift exposure of pesticides in a ditch resulting from patch application by using existing exposure models and scenarios (FOCUS SWASH) to simulate and predict distribution of exposure in space and time. We have compared the pesticide distribution from a patch application using linearly extrapolated Rautmann drift for a single patch and three patches to the measured drift values for a single patch obtained from a drift deposition field trial. The study places particular emphasis on identifying hotspots of exposure where pesticide concentrations are notably elevated, as well as the implications for effects on aquatic organisms. TOXSWA simulations were run for several scenarios, *i.e.*, applications in different months, in order to investigate the plume distribution under different hydrological conditions. The potential implications for the aquatic risk assessment would be investigated using a tiered approach, first a standard Tier 1 assessment would be done by comparing the PECmax values followed by more realistic ecological (TKTD) modelling. Also, from simulations of the effects of the concentration profiles of separate segments, a worst-case segment would be selected based on the simulated effect, rather than the exposure profile.

This study aims to provide insights on how an aquatic risk assessment for patch application could be done for regulatory purposes by establishing a link between exposure and effect modelling.

4.11.P-Tu432 New Developments in Spray Drift Modelling for Precision Applications

Henk Jan Holterman, *Koen Van Boheemen and Jan Huijsmans, Agrosystems Research, Wageningen University & Research (WUR), Netherlands*

Precision application of plant protection products (PPPs) is receiving a lot of attention as a way forward in pesticide application, since it has the potential to reduce the amount of pesticides applied and to reduce the exposure of different off-field areas and non-target organisms to PPPs. Precision application for crop protection could play a role in the exposure assessment of PPPs in the authorisation process. Basically, variable-rate and spot-spraying applications can be distinguished. In a variable-rate application the whole field is treated while the dose is varied to meet the conditions of each location in the field. In a spot-spraying application for each in-field location the decision is made whether or not a (full dose) spray application is required. Similar to full-field spray applications, with precision applications the downwind deposition of spray drift not only depends on the application technique but also on environmental conditions. In this study we focus on spray drift and its potential reduction for variable-rate and spot-spraying applications in arable crops under different environmental conditions. Recently, a new spray drift model was developed which takes into account the non-uniform dose rates applied at the crop field. Ongoing model development includes the implementation of effects of wind speed, crop height and drift mitigating measures. The model can be used for both variable-rate and spot-spraying applications. Downwind deposits of spray drift are evaluated at off-field evaluation strips, such as adjacent watercourses or non-target terrestrial areas. Spatial resolution of the downwind deposits is adjustable to a desired level by dividing the evaluation strips into imaginary segments of adjustable length. Downwind spray drift deposits depend on the location and distribution of the treated in-field areas and the dose rates applied. Wind direction is the major environmental parameter involved. Variable-rate and spot-spraying applications may lead to drift reduction, partly due to the reduced amount of PPP used. Example computations indicate that drift reductions can be higher or lower than the reduction based on reduced amount of PPP. In the current study, a few test cases are investigated for realistic distributions of wind directions throughout the year. In this way, exposure to spray drift and the potential of precision applications can be assessed on field level under realistic environmental conditions.

4.11.P-Tu433 Environmental Risk Assessment of Different Protection Zones for Non-Target Plants with Precision Application of Herbicides

Bastian H. Polst[1], ***Steven Droge***[1], *Jan Huijsmans*[2], *Henk Jan Holterman*[2], *Koen Van Boheemen*[2] *and Louise Wipfler*[1], *(1)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands, (2)Agrosystems Research, Wageningen University & Research (WUR), Netherlands*

Precision agriculture has emerged as a promising approach to optimize farming practices while minimizing the overall use of pesticides. Despite the reduction in applied pesticides in the field, it remains unclear how this translates to off-field environmental concentrations and reduced risks to non-target organisms. This study delves into the environmental implications of precision farming by conducting a comparative analysis between conventional pesticide application and mitigation methods and a targeted pre-emergence herbicide spot-treatment. The primary focus lies in evaluating the predicted environmental off-field concentrations, both terrestrial and aquatic, with a comprehensive assessment of associated environmental risks for non-target plants.

Employing a case study framework, we utilized modelling techniques to simulate herbicide spray drift to non-target plants in off-field sections (10m length) along the field in the terrestrial evaluation zone (1.5m – 2.5m) and to the surface water evaluation zone (3m – 4m). Specifically, we assessed the risk associated with a herbicide for which the label requirement for potato crops indicated a DRT90 with 3m buffer zone to protect the surface water organisms. We therefore evaluate worst-case drift scenarios for conventional full-field applications, incorporating various drift-reduction technologies and buffer zones, respectively, in comparison to a pre-emergence spot-treatment case-study.

We present and discuss the results, and give further recommendations for future case studies. This research contributes valuable insights into the environmental risks associated with different pesticide application strategies and in particular with precision agriculture. By highlighting the differential environmental impacts, we can set the environmental risk of precision agriculture in comparison to conventional measures to reduce pesticide usage. Thereby our study is a starting point to highlight the potential and limits for precision agriculture, and sets a unique example in the yet empty field of case studies related to environmental risk of precision agriculture.

4.11.P-Tu434 Consequences Of Reduced Application Of Plant Protection Products On Soil Contamination And Soil Fertility

Gilda Federica Dell'Ambrogio[1]*, Philippe Jeanneret*[2]*, Florian Walder*[2]*, Vanessa Reininger*[3]*, Sophie Campiche*[4]*, Benoit JD Ferrari*[5]*, Thomas Oberhänsli*[6]*, Mathieu Renaud*[5]*, Thomas D. Bucheli*[7]*, Marcel Van der Heijden*[8] *and Stefanie Lutz*[8]*, (1)Ecotox Centre, Switzerland, (2)Agroscope, Switzerland, (3)Swiss Soil Monitoring Network (NABO), Agroscope, Switzerland, (4)Envibiosoil, Switzerland, (5)Swiss Centre for Applied Ecotoxicology, Switzerland, (6)Department of Crop Sciences, FiBl Schweiz, Switzerland, (7)Environmental Analytics, Agroscope, Switzerland, (8)Plant-Soil Interactions, Agroscope, Switzerland*

Plant Protection Products (PPPs) are widely used in conventional agriculture to protect crops and to support yields. However, once applied, PPPs can leach into the soil where they can persist for several years. This can lead to chronic exposure of soil organisms that perform important soil functions supporting soil fertility. There is increasing evidence of adverse effects of PPPs on soil communities and their functioning, which can lead to reduced soil fertility including reduced resilience to biotic stress, such as soil-borne diseases. There is a need for a more sustainable approach to agriculture that minimizes the impact on soil organisms.

The PestiRed project aims to reduce the PPP use by 75% and to test alternative measures for weed, pest and disease control, mostly based on agroecological principles. Such innovative measures are tested on 67 farms across Switzerland. For each farm, a control plot is managed conventionally (without PPP reduction) and the impact of management change is monitored over six years.

To investigate the consequences of a reduced PPP use on soil contamination, concentrations of PPP residues will be measured on 32 farms for both innovative and control plots. Soil samples are collected in winter on four years to assess trends over time. PPP residues are measured by liquid chromatography coupled to tandem mass spectrometry using a quantification method recently established for PPP residue monitoring of agricultural soils in Switzerland. The method is highly sensitive (sub-ng/kg range), validated and precise, and allows the multi-residue detection of about 150 active substances.

Standard ecotoxicological tests will be carried out on soil samples from the PestiRed farms to assess the consequences of management change on the fitness of soil invertebrates. In addition, key soil functions indicative for soil fertility, such as nutrient cycling, plant growth promotion and disease suppression will be investigated through field assessments and greenhouse experiments. Finally, microbial and invertebrate communities will be analyzed for the sampled soils. The results of the different experiments will help to establish soil food webs and to better understand the relationships between soil organisms and functions. Overall, the information generated will provide a holistic view of the effects of a reduced PPP use and management change over time on the soil system and the consequences for soil fertility.

4.11.P-Tu435 Developing Landscape Environmental Risk Assessment (ERA) for pesticides under PARC: Conceptualization

A project under PARC Task 6.4.4 is developing Landscape ERA, linking regulatory and retrospective assessments to address the overall impact of pesticides on agricultural ecosystems. The landscape consideration is part of the integration proposed by the EFSA PERA proposal and focuses on the spatial and temporal connectivity between pesticide applications and exposure of non-target organisms in agricultural ecosystems. The proposed framework was developed following a set of expert workshops, and is highly flexible, covering generic and real landscape definitions with an implementation that should facilitate the comparison and interconnectivity of different tools. The main element of a landscape framework is the distribution of crop and non-crop areas in a spatial dimension, represented in the proposed framework by the horizontal (XY) plane. Non-target individuals or groups are associated to different crops and other areas, according to their habitat needs and behaviors. Human management includes pesticide application and other agricultural activities, and the landscape structure and the environmental conditions determine the fate of the applied pesticides according to their intrinsic properties. The spatial and temporal concordance determine the exposure of the non-target organisms, which can be modelled at individual, population or community/function/service level depending on the model. The simplest regulatory application is the assessment of aggregate effects from the use of the same pesticide in different crops and the influence of the landscape structure and management on the environmental risks. These assessments support decisions on the identification of priorities, comparative assessments, and mutual recognition. The second step is the integration of the risks associated with all pesticide uses during the season/year. This is essential for quantifying the overall risk of pesticide use, supporting regulatory decisions on sustainable use and integrated pest management, and for comparing the impact of pesticides with other stressors as part of biodiversity protection strategies and policies. The next step under the PARC project is to explore the capacities of this framework in a set of case studies, covering terrestrial and aquatic systems.

4.11.P-Tu436 Developing Landscape Environmental Risk Assessment (ERA) for pesticides under PARC: Selection and Design of Case Studies

Under PARC Task 6.4.4 a framework for Landscape ERA was proposed following expert workshops. A landscape framework is characterized by the distribution of crops, non-crop areas, and non-target organisms in a spatial dimension. The landscape structure defines the level of agricultural intensification/diversification, driving pesticide use, and environmental fate. The temporal dimension includes human management, environmental conditions, and population dynamics. The spatial and temporal concordance determine the exposure of non-target organisms as a function of their habitat and behavior. The effects can be modelled at individual, population or community/function/service levels depending on the model. In order to explore the applicability of this conceptual framework, case studies covering terrestrial and aquatic systems has been designed. The case studies are reflecting different agricultural landscape conditions and climates, four covering terrestrial systems and four covering aquatic systems. Three terrestrial case studies (CS) have been built around a common crop, vineyard, exploring

regional, agronomic, and ecological differences: CS1: Farmlands in central Spain, led by UCLM with contribution from ISCIII; CS2: Vineyard area in the south of France, led by INRAE and OFB; CS3: Bairrada wine producing region in Portugal, led by UC with contribution from UAVR. The fourth terrestrial case study, CS4: Hope Farm arable farm in UK, led by UKCEH, covers a farm with specific management for biodiversity protection. The aquatic case studies are connected to the EU Water Framework Directive and the equivalent in Switzerland; CS5: Pesticides and WFD in Poland, led by IEP-NRI; CS6 Kleingewässer-Monitoring KgM on small-medium streams in Germany, led by UFZ with contributions from UBA and UKOLD; CS7 Danish stream case study, led by NIVA; and CS8 Aquatic biodiversity status of five agricultural sites in Switzerland, led by EAWAG and the Swiss Centre for Applied Ecotoxicology. The design of the cases considers the needs of regulators, farmers, and different regional stakeholders. Validation is a key component for regulatory use; a classical approach, comparing predictions with measurements would require full knowledge of the impacts of stressors other than pesticides which currently is not available; other approaches, e.g., validation of specific steps, qualification for specific uses, or identification of key elements for regulatory results verification/use are explored.

4.11.P-Tu437 Modelling Aquatic Drift Exposure from a Patch Application

Prakash Srinivasan[1]*, Anastasiia Bolekhan*[2] *and Andrew C. Chapple*[1]*, (1)Bayer AG, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Recent technological improvements in pesticide application equipment made it possible for pesticides to be applied precisely to the intended sub-field target areas rather than as a broadcast spray. Surface water exposure of plant protection products applied in patches could be approximated by reducing the exposure from full field treatment by the percentage of treated area in some cases, for example, for exposure *via* drainage or leaching to groundwater. However, this is not the case for exposure *via* drift and runoff as exposure in such cases depends on the distance between the treated area and waterbody.

In this case-study, we have investigated the drift exposure of pesticides in a ditch resulting from patch application by using existing exposure models and scenarios to simulate and predict distribution of exposure in space and time. We have compared the pesticide distribution from a patch application using linearly extrapolated Rautmann drift for a single patch and three patches (1D) to the measured drift values for a single patch obtained from a drift deposition field trial (2D).

TOXSWA simulations were run for several scenarios, *i.e.*, applications in different months, in order to investigate the plume distribution under different hydrological conditions. We have selected the months based on the average residence times in the ditches covering very short to long residence times with the pesticide application happening on the 1st of each month. Three different approaches to drift were simulated in TOXSWA: i) drift deposition from a fully sprayed field; ii) linearly extrapolated Rautmann drift values (1D) for a single patch and three patches; and iii) spatially explicit drift from a patch obtained from the drift deposition trial. A generic substance with a Koc = 10 $L.kg^{-1}$ and a long half-life in water (DT50 = 1000d) was chosen to investigate the distribution of the substance in water after the drift event based on dynamic hydrological conditions.

The concentration plume resulting from the above approaches were compared and preliminary results have shown that distribution of the concentration plume with time depended on the hydrological conditions (flow velocities) following the application. This study aims to provide an approach to set the exposure *via* drift from patch application into the framework of aquatic risk assessment and that such an exposure assessment is possible using the existing regulatory acceptable approaches and models.

4.11.P-Tu438 Spray Drift Assessment For The Registration Of Plant Protection Products Applied By Drones – Working Within The Existing Regulatory Framework.

Sara Langa Peñalba[1]*, Laura Nuñez García-Cuerva*[1]*, Gunnar Kahl*[2]*, Olga Kulikova*[2]*, Paul Robinson*[3]*, Lorenz Fischer*[2] *and Clara Vigo Anglada*[1]*, (1)knoell Iberia S.L., Spain, (2)knoell Germany GmbH, Germany, (3)Dr Knoell Consult Ltd.*

The use of drones for precision application is fast becoming an alternative for the safe application of Plant Protection Products (PPPs) in the field. The advantage of this technology is a more efficient and safe application compared to traditional methods in areas of difficult access (e.g. steep-slopes, waterlogged soils or rice paddies), precision bait or spot application. The use of this type of precision application would result in a lower environmental impact of pesticides. The existing regulatory framework, Regulation (EC) No 1107/2009, currently lacks the integration of drone technology. Authorities have shown interest in regulation of drone application of PPPs, whilst pointing out the scarcity of reliable data on parameters such as spray drift. Several working groups with members from authorities, industry and research organisations, are collaboratively compiling data to establish use scenarios based on realistic parameters, which could be used for accurate risk assessment, and adaption of the regulatory framework for drone-applied PPPs. Until now, the most common approach is to consider the use of drones as aerial application. Several studies, however, show that the spray drift values associated with drone use are more comparable with those in terrestrial field application, and lower than those in aerial application.

This poster aims at describing the difficulties of the environmental exposure assessment of spray drift entries of drone-applied PPPs to surface water bodies during the registration process in the EU. Further, it provides example calculations of predicted environmental concentrations in surface water (PECsw) based on spray drift values from literature sources and from within the regulatory framework (aerial and airblast application based on *Rautmann et al.*). The poster proposes an interim tiered approach for a conservative environmental assessment of spray drift of PPPs applied by drones, until regulatory-accepted drone-specific spray drift values become available. As a first tier, it is suggested to consider worst-case drift rates defined for aerial application. It is further recommended to perform calculations using drift values from literature and/or field studies for drone applications, alongside standard calculations for airblast application. This dual-calculation approach gives the authorities certainty by demonstrating that literature/field study drift values result in lower drift values than those from aerial application.

4.11.P-Tu439 Assessment of Unmanned Aerial Spraying Systems as an Effective and Environmentally Friendly Tool for Citrus Growers

Rosa Ferrer[1], Jorge Martínez-Guanter[2], Pilar Sandin-España[3], Miguelina Mateos-Miranda[4] and ***Esther García-Montero[5]****, (1)Field Sciences, Corteva Agriscience, Spain, (2)Digital Agronomy, Corteva Agriscience, Spain, (3)Institute for Agricultural and Food Research and Technology, Spanish National Research Council (INIA-CSIC), Spain, (4)INIA - National Institute for Agricultural and Food Research and Technology, Spain, (5)Regulatory, Corteva Agriscience, Spain*

Precision agriculture is a key component to a productive agriculture that meets the highest safety expectations for humans and the environment. Unmanned Aerial Spraying Systems (UASS) constitute a promising tool to apply pesticides precisely, reducing carbon footprint and water waste.

The Sustainable Use Directive 2009/128/EC prohibits aerial application of pesticides. Due to the great interest and need for UASS application, many initiatives are generating data to confirm the safety of UASS applications for human health and environment.

This work aimed to design trials to determine whether efficacy and residues levels differ between UASS and ground application in 3 dimensional crops. During protocol development, we determined that working height below 1.5-2 m were needed to avoid excessive drift, and that product application over a tree in main vegetative stage made it difficult to access the innermost parts of the canopy. Preliminary trials were performed to determine if UASS' propellers movement would open the foliage sufficiently to enable a good coverage. The trials were performed with a bait formulation, Spintor® Cebo, which contains an ingredient attractive to the targeted pest, and can be used at very low doses of the active substance Spinosad. Spintor Cebo is designed for patching and banding application, this makes the treatment of the whole area unnecessary and constitutes a significant reduction of environmental impact in comparison to a conventional formulation.

Three trials were carried out in 2022 to compare drone *vs.* ground application. The objective was to determine the efficacy and residues of Spintor Cebo in mandarins to control *Ceratitis capitata* in the Mediterranean EPPO zone, according to GEP and EPPO standards. Each trial consisted in three treatments: control, ground and drone treatments and four replicates for each treatment. Determination of spinosad residues in fruit were performed by QuEChERS followed by HPLC-ESI-MS/MS.

Results show an efficacy, selectivity and residue levels in the same range between UASS and ground application. These encouraging results indicate that UASS are valid tools for precision agriculture that contributes to meet sustainability goals, while addressing farmers' needs.

4.11.P-Tu440 Review on Pesticide Pollution and Ecological Status of Lake Tana Sub-Basin, Ethiopia

Banchiamlak Getnet Admasu Mrs.*, Aquatic Ecology & Water Quality Management, Wageningen University & Research (WUR), Netherlands*

The Lake Tana sub-basin in Ethiopia has witnessed substantial changes in its ecological status over recent years, primarily attributed to the increasing prevalence of pesticide pollution due to agricultural intensification. This review aims to reveal the evolving pesticide contamination within the Lake Tana sub-basin and its consequential impact on the structure and functioning of the ecosystem. Drawing upon a wide range of studies and scientific literature, this review explores the types and uses of pesticides and their risks to aquatic biodiversity within the Lake Tana sub-basin.

The first section of the review provides an overview of the historical context of pesticide use in the region (Amhara region), highlighting the factors contributing to the intensification of pesticide pollution. Subsequently, an in-depth analysis of the various types and uses of pesticides detected in Lake Tana, tributary rivers, associated wetlands, and surrounding districts.

In assessing the ecological status of the Lake Tana sub-basin, this review also examines the risks of pesticides on aquatic biodiversity, particularly fish.

Additionally, the review examines the current regulatory frameworks (such as the Pesticide Registration and Control Proclamation, Labor Proclamation, and Environmental Pollution Control Proclamation) and management strategies to mitigate pesticide pollution in Lake Tana, its tributary rivers, and associated wetlands. Afterward, critical practice gaps are identified, and recommendations for future research directions and policy interventions are proposed.

Keywords: Agricultural intensification, Ecological Status, Lake Tana Sub-basin, Pesticide Pollution

4.11.P-Tu441 Challenges in Developing Brazilian Scenarios for the Environmental Risk Assessment for Birds and Mammals Due to the use of Pesticides

Carla Mariane Costa Pozzi[1], Cristiane Dias Saretto[2], Clara Costa[1], Grazielle Lopes[1], ***Marcelo Augusto Pereira Coelho Dias[1]****, Flávia Silva[1] and Uschi Wischhoff[1], (1)Brazilian Institute of Environment and Renewable Natural Resources (IBAMA), Brazil, (2)COAVA/DIQUA, Brazilian Institute of Environment and Renewable Natural Resources (IBAMA), Brazil*

The adoption of an environmental risk assessment methodology that has been developed by another country requires, preferably, the adaptation of exposure scenarios to meet the local reality. Climatic conditions, soil characteristics and the presence of wild animals in agricultural crops, for example, must be observed.

The brazilian government, represented by the Brazilian Institute of the Environment and Renewable Natural Resources, has historically used the United States Environmental Protection Agency's Terrestrial Residue Exposure model in its environmental risk assessments for birds and mammals due to the use of pesticides. However, the use of scenarios that were obviously built for conditions different from those in Brazil brings uncertainty regarding the degree of protection afforded to btazilian animals.

Thus, in recent years the brazilian government has tried to adapt already established risk assessment methodologies for birds and mammals based on national databases, with a main focus on that developed by the European Food Safety Agency. To this end, data such as residues in food items and sightings of birds and mammals in agricultural landscapes were collected. There are several challenges to be overcome, but it is possible to say that the greatest difficulty is related to the survey of residues, as specific studies are needed so that they can be used in exposure scenarios.

4.12 Statistics for Ecotoxicology and Environmental Fate – From Tried and Tested over New and Exciting Methods to Machine Learning

4.12.T-01 The Lack of Comparability in Machine Learning Studies for Environmental Hazard Assessment

Christoph Schuer[1], Kristin Schirmer[1] and ***Marco Baity-Jesi[2]****, (1)Environmental Toxicology, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)Siam, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*

The application of machine learning (ML) models holds promises for many domains of research. However, like classical experiment-based research, ML-based science comes with its specific set of pitfalls. Several branches of ML-based research in parallel are working on fostering awareness and implementing best practices that improve repeatability, comparability, and the quality of research in general. However, ecotoxicology seems to lag behind with the adoption of these measures like commonly used benchmark datasets and reporting standards. We assess the comparability across studies in our field by defining a set of comparability criteria that need to be met in order for the findings of studies to be comparable to each other: 1. Same dataset, 2. Same dataset processing and cleaning, 3. Same dataset splitting, 4. Same performance metrics, 5. Reporting of code & formulae of performance metrics calculation. We review literature from the latest 10 years, that used QSARS and machine learning methods to predict ecotoxicological outcomes and evaluate their comparability in accordance with these criteria. Our findings suggest that extremely few studies meet all of these criteria and can be considered comparable. We highlight the importance of implementing best practices as a necessary prerequisite for the progression of ML as a useful tool for ecotoxicological research.

4.12.T-02 Under What Circumstances Is CPCAT Suitable for Field Data?

Lijuan Yan[1]*, Pernille Thorbek[2], Frank Staab[3] and Matthias Bergtold[3], (1)BASF Services Europe GmbH, Germany, (2)Apd/EE, BASF plc, United Kingdom, (3)BASF SE, Germany*

The Closure Principle Computational Approach Test (CPCAT) is a novel statistical approach that was initially designed for conducting multiple testing of reproduction data in the field of ecotoxicology. It has been used for analyzing count data, specifically for NOEC/LOEC analysis, in various ecotoxicological studies, with a particular emphasis on soil field studies. However, it should be noted that from a statistical standpoint, CPCAT is considered a relatively new method. There are some radical differences from the statistical approaches normally used in ecotoxicology.

In this talk, we report an in-depth analysis we did of the methodological properties of CPCAT and the implications for false positives and false negatives. The crux of the matter is the underlying assumption about Poisson distribution. The inherent characteristics of the Poisson distribution assume that the mean is equal to the variance, indicating that these two parameters are not independent. As a consequence of this, the significance of observed differences in CPCAT relies on the sample mean rather than the observed signal-to-noise ratio. Furthermore, the statistical power of CPCAT is heavily influenced by the absolute abundance of organisms and the underlying distribution of the ecotoxicological data. We found that when data is under-dispersed, CPCAT has many false negatives; similarly, with high absolute abundance, CPCAT may have under some certain circumstances more false negatives than other methods. In contrast, when data is over-dispersed, CPCAT has a very high rate of false positives, under some circumstances over 50% false positives. Moreover, CPCAT can only handle simple study designs, thus, repeated measures, nested designs, split-plot designs cannot be analyzed properly using CPCAT.

We conclude when data follows a Poisson distribution, CPCAT may be used as long as the study is a simple one-factor design. In all other circumstance, extreme caution should be taken before relying on CPCAT results for regulatory purposes.

4.12.T-03 BMD estimation using model averaging for Avian Reproduction Studies

***Xiaoyi Sopko**, Corteva Agriscience*

The purpose is to summarize the simulated learnings of benchmark dose modeling for avian studies via various models fits, and various model averaging techniques of frequentist models; and assess the use of prior information in Bayesian models. From the simulated learnings, one can appropriately select on the conditions in which a BMD can be successfully estimated. The simulations cover various dose response shapes, variances, spacing of application rates, and number of application rates. Under conditions where one of more observed dose groups is close to the true BMD estimate, Bayesian models with default priors can provide much better estimates than the frequentist models as well as tighter confidence intervals in cases where limited dose groups are available under specific set of conditions (e.g. largest treatment is greater than 10% effect, etc., decent model weights). Strongly informative prior does not always perform better than Bayesian models with default priors or weakly informative prior. A set of established, published priors would prevent from creative modeling. BMD is an effective tool with benefits surpassing the use of single models to calculate ECx. However, there are certain conditions and requirements that must be satisfied in order to use model averaging successfully. We explored and summarized appropriate conditions and requirements for estimation of BMD using both the frequentist methods and the Bayesian methods.

4.12.T-04 Mother-to-Egg Transfer of Chemicals in Reptiles Using Orthogonal Regression to Account for Uncertainty in Observations

*Peter Vermeiren[1], Cynthia C. Munoz[1] and **Sandrine Charles, PhD, HDR**[2], (1)RIFCON GmbH, Germany, (2)Umr Cnrs 5558, University Claude Bernard Lyon 1, France*

To support exposure assessment of early life stages, we aimed to develop a predictive model to quantitatively link concentrations of chemicals that are measured in tissues of mother and their offspring. This model captures the relation between two continuous, quantitative variables that are both observed with a comparable degree of uncertainty. Such data violate a basic assumption of classical linear regression, namely the existence of an independent variable that is measured without error and used to explain another dependent variable. To overcome this limitation, we set up an orthogonal regression model which explicitly accounts for uncertainty in both variables. The model accounts for uncertainty in measured variables by applying a Gaussian error distribution on both variables and constraining their range in relation to the population mean. Alternative formulations were developed to improve model performance and parsimony. Parameters were then calibrated using Bayesian inference to ensure that the full parameter uncertainty could be propagated into the probabilistic model predictions. Model alternatives were compared for their goodness-of-fit and predictive performance during 3-fold cross-validation. To support model development, we utilised a large database that resulted from a systematic search, extraction, and integration of scattered data from the scientific literature regarding measurements of organic pollutants in paired samples from mother and offspring tissues across several reptile species. We specifically focussed on reptile species as a group which has traditionally been underrepresented in ecotoxicology and chemical risk assessment despite its potential high sensitivity to maternally transferred pollution burdens resulting from their unique life history traits. After identifying the most suitable model alternative (i.e., base model structure), further model extensions were made to investigate ecotoxicological questions: 1) is maternal transfer influenced by the magnitude of the mother's body burden; 2) are there taxonomic patterns in maternal transfer; and 3) does the persistence of a compound influence its maternal transfer. The database, model, and new scientific insights provide the tools and knowledge to enable quantitative integration of maternal transfer-mediated early life exposure in chemical risk assessment.

4.12.P Statistics for Ecotoxicology and Environmental Fate – From Tried and Tested over New and Exciting Methods to Machine Learning

4.12.P-Tu442 Improved and Harmonized Statistical Approaches in Non-Mammalian Endocrine Disruption Testing: Recommendations for Improved Data Analysis in OECD TG 231 and 229/230

***Maria Agnieszka Tobor-Kaplon**[1], Emily Scorgie[2], Tara Miller[3], Pelagia Xirogiannopoulou, BSc. MSc.[4] and Daniel Bruce Pickford[5], (1)Global Science Delivery, Syngenta Crop Protection B.V., Netherlands, (2)Global Science Delivery, Syngenta Seeds B.V., Netherlands, (3)Syngenta Ltd, United Kingdom, (4)Product Safety, Syngenta Hellas, Greece, (5)Product Safety Global Strategic Science, Syngenta Ltd, United Kingdom*

This presentation aims to address the challenge of inconsistent statistical approaches in non-mammalian endocrine disruption (ED) testing, specifically focusing on the Amphibian Metamorphosis Assay (AMA) and Fish Short-Term Reproduction Assays (FSTRA) as outlined in OECD TG 231 and 229/230. By harmonizing statistical analysis methods, we can improve the reliability and comparability of results obtained from these assays.

To achieve this, we compiled a comprehensive list of endpoints measured in both assays and identified the direction of possible effects. We also considered endpoints mentioned in the Office of Pollution Prevention and Toxics (OPPTS) guidelines and addressed other critical aspects, including the choice of control for effect comparison and calculation of the coefficient of variation (%CV) for mean measured concentrations. Our recommendations were derived from OECD's document on statistics in ecotoxicology and relevant scientific literature.

By establishing a consensus with industry stakeholders, including the CropLife Europe (CLE) Statistical and ED groups, we aim to advocate for the inclusion of these recommendations in the updated OECD guidelines. This collaborative effort will enhance the quality of statistical analysis not only in studies involving Plant Protection Products but also in the growing number of ED studies required for REACH registration.

This research is highly relevant as it addresses the need for standardized statistical approaches in non-mammalian ED testing. Implementing these recommendations will advance the field by improving the reliability and comparability of data across different laboratories. Furthermore, the application of harmonized statistical methods will contribute to more accurate assessments of the endocrine-disrupting potential of chemicals, ensuring the safety of both humans and the environment.

4.12.P-Tu443 Activities to revise the OECD Document No. 54 (and ISO/TS 20281) on statistical analysis of ecotoxicity data

***Benjamin Daniels**[1], Thomas Gräff[2], Susanne Walter-Rohde[2] and Pia Kotschik[2], (1)RWTH Aachen University, Germany, (2)German Environment Agency (UBA), Germany*

The OECD Document No. 54 (2006) "Current approaches in the statistical analysis of ecotoxicity data: a guidance to application" and its companion ISO/TS 20281 describe the main statistical methods used for data analysis from ecotoxicological studies. However, some of the approaches described in OECD Document No. 54 are no longer considered as state of the art. In recent years, new methods have been published and other statistical tests have been adapted to the specific data characteristics in ecotoxicology. A revision of the OECD Document No. 54 and ISO/TS 20281 is urgently needed, as the choice of statistical method and its application has a direct impact on all OECD and ISO test guidelines and thus on the assessment of effects of currently regulated chemicals on (non-target) organisms.

With this contribution, we present a project initiating this revision process. The project aims to revise the OECD Document according to the current state of science and technology. Moreover, further development in analyzing ecotoxicological biotests is focused by harmonizing advances in statistical approaches and methods.

The project background, the aims of the project and first results are presented. Central issues are the update of guidance on NOEC determination by including new approaches with specific consideration of current methods for non-parametric and parametric approaches (e.g. for non-normally distributed variables). In this context, more precise guidance on the assessment and interpretation of statistical power and the underlying distribution is sought. Regression approaches for EC_x calculation will be expanded and the use of reliability criteria for the derivation of EC_{10} values with its confidence intervals (and related concepts) as an alternative statistical measure to the NOEC concept will be outlined.

Further development will take place in collaboration with an accompanying group of statisticians. The engagement with international experts ensures a comprehensive understanding of emerging statistical approaches, guaranteeing that the revised guideline remain at the forefront of methodological advancements.

The outcomes are anticipated to contribute to the refinement of global standards, fostering improved decision-making processes in the assessment and management of chemical risks to ecosystems.

4.12.P-Tu444 MOSAIC_ssd: a turnkey web tool to facilitate Species Sensitivity Distribution analyses

*Miléna Kaag and **Sandrine Charles, PhD, HDR**, Umr Cnrs 5558, University Claude Bernard Lyon 1, France*

The use of Species Sensitivity Distribution analyses (SSDs) is acknowledged since the 1980s as a key and relevant decision support tool in environmental protection and management. To this day, statistical methods and regulatory applications continue to evolve. Ten years ago, the MOSAIC_ssd web tool was made available with the specificity of allowing the use of interval-censored data. Since then, this tool has gained in popularity and started being used around the world, in all sectors: academic, regulatory, and industrial, where SSDs prove useful, relevant and/or mandatory. Consecutively to the successive updates and added features of the MOSAIC web platform, the MOSAIC_ssd tool also needed a revampment, some improvements, and additional features. This poster presents the new version of the MOSAIC_ssd service now available either as an R-package (ssd4mosaic) which allows an autonomous use from a local installation, or as an online turnkey web tool (https://mosaic.univ-lyon1.fr/ssd) that provides formatted results in just a few clicks. The poster specifically shows the new graphical interface separating the inputs from the outputs in different tabs; the various functionalities improvements such as the possibility to group and label species observations; and the new functionalities such as the choice of the uncertainty quantiles or the propagation of the uncertainty along the fitted probability distribution curve.

4.12.P-Tu445 Can custom-written codes be GLP compliant?

***Marie Brown**[1], Hanna Samantha Schuster[1] and Bashir Mohammad Surfraz[2], (1)Cambridge Environmental Assessments (CEA), United Kingdom, (2)Environmental Fate and Behaviour, RSK Adas Ltd., United Kingdom*

Statistical programming tools such as SAS, Matlab, Python and R have revolutionized data analysis processes, particularly for large datasets. Additionally, KNIME (Konstanz Information Miner), a popular low-coding, free, analytic platform with R and Python integration, offers great future potential. The free open-source system R has become a powerful tool by providing greater flexibility and innovation in communicating data by using various packages with different functionalities. R packages are constantly updated, which is great for statistical advancements and improvements, but is problematic for use in and validation for Good Laboratory Practice (GLP) studies. Validation for GLP compliance requires proof that the program is operating correctly, a risk assessment to determine the probability that errors or misuse could occur, and documentation and evidence of change and version control. The outcome is a high level of assurance that the program and functions are fit for purpose and results are reliable and trustworthy. Whilst there are documents setting out coding standards and best practices to ensure that the data processing and analysis can be clearly followed by another user, this does not fulfil the requirements of GLP validation. There is a lack of clarity and guidance on how such customised tools e.g., codes/workflows, can be validated for GLP compliance. Although OECD guidance on computerised systems has been revised to address more sophisticated data analysis, customised systems are classified as the highest risk level. Thus, the validation process poses a significant challenge. Nonetheless, there are major advantages of coding and building data processing pipelines regarding the transparency of data handling and analysis, particularly when using open-source software such as R and KNIME. An R script or a KNIME workflow can be annotated to explain each data handling step and it can be re-run by any user on any computer, resulting in high reproducibility of the data journey. Using KNIME, together with coding software, increases the readability and understanding of each step (node) within a workflow and brings together separate data silos (loading, processing, and analyses). In this modular approach, each node or workflow can be individually validated and archived.

This poster will provide an overview on the issues of validation of programming tools, offer some potential solutions and ask some questions to open up discussions in the SETAC community.

4.12.P-Tu446 ECX estimation for Hormesis-like Effects

Thomas Gräff[1]*, Pia Kotschik*[1]*, Carmen Schweikert*[2] *and Peter von der Ohe*[1]*, (1)German Environment Agency (UBA), Germany, (2)IV 1.3-1, German Environment Agency (UBA), Germany*

The risk assessment of chemicals uses ecotoxicological endpoints based on concentrations that cause a certain effect on test organisms. In acute tests systems, the EC_{50} (i. e. concentration causing 50 % effect) is commonly used, while chronic tests are expressed in so-called No-Effect Concentrations (NOECs) or EC_{10} values. The uncertainty around EC_X-values is commonly quantified by confidence intervals. In some cases, hormesis occurs as biological (Hormesis effects) or ecological response (Hormesis-like effects). A hormesis has a biphasic dose–response relationship: Beneficial effects are present at low concentrations and decreasing effects dominate with increasing concentrations. Several examples of these phenomenon have been observed on different test parameters for plants and soil organisms in both, lab and field studies.

Non-linear regression models are widely used to fit a reasonable biphasic curve to the test data, with generally a good model performance (Brain & Cousins 1989, and Cedergreen et al. 2005). In these hormesis models, the EC_X is estimated based on the part of the fitted curve behind the turning point. Therefore, only the decreasing response is evaluated and not the positive effects (i.e. hormesis-like). This approach violates the regulatory requisite that a substance should not have any effect on the organism.

Our aim is to include the hormesis-like effect in the determination of endpoints for use in the risk assessment. Therefore, we quantify the difference between the classically used methods and our newly developed approaches, both in value and uncertainty. In this comparison, the turning point of the curve between the control response level and the point of the maximum (positive) response will be determined as the starting point for the estimation of the EC_X.

Another approach to identify the starting point is to use a two-sided hypotheses test to identify the NOEC and LOEC values. Hereby the test with the highest statistical power for that specific type of distribution will be selected. The linear interpolated midpoint of the logarithmic concentration values of the NOEC to the LOEC will approximate the starting point of the curve area for the EC_X estimation. In case there is no NOEC, i.e. the lowest concentration already signifies an effect, the midpoint of the control and the LOEC will be used. Exemplarily results show that the EC_X values of the approaches could differ up to 4 times, which would impair the risk evaluation.

4.12.P-Tu447 Equivalence Testing in Honeybee Semi-field Testing and its Consequences

Magdalena M. Mair[1]*, Zhenglei Gao*[2]*, Mark Miles*[3] *and Tobias Pamminger, Dr.*[4]*, (1)Statistical Ecotoxicology, University of Bayreuth, Germany, (2)Bayer AG, Germany, (3)Bayer AG, (4)Early Environmental Safety, Bayer AG, Germany*

In 2023, EFSA released the *Revised guidance on the risk assessment of plant protection products on bees (*Apis mellifera, Bombus *spp. and solitary bees)*, which will likely be implemented in 2024. Besides many fundamental changes to pollinator environmental risk assessment (ERA), the statistical evaluation of honeybee (*A. mellifera*) semi-field and field tests has been re-envisioned based on the equivalence testing framework. In contrast to standard null hypothesis significance tests which are built for demonstrating the presence of effects, equivalence tests aim at demonstrating that effects are smaller than a pre-specified threshold. While this approach is successfully used in pharmacology, it is unclear how it will transfer to honeybee (semi-)field data in the ERA context, given the higher intrinsic variability of these test systems and the 10% effect size set as specific protection goal.

In the present study, we use negative control data of Bayer AG semi-field honeybee tests to characterize the test system's inherent variability for the main endpoint colony strength (i.e. number of bees). Based on the estimated variability, we use data simulations to investigate which true effect sizes can be reliably (i.e. with high enough power) detected as < 10% within the equivalence testing framework. We discuss the consequences of these findings for the experimental setup of semi-field honeybee studies and for the envisioned pollinator ERA.

4.12.P-Tu448 First Experiences With the Statistical Methods From EFSA's Revised Bee Guidance Document

***Lijuan Yan*[1]**, *Pernille Thorbek[2], Inka Marie Spyridonov[3], Christof Schneider[3], Yaqi Zhang[3], Eduard Szöcs[3], Frank Staab[3] and Matthias Bergtold[3], (1)BASF Services Europe GmbH, Germany, (2)Apd/EE, BASF plc, United Kingdom, (3)BASF SE, Germany*

In May 2023, EFSA (European Food Safety Authority) released a revised guidance document (GD) on the risk assessment of plant protection products on bees (*Apis mellifera*, *Bombus* spp. and solitary bees). The document outlined methods for exposure and effect assessments using a tiered approach. In the absence of more detailed worked examples and an official calculator tool, we have been testing these methods for effect assessment to several lower tier studies.

Based on our evaluations we identified several challenges to comply with the revised EFSA GD when using common statistical software tools for evaluation of GLP studies. For example, some software tools do not apply the same model parameterization as described in the supplementary information to the GD. The inflection point, especially for the asymmetric Weibull models (which is different from the $LD(D)_{50}$), is not given explicitly in the output. Consequently, a logarithmic conversion would be needed for use in EFSA's PIE calculation equations. Another discrepancy is that some software tools use a different logarithmic base (e.g. $\log_{10}$) from the natural logarithm employed by EFSA. This results in incompatible slope values for dose-response models for the calculation of the predicted individual effect (PIE) level. Furthermore, the mostly used GLP software does not provide all four dose-response models (i.e. Log-logistic, Log-normal, Weibull-1 and Weibull-2) as required by EFSA. Additionally, some software tools only offer 2-parameter models in combination with Abbott's correction for data from studies with non-negligible control mortality, whereas the approach proposed in the revised EFSA GD requires the use of 3-parameter models, which are statistically more appropriate.

Importantly, the EFSA recommendations about the calculation of PIE is not explicit about how to include control mortality in PIE. In this poster, we propose a method to control for control mortality using both Abbott's formula and the 3-parameter models. We base this method on the EFSA BMD guidance which uses a similar approach for calculating BMR. The suitability of the method will be discussed.

4.12.P-Tu449 Predicting Fish Sensitivity Across Species and Chemicals: Combining Physiological Variables with Chemical Hydrophobicity

***Sanne van den Berg*[1]**, *Jan Baas[2], Lara Schuijt[1], Anna Huang[2] and Paul van den Brink[1], (1)Wageningen University & Research (WUR), Netherlands, (2)Wageningen Environmental Research (WUR), Netherlands*

A major challenge in ecological risk assessment is estimating the toxicity of chemicals on a diverse set of species without performing species-specific toxicity tests. A potential way to tackle this problem is by extracting as much mechanistic understanding possible from currently available toxicity data. Here, we explore the potential and suitability of linear mixed effect (LME) models to explore the sensitivity of fish across both species and chemicals simultaneously. For this, we combine both chemical hydrophobicity and physiological properties (represented by dynamic energy budget parameters) in LME models with a varying level of complexity. We find that differences in sensitivity are larger between chemicals than between species, and that hydrophobicity is therefore the strongest predictor when looking across both chemicals and biological space simultaneously. After zooming in on individual chemicals, we found that physiology explained up to 99% of the variation in species sensitivity. Our approach illustrates how both chemical and biological properties may drive species sensitivity and how these two dimensions can be combined into one statistical model, allowing for more realistic predictions of effects across species and chemicals without the need for additional animal testing.

4.12.P-Tu450 XEREDAR, an R-package for automated statistical analysis of embryo assays for studying endocrine activity

Inka Marie Spyridonov[1], Lijuan Yan[2], Casten Lange Dr[1], Ana FP Miranda Dr[1], Maike Habekost[3], Lennart Weltje, Prof. Dr.[4], Andrew Tindall[5], Gregory F. Lemkine[5] and ***Pernille Thorbek*[6]**, *(1)BASF SE, Germany, (2)BASF Services Europe GmbH, Germany, (3)BASF Corporation, (4)Agricultural Solutions - Ecotoxicology, BASF SE, Germany, (5)Watchfrog S.A., France, (6)Apd/EE, BASF plc, United Kingdom*

The statistical characteristics of ecotoxicological New Approach Methodology (NAM) assays for studying endocrine activity using aquatic vertebrate eleutheroembryos (XETA, RADAR, and REACTIV) differ from those of standard Tier-1 ecotoxicological studies. In these assays, all concentration groups are nested in the replicates (referred to as runs), while in standard Tier-1 studies, the replicates are usually encapsulated in the concentration groups. Ignoring this difference in dependency structure during the statistical analysis violates the basic statistical notion of independence and can potentially lead to erroneous conclusions.

Unfortunately, the statistical section of OECD Test Guideline No. 251 (RADAR) recommends disregarding the dependency structure, and the recommendations in OECD Test Guideline No. 248 (XETA) are at least ambiguous in this regard. However, Annex 13 of the same test guideline provides detailed statistical recommendations using a mixed ANOVA approach.

The developed xeredar R-package is an open-source tool for automated statistical analysis of ecotoxicological NAM assays, specifically for assessing endocrine activity, while considering the correct dependency structure through a mixed ANOVA. The validation of this R-package involved comparing the outcomes of the 36 XETA validation studies, with the results from the xeredar analysis. It was found that the results of using xeredar are congruent to the results presented in the original validation document. Additionally, a power analysis for the REACTIV assay (currently under development at OECD) highlights the consequences of ignoring the dependency structure, including inflated type I (false positive) and type II (false negative) errors. Ignoring the dependency structure reduces power and increases type I error compared with the mixed ANOVA approach.

Overall, xeredar is a user-friendly R-package that aims to standardize the statistical analysis of the XETA, RADAR, and REACTIV and provide reproducible results, thereby promoting the use of NAMs for ED assessment in regulatory ecotoxicology.

4.12.P-Tu451 After dark, all CATs are leopards - Casting Light on the Use of CPCAT (Closure Principle Computational Approach Test) in Non-Target Soil Organism Assessments

Torben Wittwer[1], Agnes Schimera[2], Lijuan Yan[3], Zhenglei Gao[4], Peter Vermeiren[1], Jörg Hanisch[1], Katja Henkes[1] and ***Oliver Jakoby***[1]*, (1)RIFCON GmbH, Germany, (2)ADAMA Deutschland GmbH, Germany, (3)BASF Services Europe GmbH, Germany, (4)Data Science, Bayer AG, Germany*

Recently, the 'Closure Principle Computational Approach Test' (CPCAT) was developed as a method that should overcome the shortcomings of NOEC/LOEC application in ecotoxicological pesticide risk assessments. CPCAT handles abundance data characterized by non-standard statistical properties, such as low abundances, non-normal distributions, and heteroscedasticity without restrictions. The method is recommended as a valuable tool for non-target soil organism assessments under field conditions. In this context, a common approach for guidance conform earthworm and mesofauna data collection is to transform low-resolution sampling data to a square meter scale before performing the statistical analysis.

Our research aims to evaluate the suitability of CPCAT for analysing abundance data of non-target soil organisms under field conditions. Particularly, we address the sensitivity of CPCAT to this data transformation and its implications for the reliability of the results. Specifically, to assess the performance of CPCAT, we used simulated data that covers a range of different data transformations. Therefore, we first generated typical field data sets for Collembola abundance. Then, we examined the behaviour of CPCAT when applied to such abundance data, considering data transformation and the subsequent change of data properties such as data dispersion and effect size.

Our study reveals a concerning sensitivity of CPCAT to data transformation, leading to an unexpected inflation in the false-positive rate which is correlated with the extent of the transformation applied. Transformation magnified the data's effect size as well as the dispersion within the data in violation of CPCAT's assumption regarding Poisson-distributed data. This raises concerns about the robustness and reliability of CPCAT under the current recommendations and underscores the need for caution when applying CPCAT to abundance data.

Overall, our study highlights the limitations of CPCAT in this specific context, emphasizing the importance of considering the applicability and reliability of statistical methods for ecological data in general. These findings have practical implications for researchers and environmental assessors in ecotoxicology and beyond, emphasizing the need for careful choice of methods for data analysis and potential improvements in statistical approaches and guidelines to enhance accuracy and reliability.

4.12.P-Tu452 Promoting Statistical Rigor, Reproducibility, Traceability, and Flexibility in Regulatory Environments: A Comprehensive Showcase

Zhenglei Gao[1]*, Dustin Benski[2], Raphael A(Schaffarzyk[3], Huizhe Jin[4], Jennifer Aschenbrenner[3] and Tatjana Surdin[5], (1)Data Science, Bayer AG, Germany, (2)EnSa, Bayer AG, Germany, (3)Bayer AG, Germany, (4)Bayer CropSicence LP, (5)Inconsult*

Pesticide regulations aim to prevent unintended adverse effects to human, animal health and the environment from the use of plant protection products. Proper statistical analysis of study data is crucial in deriving the hazard endpoints, forming the foundation for risk based regulatory decisions. Like the generation of quality test data, quality statistical analysis is imperative for instilling confidence in regulators regarding the validity and appropriateness of the analyses they review and the following regulatory decision-making. The minimum level of acceptance standards should include reproducibility and traceability. How reproducibility and traceability for statistical analysis can be ensured, and how the implementation and use of appropriate analysis procedures can be guaranteed are essential questions. Additionally, adopting and implementing a new statistical methodology in a controlled and verified way poses challenges. Moreover, how should the various analysis tools (including "cloud" computing) and the retention of electronic data be treated under the context of GLP (Good Laboratory Practice) principles for computerized systems? In this presentation, we will address these key questions by showcasing an ecosystem with a platform providing both a file management system and an application hosting service featuring multiple shiny apps for various statistical analysis workflows.

4.12.P-Tu453 Graphical evaluation of the results of a nonlinear dose response parameter estimation in R and SAS

Baumert Sarah[1]*, Schulz Harald Dr.*[1] *and Zhenglei Gao*[2]*, (1)Independent, Germany, (2)Bayer Crop Science, Germany*

EC_x (Effective Concentration x) calculations are widely employed in environmental risk assessment to quantify the dose-dependent relationship between a stimulus and its biological response. In regulatory contexts, ECx is defined as the concentration or dose of a substance that induces a specific effect, typically expressed as a percentage change relative to the mean control response in regulatory context. To calculate the EC_x values, the fitting of a dose-response curve to experimental data is necessary.

Quality assessments pivotal for evaluating the reliability of the results. A graphical evaluation can be instrumental in identifying factors contributing to poor fitting, particularly when employing nonlinear regression fits.

Various dose-response models assign specific meanings to parameters, with slope (parameter b), lower plateau (parameter c), upper plateau (parameter d), and reflection point (parameter e) representing distinct aspects of the curve.

When measured values are absent in certain curve regions, optimal parameter adjustments become challenging. The absence leads to poor p-values for the individual parameters (p-value > α), also affecting the lack of fit test results. Exploring graphical representations of the dose-response curve and measured values provides insights into the reasons behind suboptimal p-values and the actual usability of the fitted dose-response curve.

Different estimation methods or programs will lead to different results, if parts of the curve are not represented by measured values. In this case, there are different parameter estimations that can lead to similar fitted curves. In some cases, the fitting is no longer possible for a particular optimization algorithm without specific adjustment. However, if the measured values represent the curve well for all areas, the choice of the estimation methods or program has little influence on the result of the parameter estimation.

These relationships are illustrated with graphics showing test data and fitted dose-response curves. The results of different estimation methods and programs for the data sets are included to make clear how the graphics can be used for an interpretation of nonlinear regression results. The examples come from different growth inhibition test data with Myriophyllum spicata from laboratory studies. The non-linear models Log Normal, Weibull type 1 and 2 with three or four parameters are used to fit dose-response curves.

4.12.P-Tu454 Digital Environmental Data Management System; Easier Said than Done

***Alexandra Duguay**, Rio Tinto, Canada*

At Rio Tinto, one of our core business objective is to achieve impeccable Environmental, Social and Governance (ESG) credentials. To achieve this, a strong, reliable corporate Environmental Data Management System (EDMS) is required. Given the breadth and scale of our operations, which span across multiple jurisdictional reporting requirements and include multiple data types and values (both numerical and non-numerical), the collection, storage, organization, analysis of this data represents a significant endeavor.

With this work, we present how we have successfully implemented one of the pre-eminent ESG software packages at the Rio Tinto Aluminum Atlantic Quebec operations hub. The EDMS currently integrates environmental data related to Green Houses Gases, Air and Water quality, weather patterns and several other key metrics from all the Saguenay-Lac Saint-Jean business units including the alumina refinery, five smelters, six hydropower plants, rail network, international port as well as from the Arvida Research and Development Centre. We also present the lessons learned from the digital conversion of such a complex and diverse set of environmental data as an opportunity to highlight aspects that could have resulted in challenges.

As environmental specialists, we are all very familiar with the upmost importance of unbiased scientific data and information that serves as a foundational element for decision making. We believe that sharing the key outcomes of this work can help organizations gain a greater understanding on maintaining and improving environmental data quality through tools that provide better management, and mitigation of various environmental challenges. Furthermore, this work can support broader use of EDMS, particularly in multifaceted large and complex sites such as ours.

4.12.P-Tu455 A comprehensive screening approach to assess similarity to Substances of Very High Concern

*Yordan Yordanov[1], Emiel Rorije[2], Jordi Minnema[1], Willie Peijnenburg[1] and **Pim Wassenaar**[1], (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Centre for Safety of Products and Substances, National Institute for Public Health and the Environment (RIVM), Netherlands*

Over 350,000 chemicals and mixtures are currently being used and emitted into the environment. For many of these chemicals we lack sufficient toxicity information to assess and evaluate their toxicological profile. As *in vivo* – and to a lesser extend *in vitro* – toxicity tests are cost and time consuming, the use of *in silico* methods can be beneficial to fill the existing datagaps. In such an approach, it is crucial to identify the chemicals of highest concern. This particularly includes chemicals with C, M, R, PBT/vPvB and ED properties, which are also known as Substances of Very High Concern (SVHC) in the EU. To facilitate the identification of SVHCs, we recently developed models that evaluate the structural similarity of substances with unknown properties to known SVHC [Wassenaar et al. 2022; https://doi.org/10.1002/jcc.26859]. Substances that are structurally sufficiently similar to known SVHCs can be prioritized for further evaluation, as a high resemblance in chemical structure can be an indication of comparable effects ('similar property principle').

Although this structural similarity model works great at identifying chemicals that exhibit (small) structural differences with known SVHCs, it does not address (dis)similarities in toxicokinetic or biological activity. Extension of the SVHC similarity tool with other aspects of toxicokinetic and biological similarity, such as physicochemical properties and mode of action, can support and increase the users' confidence in the similarity predictions.

As such, in this study we extended the chemical 'global' similarity to site-specific similarity (i.e. structural alerts), and considered toxicokinetic and biological similarity in the form of a physicochemical profile and a bioassay-based profile. Although the individual similarity profiles do not outperform the global similarity model, combining these models in an extended similarity approach result in much more robust predictions, giving information for (additional) mechanistic reasoning that support (or disprove) the initial prediction based on (only) structural similarity. It particularly improves interpretability and translatability to the broader chemical universe and towards relevant follow-up evaluations. Consequently, these model additions could enhance the accuracy of identification of potential SVHCs. In future, the developed models could optimized to other chemicals and effects of concern to contribute to the development of safer chemicals.

4.12.P-Tu456 PEPPER: Machine Learning for Predicting Environmental Persistence of Pollutants under a Unified Framework

Jose Andres Cordero Solano[1]*, Jasmin Hafner*[2]*, Michael McLachlan*[3] *and Kathrin Fenner*[1]*, (1)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)Environmental Chemistry, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (3)Department of Environmental Science, Stockholm University, Sweden*

Understanding the fate of environmentally problematic substances, particularly their microbial degradation, is crucial for effective chemical risk assessment and sustainable chemical development. This study introduces PEPPER, an open-source library providing a standardized approach for handling and sharing degradation data. PEPPER aims to establish a benchmark for modeling advancements, incorporating transparent data curation and well-established machine learning methods. It addresses small datasets with uncertain experimental values, focusing on two biodegradation endpoints: primary biotransformation half-lives (DT50) and breakthrough during wastewater treatment.

Currently our curated database includes 536 chemicals and 18 plants, the largest of its kind. We present results of several modelling attempts using this dataset and several combinations of regressors and chemical descriptors. The study highlights the impact of data curation strategies and dataset size on model performance, emphasizing the need for additional chemically diverse training data for improved predictions.

We plan to expand the application of PEPPER to biodegradation in soil and sediment, with a focus on incorporating uncertainty to enhance model predictive and informative capabilities. This work represents a significant step towards a better understanding of the fate of micropollutants in the environment.

4.12.P-Tu457 High performance computing and neural network in support of toxicokinetic-toxicodynamic modelling for the understanding of mixture effects

Virgile Baudrot[1]*, Thomas Kleiber*[2]*, Sandrine Charles, PhD, HDR*[3]*, Nina Cedergreen*[4] *and André Gergs*[5]*, (1)R&D, Qonfluens, France, (2)It, Qonfluens, France, (3)Umr Cnrs 5558, University Claude Bernard Lyon 1, France, (4)Plant and Environmental Sciences, University of Copenhagen, Denmark, (5)Bayer AG - Crop Science Division, Germany*

Plant protection products are formulated to maximise efficacy to control target pest species, including mixtures of active ingredients, while at the same time limiting risks to non-target species. Being able to predict joint effects of active ingredients or of active ingredients together with formulation agents, is of great importance to both the chemical industry and risk assessors.

As a consequence, having a tool to predict potential interactions without having to test all combination in the lab would increase the efficiency of selecting optimal combinations of active ingredients and formulation products for product development as well as decrease animal testing. As toxicity is a process in time, assessing effects over time gives valuable information on the toxicity of both single chemicals and mixtures. Time variable effects can be assessed with toxicokinetic (TK) and toxicodynamic (TD) models. The mixture toxicity concepts (Concentration Addition and Independent Action) have recently been implemented in survival TKTD models. Here, we provide a standalone pipeline coupling TKTD mechanistic models with Neural Network (NN) benefiting from both worlds: (1) the TKTD approach to fit experimental data (under a Bayesian framework) on active substances alone and in combination with other active substances or additives; (2) using the NN to map potential interactions between active substances in combinations or in formulations. Ultimately this helps identifying chemical mixtures which deviate from the reference models and predicting interactions of new combinations and formulations, not yet tested.

Our model is currently tested based on 99 acute toxicity (survival) studies with fish (OECD 203 standard), grouped into 4 datasets (comprising 38, 19, 21, 21 OECD 203 studies, respectively), with 1 to 3 active substances for each study. Each of the

4 datasets allowed studying the interactions between 5 to 6 different active substances present in varying concentrations in the formulations. Here, we present a first analyis demonstrating the robustness of the model, together with preminary results on the most frequent type of interaction.

4.12.P-Tu458 Machine Learning to help identifying chemicals

***Patrick Bauerlein**[1], Xin Tian[1], Yiqun Sun[2], Frederic Béen[1,3] and Peter van Thienen[1], (1)KWR Water Research Institute, Netherlands, (2)School of Earth Sciences and Engineering, China, (3)Vrije University Amsterdam, Netherlands*

Introduction: As the volume and complexity of analytical data grow, conventional software often falls short in effectively analysing it. Consider, for example, the challenges in identifying polymers through infrared spectra that are compromised by impurities or degradation. This is where machine learning can make a significant difference. Here, we will showcase two test cases that underscore the advantages of machine learning. Our findings suggest that not only does machine learning enhance the accuracy of results, but it also expedites the analysis process. As a result, this approach offers the potential for significant cost savings. We will demonstrate this on two examples, polymers analysis using LDIR (laser direct infrared) spectroscopy and identification of salt solutions with EIS (electrochemical impedance spectroscopy).

Polymer analysis: A notable correlation between the number of training spectra and model performance is seen. As sample numbers grow, most model performances improve, with minor exceptions between 30-50 samples. Thus, scarce training samples can compromise optimal results. Distinguishing by performance, Model 1 excels with larger datasets (>30 samples), peaking at 40, while Model 2 matches this only at 100 samples. Model 3 slightly surpasses Model 4 with smaller datasets, but both need more samples for enhancement. Given computation time and peak performances by Models 1 and 2, training with over 100 samples per polymer class was deemed unnecessary in this research.

Salt solution analysis: We plotted the impedance data derived from the Electrochemical Impedance Spectroscopy (EIS) in a polar coordinate system. The visual representations of this coordinate system were employed to train a CNN model. Subsequent identifications used this trained model. The resultant confusion matrix indicates optimal performance with a limited dataset. Future work will focus on expanding both the sample count and the variety of salts under consideration.

Conclusions: (1) Even a basic model can prove its efficacy. A straightforward sub-KNN approach outperformed three other CNN models and taking less time to train. (2) Quantity of good samples is pivotal for training effective models. With a limited dataset, our data augmentation strategy led to a significant boost in performance. (3) While 2D-CNN models are not the best in this specific study, they appear promising for handling multidimensional spectroscopic data. Their potential will be explored further.

4.12.P-Tu459 Linking Machine Learning to GC/MS Data: A New Approach for Simplifying and Facilitating Environmental Data Analysis

***Day Powell**, Tamas King, Ruoji Luo and Edison Cerda, Agilent Technologies, Inc.*

GC/MS data analysis is often manual, time consuming, and human reliant. There are many automated integrators available, however, most of the time a chemist will need to manually correct baselines, combine or split peaks, and eliminate false positive or negative peaks. The manual intervention is often resulted by contamination, matrix effect, insufficient separation, bad peak shape (such as fronting and tailing), or the nature of analytes.

A machine learning (ML) architecture, designed for GC/MS data processing software allows continuous “learning” of lab-specific methods for various testing services. The plug-in tool operates first in passive mode, building a ML model based on a chemist’s current data analysis workflow. Data analysis results are continuously monitored and fed into a training pipeline to generate a model using a deep learning neural network.

A ML model for the phthalates analysis in consumer products was developed. Another ML model targeting the analytes in the EPA 8270 method is under development and evaluation. Over 1000 samples were used to train the first ML model for phthalate analysis. Data were acquired in SIM/SCAN mode. During the phthalate analysis, isomeric compounds, such as diisononyl phthalate (DINP) and diisodecyl phthalate (DIDP), result in broader peaks and irregular peak shape and usually require additional manual integration. The fully trained ML model can correctly integrate all phthalates investigated in this study, including DINP and DIDP. Retention time shift and change of qualifier ratio sometimes might occur during the GC/MS data acquisition, especially after the maintenance or column replacement. Both parameters were considered during the model training process. With the fully trained ML model both the quantifier ion as well as the corresponding qualifier ion(s) of each phthalate can be correctly integrated across the calibration range. The data analysis time was reduced to 1/5 to 1/4, when the manual integration step is replaced by the prediction of the fully trained ML model.

The GC/MS data processing plug-in tool with a continuously learning model provides reproducible and reliable results, drastically reduces number of manual integrations, therefore reduces the overall data analysis time.

4.12.P-Tu460 Bio-QSARs unlock a new level of predictive power for machine learning-based ecotoxicity predictions by exploiting chemical and biological information

*Jochen P. Zubrod[1], **Nika Galic**[2], Maxime Vaugeois[3] and David A. Dreier[3], (1)Zubrod Environmental Data Science, Germany, (2)Syngenta AG, Switzerland, (3)Syngenta Crop Protection, LLC*
Practical, legal, and ethical reasons necessitate the development of methods to replace animal experiments, so-called new approach methodologies (NAMs). Computational methods such as machine learning (ML)-based quantitative structure-activity relationship (QSAR) models are widely considered a crucial pillar among NAMs. Recently, we introduced the Bio-QSAR concept for multispecies aquatic toxicity regression tasks. For training these models, not only chemicals are represented by a set of numerical descriptor features but also the included species. While first-generation Bio-QSARs for fish and aquatic invertebrates were already of high predictive power, we identified avenues for further improvement. First, we strengthened the data foundation of Bio-QSARs by expanding training datasets by a factor of ~20. We moved from pesticides to the whole chemical landscape as well as from freshwater to aquatic species in general and allowed for flexible test durations. To realize the latter, we used an ML algorithm that is capable of handling fixed and random effects, namely Gaussian Process Boosting. Second, we tested training Bio-QSARs using different sources of biological information besides Dynamic Energy Budget parameters by including taxonomic distances and genus-specific invertebrate trait information. Moreover, we assessed the addition of chemicals' mode of action, as a link between chemical and biological information. Third, we made the improved Bio-QSARs fully explainable by algorithmically correcting datasets for multicollinearity to allow for unbiased estimates of feature importance, which were based on a state-of-the art approach from the field of explainable ML. Finally, we developed new methods to construct applicability domains that consider feature importance and tested their suitability to restrict predictions to samples the models are fit for. The developed second-generation Bio-QSARs are capable of flexible cross-chemical as well as cross-species predictions beyond levels present in training data and, to the best of the authors' knowledge, feature predictive powers unprecedented in multi-species models and tools for acute aquatic toxicity prediction (R-squared values of ~0.89-0.92). Moreover, they meet all criteria to be considered for regulatory purposes. The proposed NAM approach hence holds promise to benefit a range of applications in environmental risk assessment as well as research and development.

4.13 The Fate and Effects of Micro- And Nano-Plastics in Relation to Human Health Exposure

4.13.T-01 21GRD07 PlasticTrace Metrological traceability of measurement data from nano- to small microplastics for a greener environment and food safety

*Korinna Altmann[1], Ulrike Braun[2], Dorota Bartczak[3], Enrica Alasonati[4], Bert van Bavel[5] and **Andrea Mario Giovannozzi**[6], (1)Federal Institute for Materials Research and Testing (BAM), Germany, (2)BAM Federal Institute for Materials Research and Testing, Germany, (3)Inorganic Analysis, LGC National Measurement Laboratory (NML), United Kingdom, (4)LNE Laboratoire national de métrologie et dessais, France, (5)Norwegian Institute for Water Research (NIVA), Norway, (6)Istituto Nazionale di Ricerca Metrologica (INRiM), Italy*
Plastic pollution is recognised as a severe anthropogenic issue globally, where complex physico-chemical transformation processes (such as aging, degradation and fragmentation) producing MPs and, subsequently, NPs. Several studies have reported the occurrence, analytical methods and toxicity of larger MPs (>100 μm) in the environment and food matrices. However, MPs (< 100 μm SMPs) and NPs (< 1 μm) in natural systems have been overlooked, primarily due to significant methodological challenges associated with their micro- and nano-specific properties. The present project, PlasticTrace, aims to address the urgent need for the development and harmonisation of methods for the chemical identification, physical characterisation and quantification of released small micro/nanoplastics (SMPs/NPs) in drinking water, food and environmental matrices, as required by the EU's Circular Economy Action Plan (CEAP). In this context, hyphenated and complementary analytical approaches will be developed, optimised, compared and harmonised, leading to the establishment of metrological traceability of measurements through inter-laboratory comparison validation studies. Novel and environmentally relevant SMP/NP reference materials will be developed within the project (e.g. Polyethylene terephthalate (PET), Polyethylene (PE)). International cooperation with key stakeholders such as EURAMET's European Metrology Networks, standards developing organisations (e.g. ISO TC 229, ISO TC 61, and CEN TC 249) and end users (e.g. food and drink producers, environmental monitoring programmes and health experts) will be considered as the basis for a European Metrology network. The need for efficient and reliable measurement infrastructure is required in support of (i) the European Chemicals Agency (ECHA)'s proposed restriction targeting intentionally added MPs in consumer products, (ii) the Marine Strategy Framework Directive (MSFD) which requires specific thresholds for litter types after harmonisation of the methodology, (iii) the new Drinking Water Directive (DWD) that mentions MPs explicitly, and (iv) the new CEAP adopted in March 2020. However, to support the CEAP and reduce plastic contamination, methods for SMP/NP identification in food and environmental matrices are needed. These methods need to be metrologically validated using appropriate reference materials to establish harmonised and traceable measurements of SMPs and NPs.

4.13.T-02 Carcinogenicity of micro- & nanoplastics long-term exposure

***Alba Hernández**[1], Laura Rubio-Lorente[1], Josefa Domenech[2], Irene Barguilla[3], Javier Gutiérrez[1], Michelle Morataya[1], Boris Guyot[3], Ricardo Marcos Dauder[1], Veronique Maguer-Satta[3] and Julia Catalán[2], (1)Autonomous University of Barcelona (UAB), Spain, (2)Finnish Institute of Occupational Health, Finland, (3)Centre de Recherche en Cancerologie, France*
Micro- & nano-plastics (MNPLs) are considered emergent pollutants widely spread over all environmental compartments. There is evidence that humans can internalize these MNPLs through inhalation and ingestion and that the small size of the plastic particles may allow for absorption, systemic biodistribution and bioaccumulation. Despite of the fact that their biological effects are being intensively evaluated, their potential health effects in humans remain poorly understood. One of the most underdeveloped areas of study is the determination of the effects induced by MNPLs under chronic scenarios of

exposure, being carcinogenicity the most relevant in terms of risk. In this context, the present talk will focus on presenting the current science on MNPLs carcinogenic potential, giving special attention to the approaches developed and results obtained in the frame of the large-scale EU Project PlasticHeal (www.plasticheal.eu/en). Together with the available literature, the set of obtained data supports a potential carcinogenic risk associated to MNPLs long-term exposure. On this basis of evidence, the need of more studies becomes evident. Key research questions and remaining knowledge gaps will therefore be discussed in benefit of future research and the full assessment of MNPLs carcinogenic risk.

Funding: This work was partially supported by the EU Horizon 2020 programme (965196, PlasticHeal), the Spanish Ministry of Science and Innovation (PID2020-116789, RB-C43), the Generalitat de Catalunya (2021-SGR-00731), and the ICREA-Academia programme to AH.

Keywords - Microplastics, nanoplastics, carcinogenicity, health, risk, effects, knowledge gaps.

4.13.T-03 From in vitro to in vivo; a tiered approach to study microplastic dynamics and immunotoxicity

Tim Skrabanja, *Center For Translational Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: Micro- and nanoplastics (MNPs) are omnipresent in the environment and pose a possible risk to human health. Humans are continuously exposed to MNPs and it is known they enter the blood stream via ingestion and/or inhalation. However, MNP immunotoxicity and their dynamics *in vivo*, remain poorly understood.

Aims and methods: We developed a high-throughput survival assay to quantify if microplastics affect cell survival in freshly-isolated neutrophils and monocytes from human blood. Microplastics were also intravenously injected into mice to study neutrophil uptake and activation in vivo, as well as particle dynamics and organ accumulation over 30 days via flow cytometry.

Results: In the *in vitro* assay, spherical polystyrene beads (PS) of 10µm in diameter and 'wild-type' polyvinylchloride (PVC) (<1µm and 1-5 µm fraction) negatively affected human neutrophil survival, whereas PS 50nm, PS 1µm, 'wild-type' polyamide6.6 (PA6.6) (1-5µm and 6-10µm fraction) did not. After intravenous PS 1µm administration, we observed microplastic clearance from the blood within 16h, but increasing accumulation in the liver and spleen at day 14 and 30. We noted an initial neutrophil influx in the liver at 4h post-injection, which returned to baseline levels after 16h. Neutrophils that phagocytosed PS 1µm, exhibited an activated phenotype by increased expression of CD11b and shedding of CD62L. At day 14 and day 30 post-injection, PS 1µm mainly resided in CD11b negative immune cell subsets in the liver and spleen.

Conclusions: In our tiered approach, we assessed immunotoxicity of spherical and 'wild-type' plastics *in vitro*, guiding the selection of microplastics for *in vivo* testing. Although PS 1µm did not significantly reduce human neutrophil survival *in vitro*, intravenous PS 1µm accumulated in the mouse liver and spleen, inducing initial neutrophil phagocytosis and activation. Future work will also include intravenous 'wild-type' toxic PVC as based on our *in vitro* findings.

964766] and the ZonMw/Health Holland project MOMENTUM [Grant ID 458001101].

4.13.T-04 Influence of Simulated Gastrointestinal Digestion on the Toxicity of HDPE and PET Microplastics with and without V. parahaemolyticus Biofilm

Itziar Polanco[1], *Giulia Antonello*[2], *Cristian Simo*[2], *Francesco Barbero*[3], *Ainhoa Bilbao*[4], *Isabel Rodríguez-Llopis*[1], *Dmitri Ciornii*[5], *Korinna Altmann*[6], *Ivana Fenoglio*[3], *Chiara Riganti*[2], *Enrico Bergamaschi*[2], *Felipe Goñi de Cerio*[4] *and Alberto Katsumiti*[7], *(1)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (2)University of Turin, Italy, (3)Department of Chemistry, University of Turin, Italy, (4)Biotechnology, GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (5)Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (6)Federal Institute for Materials Research and Testing (BAM), Germany, (7)GAIKER Technology Centre, Spain*

Polyethylene terephthalate (PET) and high-density polyethylene (HDPE) are widely used in Europe for food packaging, therefore, HPDE and PET microplastics (MPs) end up in a variety of food and drink products, leading to possible health effects. Once in the environment, these MPs can be rapidly colonised by microorganisms like Vibrio parahaemolyticus, a pathogenic species that causes acute gastroenteritis and severe septicemia. In this work, we evaluated the potential toxicity of polydispersed 5 µm HDPE (D50, commercially available) and 130 µm PET (D50, top-down cryomilled by centrifugal mill) MPs with and without V. parahaemolyticus biofilm (HDPE, PET, HDPE+V and PET+V) and with and without an in vitro simulated human digestion system (SHDS) pre-treatment (HDPE-SHDS, PET-SHDS, HDPE+V-SHDS and PET+V- SHDS) to the human gastrointestinal (GI) system. For that, undifferentiated Caco-2 cells and Caco-2/HT29- MTX/M-cells co-culture were exposed for 24h to 1-100µg/mL of these MPs and after that, effects on cell viability, inflammation and barrier permeability and integrity were examined. Scanning electron microscopy (SEM) was used to analyse V. parahaemolyticus colonisation on MPs. The colony forming unit (CFU) assay was performed to determine the number of viable microbial cells in the bacterial biofilm. SEM analysis showed that after 3 days of incubation, V. parahaemolyticus colonised the MPs surface, however, the pre- treatment with SHDS decreased the number of viable bacteria on the surface of MPs. Results from in vitro exposures showed a decrease in cell viability and an increase in inflammation in Caco-2 cells exposed to MPs+V, whereas the pre-treatment with SHDS reduced this effect. In the co-culture, none of the treatments caused cytotoxicity and slight effects were observed in terms of barrier integrity and permeability. Inflammation was increased in exposures to high concentrations of MPs+V pre-treated with SHDS. Overall, results indicated that HDPE and PET MPs may act as vectors for V. parahaemolyticus and induce important cellular responses, leading to damage in the human gut. However, simulated GI fluids (SHDS) may reduce the number of bacteria associated to MPs surface, influencing the potential toxicity of the bacterial biofilm. This work was supported by the EU H2020 Project "Plastics Fate and Effects in the human body" (PlasticsFatE) under Grant Agreement no. 965367.

4.13.T-05 Developing Analytical Methods to Measure Exposure to Micro- and Nanoplastics in Early-life Matrices
Laura Miranda Zoutendijk*, Zenzi Matla, Laurens Dirk Bernardus Mandemaker, Bert Marc Weckhuysen and Florian Meirer, Chemistry, Utrecht University, Netherlands*
Plastic can break down into smaller particles, called microplastics (<1 mm) and nanoplastics (<1 μm) (MNPs). The fate of these particles and their effect on human and animal health is still mostly unknown. Studies show environmental pollutants may have an adverse health effect on the developing fetus, which makes the human placenta an important matrix in researching MNPs' health effects.

We have established a successful digestion protocol for human placental tissue which enables the characterization of MNPs in these samples. As particle number, morphology and chemical composition can affect particles' toxicity, we combine (spectro-)microscopic techniques to enable in-depth analysis on the particle level. We spiked placental tissue with defined commercial MNPs, namely fluorescent polystyrene (FPS) model spheres, to test their stability and calculate their recovery rates throughout the digestion protocol. To ensure the proper characterization of MNPs, a successful digestion protocol needs to sufficiently remove the biological matrix, assure the stability of MNPs, and lead to a high and reproducible MNP recovery rate.

1 g of placenta tissue with known concentrations of FPS spheres was digested with several different enzymes and buffers. Digestion was followed by filtration over a 700 nm pore size glass fiber filter. The amount of tissue left on the filter and the color of the filter were used as indicators for the success of the digestion. MNP stability was determined throughout all steps of the most suitable digestion protocol with Confocal Fluorescence Microscopy (CFM). Particles were seen as stable when no deformation or agglomeration was observed and detection did not suffer from potential dye leaching. Next, recovery rates were measured with CFM by imaging droplets of the liquids after digestion, and before filtration.

Proteinase K and trypsin, both in TRIS-HCl buffer, were found most suitable for tissue digestion. FPS spheres were found back after digestion and remained stable under the conditions used in this protocol. FPS particles were recovered for 110% ± 9.6 (N=30). The next steps will include different plastic species and non-fluorescence-based analysis techniques, such as Atomic Force Microscopy or Raman microspectroscopy. This development in digestion methods for complex matrices is an important step in creating a risk assessment of MNPs for the unborn child.

4.13.P The Fate and Effects of Micro- And Nano-Plastics in Relation to Human Health Exposure

4.13.P-Mo400 Ingested Nanoplastics Induced Histological, Genotoxic and Gene Expression Changes in Mouse Gastrointestinal Tract
Aswin Kuttykattil[1]*, Thomas Loret*[1]*, Sonja Holme*[2]*, Adriana Rodríguez-Garraus*[3]*, Aliro Villacorta*[4]*, Julia Catalán*[3]*, Ricardo Marcos Dauder*[5]*, Alba Hernández Bonilla*[4] *and Cyrill Bussy*[6]*, (1)School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, United Kingdom, (2)School of Biological Sciences, Faculty of Biology, Medicine and Health,, University of Manchester, United Kingdom, (3)Finnish Institute of Occupational Health, Finland, (4)Genetics and Microbiology, Autonomous University of Barcelona (UAB), Spain, (5)Autonomous University of Barcelona (UAB), Spain, (6)Division of Immunology, Immunity to Infection and Respiratory Medicine, School of Biological Sciences, University of Manchester, United Kingdom*
Despite extensive research on nanoplastics (NPs) health impact, the implications of exposure to polyethylene terephthalate (PET) remain underexplored. In particular, there is limited understanding of its potential effect on the mammalian gastrointestinal tract (GIT), even though PET is widely used for cookware coating, leading to ingestion of PET-NPs. In this study, we utilised a C57BL/6 female mouse model to assess the effects of PET-NPs after single gavage exposure and compared them with nano-sized polystyrene (PS; 50 nm and 200 nm), which have been more widely studied. Evaluations were conducted at 1, 7, and 28 days post-exposure, focusing first on histopathological changes in the small intestine and colon, as well as mesenteric lymph nodes. DNA damages using the comet assay were also evaluated in the small intestine and liver. Finally, alteration of expression of genes related to inflammation, immune and stress responses, cell cycle regulation, tissue remodeling, DNA damage, and collagen synthesis were analysed in the small intestine via multiplex RT-qPCR. Overall, histological analysis did not show significant damage to the GIT organs. However, PS exposure resulted in lymphocyte depletion and increased B cell accumulation in mesenteric lymph nodes, suggesting activation of the immune system; while PET had no effect. We also found size-dependent genotoxic effects; notably, PS200 induced significant DNA damage in the small intestine, which resolved over time, whereas PS50 and PS200 caused sustained liver DNA damage at 28 days. There was upregulation of inflammation and stress response-related genes, which correlated with PS50 robust pro-inflammatory responses at the histological level, while PS200 stimulated genes related to stress and antioxidant defense mechanisms.

Conversely, PET exposure suppressed genes vital for cell cycle progression, collagen formation, and DNA repair, hinting at long-term impacts on tissue integrity and genetic stability, with an increased xenobiotic response observed by day 28. These findings underscore the health risks associated with NPs ingestion, particularly in terms of genotoxicity and immunological reactions in the gastrointestinal tract. Crucially, this research will significantly influence the development of policies and regulations, especially in relation to NPs exposure via food contact products for food safety purposes.

4.13.P-Mo401 Immune Effects of Pristine and Microbially Contaminated PET Nanoplastics
***Oeyvind Pernell Haugen*[1]**, *Andreas Solberg Sagen[1], Torunn Kringlen Ervik[1], Pål Graff[1], Bendik Brinchmann[1], Victor Alcolea-Rodríguez[2], Raquel Portela[3], Håkan Wallin[1], Karl-Christian Nordby[1], Shan Zienolddiny-Narui[1] and Anani J. K. Afanou[1], (1)The National Institute of Occupational Health in Norway, (2)ICP, Spanish National Research Council (CSIC), Spain, (3)ICP, Spanish National Research Council (CSIC), Madrid, Spain*
Background**:** Workers in plastic processing and manufacturing industries may be exposed to airborne micro- and nanoplastics (MNPs). Due to their small size and low density, MNPs can deposit in the lower respiratory tract, including the alveoli. MNPs might carry microbial contaminants, especially those existing in waste management and recycling facilities, thereby posing a health risk when inhaled by workers in these industries. Moreover, microbially contaminated MNPs may interact differently than pristine MNPs in the lung. In the present study, we investigated cell viability and inflammatory cytokines after exposure to pristine or microbially contaminated polyethylene terephthalate nanoplastics (PET-NPs) using co-cultures of human lung epithelial cells and macrophages.

Materials and methods: Bottom-up synthesized PET-NPs from commodity PET pellets (PET c000, D50 = 77 nm) or recycled juice bottles (PET b001, D50 = 69 nm) were assessed for microbial contamination using Toll-like receptor (TLR) reporter cells expressing either TLR2 or TLR4. Submerged co-cultures of human alveolar basal epithelial cells (A549) and monocyte-derived macrophages (dTHP-1) were exposed to low (10 µg/ml) or high (100 µg/ml) concentrations of the PET-NPs for 24 hours. Cell viability was assessed using alamarBlue reagent, and gene and protein expression of inflammatory cytokines (IL-1B, IL-6, IL-8, TNF-α) were measured by RT-qPCR and ELISA.

Results**:** PET b001 activated both TLR2 and TLR4, indicating the presence of microbial contaminants from Gram-positive and Gram-negative bacteria, while PET c000 did not cause TLR activation. No change in cell viability was found after exposure to any of the PET-NPs in A549/dTHP-1 co-cultures. The PET b001 particles increased the gene expression of IL-1B, IL-6, IL-8 and TNF-α, but only IL-6 and IL-8 were increased in the cell culture supernatant. The highest concentration of PET c000 particles (100 µg/ml) increased expression and secretion of IL-8.

Conclusion: Our findings show that exposure to pristine PET-NPs increased IL-8 expression, indicating a potential to cause inflammation. However, this response was much stronger when exposure occurs in the presence of microbial contaminants, which increased the expression of all the four cytokines measured. Workers at workplaces where such MNPs are present may therefore have a higher probability of experiencing occupational health issues after exposure to airborne MNPs.

Acknowledgements: This work was supported by the EU Horizon 2020 Project "Plastics Fate and Effects in the human body" (PlasticsFatE) under Grant Agreement no. 965367.

4.13.P-Mo402 Micro-and nanoplastics migration from food packaging into food: a systematic evidence map
Birgit Geueke[1], Lisa Zimmermann[2], Lindsey V. Parkinson[1], Christoph Schuer[3], Martin Wagner[4] and ***Jane Muncke*[1]**, *(1)Food Packaging Forum Foundation, Switzerland, (2)Food Packaging Forum (FPF), Switzerland, (3)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (4)Norwegian University of Science & Technology (NTNU), Norway*
In recent years micro- and nanoplastics' (MNP) research has expanded to investigating potential sources of exposure. Emerging evidence shows that MNPs are generated during normal and intended use of plastic food packaging or other plastic food contact articles (FCA). However, to date FCAs as relevant human exposure source to MNPs has received little attention.

To provide a first overview of the available evidence, we performed a systematic evidence mapping on MNPs present in foodstuffs originating from FCAs. By identifying the extent of MNPs in food stemming from plastic FCAs we lay the foundation for refining human exposure assessment and reducing exposure.

We searched several public databases for relevant studies published until the end of 2022, screened them for eligibility, extracted a wide variety of data on the FCA, the MNPs, and the medium they were analyzed in. Finally, we assessed the reliability of the studies, and, based on the highly reliable ones, discuss the current body of evidence for plastic FCAs being the source of these MNPs in human food.

We identified 104 studies that met our eligibility criteria from which we generated 601 database entries. With more than 50 entries each, researchers focused on bottles, containers, tea bags, bags, and cups. MNPs were mostly analyzed in media simulating water while 212 entries referred to liquid and 121 to solid foodstuffs. The majority (580 entries) reported the detection of MNPs in the assessed medium. However, our critical appraisal of the study design and methods showed that many of these studies are of low quality. Of the 601 entries, only 50 were considered highly and 128 medium reliable.

Our systematic evidence mapping shows that under normal and intended use, plastic FCAs are a source of MNP migration that needs to be routinely and systematically assessed. It also points out that most published data are not reliable, indicating the need to integrate a standardized quality assessment approach in the study design. By publishing our data in an openly available database we hope to guide future research concerning study objects, methods, and ways of reporting. This will support safer plastic food packaging for critical applications.

4.13.P-Mo403 Orally ingested microplastic affects a genes and associated signalling pathways in the pig's colon

Monika Golubska[1]*, Karol Mierzejewski*[2]*, Aleksandra Kurzyńska*[1]*, Ismena Gałęcka*[3]*, Jarosław Całka*[3]*, Kamil Markuszewski*[4] *and Iwona Bogacka*[5]*, (1)University of Warmia and Mazury in Olsztyn, Poland, (2)Department of Animal Anatomy and Physiology, University of Warmia and Mazury in Olsztyn, Poland, (3)Department of Clinical Physiology, University of Warmia and Mazury in Olsztyn, Poland, (4)Department of Applied Computer Science and Mathematical Modelling, University of Warmia and Mazury in Olsztyn, Poland, (5)Department of Animal Anatomy and Physiology, Department of Animal Anatomy and Physiology, University of Warmia and Mazury in Olsztyn, Poland*

Recently, there has been a growing interest in exploring the consequences of microplastics (MPs) consumption. One of the most common polymers used in food industry is polyethylene terephthalate (PET), whose effects on human and animal health have not been fully described. Recently, consumption of MPs has been linked to the onset of colorectal cancer. We hypothesize that *in vivo* exposure to PET affects various biological processes at the molecular level in the organs of the digestive system in immature piglets. To verify our hypothesis, we examined the effect of different doses of PET on changes in the global transcriptomic profile of distal colon.

The experiment was performed on 8-week-old immature gilts (n=15), divided into three groups receiving orally: 1) control – empty gelatin capsules; 2) low dose – 0.1 g/pig/day PET MPs in gelatin capsules; 3) high dose – 1 g/pig/day PET MPs in gelatin capsules for 4 weeks. Total RNA from distal colon tissues was isolated, and RNA-Seq analysis to identify differentially expressed genes (DEGs) on the NovaSeq 6000 Illumina platform was performed. Then g:Profiler enriched signaling pathways analysis was performed.

A low dose of PET revealed 251 DEGs (181 downregulated, 70 upregulated). The Gene Ontology (GO) annotation of biological processes (BP) indicated 26 terms, 4 ontology terms have been classified as molecular functions (MF) and 5 terms as cellular components (CC). KEGG, Reactome (REAC) and Human Phenotype Ontology (HP) databases revealed another 6 signaling pathways in which detected DEGs were engaged. DEGs were connected to e.g.: regulation of immune system processes (23 DEGs), biological regulation (138 DEGs), regulation of fatty acid metabolic process (6 DEGs). In turn, a high dose of PET revealed 358 DEGs (163 downregulated, 195 upregulated). The GO annotation of BP indicated 26 terms, 1 ontology term have been classified as MF and 3 terms as CC. KEGG, REAC and HP databases revealed another 7 signaling pathways in which detected DEGs were engaged. DEGs were connected to e.g.: lipid metabolic process (34 DEGs), retinol metabolism (6 DEGs) and cell differentiation and cellular developmental process (73 DEGs).

In this study, we identified for the first time signaling pathways that may be disrupted by microplastic ingestion, shedding light on the novel mechanisms that may lead to the adverse health effects of microplastic consumption.

Funding: National Science Centre, Poland: No. 2022/45/N/NZ7/01895.

4.13.P-Mo404 Development of Sampling and Analytical Methods for Measuring Microplastics with Sizes Greater than 20 μm in Tap Water

Yutaka Kameda *and Emiko Fujita, Chiba Institute of Technology, Japan*

A novel sampling method with an analysis for microplastics （MPs） with sizes greater than 20 μm in tap water was developed to reveal their occurrence characteristics, such as their concentrations, polymer compositions and size distributions, with high precision. Micro-Fourier transform infrared spectroscopy followed by density separation could recover 91.0％ of MP particles in tap water. Large amounts of water could make the standard deviations of detected MP concentrations much smaller, and the coefficient of variation decreased to 14.9％ when the sampling volume was 1000 liter. The sampling method for MPs under faucets with unused plankton nets outside collected 16.7 ± 6.4 particles by dry deposition from the atmosphere, but the coverage by lids could reduce the level of deposition. Finally, MPs in 1000 L of tap water originating from groundwater were analyzed. Twelve polymers were detected and their total concentrations ranged from 78 ± 10.4 to 2130 ± 358 particles $m^{-3.}$ Polyethylene, alkyd resins and polymethyl methacrylate were dominant and their total concentrations contributed 56.5 to 94.0％ to the total MP concentrations. The median sizes of MPs observed in all samples ranged from 30.1 to 60.4 μm and their dominant shape was of the fragment type. Tap water samples were also collected at 30 sites all around Japan. Tap water samples were also collected at 30 sites all around Japan to reveal occurrences of MPs in Japanese tap waters. Their concentrations ranged from 30 to 2110 pieces m^{-3}. Eleven polymers were detected in all samples, and polyethylene, polypropylene, polyethylene terephthalate, and polymethyl methacrylate were dominant. Principal component analysis of these data showed that their sources were polyethylene pipes, polypropylene pipes, lining fragments from pipes, and adhesive used to connect pipes.

4.13.P-Mo405 International standardization of hazardous substance testing methods for recycled plastics for the Plastic Circular Economy

***Jaehak Jung**, Korea Institute of Science and Technology (KIST), Seoul, Korea, Republic of*

With the rapid growth of the electrical products, automotive and various plastic industries, the exposure and risk of micro & nano plastics is increasing, but the risks of various harmful substances to the human contained in plastic are being taken more seriously. Therefore, related international environmental regulations are being strengthened and research is being actively conducted. Accordingly, recent activities to reduce plastic usage and increase recycling of plastic waste to create a Plastic Circular Economy are highly active. However, as it is known that hundreds of types of hazardous substances can be detected in the human from recycled raw materials and products [1], actual industries want to confirm that exported/imported products do not contain hazardous substances and require qualitative/qualitative analysis of hazardous substances for QA/QC.

The need for standardization is also increasing on hazardous substances related to E&E, automotive, and various imported/export industrial products related to EU regulations (RoHS/ELV/REACH SVHC). WG 3 is taking the lead. Accordingly, WG 3 regularly conducts substance selection task activities to select candidates for future test method by survey. The recent candidate substances (Phthalates, PAHs, BPA, SCCP/MCCP) selected through this process were developed to the IEC 62321-series standard to develop test methods for the hazardous substances and conduct an IIS (international inter-laboratory study). Through the process of verifying test methods, we are developing horizontal standards that can be used around the world.

Recently, WG 3 are preparing to develop a test method for PFAS, which has been detected in various environments & human around the world and is of great interest and concern. WG 3 plan to develop an international standard by reflecting the requirement of various stakeholders regarding analysis methods & risk assessment that satisfy EU ECHA regulations. To achieve this, it is essential to secure samples with actual PFAS detected and RM/CRM, and the participation of global laboratories for future test method validation is necessary. Through this, WG 3 seeks to develop and provide to future core capabilities to verify whether recycled plastic raw materials contain hazardous substances, which are important in realizing the Plastic Circular Economy for the future society.

4.13.P-Mo406 EFFECTS OF NANO- and MICROPLASTICS on THE HUMAN IMMUNE SYSTEM: HOW MUCH SHOULD WE WORRY?

***Claudio Fenizia**[1], Claudia Vanetti Dr.[2] and Martina Broggiato[1], (1)Department of Pathophysiology and Transplantation, University of Milan, Italy, (2)Department of Biomedical and Clinical Sciences, University of Milan, Italy*

Humans are broadly exposed to nano- and microplastics (NMPs). The main route of exposure is via alimentary intake, with an annual consumption of millions of particles. Once entered the human body, NMPs can spread via bloodstream, then supposedly reaching distant sites. To date, scarce information is available on the inflammatory responses, in particular on human primary cells. It is known that NMPs can induce cellular lysosomal toxicity, resulting in an increased expression of the pro-inflammatory nuclear factor NFkB, activated during stress responses and, in turn, the secretion of the pro-inflammatory cytokines interleukin(IL)8, IL1β, IL6 and tumor necrosis factor (TNF)α. In this context, we aimed at dissecting the effects of NMPs on human primary monocytes, cells endowed with a high phagocytic capacity and a pivotal role in the immune system.

First, we exposed freshly isolated human primary monocytes to plain fluorescent polystyrene spheres (diameter 10, 5, 1, 0.5 or 0.1μm). Results by microscopy and flow cytometry showed that NMPs were indeed internalized within monocytes, proportionally to the amount of NMP the cells were exposed to (ranging from 5000 to 5μg). NMPs exposure caused a sharp drop in cell vitality and viability primarily proportional to the amount of NMPs seeded, but also to the NMPs size. Then, a preliminary 27-target real-time PCR array, based on 18 cytokines, 4 chemokines and 5 growth factors, showed an overall pro-inflammatory profile elicited by NMPs, compared to the untreated control. Peculiarly, the smaller NMPs sizes induced a more pronounced inflammation, while the bigger ones were accompanied by a slightly higher transcription of the growth factors FGF and VEGF, together with the anti-inflammatory decoy receptor IL1ra. As the pro-inflammatory interleukine (IL)1β is directly linked to the activation of the inflammasome pathway, evaluation of ASC speckle formation. Indeed, an higher inflammasome activation was detected in particular with 0.5 and 0.1μm NMPs administration.

By these preliminary observations, we obtained a first insight into the pro-inflammatory effects of human primary monocytes exposure to NMPs. Our data point at what already presumed in the literature: the smaller it is, the worse it gets! Altogether, we aim at obtaining a detailed picture of the NMPs-elicited inflammatory response, to than be able to assess the putative detrimental contribution of NMPs to a number of clinical observation and inflammatory diseases.

4.13.P-Mo407 Unraveling Photodegradation Mechanism of Surgical Masks from Microplastics and Nanoplastics Release

***Guyu Peng**[1], Matthias Schmidt[2], Orasai Faikhaw[1], Dusan Materic[1] and Thorsten Reemtsma[2,3], (1)Department of Analytical Chemistry, Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Helmholtz Centre for Environmental Research (UFZ), Germany, (3)University of Leipzig, Germany*

Since the Covid-19 pandemic, 129 billion masks have been consumed each month worldwide. Fate of masks not only include atmospheric, freshwater and seawater, but degraded masks may release micro(nano)plastics (MNPLs) that enter human body through inhalation and ingestion. Here, we simulated the photodegradation of surgical masks made from polypropylene in air, freshwater and seawater (equivalent to 71 days). Size-fractionated MNPL release was quantified using various vibrational spectroscopic imaging methods, and the morphology of nanoplastics were characterized with correlative microscopy. Macroplastics, microplastics, small microplastics and nanoplastics demonstrated various degree of sensitivity to degradation. Formation of hydroxyl and carbonyl groups were observed for microplastics > 10 µm in contrast to three layers of masks (macroplastic), indicating that MNPLs being a more sensitive indicator of photodegradation. Masks and microplastics exhibited a linear increase in crystallinity calculated from FTIR and Raman spectra, and a transition from ductile to brittle fibers that facilitated faster fragmentation into MNPLs. The total released microplastics and small microplastics was 30,696 and 7,864 particles per mask calculated from FTIR and Raman imaging data, respectively, with the most MNPLs released from the melt-blown middle layer as shown by cluster analysis. Nanoplastics with a minimum size of 66 nm were characterized correlatively by Raman imaging and scanning electron microscopy. This study quantified MNPL release and the alteration in physical and chemical properties after degradation, which have major implications for their environmental fate and human health risks.

4.13.P-Mo408 Risk assessing micro- and nanoplastics for early-life human health: the AURORA Horizon 2020 research project

*Roel Vermeulen[1], **Jane Muncke**[2], Justin Michael Boucher[2], Runyu Zou[3], Barbara Scholz-Boettcher[4], Amanda A Durkin[1], Laura Miranda Zoutendijk[5] and Joel Scheuchzer[6], (1)Utrecht University, Netherlands, (2)Food Packaging Forum Foundation, Switzerland, (3)UMC Utrecht, Netherlands, (4)University of Oldenburg, Institute for Chemistry and Biology of the Marine Environment, Germany, (5)Chemistry, Utrecht University, Netherlands, (6)Food Packaging Forum, Switzerland*

The scale of micro- and nanoplastic (MNP) pollution is becoming increasingly clear yet little is known about how this pollution impacts human health, particularly during early-life stages. The AURORA project will deliver an actionable European roadmap for early-life health risk assessment of MNPs to support regulation of MNPs, the products and processes that generate secondary MNPs, and development of safer alternatives. Within the project, we are focusing on MNP exposures and toxicological and health effects during pregnancy, in utero, and in early life. MNPs have been shown to cross the placental barrier *in vitro* and *in vivo*, underlying the urgent need to understand the impact of MNPs on reproductive and early-life health. AURORA will advance this understanding by significantly enhancing exposure assessment capabilities for measuring MNPs and MNP-associated chemicals (e.g. additives) in tissues relevant for early-life development (placenta, cord blood, amniotic fluid, meconium, fetal tissue).AURORA adapts and integrated approach by combining in-depth characterization methods (microscopy and spectroscopy) and scalable methods (mass-spectrometry) to develop strategies for both detailed and large-scale toxicological characterization, exposure assessment, and epidemiological studies. This will be combined with a novel tiered-testing approach and epidemiological investigations to provide the first extensive evaluation of maternal and fetal MNP exposures and health perturbations, including placental function, immune-inflammatory responses, oxidative stress, accelerated aging, endocrine disruption, and child development. While developing and applying the tools and methodological workflows of the AURORA research program, we are creating a risk assessment framework specific to MNPs and identifying the remaining knowledge gaps and priorities needed for comprehensively evaluating the impact of MNPs on early-life health. The AURORA project started on April 1, 2020 and is part of the EU Horizon 2020 funded research CUSP cluster. The project is a collaboration between 11 partners based in Europe and the US, and it will run for 5 years. A central focus of AURORA is effective dissemination of the research findings, and for this reason we will closely collaborate with different stakeholders from academia, policy arenas, civil society and industry.

4.13.P-Mo409 Nanoplastic type influences their biological effects on brain microglia

*Jeong Yeob Baek[1], Bohyeon Jeong[2], Wangsik Lee[3], Subin Park[2], Jahong Koo[2], Giyoung Gong[2], Nam-Soon Kim[2], **Jinyoung Jeong**[2] and Da Yong Lee[2], (1)Korea Institute of Toxicology (KIT), Korea, Republic of (South), (2)Korea Research Institute of Bioscience & Biotechnology (KRIBB), Korea, Republic of (South), (3)Adolph Merkle Institute*

As plastic pollution continues to grow in various ecosystems, potential harmful effects of micro/nanoplastics have become a great concern. So far, the biological effects of nanoplastics were investigated by mainly using polystyrene as a model plastic type. However, a majority of environmental plastic wastes is the mixture of various types of plastics, such as polypropylene (PP), polyethylene (PE), polystyrene (PS) and polymethylmethacrylate (PMMA) and so on, in real ecosystem. In this study, we investigated the biological effects of nanoplastics with the similar size on microglia functions using three different types of plastics (PS, PP and PMMA). In our cultured primary rat microglia, three different nanoplastics were rapidly internalized into the cell within 3 hours by confirming fluorescent imaging. Among the groups with these nanoplastics, the group exposed to PMMA nanoplastics showed the highest morphological change and expression of the markers for microglia activation. In addition, we found that PMMA nanoplastics increased the migration ability of microglia by inducing the expression of chemokines, such as CXCL1 and 2. These data demonstrate the possibility that the nanoplastics exposed microglia may accelerate neurological disorders by enhancing the recruitment of microglia and peripheral immune cells across the blood brain barrier in neuropathological conditions.

4.13.P-Mo410 Extended application of physiologically based pharmacokinetic: developing particle- and species-related parameters

***Bingqing Lu**[1], Jiaqi Wang, MSc[2], E. Ribbers[2] and Jan A.J. Hendriks[2], (1)Department of environmental science, Radboud*

University Nijmegen, Netherlands, (2)Radboud University Nijmegen, Netherlands

Distribution of particles in the human body is associated with the nanotoxicity. Physiologically based pharmacokinetic (PBPK) tools can simulate the distribution and elimination of NPs but are primarily dependent on experimental data. PBPK tools require parameters related to properties of various particles and species. However, it is difficult to quantify the effect of particle properties on particle behavior *in vivo*. The derivation of PBPK models from mice to humans is also necessary for human risk assessment.

In this study, we developed a scope on extending the application of PBPK models to various particles and species, estimating particle-related and body/species-related parameters involved in PBPK models. Previous results show that the phagocytosis rate and clearance rate constants of nanoparticles from blood can be estimated by simulating interaction between nanoparticles and tissues. Generic allometries of species-related parameters can estimate physiological data for different species. Our results proved the allometries of organ blood flow and metabolic rates for high-perfusion organs are organ weight-dependent. We expect the methods for deriving particle- and species-related parameters can extend the application of PBPK models to various nano/micro plactics and species.

4.13.P-Mo411 Polypropylene nanoplastics enhances the intestinal inflammation induced by disinfectants in zebrafish larvae

Yugyeong SIM[1,2]*, Hyun-Ju Cho*[3]*, Jae-Geun Lee*[3]*, Jeong-Soo Lee*[1,3] *and Jinyoung Jeong*[3]*, (1)University of Science and Technology (UST), (2)University of Science and Technology (UST), Korea, Republic of (South), (3)Korea Research Institute of Bioscience & Biotechnology (KRIBB), Korea, Republic of (South)*

Microplastics are ingested through various routes, including drinking water, food packaging, and food itself. Previous study suggests that ingestion of microplastics can lead to oxidative stress, intestinal inflammation, and alterations in the gut microbiota composition. However, most research has focused on healthy conditions that do not accurately represent the real-life situations of individuals undergoing intestinal inflammation due to various factors such as dietary choices, drugs, and environmental pollutants. Therefore, our research aims to design experimental conditions that are in line with the health status of individuals experiencing intestinal inflammation. Here, we used benzalkonium chloride (BAC) as a representative disinfectant which could induce intestinal inflammation. BAC is a well-known environmental pollutant which ingested into the intestine via drinking water and personal health care products, including mouthwash. Additionally, polypropylene nanoplastics (PPNPs) were used as a microplastic model which was ingested into the gut via drinking water, food, and mask. In this study, zebrafish (*Danio rerio*) was used as an animal model to detect intestinal toxicity between BAC and PPNPs. Zebrafish larvae were exposed to BAC at 3 days post fertilization (dpf) for 48 h to induce inflammation in the gut. Then, larvae were exposed to PPNPs at 5 dpf for 48 h by ingestion. Our results revealed that PPNPs enhanced toxic effects in the inflamed intestine induced by BAC. PPNPs with pre-exposure of BAC were more 2.8 times accumulated in the intestine than that with single-exposure of PPNPs. PPNPs was mainly distributed in the intestine but did not induce the migration of immune cell. However, in the inflamed intestine by BAC, PPNPs induced 3 times the macrophage activity and also increased expression of inflammatory responses such as TNF-a, IL-1B, and IL-8. In this result, although PPNPs did not induce severe intestinal inflammation in zebrafish larvae, they enhanced toxic effects in the weak gut by BAC. The findings show to better understanding of the potential risks of microplastic by ingestion in terms of multiple toxicity in human health.

4.13.P-Mo412 Micro and Nanoplastics (MNPs) as Potential Hazards for Human Health: Effects of Polystyrene NPs, Polyethylene MNPs and Fishing Net Leachates on Human Intestinal Caco-2 Cells

Karla Pérez[1]*, Edgar Dusacre*[2]*, Jérôme Cachot*[3]*, Alberto Katsumiti*[4] *and* ***Miren P. Cajaraville PhD, PhD***[5]*, (1)Zoology and Animal Cell Biology, CBET+, PiE, University of the Basque Country UPV/EHU, Spain, (2)University of Bordeaux, France, (3)EPOC CNRS, University of Bordeaux, France, (4)GAIKER Technology Centre, Spain, (5)CBET+ Research Group, Department Zoology and Animal Cell Biology, Faculty of Science and Technology and Research Centre for Experimental Marine Biology and Biotechnology PiE, University of the Basque Country UPV/EHU, Spain*

Plastic pollution has increased exponentially in recent years, and both aquatic and terrestrial ecosystems are affected by their presence. Small-sized plastics, known as microplastics (MPs, 1 to 1000 μm) and nanoplastics (NPs, 1 to 1000 nm), stand out for their ubiquity and potential interactions with living organisms. Among plastic polymers, polystyrene (PS) and polyethylene (PE) are two of the most widely used thermoplastic polymers in food packaging in Europe. Fishing nets contribute to MNP pollution in the marine environment and are made of different polymers including polyamide (PA) and additives. The objective of the present work was to carry out a hazard assessment of commercial MNPs and fishing net leachates containing MNPs using a human intestinal cell line *in vitro*. For this, Caco-2 cells were exposed to different concentrations of commercially available PS NPs (50, 500 and 1000 nm) and PE MNPs (200-9900 nm) and to polyamide 6 (PA 6) and 50% bio-based polybutylene succinate (PBS) fishing net leachates containing MNPs. The behavior of PS and PE MNPs and leachates in cell culture medium was characterized by Dynamic Light Scattering (DLS) and cell viability was assessed by the MTT assay after 24 hours exposure. The results obtained by DLS showed that particles had a negative surface charge and high polydispersity, and that most of them tended to aggregate in cell culture medium. According to the results obtained *in vitro*, commercial pristine PS and PE MNPs did not show any cytotoxicity towards Caco-2 cells, whereas PA 6 and PBS fishing net leachates significantly reduced cell viability after 24 hours exposure, possibly as a result of released additives present in plastic formulations. Our results suggest that the next steps of research into MNPs hazardous effects should be focused on testing environmentally relevant MNPs and plastic additives on human cell models, as they may produce higher toxicity than pristine MNPs. *Funded by the Basque Government project MIKRONANOPLAS (PA22/01) and grant to consolidated research groups (ref. IT1743-22) and projects CAS6 (DG JRC, S.4 Unit), PLASFITO (Euskampus EUSK22/03) and FIERA (PID2021-128600OB-I00, MCIN/AEI/ 10.13039/501100011033 and "ERDF A way of making Europe").

4.13.P-Mo413 Physiologically Based Kinetic (PBK) Modelling for Human Exposure to Micro- and Nanoplastics
Jiaqi Wang, MSc[1], *Damian Roelofsen*[1], *Jordi Minnema*[2], *Matthijs de Winter*[2], *Christiaan Delmaar*[2], *Jan A.J. Hendriks*[1] *and Ad M. J. Ragas*[3], *(1)Radboud University Nijmegen, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Environmental Science, Radboud University Nijmegen, Netherlands*
Microplastics (plastic particles < 5 mm, including nanoplastics < 1 µm) have become a global concern. Humans are exposed to microplastics via inhalation, food consumption and dermal contact, potentially adversely affecting human health. Physiologically based kinetic (PBK) models are valuable tools for understanding the internalisation of chemicals. PBK models provide chemical concentration estimates over time in specific tissues based on descriptions of absorption, distribution, metabolism, and excretion (ADME) processes and the physiology and anatomy of the organism. However, human PBK models for microplastics are currently lacking. Therefore, the present study integrates the existing information on relevant absorption, distribution and excretion pathways of microplastics in the human body and develops a conceptual PBK model for human exposure to microplastics.

An extensive literature search was conducted regarding relevant ADME processes of microplastics in humans. Only ten studies on *in vivo* and *in vitro* mammal models were identified as relevant. As nanoplastics are expected to penetrate the organism sharing similar physiochemical characteristics with nanoparticles (e.g. inert, nano-sized), information on engineered nanoparticles from nanomedicine and nanotoxicology was also included.

Absorption largely depends on particle size, where particles < 10 µm are most likely to penetrate the gastrointestinal barrier and particles < 1 µm could cross the alveolar wall. The distribution of microplastics between tissue and blood is governed by permeability and surface energy. The reticuloendothelial system plays a major role in taking up microplastics in the liver, spleen and lungs. We present the conceptual PBK model with mass balance equations and required input parameters which can be potentially derived from the collected data. We propose combining mechanistic (estimating input parameters as functions of organisms' and particles' properties) and probabilistic approaches (e.g. the Bayesian method) to estimate parameter values to expand the applicability domain of PBK models to diverse microplastics. Future work includes evaluating the model using data from microdosing and epidemiological studies, examining variations from cell cultures and animal models with varying conditions, and understanding the role of biomolecular corona in the uptake and biodistribution of microplastics.

4.13.P-Mo414 Impact of Polystyrene Nanoparticles on Lung Epithelial Barrier Formation and Functionality
Sara Michelini[1], *Neza Repar*[1], *Ema Kurešepi*[1], *Katarina Šimunović*[2], *Francesco Barbero*[3], *Martin Schicht*[4], *Victor Ganin*[5], *Ivana Fenoglio*[3], *Friedrich Paulsen*[6], *Andreja Erman*[7], *Barbara Šetina Batić*[5], *Ines Mandič-Mulec*[2], ***Anita Jemec Kokalj***[8], *Damjana Drobne*[8] *and Katharina Jungert*[9], *(1)Department of Biology, University of Ljubljana, Biotechnical Faculty, Slovenia, (2)Department of Microbiology, University of Ljubljana, Biotechnical Faculty, Slovenia, (3)Department of Chemistry, University of Turin, Italy, (4)Dep. of Functional and Clinical AnatomyDep. of Functional and Clinical Anatomy, Friedrich Alexander University of Erlangen-Nürnberg, Germany, (5)Institute of Metals and Technology, Slovenia, (6)Friedrich Alexander University of Erlangen-Nürnberg, Germany, (7)University of Ljubljana, Faculty of Medicine, Institute of Cell Biology, Slovenia, (8)University of Ljubljana, Biotechnical Faculty, Slovenia, (9)Friedrich Alexander University of Erlangen-Nürnberg, Slovenia*
Micro- and nanoplastics (MNPs) are one of the most widespread pollutants of our time. They can be manufactured in specific size for a specific purpose or be released into the environment through the degradation of plastic products. Humans are generally exposed to MNPs via two main routes: food ingestion or inhalation of air. In the latter case, it has already been reported that airborne particles can enter and accumulate in the lower respiratory tract, leading to occupational diseases in textile workers. The aim of this study is to assess the impact of 300 nm europium doped polystyrene (PS-Eu) particles on the integrity and functionality of the lung barrier, especially in terms of surfactant production. In this context, the use of europium doped particles is instrumental to study particle translocation and uptake as europium is a fluorescent heavy metal that can be detected via different imaging techniques. After characterizing our particles in detail, we performed standard cytotoxicity assays on A549 cells grown under submerged conditions and found that PS particles can affect the activity of acidic organelles in a dose-dependent manner using the neutral red uptake assay. In contrast, no effects of PS-Eu on viability were detected using lactate dehydrogenase (LDH) or resazurin assay, although particle uptake was confirmed by TEM. We then examined the effects of PS-Eu on the same cells grown either in air-liquid interface (ALI) or submerged conditions using transwells. No clear effects on epithelial permeability or electrical resistance were detected by Lucifer Yellow assay or TEER measurement. Similarly, these particles did not appear to induce cell death or translocate towards the barrier compared to controls. However, a dose-dependent decrease in surface tension associated with increased mitochondrial activity was observed in both types of culture systems. Overall, this could indicate that the nanoplastics may boost, upon uptake, surfactant production and influence vesicle acidification (which are both ATP-demanding processes) ultimately leading to an increase in mitochondrial respiration to meet the new energetic requirements. Future analysis aiming to study the production and recycling of surfactants by ELISA and TEM could shed more light on the molecular mechanisms triggered by these particles.

4.13.P-Mo415 Correlative Spectroscopy and Microscopy Analysis of Micro- and Nanoplastics in Complex Biological Matrices

George Sarau, *Fraunhofer Institute for Ceramic Technologies and Systems (IKTS), Germany*
Micro- and nanoplastic (MNP) particles are widespread environmental pollutants, with recent studies detecting their presence in various human tissues and bodily fluids. However, the precise detection and quantification of MNPs in biological samples, particularly nanoplastics, face challenges due to biological backgrounds and variations in sample preparation, measurement settings, and data evaluation protocols. Here, we developed novel analytical workflows based on context application of cutting-edge spectroscopy and microscopy techniques supported by Machine Learning (ML) data evaluation to enable identification and differentiation of MNPs in intricate biological contexts, associated with human interaction. We utilized optical and electron microscopy methods for high-resolution imaging at various scales, complemented by spectroscopy techniques for definitive MNP identification based on their chemical fingerprint. In-vitro exposure of human lung Calu-3 cells to polystyrene (PS) particles (<2 µm in diameter) in a submerged setting resulted in cell adhesion and ingestion, as confirmed by Scanning Electron Microscopy (SEM) and 3D Stimulated Raman Scattering (SRS) imaging. The existence of PS particles both on the cell surface and within cells hinders nutrient absorption, leading to cytotoxic effects, as evidenced by cell viability assays, particularly at a PS concentration above 1 mg/ml. Adaptive ML algorithms applied to SRS images facilitated MNP localization, counting, and categorization by size and shape. Zebrafish and mouse in-vivo exposure to PS particles through drinking led to organ accumulation, with zebrafish taking up 50 nm PS particles via digestion, as measured by Fluorescence (FL) and SRS. Mice showed 250 nm PS particles in various organs including brain, indicating blood-brain barrier crossing and accumulation at lipid-rich regions, as shown by Second Harmonic Generation (SHG), SRS, and Coherent Anti-Stokes Raman Scattering (CARS). This study demonstrates how correlative molecular and microscopy imaging can be employed to detect MNPs in complex biological matrices and understand their effects and fate, focusing on cytotoxicity, disruption of nutrient uptake, and organ accumulation. These findings reveal MNPs' translocation across cells, tissues, and organs, being relevant to human exposure through inhalation and ingestion and providing grounded risk assessment.

4.13.P-Mo416 True-to-life Nanomaterials for Evaluating Nanoplastics Impacts on Human Health
Serena Ducoli[1], *Stefania Federici*[1], *Miriam Romano*[2], *Andrea Zendrini*[2], *Paolo Bergese*[2] *and Laura Eleonora Depero*[1], *(1)University of Brescia, Department of Mechanical and Industrial Engineering, Italy, (2)University of Brescia, Department of Molecular and Translational Medicine, Italy*
Environmental nanoplastic pollution is a great issue affecting all ecosystems. The need to understand the possible implications of nanoplastic pollution on the environment and human health is becoming increasingly pressing. Given the complexity of separating nanoplastics from environmental samples, studies have been so far conducted using synthetic polystyrene nanobeads (NBs). There is an urgent need to create nanomaterials that better reflect the real characteristics of nanoplastics naturally formed, viz. true-to-life nanoplastics (T2LNPs), to close the gap between the laboratory parameters and the rules of nature, and to provide more realistic understandings of the characteristics of nanoplastics.

Here, we present a study on the production and characterization of T2LNPs from daily-used plastics, the investigation of bio-interfaces through the study of protein corona formation on T2LNPs with respect to synthetic NBs, and the assessment of their toxicity of human cells. T2LNPs samples were produced from daily life plastic items subjected to mechanical fragmentation through an ultracentrifugal mill operating in cryogenic conditions. The produced T2LNPs were characterized by Fourier transform Infrared spectroscopy to investigate their chemical nature and check the absence of induced chemical modifications. Morphology and size distribution analyses were performed through Atomic Force Microscope and Scanning Electron Microscopy. Finally, the protein corona formation from human plasma on T2LNPs and NBs was examined by electrophoresis and *in-vitro* toxicity at different exposure time and concentrations was assessed through MTT assay.

The differences detected in the protein corona profiles of T2LNPs and NBs confirm the gap between controlled models and the complexity in real-life scenarios, supporting the need to develop true-to-life materials as reasonable models for environmental nanoplastics. The broad heterogeneity in size and shape shown by fragmented T2LNPs gives the nanomaterial a peculiar and different behavior compared to the defined pristine nature of NBs, nominating T2LNPs as a more faithful material for naturally occurring nanoplastics and opening the possibility to new and unexpected results in biological interactions, as suggested by the preliminary results of *in-vitro* toxicity tests.

4.13.P-Mo417 Human oral exposure to nano- and microplastic polymers and plastic additives in a cross-sectional population-based study of Barcelona (Spain)
Emma Calikanzaros[1], *Carolina Donat-Vargas*[2], *Marta Llorca*[3], *Marinella Farre*[3] *and Cristina Villanueva*[2], *(1)University Pompeu Fabra (UPF), Spain, (2)Barcelona Institute for Global Health (ISGlobal), Spain, (3)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*
BACKGROUND: Micro and nanoplastics (MNPs) are emerging contaminants found in food, drinking water, and air. Humans are continuously exposed to MNPs through ingestion and inhalation. However, the magnitude of the exposure in the population and the associated potential health effects remain unknown. **OBJECTIVES:** We characterized human exposure to MNPs and plastic additives through drinking water and food in the general adult population of Barcelona, Spain. **METHODS:** The study population includes 50 healthy adults of the Metropolitan Area of Barcelona. Personal information on diet, socio-demographics, lifestyle, *etc.* has been ascertained through questionnaires. We conducted home visits to collect tap water samples (5 liters). Food consumed during 4 days was collected in a subset (N=10). Water samples were first filtered through a stainless-steel sieve with a 20 µm mesh, followed through a 0.70 µm glass microfiber filter. An ultrasonic-assisted extraction was performed to extract MNPs with 10 mL of toluene for 10 minutes. For MNPs analyses, a double suspect screening

approach based on size exclusion liquid chromatography combined with high-resolution mass spectrometry (LC(SEC)-HRMS) was employed. Plastic additive analyses were carried out based on high-performance liquid chromatography coupled to HRMS. Statistical analysis included a univariate description of variables. **RESULTS:** A total of 49 tap water samples were analyzed, with 26% of samples containing polyethylene (median 1016.6 ng/L; range 26,75 – 8114,0). Polyisoprene was detected in 1 sample (0,63 ng/L). All tap water samples revealed the presence of 9 to 10 different plastic additives above detection limits, with varying quantification rates. Dipropylene glycol dimethyl ether was quantified in 44 (90%) samples, tributyl phosphate in 28 (57%), triethyl phosphate in 22 (45%), laurolactam in 21 (43%), diethyl phthalate in 19 (39%), diacetone acrylamide in 3 (6%), hexamethylcyclo-trisiloxane in 1 (2%), and triphenyl phosphate, tris (2-butoxyethyl) phosphate, and dibutyl phthalate in none. Diethyl phthalate displayed the highest concentrations (median 5.91 ng/L). When compared to previous studies in Barcelona, we observed lower occurrence of polymers, suggesting temporal variability. Results for food items will be available for the time of the conference. **IMPACT:** This project generates novel scientific evidence on the extent of exposure to MNPs as a basis for further health risk assessments.

4.13.P-Mo418 Cytotoxic And Genotoxic Effects Of Nanopolystyrene And Bisphenol A Per Se And In Combined Exposure In A Gastric Cell Line – How High Is The Current Exposure Risk?

*Cláudia Brito[1], Ana Ramos[1], Edna Ribeiro[1], **Luís André Mendes**[2] and Carina Ladeira[1,3,4], (1)H&TRC – Health & Technology Research Center, Escola Superior de Tecnologia da Saúde de Lisboa (ESTeSL), Instituto Politécnico de Lisboa, Portugal, (2)University of Vigo, Spain, (3)NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Portugal, (4)Comprehensive Health Research Center (CHRC), Universidade NOVA de Lisboa, Portugal*

Currently, due to the massive use of plastics worldwide, it is inevitable that nanoplastics (NPs) and its additives such as plasticizers, including Bisphenol A (BPA), enter in the body as single substances or/and as mixtures. NPs present a high hazardous potential given the evidence of toxic effects on a cellular level and the levels of plastic oral exposure via ingestion and absorption of these substances in gastric tissues. Furthermore, the ability of acting as a vector for other pollutants and its ability to be internalized by cells potentiate long term effects. Therefore, in order to efficiently assess the risk for human health, it is crucial to evaluate the exposure response in complex and realistic scenarios.

The aim of this *in vitro* study was to investigate the cytotoxic and genotoxic effects of polystyrene (PS)-NPs and BPA through individual and combined exposures on the gastric GP202 cell line. Environmental relevant concentrations previously tested in literature were selected, for PS-NPs - 20, 100 and 200 µg/mL and for BPA - 0.1, 1 ng/mL, and 0.04 ng/mL as the new reference value proposed by EFSA. Cytotoxicity was assessed by Cell Titer- Blue® assay and genotoxicity by cytokinesis-block micronucleus assay, following the 487 OECD Guideline. Colchicine (5µg/mL) was used as positive control.

Our results indicate no cytotoxicity associated to either individual or combined exposures of NPs and BPA. Regarding to genotoxicity it was found that all the endpoints – micronucleus, nucleoplasmic bridges and nuclear buds – were significantly increased in the worst case-scenario of combined exposure (200 µg/mL PS NPs + 1 ng/mL BPA) (69±6.15, 26±2.73 and 37±3.15) in comparison with negative control (40±6.56, 11±1.53 and 4.0±0.58), respectively. These results highlight the importance of further studies with combined exposures of NPs and BPA in order to develop, carry out and evaluate the safety risks of chemical mixtures.

4.13.P-Mo419 Influence of in vitro Gastrointestinal Digestion and UV-Aging of Tire Rubber Microplastics on the Release of Chemical Additives and Toxicity Assessment

***Amelie Vogel**[1], Emeka Ephraim Emecheta[2], Antje Bergert[2], Roman Schmidt[2], Alexander Roloff[3] and Andrea Haase[4], (1)Technical University Berlin, Germany, (2)BfR Federal Institute for Risk Assessment, Germany, (3)Chemical and Product Safety, German Federal Institute for Risk Assessment (BfR), Germany, (4)Federal Institute for Risk Assessment (BfR), Germany*

Microplastics (MPs) contain a broad variety of additives, including antioxidants or plasticizers, along with unreacted monomers and sorbed contaminants. Traffic abrasives from tires and crumb granulates from discarded tires have emerged as significant contributors to MP pollution. Concerns have often arisen about the potential for toxic compounds to leach from MPs, yet implications for human health are not well understood.

In this study, we investigated the release of potentially toxic chemicals from three types of polydisperse MPs: tire rubber (TR), polyamide-6 (PA-6), and thermoplastic polyurethane (TPU). The effects of *in vitro* digestion in human gastrointestinal fluid simulants and UV-aging of the MPs on the chemical leaching was investigated. Leached chemicals were analyzed using gas chromatography-mass spectrometry. Released metal contents were quantified by microwave-assisted extraction followed by inductively coupled plasma-mass spectrometry. All MPs were characterized for their cellular effects, specifically for cell viability and cytochrome P450 1A1 (CYP1A1) induction in human intestinal CaCo-2 cells.

Most chemicals were leached from TR particles. In particular, benzothiazole (~170 µg/g), (3H)-benzothiazolone (~168 µg/g) and zinc (~1150 µg/g) were quantified in high concentrations in small and large intestine fluid simulants. Cell viability did not decrease within 24 h of exposure. TR particles induced CYP1A1, but this effect decreased after UV-aging. Benzothiazole derivatives as well as diethyl and dibutyl phthalates were identified as important contributors to CYP1A1 induction. Selected leached additives were further investigated for potential toxic effects by utilizing the EPA ToxCast database, revealing links of

20 leached compounds to specific adverse outcome pathways. Our findings indicate that the release of specific additives, particularly from TR particles, might pose a risk to human health and that *in vitro* digestion and UV-aging modulated the leaching of these additives.

4.13.P-Mo421 Washable vs Disposable Face Masks: Million microfiber releases and their toxicities

Yuyue Huang[1], *Ayoub Laghrissi*[2], *Jacek Fiutowski*[3], *Martin Aage Barsøe Hedegaard*[4], *Xiaoyu Duan*[5], *Xin Wang*[6], *Mohamed Helal*[6], *Henrik Holbech*[7] *and Elvis Genbo Xu*[6], *(1)Southern of Denmark, University of Southern Denmark, Denmark, (2)NanoSyd, NanoSyd, University of Southern Denmark, Denmark, (3)NanoSyd, University of Southern Denmark, Denmark, (4)Department of Green Technology, University of Southern Denmark, Denmark, (5)Department of Biology, University of Southern Denmark, Denmark, (6)Biology, University of Southern Denmark, Denmark, (7)University of Southern Denmark, Denmark*

The widespread use of face masks has raised environmental concerns related to microplastic fibers. While various studies have explored the release of microfibers from disposable masks in controlled environments, their release in real-life conditions has been understudied. Similarly, the release of microfibers from washable masks has received limited attention. In this study, we comprehensively investigated the release and toxicity of microfibers from disposable and washable masks in simulated aquatic environments and real-life scenarios (disinfection, hand washing, and machine washing). We quantified microfiber release using Nile red visualization and identified the polymer composition by µ-Raman spectrometry. Our findings revealed that disposable masks released microfibers ranging from 18 to 3042 microfiber/piece, whereas washable masks released 6.1×10^4 - 6.7×10^6 microfibers/piece. Hand and machine washing released a higher number of microfibers among all simulated conditions. Notably, a negative correlation was observed between microfiber release and the proportion of embossing on the surface of disposable masks. Microfibers from disposable masks primarily comprised polypropylene (PP), while washable masks predominantly released polyethylene terephthalate (PET) and cellulose microfibers. Furthermore, our results indicated that PP microfibers affected the swimming behavior of zebrafish, while PET microfibers hindered early-stage zebrafish hatching. This study offers new insights into the source of microplastic fibers in realistic settings and contributes to our understanding of the environmental impacts of discarded face masks and microfibers, with implications for both environmental and human health.

Keywords: Single-use masks, Reusable masks, Microplastics, Microfiber shedding, Microfiber release, Biological impacts, Toxicity, Zebrafish.

4.13.P-Mo422 Pro-inflammatory responses in cells induced by nanoplastic exposure

Joana Antunes[1], *Paula Sobral*[1], *Marta Martins*[1] *and Vasco Branco*[2], *(1)MARE - Marine and Environmental Sciences Centre, ARNET - Aquatic Research Network Associate Laboratory, Portugal, (2)Research Institute for Medicines (iMed.Ulisboa), Faculty of Pharmacy, Universidade de Lisboa*

The increasing global production of plastic items has led to a critical pollution issue, namely due to their improper disposal in the environment, especially in marine ecosystems. Polystyrene, one of the most produced polymers in 2021, finds extensive use in packaging, insulation, electronics, and construction. The exposure of this material to environmental factors facilitates fragmentation into smaller particles, namley into nanoplastics (NPs), posing substantial threats to both animal and human health.

NPs has the capacity to traverse biological membranes, are easily ingested and have a great potential to bioaccumulate in organisms. Internalization of NPs is associated with oxidative stress and tissue damage, with potential disruptions to membrane receptors and activation of inflammatory signaling cascades, inducing inflammation and several adverse outcomes. However, the underlying mechanisms of these effects are poorly understood. This study hypothesized that NPs induce inflammatory signaling through the NF-κB and/or p38 MAPK pathways. To test this hypothesis, human colorectal adenocarcinoma cells (HT29) and mouse microglia cells (N9) were exposed to different concentrations and sizes of polystyrene NPs. Cell viability, protein expression levels of p50 NF-κB subunit, p38, and TLR4, as well as pro-inflammatory gene transcription, namely IL-1β , iNOS and TNFα were assessed.

Results indicated that NPs did not significantly impact HT29 cell viability but markedly reduced N9 cell viability, especially with smaller-sized particles. Nuclear translocation of p50 NF-κB and p38 was observed in HT29 cells, suggesting inflammatory responses. However, N9 cells exhibited no significant variations in translocation. Pro-inflammatory gene expression showed increased IL-1β in both cells and iNOS in N9 cells, with TLR4 and p38 inhibitors attenuating these responses.

In conclusion, this research highlights the inflammatory effects of NPS, with variability depending on cell type and signalling pathways. TLR4 appears to play a central role, and further investigation is needed to elucidate the involvement of additional factors such as p38. The study underscores the potential disruption of tissue homeostasis by nanoplastics, emphasizing the need for continued research to understand their implications for inflammation and human health.

4.13.P-Mo423 Combined effects of polyethylene nanoplastics and mercury on viability and migration capacity of human cell lines

Fernanda De Oliveira Esteves Rosário[1]*, Ana Teresa Reis*[2,3,4]*, Teresa Rocha-Santos*[5] *and Helena Oliveira*[6]*, (1)University of Aveiro, Portugal, (2)Department of Environmental Health, Portuguese National Institute of Health, Portugal, (3)EPIUnit, Institute of Public Health, University of Porto, Portugal, (4)Laboratory for Integrative and Translational Research in Population Health (ITR), Portugal, (5)Chemistry, Centre for Environmental and Marine Studies (CESAM) and Department of Biology, University of Aveiro, Portugal, (6)Centre for Environmental and Marine Studies (CESAM) and Department of Biology, University of Aveiro, Portugal*
The accumulation of plastic waste and the widespread presence of its degradation products, micro- and nanoplastics, demand an urgent evaluation of their potential health risks. Nanoplastics (NPLs) have a negative impact on human health and the environment due to their high persistence and high level of fragmentation. In the environment, NPLs coexist and interact with pre-existing contaminants, leading to biological effects (bioaccumulation and/or toxicity) that are poorly understood. Metal(loids) have a particular affinity for nanoadsorbents, and considering their persistent and toxic nature it is imperative to assess the toxic profile resulting from these interactions. Therefore, this work assesses and compares the joint effects of two relevant water contaminants: polyethylene nanoplastics (PENPLs) and mercury (Hg), on the major routes of human exposure: inhalation and ingestion. For that, A549, HepG2 cells were exposed to single and binary mixtures of PENPLs at 6.25 – 400 µg/mL and Hg 0.5 - 40 mg/L. For binary mixtures, two concentrations were selected based on the results of single exposure: (1) no observed effect concentration and (2) lowest observed effect concentration. Viability was assessed by MTT after 24 hours exposure and the ability of a single cell to grow into a colony was assessed by the colony formation assay after 7 days exposure. Meanwhile, cell migration, a biological process that is critical to a variety of physiological functions such as inflammatory responses, was assessed by wound healing assay at 0, 6, 24h. Our results showed that PENPLs can induce cytotoxicity to human cell lines after 24h for concentrations above 50 µg/mL and for prolonged exposure (7days) cytotoxicity was visible for lower concentrations (6.25 µg/mL). Migratory capacity was decreased after 24h exposure, in a concentration-dependent manner. The relative migration rate of A549 and HepG2 cells treated with only PENPLs was 25% and 11% at 24h, respectively. We hypothesised that i) PENPLs significantly enhance Hg toxicity; ii) PENPLs co-exposure with Hg will affect each other's individual toxicity, either by antagonism or synergy; iii) migratory capacity will be affected differently in cells exposed to binary mixtures. The results of this study will improve our understanding of how NPLs affect human health and provide insights into the complex interactions between NPLs and metals, contributing to a comprehensive assessment of their combined toxicity in humans.

4.13.P-Mo424 Developing Human Noncancer and Reproductive/Developmental Effect Factors for Nano- and Microplastics in LCA

Arthur Léo, Simon Beteille[1]*, Eva Prötzl*[2]*, Olivier Jolliet*[3] *and* ***Anne-Marie Boulay***[4]*, (1)CIRAIG Polytechnique Montreal, Canada, (2)Technical University of Munich (TUM), Germany, (3)Department of Environmental and Resource Engineering, Quantitative Sustainability Assessment, Technical University of Denmark, Denmark, (4)CIRAIG - Ecole Polytechnique de Montreal, Canada*
Background: Nano- and microplastics (NMPs) are ubiquitous in our environment (air, water, food chain) and their presence is believed to be responsible for numerous effects on ecosystems and human health. However, toxicological assessment of potential impacts of NMPs on human health is still lacking in life cycle impact assessment (LCIA), and the detection of these microparticles in human bodies has made it crucial to better understand and characterise such potential impacts.

Objective: The aim of this research is to develop human noncancer and reproductive/developmental effect factors for NMPs in LCIA as part of the MarILCA project, based on the study of *in* vivo animal data and the latest framework in human health impact assessment

Methods: Experimental studies concerning *in vivo* mammal toxicity, and in which a critical effect was observed through daily oral ingestion of NMPs (virgin or with additives) were selected. The obtained curated database was then processed to generate a representative chronic human benchmark dose (BMDh), later extrapolated into an effect factor for LCIA.

Results: A preliminary regulatory BMDh for general noncancer effects of polystyrene NMP changes from 1.06·10^(-2) (all recovered data) to 2.07·10^(-2) mg/(kg.d) when considering only true adverse data (when an experiment). The associated effect factors are 44.0 and 22.7 DALY/kg for all and real adverse data respectively. Concerning reproductive/ development effects, BMD_hwere found of the same order of magnitude (2.13·10^(-2) to 3.21·10^(-1) mg/(kg.d)) with a calculated effect factor of 404.3 or 26.8 DALY/kg for all and real adverse data respectively.

Discussion: Polystyrene NMP has been allegedly found among the most toxic chemicals. This research calls for a larger discussion and deeper analysis of the obtained results to (in)validate them, as the findings are concerning. Future research into NMPs is needed to improve our understanding of their mode of action and factors affecting their potential effects.

4.13.P-Mo425 Production and Testing of Micro- and Nano-PET Materials for Human Digestion and Enzymatic Hydrolysis Studies

Victor Alcolea-Rodríguez[1]*, Iris Pinillos*[2]*, Laura Fernandez-Lopez*[1]*, Julian J. Reinosa*[3]*, José F. Fernández*[3]*, Mikel Roldán*[2]*, Manuel Ferrer*[1]*, M. Victoria Moreno-Arribas*[2]*, Miguel A. Bañares*[1] *and* ***Raquel Portela***[4]*, (1)ICP, Spanish National Research Council (CSIC), Spain, (2)Cial, Spanish National Research Council (CSIC), Spain, (3)Icv, Spanish National Research Council*

(CSIC), Spain, (4)ICP, Spanish National Research Council (CSIC), Madrid, Spain
MNP research is a rapidly growing field, but it is hampered by the lack of relevant, harmonised analytical techniques as well as test and reference materials with a variety of controlled properties, which are essential for representative, accurate and reproducible results. The aim of this work is to present current options for laboratory production of micro-and nano-sized particles of polyethylene terephthalate (PET), one of the most common polymers that has been detected, among other matrices, in beverages and human feces, suggesting an active interaction with the human digestive system. Irregular PET MPs obtained by a mechanical top-down method were subjected to simulated static gastrointestinal digestion (INFOGEST method) and dynamic colonic fermentation (simgi®) in vitro to investigate the mechanism and effects of this interaction that may potentially lead human health risks; the microPET suffered biotransformations and altered the microbiota. Spherical PET NPs, obtained by dissolution and subsequent precipitation, were submitted to enzymatic hydrolysis by a recently engineered protein nanopore (npFraC$_{m1}$) to evaluate innovative end-of-life biotechnology-enabled strategies for PET re- or up-cycling that may minimize the plastic debris. µ-Raman spectroscopy, a powerful technique to characterise filtered samples in terms of polymer type as well as particle number, shape and size distribution up to sub-micron sizes, is used in this work to monitor both processes as well as the synthesis, to obtain relevant structural information from the MNPs. The results highlight the pivotal role of advanced analytical techniques and tests materials in unraveling the intricacies of polymer degradation pathways and effects.

4.13.P-Mo426 Chronic Effects of Nano and Microplastics on Reproduction and Development of Marine Copepod Tigriopus Japonicus

Kanghee Kim[1], Hakwon Yoon[1], Jin-Soo Choi[1], Youn-Joo Jung[1], Yunwi Heo[1] and ***June-Woo Park**[1,2]*, *(1)Korea Institute of Toxicology (KIT), Korea, Republic of (South), (2)Human and Environmental Toxicology Program, Korea University of Science and Technology (UST), Korea, Republic of (South)*

This study aimed to examine the impact of chronic (30 days) exposure to polystyrene microplastics (PS-MPs) of different sizes (50 nm and 2 µm) and at different concentrations (0.5 µg/L and 100 mg/L) to marine copepod *Tigriopus japonicus*. Polystyrene microplastics affected survival rates in size- and concentration-dependent manners. The LC$_{50}$s values of 50 nm and 2 µm PS-MPs were 0.10 mg/L and 3.92 mg/L, respectively. The developmental time was delayed by 50 nm PS-MPs, and *Usp* expression was downregulated. Reproduction was negatively affected by 2 µm PS-MPs even at environmentally relevant concentrations; however, the expression of *Vtg* was not altered. The production rates of reactive oxygen species and nitric oxide also increased after exposure to PS-MPs; but this effect was independent of particle size. The expression levels of *Cat* and *Tnf*, genes related to oxidative stress and inflammation, respectively, were upregulated by exposure to PS-MPs, independently of particle size. Meanwhile, the level of oxidative stress in *T. japonicus* was not significantly affected by PS-MPs at environmentally relevant concentrations. This study suggests that nano-sized PS-MPs are not always more toxic than micro-sized PS-MPs, and that oxidative stress is a key factor in determining the toxic effect on *T. japonicus* at high concentrations.

4.13.P-Mo427 In Vitro Cell Transforming Capacity of 3D Printed Objects-Derived Plastic Particles

Adriana Rodríguez-Garraus[1], Mari Venäläinen[1], Jussi Lyyränen[1], Apostolos Salmatonidis[2], Hanna Pulli[1], Davide Lotti[3], Josefa Domenech[1], José F. Fernández[4], Jesús Guzmán-Mínguez[5], Alberto Katsumiti[6], Isabel Rodríguez-Llopis[7], Socorro Vázquez-Campos[2], Marie Carriere[8] and ***Julia Catalán**[1]*, *(1)Finnish Institute of Occupational Health, Finland, (2)Leitat Technological Center, Spain, (3)LATI Industria Termoplastici S.p.A., Italy, (4)Icv, Spanish National Research Council (CSIC), Spain, (5)Instituto de Cerámica y Vidrio, ICV-CSIC, Spain, (6)GAIKER Technology Centre, Spain, (7)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (8)Univ. Grenoble Grenoble Alpes, CEA, CNRS, IRIG-SyMMES, CIBEST, France*

Humans are continuously exposed to micro- and nanoplastics (MNPs) generated from the fragmentation of larger waste plastics. MNPs can accumulate in tissues and organs, raising concerns on their potential effects on human health, especially the induction of cancer. Opposite to the expensive and ethically concerned carcinogenesis studies in rodents, *in vitro* cell transformation assays (CTA), as the validated Bhas-42 CTA, allow the *in vitro* simulation of the *in vivo* initiation and promotion stages of carcinogenesis.

The aim of the present study was to assess the cell transforming capacity of MNPs generated during breaking down and degradation of 3D printed objects at the end of the lifecycle. For that purpose, different materials were generated by cryomilling 3D objects printed using four different types of plastic fibers: polycarbonate without and with single walled carbon nanotubes (PC and PC-CNT, respectively), and polypropylene without and with silver nanoparticles (PP and PP-Ag, respectively). Then, the materials were sieved to obtain particles below 5 µm, which were characterized and dispersed in water according to the NanoGenotox protocol. The cell transformation and concurrent cell growth assays were performed as recommended by the OECD guidance 231. Bhas 42 cells were treated with each type of particles (6.25 – 100 µg/mL) either from day 1 to 4, or from day 4 to 14, for the initiation and promotion assays, respectively, and the number of transformed foci was scored on day 21. Parallel cultures were set to assess cell growth, cellular internalization and the expression of genes involved in cell proliferation and adhesion on day 7.

Under the exposure conditions of the initiation assay, a dose-dependent decrease in cell growth was observed for all the materials, and it was especially pronounced for PP-Ag particles. On the other hand, a slighter effect was observed under the promotion conditions. None of the particles significantly increased the number of transformed foci in the initiation or promotion assays, despite having been efficiently internalized by the Bhas 42 cells. Gene expression analyses are in progress.

In conclusion, none of the 3D printed objects-derived MNPs analyzed in the present study seem to induce the transformation of Bhas-42 cells either by genotoxic or non-genotoxic modes of action.

This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No. 862419 (SAbyNA).

4.13.P-Mo428 The Fate and Effects of Micro and Nanoplastics in the Human Body – Insights from the EU-funded PlasticsFatE Project
Mark David Morrison[1], *Lesley Tobin*[1], *Hildegard Luhmann*[2] *and Rudolf Reuther*[3], *(1)Optimat Ltd., United Kingdom, (2)European Research Services, (3)ENAS*
In the environment, plastics degrade slowly to micro-plastics (MP) (< 5 mm) and nano-plastics (NP) (< 1 um). These can consist of a complex mixture of polymers and associated chemicals (AC) added to improve performance or adsorbed from the environment. There is strong evidence that humans are exposed to MNP through diet, drinking water or inhalation. However, our understanding of the extent of human exposure to MNP is poor. One challenge in assessing the impact of MNP and AC on human health is ensuring our measurement and testing methods are capable of producing reliable data. Despite progress in measuring plastic particles in environmental media, reliable measurements and toxicity testing of these particles in the human body, in food, drinking water or air is lacking, even more so for NP that may enter human cells. This hampers the development of standards and test guidelines for science-based risk assessment and the implementation of relevant policies and regulations.

We have established a test materials strategy, using a range of polymers that humans are routinely exposed to, to address these issues. These materials have been produced by established physicochemical and mechanical techniques and characterised by relevant measurement methods. We have further developed methods for measuring MNPs in complex matrices, such as food, beverages and human tissues. This has provided us with a solid foundation on which to assess these materials in a variety of *in vitro* and *in vivo* model systems, that mimic normal exposure routes for humans (mainly inhalation and ingestion). Importantly, these well-characterised materials allow comparison and read across of different experiments.

Most of the common plastics have very limited effects on biological systems when in pure or virgin form. However, many contain additives when processed into final products, can change their physicochemical properties as they age and can adsorb contaminants from the environment during their use phase. These additional chemical and biological materials can be carried across cellular barriers, leading to inflammatory and cytotoxicity responses. We have also observed bacterial colonisation of microplastics and gene transfer between bacteria on microplastics and tyre wear particles.

This knowledge has been applied in a series of occupational and environmental case studies to investigate exposure and biological responses to MNPs of workers at plastic packaging, production and recycling sites.

4.13.P-Mo429 The European Research Cluster to Understand the Health Impacts of Micro- and Nanoplastics - CUSP
Mark David Morrison[1], *Roel Vermeulen*[2], *Runyu Zou*[3], *Tanja Ćirković Veličković*[4], *Michelle Epstein*[5], *Alba Hernández Bonilla*[6], *Raymond Pieters*[7], *Rudolf Reuther*[8] *and Ricardo Marcos Dauder*[9], *(1)Optimat Ltd., United Kingdom, (2)Utrecht University, Netherlands, (3)UMC Utrecht, Netherlands, (4)University of Belgrade, (5)Medical University of Vienna, (6)Genetics and Microbiology, Autonomous University of Barcelona (UAB), Spain, (7)Institute for Risk Assessment Sciences, Utrecht University, Netherlands, (8)ENAS, (9)Autonomous University of Barcelona (UAB), Spain*
Micro- and nanoplastics (MNPs) are in the environment and part of our everyday life. They find their way into our body through the food we eat, the water we drink and the air we breathe, yet we currently do not know how they might be affecting human health. They may emanate from the degradation of larger plastic items, or are intentionally manufactured and added to commercial products such as cosmetics, synthetic textiles or paints. Pollutants, such as heavy metals, allergens, toxicants, and microorganisms, can latch on to them and may further endanger the environment as well as human and animal health.

CUSP brings a critical mass of researchers together that are funded through 5 Horizon 2020 projects to investigate the effects of MNPs on human health. While each project has a unique focus all are collaborating closely across a number of areas to maximise impacts. This has included sharing materials, standard operating procedures and results, and participating in interlaboratory studies. Highlights from our work are presented below.

- Developed a list of common materials and SOPs that are available to partners across the projects to access, thus increasing the opportunity to extend and enhance experiments through additional efforts and read across to different systems.
- Contributed to a successful interlaboratory comparison study under VAMAS to assess the ability of different microscopy and spectroscopy methods to accurately measure particle numbers and mass fractions of different plastics.
- Compiled an AI-assisted systematic review of the current evidence on human internal exposure to MNPs in different sample matrices, and identified key aspects of exposure assessment, notably uncertainties in the sample analysis, methodological improvement opportunities, assessing the quality of biomonitoring data and their regulatory relevance.
- Investigated the optimisation of human biomonitoring studies through sharing data and samples and extending the analysis performed by individual partners to benefit the data requirements of others

All CUSP data and metadata are being stored in eNanoMapper to ensure that knowledge gained is accessible for future research. Furthermore, we have published policy briefs that assesses relevant EU regulations and strategies across diverse fields including plastics, chemicals, water, food and the circular economy and identify where CUSP research can help address science-policy gaps.

4.13.P-Mo430 Interlaboratory comparisons for obtaining reliable data on microplastic detection methods

Dmitri Ciornii[1]*, Dan Vasile Hodoroaba*[2]*, Nizar Benismail*[3] *and Korinna Altmann*[4]*, (1)Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (2)Materials Chemistry, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (3)Nestle Waters MT, France, (4)Federal Institute for Materials Research and Testing (BAM), Germany*

Since microplastics can be found everywhere and are becoming a problem of high concern, it is necessary to understand their fate and occurence in the environment. To obtain reliable analytical data a set of validated methods for sampling, sample preparation, detection, and data evaluation are needed.

One way to adress these issues is an interlaboratory comparison. The interlaboratory comparison on microplastic detection methods has been organized under the international pre-standardisation platform VAMAS as Project 2 “Development of standardized methodologies for characterisation of microplastics with microscopy and spectroscopy methods” under the Technical Working Area TWA 45 “Micro and Nano Plastics in the Environment”. In this interlaboratory comparison thermo-analytical methods (Pyrolysis Gas Chromatography Mass Spectrometry and Thermal Extraction - Desorption Gas Chromatography Mass Spectrometry) and vibrational methods (µ-Raman and µ-Infrared Spectroscopy) have been tested and compared by providing a set of microplastic reference materials and standard operating protocols developed at Bundesanstlt für Materialforschung und -prüfung. It was asked for particle number concentration, particle size distribution, polymer identity and mass fraction. To increase the statistical quality, 6 samples were shipped next to blank samples. The interlaboratory comparison will provide information on precision and accuracy of the methods as well as strengths and weak points in the proposed standard operating protocol.

4.13.P-Mo431 Nanoplastics Affect the Behavior of the Different Cell Populations in Peripheral Blood from Healthy Donors

Jéssica Arribas Arranz[1]*, Claudia Pommerenke*[2]*, Javier Gutiérrez*[1]*, Raquel Egea*[3]*, Aliro Villacorta*[3]*,* ***Ricardo Marcos Dauder***[1] *and Alba Hernández Bonilla*[3]*, (1)Autonomous University of Barcelona (UAB), Spain, (2)Leibniz Institute DSMZ-German Collection of Microorganisms and Cell Cultures, Germany, (3)Genetics and Microbiology, Autonomous University of Barcelona (UAB), Spain*

Humans can internalize nanoplastics (NPLs) through inhalation and ingestion due to their small size, allowing for their absorption, reaching the bloodstream, and permitting their systemic biodistribution. Indeed, NPLs have been detected in human whole blood samples representative of the general population.

While some knowledge of the hemocompatibility and inflammatory effects of specific NPLs exists (mainly from *in vitro* studies), humans will be exposed to a heterogeneous mixture of NPLs that varies, among others, regarding the polymer type. Since information is missing, our study aims to characterize the effects of different NPL polymers in human whole blood.

We used an *ex vivo* model in which we exposed human peripheral blood from healthy donors not only to the NPL most used polystyrene but also to polyethylene terephthalate and polylactic acid. To explore the influence of the NPLs physicochemical characteristics on the analyzed effects, different sizes, and surface modified NPLs were chosen. After 24h of blood exposure to NPLs, white blood cells (WBC) were isolated and processed for scRNA seq. Furthermore, as cell-based endpoints, we determined the platelet activation due to NPLs exposure and the internalization rates for each major type of WBC separately as well as the induction of intracellular reactive oxygen species after NPLs *ex vivo* exposure. In addition, we assayed NPLs haemotoxicity measuring the hemolysis and changes in clinical coagulation parameters. Finally, to study potential secretome alterations, we evaluated the expression levels of a panel of representative cytokines.

This study provides the first report of the toxic effects of NPLs on human blood. Through an *ex vivo* model, we have been able to show the different rates of NPLs depending on their polymer nature in the three major WBC (lymphocytes, polymorphonucleated cells, and monocytes). The NPLs toxicity might be associated with ROS and hemolysis generation. In addition, we also report enhanced inflammatory signals by the induction of pro-inflammatory cytokines. Remarkably, the analysis of the scRNA seq data has permitted us to identify differentially expressed genes for the different NPLs exposures, suggesting the influence of NPLs in the production of an inflammatory environment in the body, thus altering human health.

Overall, these findings show us for the first time the NPLs effects on human blood cells and emphasize that may be fundamental to control NPLs exposure.

4.13.P-Mo432 Describing the Fate of Food Packaging-Derived Nanoplastics in the Intestinal Epithelium

Alba Garcia-Rodriguez[1]*, Gooya Banaei*[2]*, Alireza Tavakolpournegari*[3]*, Ricardo Marcos Dauder*[1]*, Juan Martín-Pérez*[3] *and Alba Hernández Bonilla*[3]*, (1)Autonomous University of Barcelona (UAB), Spain, (2)Genetics and Mcirobiology, Autonomous University of Barcelona (UAB), Spain, (3)Genetics and Microbiology, Autonomous University of Barcelona (UAB), Spain*

The increasing presence of micro- and nano-sized plastics (MNPLs) in the environment and food chain, has already been proved and is of emergent concern. Plastics from consumer food packaging can leachate in the form of MNPLs, migrate into the food, and directly enter the human body by the ingestion route. A well-known example is teabags, which has become the main source of MNPLs since the traditional paper bags were substituted with "biodegradable" plastic bags.

However, we have detected an important gap of knowledge on the risk assessment of these true-to-life MNPLs, since the lack of reference materials together with the limited analytical methods available for MNPLs detection has complicated its research. To cover this gap, we have aimed to isolate MNPLs from the leaching of food packaging (teabags) and used them to expose the *in vitro* model of the intestinal epithelium (Caco-2/HT29) to evaluate the fate and effects.

Briefly, four different teabags purchased online and in a local supermarket were submitted to a cup-of-tea-like extraction protocol and then collected in big quantities to perform toxicological assays. The results from SEM-EDX and FTIR confirmed that the particles derived from teabags were made of Nylon, Polypropylene (PP), polylactic acid (PLA), and Cellulose (CS). Moreover, using the Nano Z-sizer we detected hydrodynamic sizes ranging from 120 nm to 250 nm. Finally, TEM and SEM images showed different MNPLs morphologies including spherical PLA-NPLs, amorphous and irregular Nylon- and PP-NPLs and filamentous CS-NPLs. Following, we aimed to study the fate, interaction and biopersistance of those NPLs on human intestine-derived cells. Using confocal microscopy, we confirmed that NPLs could internalize into all the cells after 24 h, reaching the cell nucleus compartment. Flow cytometry data demonstrated that the internalization rate depends on the polymer-type and the cell clone used. For example, while PLA-NPLs internalized 100% of HT29 cell clone, Nylone-NPLs only internalized 60%. Despite the high internalization rate, no significant cytotoxic effects were observed when analyzing cell viability, intracellular ROS, and barrier integrity.

This study opens new insights regarding the fate and effects of MNPLs, reinforces the urgent need for multidisciplinary studies and physiologically relevant exposures, and serves as an example for regulatory agencies to pay close attention to the regulation of MNPLs production and management.

4.13.P-Mo433 Assessment of Pyrolysis-GC-MS as a technique for quantifying in vitro uptake of micro- and nanoplastics in human cells

Markus Julius Kirchner[1]*, Francesca Bennet*[2] *and Alexander Roloff*[2]*, (1)Chemical and Product Safety, University of Bayreuth, Germany, (2)Chemical and Product Safety, German Federal Institute for Risk Assessment (BfR), Germany*

Although no direct evidence for adverse effects of micro- and nanoplastic particles (MNPs) on human health has been demonstrated so far, human exposure to MNPs present in the environment via ingestion and inhalation has been shown, and therefore the hazards of these particles to human health needs to be evaluated. To assess potential cellular toxicity of MNPs, *in vitro* testing is commonly performed with human-derived cell lines, however the actual amount of test particles which reach and are taken up into the cells must be determined. Particularly for nanoscale particles (< 1000 nm), handling, particle agglomeration, dosage determination, and most importantly the reliable detection and quantification of actual particle uptake in cells remains challenging. Among other physicochemical properties, particle size is a key parameter influencing cell uptake, and therefore particles in both the micro- and nano-size ranges need to be investigated.

Current detection methods for measuring plastic particle uptake in cells have several limitations, such as the requirement for a fluorescent label for confocal microscopy, a size limitation in the lower µm range for µ-Raman spectroscopy, or challenging sample preparation and limitations for quantification for ToF-SIMS analysis. A commonly available method which enables the detection and quantification of MNP uptake in cells, that overcomes these limitations, is still missing.

Online-coupled pyrolysis gas chromatography mass spectrometry (Pyr-GC-MS) has been shown to reliably quantify MNPs and dissolved polymers in different complex matrices including human blood and *Daphnia magna* phylopods. Yet, no attempt to use this method for detection and quantification of MNP uptake in human cell culture has been reported. Pyr-GC-MS features polymer quantification over a wide concentration range reaching from ng to µg quantities, and is also applicable to environmentally relevant MNPs, where the use of e.g. fluorescent labels could lead to changes in surface chemistry and charge and is therefore not appropriate.

We present the development of a Pyr-GC-MS-based method for the quantification of the in vitro uptake of polyethylene MNPs of nano- and micrometre sizes in human-derived A549 lung cells. The development of this method focuses on the assessment of linearity, repeatability, and limits of detection and quantification, in order to establish the applicability of Pyr-GC-MS for quantification of MNPs in cell culture toxicity testing.

4.13.P-Mo434 3D In Vitro Tissue Model of Human Alveoli to Assess the Toxicity of MNPLs Following Exposure to the Air-Liquid Interface (ALI)

Laura Rubio-Lorente[1]*, Javier Gutiérrez*[1]*,* ***Alba Garcia-Rodriguez***[1]*, Ricardo Marcos Dauder*[1] *and Alba Hernández Bonilla*[2]*, (1)Autonomous University of Barcelona (UAB), Spain, (2)Genetics and Microbiology, Autonomous University of Barcelona (UAB), Spain*

In vitro modeling of cell cultures is widely used in pharmaceutical, medical, food/nutrition and toxicology science. These constructed growth environments support tissue differentiation and mimic tissue-tissue, tissue-liquid, and tissue-air interfaces in a variety of conditions. In toxicology, human-derived *in vitro* culture models are attracting increasing interest because of the numerous benefits including non-animal studies, rapid and cost-effective methodologies, and the simulation of human physiology in a controlled situation. Therefore, our research group has focused on the modeling of *in vitro* barrier tissue interfaces for their use in environmental toxicology. Concretely, we aimed at characterizing and validating a 3D in vitro model mimicking the human alveoli. To such end, Calu-3 cells (human lung adenocarcinoma) were seeded on top of a porous (0.4 um) transwell and let proliferate and differentiating for 9 days. On day 9, the apical medium was mostly removed recreating an air-liquid interface (ALI). Then, cells were left in ALI conditions for 7 more days, where the barrier was established as a pseudostratified epithelium expressing tight junctions, microvilli and mucosa. Afterward, the 3D in vitro model was used to study the effects of MNPLs such as polystyrene (PS), polylactic acid (PLA) and polyethylene terephthalate (PET).

Our results indicate that either after short (24 h) and long-term (1 week) exposures PLA-NPs internalized the most compared to PS and PET. While the presence of PLA-NPLs did not disrupt the barrier morphology nor the stability, significant genotoxic damage was observed already after 24 hours. Most likely, the high internalization rate of these NPLs increased the chances of nucleus-NPLs interactions. PLA-NPLs also induced big cytokine alterations especially after long-term exposures.

Therefore, (i) the ALI model is a useful tool for high throughput screenings and to perform longer and repeated MNPLs exposures; (ii) the presence of mucus might be modulating the differences on adhesion, interaction and cell internalization depending on the polymer-type and its physicochemical characteristics; (iii) PLA-NPLs were detected to induce genotoxicity; and (iv) also dysregulated the cytokine release, which can potentially alters the immune response of the lungs.

4.13.P-Mo435 Characterization of sunlight- and laboratory-weathered MNPs for Toxicological Studies: limits and perspectives

***Sonia Manzo*[1], *Simona Schiavo*[2], *Anna De Girolamo Del Mauro*[3], *Laura Caiazzo*[4], *Maria Rita Montereali*[4], *Markus Julius Kirchner*[5], *Philipp Reichardt*[6], *Ievgen Donskyi*[7], *Robert Schusterbauer*[7], *Francesca Bennet*[8] *and Alexander Roloff*[8], *(1)ENEA CR Portici, Italy, (2)National Agency for New Technologies, Energy and Sustainable Economic Development (ENEA), Italy, (3)ENEA, (4)ENEA Environmental Chemistry Division, Italy, (5)Chemical and Product Safety, University of Bayreuth, Germany, (6)BfR Federal Institute for Risk Assessment, (7)Free University of Berlin, Germany, (8)Chemical and Product Safety, German Federal Institute for Risk Assessment (BfR), Germany*

The toxicological assessment of micro- and nanoplastics (MNPs) requires test materials that are well characterised and relevant to those found in the environment. Natural weathering of MNPs resulting from different environmental conditions consists of moderate but continued exposure to various environmental stressors such as UV radiation, heat and mechanical abrasion, which may continue for months or years. Importantly, by modulating size, charge and surface chemistry, these alterations can have substantial effects on the uptake of MNPs in cells. To overcome limitations associated with time-consuming and variable weathering under natural conditions, a laboratory-scale apparatus was set up with the aim of producing weathered MNPs with comparable physicochemical properties to those obtained from environmental weathering. The resulting weathered MNPs could then be applied in toxicity assessments. To fill in gaps of information between the outcomes of artificial and natural weathering processes, we investigated the influence of light and media (e.g., deionized water and artificial seawater) on microplastics weathered either artificially in the laboratory or naturally via exposure to summer sun. In particular 1–4 um polyethylene (PE) particles in artificial seawater or in MilliQ water were exposed for 770 h to UVA/UVB light (115 W/m^2, T = 63 ± 5 °C, stirred at 460 rpm), and, as powder, to natural summer sunlight in Portici, Naples (40°48′56″ N; 14°20′13″ E, *T* = 29.8 °C, UV radiation index = 5.1) for 12 weeks without stirring. A variety of analytical methods (including FTIR, SEM and ToF-SIMS analysis) were used to compare the physicochemical properties of the aged MNP variants as well as non-degraded particles. The MilliQ and artificial seawater media in which particles were dispersed during the exposure period were also investigated (by GC MS and ICP MS analysis) to determine the presence of leached organic and inorganic species. To improve our understanding about how particles resulting from different types of weathering can influence MNP-induced cellular effects, we also investigated ROS production, lysosomial membrane stability and cell viability in MNP-exposed *Mytilus galloprovincialis* hemocytes.

4.13.P-Mo436 Micro-nanoplastics, their effect on composition and metabolic functionality of human microbiota and microbial-derived metabolites´ impact on the gut barrier

***Mikel Roldán*[1], *Iris Pinillos*[1], *Natalia Molinero*[2], *Victor Alcolea-Rodríguez*[3], *Julian J. Reinosa*[4], *Raquel Portela*[5], *Miguel A. Bañares*[3], *José F. Fernández*[4], *Ainhoa Bilbao*[6], *Alberto Katsumiti*[7] *and M. Victoria Moreno-Arribas*[1], *(1)Cial, Spanish National Research Council (CSIC), Spain, (2)Spanish National Research Council (CSIC), Spain, (3)ICP, Spanish National Research Council (CSIC), Spain, (4)Icv, Spanish National Research Council (CSIC), Spain, (5)ICP, Spanish National Research Council (CSIC), Madrid, Spain, (6)Biotechnology, GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (7)GAIKER Technology Centre, Spain*

In recent years, the presence of micro- and nanoplastics (MNPs) has been detected almost ubiquitously. As environmental contaminants, these particles can be deposited on food along the production and consumption chain. Concomitant unconscious ingestion could have yet to be elucidated effects on human health. In addition, pathogens capable of surviving hostile conditions may colonize MNPs, establishing a microbial biofilm and using it as a route of transmission. The interaction of either pristine or colonized particles with gastrointestinal fluids and/or gut microbiota during human digestion is still unknown.

In this intergroup collaboration, relation between MNPs ingestion, their physical changes during digestion and by colonic microbiota and its microbial-derived metabolites was examined *in vitro*. Firstly, PET particles were subjected to gastrointestinal digestion using INFOGEST method with modifications for MNPs. Later, colonic fermentations with healthy human microbiota from fresh fecal donors was carried out. Furthermore, the digested particles were exposed to the Caco-2/HT29-MTX/M intestinal barrier cell model to evaluate their effects on cell viability and barrier permeability and integrity. On the other hand, colonic effluents supernatants were tested in the same way to assess the effect of microbial metabolites as result of PET MNP exposure.

Finally, the simulation of *in vitro* colonic fermentation with artificial pathogen biofilms was carried out. Further analyses will evaluate their impact on human health by studying the composition and functionality of the colonic microbiota (16S gene meta-taxonomy), short chain fatty acids and ammonium ion production, as well as by exposure of colonic supernatants in intestinal cell models.

Acknowledgments**:** This work was supported by the EU H2020 Project "Plastics Fate and Effects in the human body" (PlasticsFatE) under Grant Agreement no. 965367.

4.13.P-Mo437 Three-Dimensional A549 Cell Cultures to Study the Chronic Toxicity of Micro- and Nanoparticles in the Respiratory System

***Mahboubeh Hosseinzadeh** and Cinta Porte, Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Air pollution is the main cause of the development and exacerbation of respiratory diseases such as asthma, bronchitis, and chronic obstructive pulmonary disease. Recently, scientists have detected the presence of microplastics (MPs) and nanoplastics (NPs) in various outdoor and indoor air settings. Consequently, there is a growing concern over the access of these particles into the respiratory system through inhalation.

In this study, a 3D human alveolar epithelium adenocarcinoma A549 model was established to evaluate the chronic toxicity of polystyrene MPs (1 µm) and NPs (50 µm), with a special focus on changes in cell lipidome and the transcription of genes involved in cell proliferation pathways and pro-inflammatory cytokines. Spheroid growth was monitored for 14 days. Spheroids aged 6 days, with a size of approximately 400 µm, were chosen for toxicity tests, which by the end of the experiment (13 days), increased to 642 ± 20 µm. Chronic exposure (7 days) of MNPs (2.6 µg/mL) did not significantly affect spheroid size nor decrease cell viability. Nonetheless, exposure to polystyrene NPs significantly upregulated various lipid species, particularly triglycerides (TGs) (up to 1.5-fold) and plasmenyl/plasmanyl phosphatidylcholines (PC-O/PC-Ps) (up to 1.5-fold). The accumulation of neutral lipids (TGs) is linked to lipid storage and the development of lipid droplets within lung cells. Meanwhile, PC-P/PC-Os are crucial in neutralizing free radicals and safeguarding against oxidative damage, and they are also precursors of pro-inflammatory factors. Overall, the study highlights the potential of the A549 spheroid model for assessing the effects of MPs and NPs on lung toxicity and provides insights into lipidomic and molecular alterations in response to these particles.

4.13.P-Mo438 Polyethylene Terephthalate Microplastics Alter Adrenal Transcriptome Profile Of Immature Gilts – In Vivo Studies

***Aleksandra Kurzyńska**[1], Karol Mierzejewski[2], Monika Golubska[1], Ismena Gałęcka[3], Jarosław Całka[3] and Iwona Bogacka[4], (1)University of Warmia and Mazury in Olsztyn, Poland, (2)Department of Animal Anatomy and Physiology, University of Warmia and Mazury in Olsztyn, Poland, (3)Department of Clinical Physiology, University of Warmia and Mazury in Olsztyn, Poland, (4)Department of Animal Anatomy and Physiology, Department of Animal Anatomy and Physiology, University of Warmia and Mazury in Olsztyn, Poland*

Polyethylene terephthalate (PET) is the most commonly used polymer in the packaging industry. PET microplastic particles (MPs) can be released during food storage and few studies confirmed their accumulation in human tissues and blood. Polymers have been shown to disturb physiological processes in living organisms, therefore the aim of our study was to investigate whether oral administration of PET MPs affects the transcriptome profile of the adrenal glands of immature gilts.

The experiment lasted 4 weeks and was conducted on 8-week-old (Pietrain x Duroc) immature gilts (n = 15) with an estimated body weight of 20 kg. The animals were divided into three groups: 1) control group (CTR; n = 5), which received empty gelatin capsules per os; 2) experimental group (LD_PET; n = 5), which received a low dose of PET MPs (0.1 g/pig/day) per os; 3) experimental group (HD_PET; n = 5), which received a high dose of PET MPs (1 g/pig/day) per os. The plastic used for the experiment is a semi-crystalline polyethylene terephthalate powder (Goodfellow Cambridge Ltd., Huntingdon, England). To determine the expression profiles of the adrenal genes, RNA-Seq was performed on the NovaSeq 6000 Illumina platform. To identify differentially expressed genes (DEGs), 74 Cufflinks method was used. The final results represented DEGs that were significantly confirmed by statistical test (p-value < 0.05; log2 fold-change>1,5 or log2 fold-change <1,5). Gene ontology (GO) enrichment and pathway analysis were performed using gProfileR based on the GO and Kyoto Encyclopedia of Genes and Genomes (KEGG) databases.

The statistical analysis revealed 344 DEGs (101 up and 243 down) in adrenals of LD_PET group relative to control group. Selected genes were related to regulation of anoikis, CREB transcription factor activity or cellular response to glucose starvation. We identified 628 DEGs (161 up and 467 down) in adrenals of gilts of HD_PET group relative to control individuals. The GO analysis revealed that these genes refer to the biological processes connected with chemokine-mediated signaling pathway, anatomical structure development or antimicrobial humoral response. These findings, for the first time, indicate that PET MPs can interrupt basic physiological processes in the adrenal gland of immature organism, and in consequence may cause serious endocrine disorders.

Supported by National Science Centre, Poland, grant no. 2021/43/B/NZ7/01093.

4.13.P-Mo439 Development and Understanding of Adopted Bioassays for the Hazard Assessment of Plastics in the Environment

***Marcus Lukas**, Richard Becker and Ulrike Braun, German Environment Agency (UBA), Germany*

Plastics, especially particles in micro- and nanometer range, are persistent contaminants in ecosystems, with only incomplete information available particularly on their specific hazards. In most cases plastics are equipped with additives and further chemicals. Plastic containing waste is a broad combination of polymers, additives and further compounds. Therefore, eluates from shredded plastic waste can serve as a model substance to develop and optimise standardized bioassays for assessing hazards of plastics.

Plastic containing waste of two different waste treatment plants were fractionated (</>300µm) and aqueous extracts were prepared. The study used bioassays (e.g. algae growth inhibition test, in vitro test for estrogenicity) and chemical analyses to profile organic pollutants, heavy metals and other chemical constituents of extracts.

Algae growth rate inhibition showed higher effects for extracts of the smaller fraction, with no differences between the two plants. Extracts of unfractionated samples caused comparable growth inhibition as the smaller fraction, indicating a major part of ecotoxicologically relevant compounds are present in this fraction. Assuming particles of this fraction have a higher surface to volume ratio, stronger ecotoxicological effects should be caused by surface-controlled release of pollutants into the extract. In turn, estrogenicity results revealed strong differences between both tested plants, but remarkably nearly no difference between different fractions. The latter indicates the surface-controlled release of pollutants in the eluate not to be the underlying effect.

Chemical analyses confirmed higher concentrations of anionic substances and several heavy metals (e.g. copper) in the smaller fraction of one plant. For the same plant relatively high contents of estrogenic substances, particularly bisphenols, were detected. As no difference between the different fractions was observed, the migration kinetics of bisphenols, as additives of polymers, are suggested to be responsible for their concentrations in the eluate.

In sum, established bioassays can be used for the hazard assessment of plastics (here shredded plastic waste as model substance) in the environment. However, a suitable method for converting potential pollutants into an eluate is essential. Further, fractionation of samples can alter ecotoxicological and chemical results probably due to particle size and compound migration dependent extraction mechanisms.

4.13.P-Mo440 Immunomodulatory effects of micro-and nanoplastic particles (MNPs) in human immune cells

***Sebastian Wolf**[1], Antonia Körber[2] and Hermann-Josef Thierse[1], (1)Chemical and Product Safety, German Federal Institute for Risk Assessment (BfR), Germany, (2)Institute of Chemistry & Biochemistry, Free University of Berlin, Germany*

Background: Micro- and nanoplastic particles (MNPs) have been frequently shown to be taken up by various human cell types, thereby affecting inflammatory responses such as distinct levels of reactive oxygen species (ROS), which might be protective and/or toxic. This raises the question of possible harmful molecular and cellular effects of MNPs on human immune cells and their (patho-)physiological signalling pathways.

Methods: To address this issue within the PolyRisk Project, molecular and cellular in vitro studies were carried out with human immune cells. In a two-tiered approach we investigated molecular effects of polystyrene MNPs (PS-MNPs,100 nm size) on selected enzymes e. g. of cellular apoptosis, and on monocytic cells. Human immune cells were derived from peripheral blood mononuclear cells (PBMC), and analysed by flow cytometry (FACS, fluorescent activated cell sorting).

Results: (1) Biochemical studies showed an inhibitory effect of PS-MNPs on a key enzyme (caspase) of cellular apoptosis. (2) Flow cytometric studies after exposure of PBMC to PS100nm showed e.g. an increased expression of the surface molecule CD40, which is obligatory for antibody class switching during human type I allergic reactions. In addition, a clear shift in the distribution of human monocyte subsets was observed after PS-MNPs stimulation. All experiments were performed at least with n=3; and data were compared with standard LPS (lipopolysaccharide) stimulation.

Conclusions: The results to date suggest that (1) PS-MNPs interfere with enzymes responsible for apoptotic cell death; (2) an immune cell response to PS-MNPs occurs, as indicated by the upregulation of CD molecules, e.g. CD40; (3) an immunomodulatory response to monocytic subsets from human PBMC occurs, which has been also observed under septic conditions.

Since plastic polymers are usually chemically inert, there is probably an indirect mode of action for triggering the effects described above and previously. A closer look at different activation markers and phenotype distributions could (1) unravel the underlying mechanisms and (2) serve as a potential descriptor for future risk assessment frameworks related to MNPs and certain cellular human immune responses.

Without chemical activity and without structures suitable as receptor ligands, PS-MNPs (100nm) may have triggered the response by affecting endosomal homoeostasis upon uptake, due to possible enzyme adsorption. This will be subject of further investigations.

4.13.P-Mo441 Identification of toxicologically relevant functional groups on micro- and nanoplastic particles surface
Dmitri Ciornii[1]*, Dan Vasile Hodoroaba*[2]*, Xenia Knigge*[2]*, Jörg Radnik*[2] *and Korinna Altmann*[3]*, (1)Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (2)Materials Chemistry, Bundesanstalt für Materialforschung und -prüfung (BAM), Germany, (3)Federal Institute for Materials Research and Testing (BAM), Germany*
Microplastic and nanoplastic particles (MNP) are spread all over the world in various types, shapes and sizes making it very challenging to accurately analyse them. Each sampling procedure, sample preparation method and detection technique needs suitable reference materials to validate the method for accurate results. Furthermore, the effects of these MNPs should be evaluated by risk and hazard assessment with test particles close to reality. To better understand MNP behavior and contribute in clarification of their interactions with organisms, we produced several MNP test materials by top-down procedure and characterized their properties. Since surface properties mostly determine particles' toxicity, the aim of the present study was to determine which functional groups are present on MNPs and how the surface can be affected by the production process and particle's environment.

Our study showed that the production process influences the surface properties of every plastic particle. Furthermore, analysis of surface characteristics of the tested particles seems to be mandotory for interpretation of experimental results. Especially toxicological experiments should be supported with information on surface properties.

4.13.P-Mo442 PolyAmidst the crisis: Exploring immunotoxic, genotoxic, and endocrine disrupting effects of polyamide microplastic particles and chemicals
Andi Alijagic PhD[1]*, Oleksandr Kotlyar*[2]*, Maria Larsson*[3]*, Samira Salihovic*[4]*, Alexander Hedbrant*[4]*, Ulrika Eriksson*[5]*, Patrik Karlsson*[4]*, Alexander Persson*[4]*,* ***Nikolai Scherbak***[2]*, Kim Färnlund*[6]*, Eva Särndahl*[4] *and Magnus Engwall*[7]*, (1)Oerebro University, Sweden, (2)School of Science and Technology, Orebro University, Sweden, (3)MTM Research Centre, Orebro University, Sweden, (4)Orebro University, Sweden, (5)Örebro UniversitySchool of Science and Technology, Oerebro University, Sweden, (6)AMEXCI AB, (7)Orebro University, MTM Research Centre, Sweden*
Due to their outstanding characteristics and cost-effectiveness, polyamides or nylons have become prevalent materials, transforming various industries, including industrial 3D printing, aka additive manufacturing (AM). Powder-based AM technologies utilize tons of polyamide microplastics annually to manufacture complex components. However, the urgent need for a comprehensive toxicity assessment of particulate polyamides and associated chemicals, particularly amidst the global microplastics crisis, is evident. Hence, this research delved into the physicochemical properties of polyamide-12 microplastic particles employed in AM by focusing on toxicity endpoints, such as inflammation, immunometabolism, genotoxicity, aryl hydrocarbon receptor (AhR) activation, endocrine disruption, and cell morphology. Field emission scanning electron microscopy revealed that the reuse of material in the AM workflow generate smaller particles (1-5 µm), readily available for the uptake by human cells. Chemical analysis via gas chromatography high-resolution mass spectrometry identified various polyamide-associated chemicals, including starting material, plasticizers, thermal stabilizer/antioxidant, and migrating slip additive. Although polyamide particles and chemicals did not induce acute inflammation, prolonged exposure of human primary macrophages led to a steady increase in proinflammatory chemokine interleukin-8 (IL-8/CXCL-8). Additionally, targeted metabolomics indicated modulation of the kynurenine, NAD, and FAD levels. A p53-responsive luciferase reporter gene assay revealed that prolonged exposure to polyamide particles elicited genotoxic stress. Polyamide-associated chemicals moderately activated AhR and exhibited anti-androgenic activity. A high-throughput, non-targeted morphological profiling by Cell Painting assay highlighted bioactivity sites and suggested potential toxicity mechanisms in cells. These findings underscore the potential health risks associated with the growing use of polyamide microplastics.

4.13.P-Mo443 Developmental Nanoplastic Exposure Disrupts the Thyroid Hormone Axis in Zebrafish Embryos
Patricia Iglesias-Hernandez[1]*,* ***Monica Torres-Ruiz***[2]*, Maria Muñoz Palencia*[2]*, Ana Isabel Cañas Portilla*[2] *and Antonio De la Vieja*[3]*, (1)National Centre for Environmental Health and Endocrine Tumors Unit , Instituto de Salud Carlos III, Spain, (2)National Centre for Environmental Health, Instituto de Salud Carlos III, Spain, (3)Endocrine Tumors Unit, Unidad Funcional de Investigación en Enfermedades Crónicas (UFIEC), Instituto de Salud Carlos III, Spain*
Worldwide plastic production has greatly increased in the past decades. Mechanical, physical, and biological processes degrade this material producing Micro- (MP) and Nanoplastics (NP). The ubiquitous nature of MP and NP is a growing environmental and human health concern. The small size of NPs allows them to accumulate within and adversely affect

tissues, causing disruptions in metabolism, development, and fertility. Mechanisms of NP toxicity are largely unknown and the zebrafish embryo (ZFE) poses an ideal model to investigate them due to it is high homology with humans.

The present work was aimed at determining the potential impact of developmental exposure to polystyrene (PS) NP on the thyroid endocrine system in ZFE. To this end, embryos were exposed to a concentration gradient of PS NP (0 -3 mg/L) up to 120 hours post-fertilization. After exposure, alterations in gene transcriptions and thyroid hormones (THs) were examined. Our results show that exposure to PS NPs decreased the levels of thyroid stimulating hormone (TSH) and L-triiodothyronine (T3); whereas L-thyroxine (T4) varied depending on NP concentration. In addition, the T3/T4 ratio was affected. Furthermore, we observed that expression of several transcripts related to the thyroid axis were modified. Together, these results provide further evidence of a potential mechanism of action of NPs as endocrine disruptors and highlight the pressing need for more research on potential human health effects.

4.13.P-Mo444 Short-term exposure to polystyrene micro- and nanoplastic (PS MNP) – in vivo uptake and effects in a colitis mouse model

***Verena Dr. Kopatz**, Pathology, Medical University of Vienna*

Micro- and nanoplastic particles (MNP) have been found in recent years in all parts of the world and in various organisms. In the human body MNP have been detected e.g. in stool, blood, placenta, kidney or lungs - not surprising considering that we consume on average up to 5 grams (!) of MNP per week. Until now, the health effects of this exposure to MNP are almost completely unexplored, especially regarding tumor development, growth and dissemination. For the gastrointestinal tract, as one of the organs that is exposed to high amounts of MNP on a daily basis, already MNP related changes to the gut microbiome, barrier function and inflammatory processes have been described – all three being factors potentially influencing (colorectal) tumor development and progression.

Thus, our main research interest within this project is to explore the potential health risks of various MNP types, with a special focus on colorectal cancer development and progression, using in vivo mouse models. First short-term exposure studies were conducted with polystyrene (PS) MNPs of three distinct sizes. Uptake and potential accumulation in various organs was assessed in mice using a DSS-induced colitis model, which mimics increased MNP uptake due to an inflamed/leaky gut barrier. As a future perspective also colorectal mouse models (genetic an inflammation based) will be used to study the relationship between MNP and colorectal cancer in more detail.

4.13.P-Mo445 Development of Analytical Methods for the Quantification of Microplastics in Animal Feed Containing Former Food Products

***Mara Putzu**[1], Rosa Avolio[2], Giovanna Berti[2], Stefania Squadrone[2], Luciano Pinotti[3], Andrea Mario Giovannozzi[1], Alessio Sacco[1], Francesco Romaniello[1], Daniela Marchis[4] and Andrea Rossi[1], (1)Istituto Nazionale di Ricerca Metrologica (INRiM), Italy, (2)Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, (3)Department of Veterinary Medicine and Animal Science, DIVAS, University of Milan, (4)Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta; Italian National Reference Laboratory of Animal Proteins in Feed*

Considering the current increase in population accompanied by high food demand/production and food waste, the long term goal of our society is to encourage the practice of an increasingly Circular Economy. Recycling food no longer suitable for sale and human consumption due to logistical or production errors (for example packaging defects), are indicated as former food products (FFPs). These foodstuffs are recovered, mechanically unpacked, and then ground. This treatment, however, does not always guarantee the total elimination of packaging residues that can become part of the product and potential contaminants. Plastic is the most used food packaging material but its carry over into food products and subsequent transfer in the food chain, especially in its micro sizes (1 μm – 5 mm), represents a threat to human health. To maximise the exploitation of former food products and minimise the associated toxicity risks, the development of analytical methods for the identification and quantification of microplastics in animal feed containing FFPs, for which limited data are available so far, is necessary. Twelve animal feed samples were analysed, including blank sample. After a manual sift through different mesh sizes (2, 1.3, 1, 0.7 mm) and visual sorting procedure, presumed plastic packaging residues in the form of fragments and fibres (main forms of plastic in food) were analysed by μRaman (DXR-xi Raman Imaging Microscope, by Thermo Scientific). The analysis confirmed the presence of plastic residues identifying polypropylene (PP), polyethylene terephthalate (PET), polylactate acid (PLA) as the main polymers, with a predominance of polyethylene (PE). In accordance with the Europan Commission Agency's size classification of plastics, an abundance of microplastics (1 μm – 5 mm) and remaining low amount of mesoplastics (> 5 mm) were found in the analysed samples.
The results showed that μRaman measurements provide quantitative and qualitative analyses of plastic packaging residues. Accordingly, it can be considered as an innovative method to investigate their presence in feed and food by supporting the protection of animal, plant and environmental health, which represents the basis of public health. The future prospective this study also aims at the development of method of digestion of the same samples in their sieved component < 0.7 mm, to investigate the presence of submicron sizes (1 μm – 0.7 mm) packaging residues.

4.13.P-Mo446 Asymmetric Field Flow Fractionation-Dielectrophoresis-Raman Combination for Chemical Identification of Nanoplastics in Aqueous Matrices

***Marta Fadda**[1], Alessio Sacco[1], Andrea Rossi[1], Korinna Altmann[2] and Andrea Mario Giovannozzi[1], (1)Istituto Nazionale di Ricerca Metrologica (INRiM), Italy, (2)Federal Institute for Materials Research and Testing (BAM), Germany*

Nowadays, identification, quantification and characterization of micro (MPs) and nano-plastics (NPs) in food and environmental matrices have been gaining a lot of attention due to their suspected toxicological effect on human health. While several studies have been conducted on MPs, for NPs big challenges have to be taken in consideration because of their diversity in size (1 nm – 1 µm), shape, and type of polymers. In this work, we demonstrate the feasability of using Raman microspectroscopy (µ-Raman) enabled by dielectrophoresis (DEP), which allows the trapping of particles, to chemical identify NPs up to 100 nm in diameter. Furthermore, binary mixtures of NPs, in particular nano-polypropylene (nPP) and nano-polystyrene (nPS), have been developed, proposing different percentages of them. These nanoparticles were selected in the same size range, approximately 200 nm, as demonstrated by dynamic light scatering measurements. A multivariate predictive model will be trained and validated using these mixtures. Then, size separation of NPs was obtained by asymmetric flow field-flow fractionation (AF4) and the collected fractions were analyzed by multi-angle dynamic light scattering to have information about their size and size distribution. The chemical composition of the same collected fractions were analyzed by µRaman enabled by DEP, as explained above. The multivariate predictive model will give information about relative concentration of nPP and nPS in collected fractions. At the end of this study, we will have the possibility to chemically identify both NPs smaller than 200 nm up to 100 nm, as well as NPs with the same size but different polymer type in the same mixture, obtaining their relative quantification.

4.13.P-Mo447 Standardization Methods for the Analysis of Microplastics (10-100µm) in Food Matrix: Sample Preparation, Contamination Control and Digestion of Milk Powder.

***Claudia Drago**[1], Richard Becker[1], Marcus Lukas[1], Korinna Altmann[2], Yosri Wiesner[2], Andrea Mario Giovannozzi[3] and Ulrike Braun[1], (1)German Environment Agency (UBA), Germany, (2)Federal Institute for Materials Research and Testing (BAM), Germany, (3)Istituto Nazionale di Ricerca Metrologica (INRiM), Italy*

The ubiquitous presence of microplastics in the environment is recognised as a global issue. Microplastics have been found in each environmental compartment and also in humans. The direct exposure of microplastics to the people due to the food matrix has gained more and more attention in the last years. Although the presence of microplastic in various human tissues has been found, the information on the ingestion of microplastics due to the food matrix has been scarcely investigated. Microplastics in fact could be released in the food during the production, through packaging and by consumer’s use. The lack of data and their comparison, is mainly due to the methodological challenge of microplastics’ properties (from 10 to 100 µm). Moreover, the absence of standard methods to quantify and detect different size range and type of microplastics has led to series of analytical issues such as difficult and time-consuming procedural steps and poor accuracy. In this work, through literature research and laboratory experiments, we compile a standard procedure, for the contamination control, sample preparation and digestion of common milk powder to detect different particle sizes and types of polymers. This information is crucial for establishing a standard method that would determinate the human exposure to microplastics, by direct ingestion, from the earliest years of life.

4.13.P-Mo448 Proposal of exposure reduction measures according to microplastic exposure scenarios in household chemical products

***Yeonjung Park**[1], Heekyung Bae[2], Jeonggue PARK[3], Ok-Nam Bae[4] and Hyunook Kim[5], (1)Chemical Management Institute, TO21 Co. Ltd., Korea, Republic of (South), (2)Chemical Management Institute, TO21 Co., Ltd., Korea, Republic of (South), (3)Division for Environmental Risk, Korea Environment Institute (KEI), Korea, Republic of (South), (4)College of Pharmacy, Hanyang University, Korea, Republic of (South), (5)Department of Energy and Environmental System Engineering, University of Seoul, Korea, Republic of (South)*

Recently, as microplastics have been recognized as a serious environmental problem, interest in microplastics is increasing around the world. Currently, research on microplastic exposure assessment in living environments is insufficient, and it is difficult to secure microplastic exposure assessment methodology and applicable exposure coefficients. Accordingly, in this study, a data research study was conducted to obtain information that can be used to evaluate exposure to microplastics during living environment activities, including exposure coefficients, exposure routes, and exposure scenarios. Products that have the potential to cause microplastic exposure to the human body and the environment, such as household chemicals, laundry detergents, detergents, microfibers, disposable masks, and sanitary products, were selected as the target products for this study. A survey was conducted on the selected products to derive exposure factors. The purpose of the survey was to set the exposure scenario, derive the exposure factor, and obtain the necessary information to set the exposure assessment model, and the survey was conducted by dividing the questionnaire according to the characteristics of each target product. Additionally, we sought to identify possible factors that could reduce exposure according to the exposure scenario derived from the survey results. We propose a management plan that reflects the use scenarios for products containing microplastics identified through this study and international regulatory trends on microplastics.

4.13.P-Mo449 Granulated rubber used in playgrounds: a potential source of atmospheric contamination

***Marta Llorca**, Katerina Savva, Xavier Borrell-Diaz, Marinella Farre and Teresa Moreno, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Granulated “crumb” rubber sourced from recycled tyres and other elastomeric materials such as ethylene propylene diene monomer is versatile and its many uses include installation as cushioning surfaces and synthetic turf infill in environmentally sensitive areas such as children playgrounds and sports facilities. When installed outdoors, these artificial surfaces are subjected to physical and chemical degradation by weathering during which chemical pollutants can be released.

In this context, we exposed seven granulated and 3 resin-agglomerated crumb rubber materials to natural weathering effects between June and July 2021 in Barcelona city (NE of Spain). The samples were taken using three hung Personal Monitoring Equipments air samplers equipped with quartz fiber filters of PM2.5 (n=2) for analyses of micro- and nanoplastics (MNPLs) and plastic additives and PM10 (n=1) for inorganic analysis. In addition, the toxicity of aged material after emulating rain events was assessed with *Daphnia magna* immobilization test.

The studies of MNPLs and plastic additives were based on suspect screening procedures. PM2.5 filters were extracted by toluene and analysed by size exclusion chromatography coupled to high resolution mass spectrometry (HRMS) for MNPLs while for plastic additives these were extracted with methanol for further analysis by liquid chromatography coupled to HRMS. Finally, the analysis of trace elements was done by ICP-AES and ICP-MS.

The main results showed the presence of 5 polymer types that were lixiviated from cum rubber including PE, PP, PBD, polysiloxanes and PB-1, varying the profile along the exposition days, denoting that MNPLs can be detected in the air due to the natural erosion of crumb rubber. In the case of plastic additives, the presence at level 2 of confidence of 56 plastic additives including adhesives, antioxidants, pigments, copolymers, flame retardants, fungicides, lubricants, plasticizers, polymer preservatives and UV filters were identified. As regards to the elemental composition of PM10, the levels were notably higher on the first day of the experiment compared to the rest of experiment.

Finally, the immobilization tests showed that the acute toxicity with *D. magna* of leached compounds after raining period, either virgin material or aged material, are toxic for the organisms. However, the concentrations tested here were much higher than the ones expected to occur during rainstorm events in a playground.

4.13.P-Mo450 Exposure to Tire Rubber Compounds via Dermal Contact

Sergio Soñora[1]*, Andres Duque-Villaverde*[1]*, Thierry Dagnac*[2]*, Maria Llompart*[3] *and Nieves Carro*[4]*, (1)Department of Analytical Chemistry, Nutrition and Food Science, University of Santiago de Compostela, Spain, (2)Unit of Organic Contaminants, Apartado 10, Agronomic and Agrarian Research Centre (AGACAL-CIAM), Spain, (3)Department of Analytical Chemistry, Nutrition and Food Science, CRETUS, Spain, (4)Chemical pollution, INTECMAR (Techonological Institute for the Control of the Marine Environment of Galicia), Spain*

Due to the wide use of recycled tire crumb rubber (RTCR) as infill in turf fields and inurban recreational pavements, tire rubber compounds are in direct contact with people, especially with children that are the main user of this type of facilities. The European legislation only limits the content of 8 PAHs (Polycyclic Aromatic Hydrocarbons) to 20 µg/g in this type of materials. Besides, for other compounds, such as antiozonants, vulcanizing and crosslinking agents, there is no current regulation. However, in September 2023 the European Commission announced the ban of the use of crumb rubber as infill allowing manufacturers eight years to adapt to the new regulation.

The aim of this work is to assess the exposure to several hazardous chemical such as PAHs via dermal contact. To evaluate this, wipes and cotton pads are used to clean children’s hands after playing in artificial turf football fields. Two different techniques, Pressurized Liquid Extraction (PLE) and Ultrasound Assisted Extraction (UAE) are used to extract the wipes and pads. The identification and quantification of the target analytes is performed by gas chromatography coupled to tandem (GC-MS/MS).

4.13.P-Mo451 Microplastic polyethylene induces hearing and sensorimotor deficit in mice

Jin SU KIM[1]*, Javeria Zaheer*[2]*, Ho Sun Lee*[3] *and Min-Hyun Park*[3]*, (1)Division of RI Application, Korea Institute of Radiological and Medical Sciences (KIRAMS), Korea, Republic of (South), (2)Korea Institute of Radiological and Medical Sciences, Korea Institute of Radiological and Medical Sciences, Korea, Republic of (South), (3)Department of Otorhinolaryngology, Boramae Medical Center, Korea, Republic of (South)*

Balance and hearing loss are not uncommon in any of the age groups. The hazardous effects of microplastics (MPs) are increasingly reported; however, whether the balance and hearing loss are induced by MPs remains unknown. In this study, we investigated whether MP polyethylene induced hearing loss in a mouse model. To detect hearing loss and balance defect after polyethylene (PE) exposure, we evaluated genetic changes, hearing levels, and cerebral glucose metabolism using auditory brainstem responses and ^{18}F- fluorodeoxyglucose (FDG) PET in addition to behavioral study. C57BL/6J mice (5-week-old) were grouped into control (n = 10) and PE-fed groups (n = 10). Mice were orally administered 100 ppm/100 µL of PE every day for 4 months. We identified the accumulation of PE in the cochlea and vestibular region. The fragmented PE in inner ear was 3.00 ± 0.38 μm in size; the administered PE concentration was 1.14 ± 1.06 mg/g. Fourier transform infrared spectrometry confirmed that the properties of the recovered MP were similar to those of PE fed to the mice. Exposure to PE increased the hearing thresholds and decreased glucose metabolism in the bilateral lateral entorhinal cortex, right primary auditory cortex, and right secondary auditory cortex. We observed changes in gene expression levels and abnormalities in balance related behavior assessment in the PE group. Therefore, PE exposure induces hearing loss and affects balance. MP environmental pollution could be one of the causes of hearing loss and balance defects.

4.13.PC The Fate and Effects of Micro- And Nano-Plastics in Relation to Human Health Exposure

4.14 Understanding, Detection, Monitoring, and Management of Harmful Algal Blooms (HABs) and Biotoxins for a Safer Environment and Public Health

4.14.T-01 Abundance and Co-variation of Toxins and Secondary Metabolites from Cyanobacteria of 4-year Lake Study
***Xuejian Wang*[1]**, *Simon Wullschleger[2] and Elisabeth Janssen[3], (1)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)Eawag - Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (3)Eawag, Switzerland*
Cyanobacterial blooms are increasing globally, posing threats to aquatic ecosystems and human health especially by the release of toxins. Besides widely studied microcystins, a legion of other secondary metabolites has been identified over the past decades including anabaenopeptins, cyanopeptolins and microginins among others. However, we still lack data on their co-occurrence in surface waters. Here, we investigated the diversity and the temporal trends of co-produced metabolites across a four-year lake study. We performed target analysis and suspect screening with high-resolution mass spectrometry on lake samples using CyanoMetDB, a comprehensive, open-access structural database of known metabolites from cyanobacteria. Overall, the lake was dominated by 9 target toxins and 27 suspect metabolites. While [D-Asp^3, E-Dhb^7] MC-RR was the most abundant microcystin, Oscillamide Y, an anabaenopeptin, occurred at up to 100-fold higher concentrations, which can be further considered as an indicator substance for the monitoring program of this lake. Our results further indicate that anabaenopeptins and microginins were dominant co-occurring metabolites in this lake with oscillating concentration profiles throughout the year but with opposing relative abundances. We use hierarchical clustering and correlation analysis to group metabolites by their temporal trends and further explore relationships with physical-chemical water quality parameters and phytoplankton species composition that we recorded along with the metabolites data. We demonstrate the complexity of toxin/metabolite profiles across seasons and years with new implications for selecting indicator substances in monitoring programs. Such data open new opportunities to explore the link between relative abundances of cyanotoxins/metabolites and the evolution of bloom dynamics also for the development of early-warning strategies.

4.14.T-02 Genetic and Metabolic Diversity of Cyanobacteria and Their Toxins on Rock-water Interfaces in Mountain Habitats
***Juliana Oliveira*[1]**, *Francesca Pittino[2], Sabine Fink[3], Christoph Scheidegger[3] and Elisabeth Janssen[4], (1)Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)University of Milano-Bicocca, Italy, (3)WSL, Switzerland, (4)Eawag, Switzerland*
Subaerial, often dark-colored surfaces, termed *Tintenstrich communities* (TCs), extend on rock faces in semi-aquatic environments. These communities are widely distributed in high mountain areas, including large parts of the Alpine region, and are predominantly composed of free-living cyanobacteria and associated with lichen-forming fungi (e.g., cyano-lichens). Toxins of cyanobacteria are an ongoing subject of studies in surface waters around the world, as they pose a major concern for environmental and public health, and the World Health Organization defined limits for cyanotoxins in drinking and recreational water quality guidelines. Despite that, many questions remain unsettled about their role at the land-water interface, and its occurrence in the Swiss Alps is currently unknown. Therefore, we explore for the first time, the genetic diversity of cyanobacteria and the metabolic diversity of toxins and other bioactive compounds in alpine regions. A total of 214 TCs specimens examined exhibited the presence of cyanobacterial strains (16S rRNA gene sequencing). PCR analyses suggest that 30% of samples were positive for gene encoding for anatoxin (atxA), 29% for cylindrospermopsin (cryJ) and 25% for microcystins and/or nodularins production (HEPF). Methanolic extracts of samples that obtained positive results for genes associated with toxin production were analyzed by online-SPE-LC-MS/MS. Suspect-screening against CyanoMetDB was used to annotate tentative candidates. Cyanotoxins and other bioactive metabolites from cyanobacteria were detected in the majority of the sampled areas. Variants of anatoxins were identified in the metabolic screening in 84% of all analyzed samples obtained from siliceous rock. In contrast, anabaenopeptins were most frequently detected in limestone samples, which suggests that substrate type may select for different species. Our results present the first empirical data on TCs toxin production in alpine regions. Further studies are required to understand the selection pressure of biosynthetically different cyanobacteria in these areas and, our obtained cyanobacterial isolates from these sites will facilitate such investigations.

4.14.T-03 Zebrafish Larvae Exposed to BMAA and Isomers DAB and AEG: A Morphological and Behavioural Study

Jeanne Lichtfouse*, University of Nimes, France*

BMAA (beta-methylamino L-alanine) is a neurotoxin produced mainly by cyanobacteria and the subject of several hypotheses suggesting a link with amyotrophic lateral sclerosis (ALS). It has historically been found in cycad roots, consumed in various ways by the Chamorros on the island of Guam, where the incidence of ALS is much higher than the global average. Other clusters have also been identified by the scientific community and several studies have highlighted multiple mechanisms of toxicity of this molecule. Two isomers are also identified and studied: DAB (2,3-duaminobutyric acid) and AEG (N-(2aminoethyl) glycine).

In France, in the Occitanie region, BMAA and/or isomers have been detected in the Thau lagoon in bivalves and, depending on the time of year, in water and/or air samples. Other global studies show the possible presence of toxins in the environment at nanogram concentrations. As highlighted by the 2017 French National Agency for Food, Environmental and Occupational Health and Safety report, information on the effects of environmental concentrations remains to be completed.

We therefore tested BMAA, DAB and AEG on a common use toxicological model: *Danio rerio*; at the doses of 1-10-100 $ng.L^{-1}$ and 1-500 $\mu g.L^{-1}$. Zebrafish larvae were exposed from 28 to 100 hours post-fertilization. A morphological analysis evidenced effects (e.g. edema, scoliosis, etc.) of each toxin even at the lowest concentrations. Additionally, the swimming behaviour of exposed zebrafish was studied (Daniovision®). Larvae were observed for three minutes of free swimming, followed by a tap stimulus and two more minutes of free swimming. Effects on swimming distance have been highlighted for the three molecules, confirming an impact of the toxins at the nanogram concentrations. Statistical significance differed depending on the parameter analysed (total distance, distance covered 1 or 5 seconds before and after the tap stimulus). From these results, DAB and AEG seem to have a higher toxicity if compared to BMAA as their impact is stronger and highly statistically significant. To note, these data suggest also a nonlinear dose-response relationship, supporting the value of studies at environmental concentrations. To our knowledge, this is the first study to focus on such low doses.

Overall, the morphological and behavioural analysis show complementary results and indicate the importance of pursuing research.

4.14.T-04 Spatiotemporal Distribution and Driving Mechanisms of Algal Toxins and Their Producers in Hong Kong Coastal Waters

Li Zhang[1]*, Anqi Xiong*[2]*, Xintong Liu*[3] *and Ling Jin*[1]*, (1)Hong Kong Polytechnic University, Hong Kong, (2)CEE, Hong Kong Polytechnic University, Hong Kong, (3)Hong Kong Polytechnic University, Hong Kong (China)*

The global incidence and impact of harmful algal blooms (HABs) are escalating, primarily driven by anthropogenic pollution and climate change in coastal regions. Lipophilic algal toxins (LATs) produced by toxigenic microalgae pose threats to marine ecosystems and human health. However, the ecological dynamics influencing HAB trends and patterns at both global and local scales remain poorly understood as the effects of climate change and eutrophication differ among species. Hong Kong, renowned for its diverse marine ecosystems and thriving aquaculture industry, understanding the spatiotemporal distribution and the underlying mechanisms of algal toxins and their producers is crucial. To address this, a comprehensive investigation of LATs in Hong Kong's coastal waters was undertaken, employing a DNA metabarcoding technique to identify potential toxin producers during wet and dry seasons. Among the nine targeted LATs, pectenotoxin-2 (PTX-2), okadaic acid (OA), dinophysistoxin-1 (DTX-1), and gymnodimine (GYM) were detected in surface seawater across two seasons, with concentrations ranging from 0.064 to 8.07 $ng\cdot L^{-1}$. PTX-2 and OA emerged as the predominant toxins, collectively contributing to more than 70% of the total detected LATs. Notably, PTX-2 concentrations were significantly higher in the dry season throughout the entire study area. Significant spatial variations occurred in the concentrations of OA, DTX-1, and GYM, with the eastern waters exhibiting the highest levels. Of the 35 potentially harmful algal taxa identified, 25 showed a significant correlation with the detected toxins. The analysis further highlighted that *Dinophysis spp.* and *Alexandrium spp.*, known potential producers, exhibited a positive correlation with the concentrations of PTX-2 and DTX-1. Similarly, a positive correlation was observed between *Gymnodium spp.* and GYM levels. These related harmful taxa contributed more to the LATs than environmental parameters based on variation partitioning analysis and hierarchical partitioning (42%). Among the environmental factors screened, temperature and salinity emerged as key influencers on the harmful taxa, thereby regulating the distribution of toxins. These findings hold significant relevance for predicting how toxigenic marine algae may respond to future changes in the coastal environment, thereby providing valuable insights for the management and conservation of marine ecosystems in the face of climate change and anthropogenic pollution.

4.14.T-05 Mixtures of Organic Micropollutants Exacerbated the In Vitro Human Neurotoxicity of Prymnesins and Contributed to Aquatic Toxicity During a Massive Fish kill in the Oder River in 2022

Beate Escher[1]*, Jörg Ahlheim*[2]*, Werner Brack*[2]*, Dietrich Borchardt*[3]*, Georg Braun*[3]*, John K. Colbourne*[4]*, Janek Dann*[3]*, Annika Jahnke*[5]*, Joern Gessner*[6]*, Nils Kluver*[3]*, Xiaojing Li*[4]*, Elisabeth Varga*[7]*, Stefan Lips*[8]*, Mechthild Schmitt-Jansen*[9]*, Stefan Scholz*[10]*, Tobias Schulze*[2]*, Stephanie Spahr*[11]*, Karsten Rinke*[3]*, Nadin Ulrich*[12] *and Markus Weitere*[3]*, (1)Department of Cell Toxicology, Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany, (3)Helmholtz Centre for Environmental Research (UFZ), Germany, (4)School of Biosciences, University of Birmingham, United Kingdom, (5)Department of Exposure Science, Helmholtz Centre for Environmental Research (UFZ), Germany, (6)Leibniz Institute of Freshwater Ecology and Inland*

Prymnesins produced during an the algal bloom by *Prymnesium parvum* led to the death of several hundred million tons of freshwater fish in the Oder River in summer 2022. We investigated effects on aquatic life and human health from exposure to contaminated water or fish. Prymnesins and >120 organic micropollutants were quantified in water samples collected during the peak of the fish kill. Chemicals from diverse sources led to mixture effects with the predicted mixture risk quotient exceeding the threshold of one. Extracts of water and filters (biomass and particulates) induced moderate effects *in vivo* in algae, daphnids and zebrafish embryos but caused remarkably high effects in a human neuronal cell line indicating the presence of neurotoxicants. Prymnesin standards and standards of the detected chemicals were tested with the *in vitro* neurotoxicity assay. Mixture toxicity modeling demonstrated that the neurotoxic effects were mainly caused by the detected prymnesins with minor contributions by the detected organic micropollutants. Extracts from gills and muscle of exposed fish from the Oder River were only moderately neurotoxic and prymnesins could not be detected in fish. The high neurotoxicity of water and extracts of algal biomass is a warning sign that human health could be compromised by exposure to water and fish during hazardous algal blooms. The high toxicity of prymnesins was exacerbated by the high micropollutant loads that clearly led to mixture effects in cytotoxicity and neurotoxicity assays based on differentiated human neuronal cells However, organic micropollutants were not deemed to be a major contributor to the actual fish kill due to the high ichthyotoxicity of prymnesins that clearly dominated.

4.14.P Understanding, Detection, Monitoring, and Management of Harmful Algal Blooms (HABs) and Biotoxins for a Safer Environment and Public Health

4.14.P-Th449 Bloom Dynamics Monitoring Program of the Toxic Benthic Dinoflagellate Ostreopsis along the Basque Coast (South East Bay of Biscay)

Yago Laurenns-Balparda[1]*, Pablo Aramendi*[1]*, Jone Bilbao*[1,2]*, Marina Salido*[1,2]*, Estibalitz Txurruka*[1] *and Sergio Seoane*[1,2]*, (1)Plant Biology and Ecology, University of the Basque Country (UPV/EHU), Spain, (2)Research Center for Experimental Marine Biology and Biotechnology (PiE-UPV/EHU), Spain*

Ostreopsis is a potentially toxic benthic dinoflagellate genus that, originally, was mostly distributed in warm and tropical waters. Its presence has been related to toxic outbreaks affecting humans with symptoms such as coughing, fever, rhinorrhoea, mild breathing problems and skin irritation. Since the first report in the Basque Country in 2007, its abundance and distribution have grown to such an extent that, in the summer of 2021, toxic blooms of these dinoflagellates were reported for the first time in the Bay of Biscay, forcing the closure of some beaches. Consequently, a monitoring program was developed to know the current dynamics of this genus in Basque waters. The sampling took place at six sites along the Basque coast, and was carried out on a monthly basis throughout two whole years, with an intensification in summer, when it was fortnightly. The study consisted of the microscopic analysis of samples from the water column and macrophytes (Utermöhl method), the characterization of environmental variables (temperature, salinity, pH, oxygen and nutrients) and molecular analyses (rDNA barcoding) to identify the different *Ostreopsis* species.

In both sample types, the months with greater *Ostreopsis* abundances were July, August and September. Regarding the counts from water samples, although some peaks took place in Mutriku and Zumaia, the maxima were most frequently observed in San Sebastian, with a maximum value of $1.33 \cdot 10^5$ cells/L. In the case of macrophyte samples, indicators of *Ostreopsis* reservoirs, the pattern was similar, occurring some peaks in Mutriku, Zarautz and Hondarribia, but mostly in San Sebastian, where the maximum value was recorded ($1.86 \cdot 10^6$ cells/g) on *Centroceras clavulatum*. Molecular analyses confirmed the presence of both *Ostreopsis* cf. *ovata* and *O*streopsis cf. *siamensis* in San Sebastian. These results aim to help to understand the behaviour of this microalga and prevent future harmful events.

4.14.P-Th450 High-Frequency Monitoring of Lake Plankton Abundances

Sreenath P Kyathanahally[1]*, Cheng Chen*[1]*, Marta Reyes*[2]*, Stefanie Merkli*[2]*, Ewa Merz*[2]*, Francesco Pomati*[2] *and* ***Marco Baity-Jesi***[1]*, (1)Siam, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (2)ECO, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland*

Plankton is relevant due to its crucial role in ecosystem processes, such as carbon fixation and oxygen production, as well as its significance in aquatic food webs and the monitoring and forecasting of harmful algal blooms. Algal blooms are of great importance due to their significant impact on aquatic ecosystems and human activities. These blooms can lead to the depletion of oxygen in water bodies, causing harm to fish and other aquatic organisms, and can also produce toxins that pose a threat to human health when consumed through contaminated water or seafood.

In order to explain, and possibly even predict, algal blooms, we need a deep understanding of the community dynamics regulating the presence of (phyto)plankton. Ideally, this would require real-time access to the abundances of all the species present in an aquatic ecosystem.

We approached such an endeavor by installing an underwater plankton camera at 3m depth, in a medium-sized Swiss lake.

This camera records pictures of plankton at a 6 s frequency, and can detect objects ranging from 10s of micrometers to several millimeters in size. We use deep learning classifiers to identify the objects in the images. These classifiers have very high performances, which allow us to track the abundances of each taxonomic unit in real time. This methodology gives us access to real-time data on plankton abundance, biomass, and community composition, allowing for immediate detection and response to changes in the ecosystem, such as harmful algal blooms or shifts in plankton populations.

4.14.P-Th451 Seasonal variability of tetrodotoxin and analogues in trumpet shell, Charonia Lampas

*Maria Pais[1], Flávia Carvalho[1], Magda Frade[1], Ana Marçalo[1], Pedro Reis Costa[2], José Paulo da Silva[1], Adelino V.M. Canário[1] and **Sandra Lage**[1], (1)CCMAR - Center for Marine Sciences, Portugal, (2)IPMA - Instituto Português do Mar e da Atmosfera, Portugal*

Tetrodotoxin (TTX) is a potent neurotoxin responsible for numerous human poisonings, the majority of which have been linked to pufferfish consumption and were until the last decade restricted to Japan and other Southeast Asian countries. As of 2005, TTX-bearing species started to appear in European coastal countries. The only known case of human TTX poisoning in Europe has been linked to the consumption of trumpet shell *Charonia lampas* purchased in a market in Malaga (south of Spain) but presumed to have been caught off the Algarve coast (south of Portugal). To date, TTX is still not regulated or monitored in Europe. However, to protect public health, the European Food Safety Authority (EFSA) recommends a maximum limit of 44 g TTX equivalent (eq)/kg of shellfish meat.

To assess consumer risk from TTX-contaminated trumpet shell, we studied the seasonal variability of TTX and analogues concentrations in edible and non-edible fractions of trumpet shell specimens caught off the Algarve coast. TTX was found in varying concentrations, most of which were above EFSA recommended maximum limit, in the non-edible parts of 16 of 25 specimens collected between 2021 and 2022. No TTX was detected in the edible parts of any of the specimens analysed. However, TTX analogues were present in the majority of both edible and non-edible parts. These results suggest that although thorough evisceration may lower the amount of TTX consumed, it may not be sufficient to ensure consumer safety.

4.14.P-Th452 Enhanced Control of Biological Contaminants and Biotoxins in Shellfish Aquaculture through UV-LED Technology

***Javier Moreno-Andrés**[1], Leonardo Romero-Martinez Dr.[2], Elena Villar-Navarro Dr.[2] and Enrique Nebot Sanz Dr.[2], (1)Environmental Technologies, University of Cadiz, Spain, (2)Environmental Technologies, University of Cádiz. Marine Research Institute (INMAR), Spain*

Effective control of biological contaminants and associated biotoxins is critical in shellfish cultivation, ensuring both food safety and ecological sustainability. This necessitates the integration of effective treatment systems. This study explores an emerging UV radiation technology employing LED diodes, coupled with widely utilized aquaculture oxidizing agents, namely H_2O_2 and O_3. The synergistic application of UV-LED technology and oxidative agents is designed to trigger photochemical reactions, able to effectively inactivate microorganisms and degrade biotoxins.

Preliminary findings indicate the UV-LED technology's capacity to effectively inactivate marine microorganisms, including certain *Vibrio* species and harmful microalgae. Nonetheless, some biotoxins exhibit resistance to these treatments, warranting advanced methodologies. Factors such as dissolved salts and other components within the aquatic matrix can influence biotoxin degradation, necessitating specific optimization of treatment protocols.

In conclusion, the integration of UV-LED technology, complemented by oxidative agents, presents a promising avenue for supporting the water-energy nexus in shellfish aquaculture. The demonstrated efficacy in inactivating marine microorganisms and harmful microalgae highlights its potential in ensuring the safety and sustainability of shellfish production systems. The need for laboratory studies is needed to guarantee the successful scaling of these processes from controlled environments to practical, large-scale applications.

4.14.P-Th453 Efficient Adsorbents based on Covalent Organic Frameworks and Polymers for Biotoxins from Harmful Algal Blooms

***Begoña Espina**[1], Miguel Chaves[2], Tianxing Wang[2], Vanesa Romero[3], Soraia Fernandes[2], Laura Rodriguez-Lorenzo[4], Laura M. Salonen[5], Tolga Zorlu[2] and Joana Campos Araújo[2], (1)International Iberian Nanotechnology Laboratory, Portugal, (2)International Iberian Nanotechnology Laboratory, (3)Centro de Investigación Mariña, Universidade de Vigo, Spain, (4)Water Quality Group, International Iberian Nanotechnology Laboratory (INL), Portugal, (5)CINBIO, Universidade de Vigo, Department of Organic Chemistry, Spain*

Recently, covalent organic frameworks (COFs), crystalline porous materials, were shown to adsorb okadaic acid (OA) from synthetic seawater with a much higher efficiency as compared to polymeric resins. Equilibrium was reached in 60 min and maximum adsorption capacity, q_m, was calculated to be 279 mg g^{-1}, resulting in a 200-fold increase compared to the state -of-the-art. In a follow-up study, the isolation of this powder-form adsorbent from the water matrix was improved by preparing a magnetic COF composite (mTpBD-Me_2) that can be collected using an external magnetic field, which resulted in a further enhancement of the adsorption efficiency by a factor of three.

In the present study, we report a new, efficient synthesis procedure for mTpBD-Me_2 in one step that retains its adsorption efficiency as well as the use of TPB-DMTP COF for an even higher adsorption capacity and much faster adsorption reaching equilibrium in only 1 min.

On the other hand, herein, we report a covalent organic polymer (COP) for the efficient adsorption of saxitoxin (STX), the carboxylic acid functionalized TpPa-COOH. The adsorption being fast with equilibrium reached within 1h, and a calculated maximum adsorption capacity, q_m, of 4.92 mg g^{-1}, making this material the best reported adsorbent for this toxin. More importantly, TpPa-COOH showed good reusability and high recovery rates for STX in natural freshwater.

We have prepared a carboxyl-functionalized TpPa-COOH COP with high adsorption efficiency towards STX, and reusable with high recovery efficiency. We have also improved the cost, time and sustainability of the production of mTpBD-Me_2 previously reported for extraction of OA from marine water and reported the high capacity and efficiency in OA adsorption of a TPB-DMTP COF. All those developments shows COFs/COPs and their composite's potential for biotoxins extraction and preconcentration for analytical applications.

4.14.P-Th454 Assessment of Heterosigma akashiwo Inactivation by UV Irradiation at Different Wavelengths
*Elena Villar-Navarro Dr.[1], Leonardo Romero-Martinez Dr.[1], Enrique Nebot Sanz Dr.[1] and **Javier Moreno-Andrés**[2], (1)Environmental Technologies, University of Cádiz. Marine Research Institute (INMAR), Spain, (2)Environmental Technologies, University of Cadiz, Spain*
Ships load ballast water (ballasting) to increase maneuverability and balance. This water is a source of pollution and can generate ecological problems related to invasion of exogenous species, since it is discharged (de-ballasting) into the ocean or ports in a different area from where it was loaded. To prevent such contamination, various strategies have been proposed to minimize the number of viable organisms, such as the implementation of ballast water treatments systems as it is established by the Ballast Water Management Convention (IMO 2004). However, there are different challenges to be faced in order to improve the proposed treatments, such as the search for alternatives to traditional UV treatment based on low or medium pressure mercury lamps through the use of UV LEDs.

The present study aims to determine the effect of different wavelengths and radiation sources on a monoculture of a harmful algal bloom species, *Heterosigma akashiwo*. A low-pressure mercury lamp (254 nm) and two collimated UV LED reactors (265 nm and 275 nm) were used. Experiments were performed in duplicate and up to five doses of UVC radiation (25 - 200 mJ·cm^{-2}) were applied. The treatment was performed using a Petri dish with a volume of 50 mL. The microalgae culture was used in exponential state, with high photosynthetic activity and a surplus nutrient medium (Guillard f/2). After applying the treatment, the culture was kept in a culture chamber at a constant temperature (24 ºC) and photoperiod (16 h light: 8h dark). Fluorescence and quantum yield (QY) were measured for 14 days by using the fluorescence meter AquaPen AP-110.

Preliminary results indicate that doses of 100 and 200 mJ·cm^{-2} reduced cell concentration by 70 and 90%, respectively, using low-pressure mercury lamps (254 nm). In the case of UVC LEDs only cell concentration was reduced (70%) with doses of 200 mJ·cm^{-2}. Data modeling using logistic models will provide insight into how different doses affect the growth kinetics of the microalgae. In addition, the use of photosynthetic activity will be evaluated to determine the effect of UVC treatment in a rapid manner. Finally, cell damage after the application of different doses and wavelengths will be assessed.

The study of UVC treatment in monocultures of harmful microalgae is essential to develop effective control strategies, understand the impacts on the aquatic ecosystem and ensure water safety and the preservation of aquatic resources.

4.14.P-Th455 Impact of Intense Agricultural Activities on Biota in a Natural Protected Area in SW Spain
***M Dolores Basallote**[1], Steven Buzón[2], Cristina Pérez-Carral[3], Pablo J Hidalgo[2], Nuria Montiel[4], Manuel Olías[5] and Carlos R Cánovas[5], (1)Department of Ecology and Coastal Management, Spanish National Research Council (CSIC), Madrid, Spain, (2)Department of Integrative Science & Research Center on Natural Resources, Health and the Environment, University of Huelva, Spain, (3)Department of Agroforestry Science, University of Huelva, Spain, (4)2Department of Integrative Science & Research Center on Natural Resources, Health and the Environment, University of Huelva, Spain, (5)Department of Earth Sciences & Research Center on Natural Resources, Health and the Environment, University of Huelva, Spain*
Repeated dramatic ichthyofauna mortally events have been registered at the end of summer in 2022 and 2023 in the Estero de Domingo Rubio Protected Area (Huelva, SW Spain). Included in the Natura 2000 and Special Protection Area for Birds, this wetland of great ecological and landscape importance is bordered to the south by an industrial complex, to the west by the Tinto River estuary, to the east by the Special Area of Conservation (SAC) known as Dehesa del Estero y Montes de Moguer, and to the north by agricultural lands, which exerts strong pressure on the system due to polluted irrigation returns. In October

16th 2022, 200 tons of fish (mainly mullet but also common carps) appeared dead in the surface waters being reported toxins from cyanobacteria (*Prymnesium* sp. and *Pseudanabaena catenata*) proliferation as the cause of mortality by the regional government. With the aim of understanding the process causing the increase in cyanobacteria in the Domingo Rubio waterbodies, the system was monitored during one year. To address this issue, the determination of physico-chemical parameters (pH, electrical conductivity, oxidation-reduction potential and dissolved oxygen) as well as nutrients, organic compounds such as pesticides and metals concentrations were determined in waters of the system and its natural and anthropogenic tributaries. The appearance of the toxins that cause fish mortality was suggested to be associated with high levels of eutrophication, which, in turn, are directly associated with discharges of irrigation return flows from the surrounding agriculture that feed the system. In this context, the protection of the wetland and the implementation of sustainable agricultural practices are key measures to ensure the preservation of this system and the associated biota. Thus, cooperation between farmers, ecologists and the authorities is essential to find solutions and keep the ecological balance of this wetland and its sustainable conservation

4.14.P-Th456 Cigarette Butts can Enhance Toxigenic Cyanobacteria Growth Through Fungal Parasite Infection Suppression

Nele Guttmann[1], Stephanie Spahr[2], Justyna Wolinska[1] and ***Erika Berenice Martinez Ruiz****[3], (1)Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB), Germany, (2)Ecohydrology and Biogeochemistry, Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB), Germany, (3)5, Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB), Germany*

Smoked cigarette butts (CB) are one of the most common types of litter around the world, with approximately 4.5 trillion discarded annually worldwide. CBs contain more than 1000 chemicals, including metals, nicotine, and cotinine, which can leach into water threatening aquatic organisms such as cyanobacteria and fungi. Despite their prevalence, the effects of CB on freshwater organisms remain poorly understood. Chytrids are zoosporic fungi ubiquitous in freshwater environments that parasitize cyanobacteria and, thus, affect harmful bloom dynamics by delaying or suppressing their formation. Little is known about the effects of pollutants such as CB on chytrid infections and the ecological processes associated with these parasite interactions. Traditionally, ecotoxicological tests have focused on single-species systems. However, it is critical to understand how pollutants affect ecological interactions between species using multi-organism systems, like host-parasite. In this study, we investigated the effect of CB leachate at concentrations of 0.2, 2, and 10 CB L^{-1} on the interaction between the toxigenic cyanobacterium *Planktothrix agardhii* and its chytrid parasite *Rhizophydium megarrhizum*. Cyanobacteria growth was lower in uninfected cultures exposed to 2 and 10 CB L^{-1} than in the control. In infected cultures, parasite fitness was adversely affected at all tested concentrations, with complete suppression of the infection at 2 and 10 CB L^{-1}. Consequently, infection suppression promoted cyanobacteria growth at the highest tested concentration. Our results suggest that while CB hinder cyanobacteria growth, in an epidemic scenario it could foster cyanobacteria by inhibiting chytrid infections. This study sheds light on how CB leachate could favor cyanobacterial bloom formation and impact several ecological and evolutionary processes involving chytrids

4.14.P-Th457 Acute Toxicity of Harmful Algae on Marine Zooplankton in the Context of Climate Change

Wenxin Liu*, Ghent University (UGent), Belgium*

The increase in human activities and their expansion into oceans and lakes have significantly disturbed aquatic environments. For instance, continuously increasing greenhouse gas emissions have resulted climate change, affecting the temperature, salinity, and pH levels in water bodies. Additionally, the overuse of agricultural fertilizers has altered the nutrient content in most of these environments. Harmful algal blooms are proliferated algae densities that are often able to produce different kinds of toxic metabolites. An increasing number of harmful algal blooms have been recorded in the last decades due to anthropogenic pressure. Some studies have even found that cyanobacteria that originally lived in freshwater environments are invading estuaries. Research has established that sudden increases in nutrients contribute to HAB occurrence and it has also linked warming temperatures to individual events. Zooplankton, vital to aquatic ecosystems, connect producers and higher-level organisms in food webs as both consumers and prey. Not much is known about the toxicity of these toxic blooms on zooplankton communities in different climate change scenarios. Therefore, in this study, we investigated the impact of climate change proxies on the toxicity of harmful algae to a harpacticoid and a calanoid copepod—*Nitokra spinipes* and *Acartia clausi*, respectively . We constructed a series of laboratory experiments with relevant temperature, salinity, pH and nutrient conditions, focusing on two microalga species the dinoflagellate *Alexandrium ostenfeldii* and the cyanobacteria *Microcystis aeruginosa*. After collecting algae, grown in these different scenarios, we assessed their toxicity in these copepods, studying mortality, swimming behaviour and ingestion rate. First, we observed variations in mortality rates, swimming speeds, and swimming distance between *N. spinipes* and *A. clausi* exposed to the same toxic algae, indicating an interspecies difference in sensitivity towards HAB blooms. Moreover, both *N. spinipes* and *A. clausi* exhibited varying sensitivities to algae grown under different conditions, suggesting that environmental factors indeed influence algal toxin production. These results provide better insights into environmental consequences of harmful algae blooms on the marine food web in the warming future.

4.14.P-Th458 CYANOBACTERIA BLOOMS IN CITY PARKS: IMPLICATIONS FOR URBAN ECOLOGY IN A CLIMATE CHANGE SCENARIO

Bruna Veira[1], Mário Pereira[2], JOão Amaral[3] and ***Ines Domingues****[1], (1)CESAM - Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro & Centre for Environmental and Marine Studies (CESAM), Portugal, (3)Department of Biology & CESAM, University of Aveiro, Portugal*

Cyanobacteria can produce toxins that can have negative effects on aquatic organisms, wildlife, domestic animals and humans. Lakes and ponds in urban parks, due to their location and importance raise important attention. They are frequented by people and pets, and, from an urban ecology perspective, they are important biodiversity spots and climate regulators in large cities. However, along with the increasing temperatures driven by global changes, the fact that lakes are usually shallow, tend to have stagnant water and may receive input of urban effluents makes them prone to cyanobacterial blooms to proliferate. In this work, the effects of a cyanobacterial bloom, collected from an urban park in Aveiro (Portugal), on zebrafish embryos (*Danio rerio*) were assessed, evaluating toxicity in terms of mortality, hatching, embryo development, behavior endpoints (total distance, slow and rapid movements, peripheral distance and different angle classes) and biochemical effects (oxidative stress - Glutathione-S-transferase (GST), Catalase (CAT), Glutathione Peroxidase (GPx) and Glutathione Reductase (GR); neurological damage - Acetilcholinesterase (AChE) and indicator of tissue damage - Lactate dehydrogenase (LDH)) after five days of exposure to cyanobacteria extract. The results showed that the exposure affected development (hatching and delayed development) and caused neurotoxicity, translated into hypoactive behavior, increased thigmotaxis and inhibition of ChE in zebrafish embryos. This study showed that cyanobacteria blooms in urban parks may pose risks to wildlife, pets and people that must be evaluated.

Keywords: Cyanotoxins, climate change, anthropogenic pressures, neurotoxicity, urban ecology, *Danio rerio* embryos

4.14.P-Th459 Influence of Temperature on Acute and Chronic Toxicity of Marine Algal Toxins — A Case Study with Copepod Nitokra spinipes

***Wenxin Liu**, Ghent University (UGent), Belgium*

Harmful algal blooms (HABs) – proliferated algae densities with often a toxin producing ability – have been found increasingly in both northern and southern oceans. Recent studies have established that increasing temperatures contribute to HABs occurrence. But the broader influence of climate change on these outbreaks is less well quantified. Of particular concern is the limited research on HABs toxin effects under varying temperatures, especially concerning zooplankton, a crucial component of aquatic ecosystems. They do not only consume algae but also serve as prey for organisms at higher trophic levels, hence, are pivotal in energy transfer and nutrient cycles in aquatic food webs. Therefore, we examined the impact of marine toxins on marine zooplankton in the context of climate change. We designed a series of laboratory experiments using filtered seawater to assess the toxicity of four commonly occurring algal toxins, purified and sourced from CIFGA Laboratory, on a model organism for ecotoxicological studies, *Nitokra spinipes*, exposed to three different temperatures. We evaluated acute toxicity of domoic acid and yessotoxin, respectively. Adult females were exposed to these toxins at 15, 20, and 25°C for 48 hours. EC50 values of domoic acid arranged from 11.08±3.81 to 88.51±164.89 μg/L, respectively. Also, juveniles, aged 48 to 72 hours, were exposed at 18, 20, and 22°C for the same duration. The EC50 of domoic acid in this case arranged from 65.36±10.66 to 102.76±9.52 μg/L. Mortality rates across temperatures showed no significant difference. In chronic toxicity test, larval development ratio (LDR), brood size and inter-brood time of domoic acid, yessotoxin, saxitoxin, and microcystin-LR were examined at 18, 20, and 22°C. We observed that with increasing temperatures, LDR for domoic acid increased, whereas brood size significantly decreased as toxin concentration rose. While these results are preliminary, they indicate a temperature dependent sensitivity of copepods towards toxins produced by HABs.

4.14.P-Th460 Gene Expression Response in Marine Mussels Exposed to Toxic Cyanobacteria

***Cristina Plata Calzado**[1], Juliana Rodrigues[2], Angeles Jos[1], Ana Camean[1], Vitor Vasconcelos[2,3] and Alexandre Campos[2], (1)University of Sevilla, Spain, (2)University of Porto, Interdisciplinary Centre of Marine and Environmental Research (CIIMAR), Portugal, (3)Department of Biology, Faculty of Sciences, University of Porto, Portugal*

The increase in cyanobacterial blooms poses a challenge to environmental and human health due to their potential ability to produce cyanotoxins. Exposure to these cyanotoxins can affect different marine trophic levels, including marine bivalves which have been shown to accumulate microcystin (MC) and cylindrospermopsin (CYN), two of the main cyanotoxins in freshwaters. The impact of cyanobacteria and cyanotoxins on this organism is of great relevance given its worldwide distribution and the fact that mussels are consumed by both humans and animals. Hence, the main objective was to analyze the expression of genes involved in xenobiotic metabolism in marine bivalves (*Mytilus galloprovincialis*) after short exposure to different cyanobacteria strains. Animals treatment consisted in the exposure to MC-producing *Microcystis aeruginosa* cells (LEGE-CC 91094) or CYN-producing *Chrisosporum ovalisporum* cells (LEGE-CC X-001). Two different control groups were used, consisting of non-feeding animals and animals feeding with the green algae mixture *Tetraselmis* and *Isochrysis*. After treatment for 3 and 5 days, samples were taken from the gills and digestive glands of the mussels and the expression of following genes were analyzed by quantitative polymerase chain reaction (qPCR): four nuclear receptor 1 family J identified in Mediterranean mussels (NRj1jα, NRj1jβ, NRj1jγ and NRj1jδ), three cytochrome P450s genes (CYP3L1, CYP3L2 and CYP3L3) and a membrane transporter gene (ATP binding cassette subfamily B member 1, ABCB1). The expression of genes was different depending on the organ analyzed, the time of exposure to algae or algae intake and the type of cyanobacteria. Thus, *C. ovalisporum* caused a significant increase in the expression of NRj1jα, NRj1jβ, NRj1jγ, CYP3L1 and CYP3L3 genes in gills after 5-days of exposure in comparison to both control groups, while *M. aeruginosa* mainly produced a significant increase in ABCB1 expression in the digestive gland after both exposure periods. The results indicated that cyanobacteria may produce changes in the expression of genes involved in the xenobiotic pathways.

4.14.P-Th461 Cylindrospermopsin Neurotoxicity in a Human Brain Spheroid Model

***Antonio Casas Rodríguez**[1], David Pamies[2,3], Marie-Gabrielle Zurich[2,3], Ana Camean[1] and Angeles Jos[1], (1)University of Sevilla, Spain, (2)Department of Biomedical Sciences, University of Lausanne, Switzerland, (3)Swiss Centre for Applied Human Toxicology (SCAHT), Switzerland*

Cylindrospermopsin (CYN) is a cyanotoxin produced by cyanobacteria that is of increasing global concern due to its wide distribution, bioaccumulation capacity and toxic effects. CYN is mainly considered to be nephrotoxic and hepatotoxic. However, it can also induce toxicity in other organs, including the nervous system, although effects at this level are still poorly understood. Therefore, the aim of this study was to evaluate the effects of CYN on an iPSC-derived human 3D brain microphysiological system (BMPS). For this purpose, neural progenitor cells (NPC) were used to establish the BMPS model. The CRL-2097 fibroblast-derived iPSC cell line was used as neuronal progenitor cells (NPCs), and the toxicity of CYN was tested after 24 and 48 hours of exposure. CYN significantly reduced cell viability, with EC_{50} values of 3.07 ± 0.38 and 1.63 ± 0.05 µM after 24 and 48 h, respectively. The BMPS model was established and to characterise the different stages of differentiation and maturation, BMPS were harvested every two weeks for 8 weeks of differentiation. Analysis of different neuronal and glial cell specific genes was performed by quantitative RT-PCR. The cytotoxicity of CYN in the BMPS model was also evaluated after 1 week of exposure to different concentrations (0, 0.01, 0.1, 1, 2 and 5 µM). A significant decrease in cell viability was observed after exposure to 1, 2 and 5 µM. The EC_{50} was 4.26 ± 0.77 µM. The effects at non-cytotoxic concentrations on the mRNA expression of different genes were evaluated by RT-PCR. The results showed a concentration-dependent decrease in the expression of B3T and GFAP, while other nervous markers (NFH, OLIG1, SYP) showed a high increase at 1 µM. Oxidative stress related genes (HMOX, GSST, SOD1) and inflammatory genes (IL-1β, Nf-κβ, TNF-α) showed a significant increase at 1 µM CYN compared to the control group. Finally, immunohistochemical analysis are currently under way. These first results showed that the toxin could induces neurotoxicity in an *in vitro* 3D human model. However, more studies are necessary to determine the effects of CYN in the nervous system.

4.14.P-Th462 Neurotoxic Assessment of Cylindrospermopsin and Microcystin-LR Mixtures in Rat Brain

***Cristina Plata Calzado**, Ana Isabel Prieto, Ana Camean and Angeles Jos, University of Sevilla, Spain*

Anthropogenic activities and climate change are increasing the extent and frequency of cyanobacterial blooms capable of producing cyanotoxins. Cylindrospermopsin (CYN) and microcystin-LR (MC-LR) are among the most frequent cyanotoxins. Although they are considered mainly as a cytotoxin and a hepatotoxin respectively, different studies have revealed neurotoxic properties for both. Furthermore, the simultaneous presence of CYN and MC-LR has been described in nature. Therefore, the aim of this study was to evaluate the potential neurotoxicity of CYN/MC-LR combinations based on the measure of acetylcholinesterase (AChE) activity and different biomarkers of oxidative stress: lipid peroxidation (LPO) levels and superoxide dismutase (SOD) activity in brain of Wistar rats. Rats of both sexes were exposed orally to different concentrations of CYN/MC-LR (7.5 +75, 23.7 + 237, and 75 + 750 µg CYN + MC-LR/kg body weight). The methodology used to analyze these parameters was as follows: Ellman's procedure with modifications for AchE activity, the thiobarbituric acid method for LPO levels and the xanthine-oxidase cytochrome C method for SOD activity. Interestingly, the results showed a greater alteration in the parameters analyzed at the intermediate dose employed (23 + 237 µg CYN + MC-LR/kg body weight), being these alterations different depending on the gender of the animals. Specifically, in males the exposure to the intermediate dose produced a significant increase in LPO levels (1.5-fold) and in SOD activity (1.4-fold) with respect to the control, whereas in females the parameter with the greatest alteration at this dose was AChE activity, in which an inhibition of 20% of activity compared to the control group was observed. These results demonstrated that the CYN + MC-LR mixture may cause neurotoxic effects in rats after oral exposure and highlight the need for further studies focused on the neurotoxicity of these cyanotoxins.

Acknowledgement - The authors thank the Spanish Ministerio de Ciencia e Innovación (PID2019-104890RB-I00/AEI/10.13039/501100011033) for funding. C. Plata-Calzado is grateful for the financial support from the Junta de Andalucía (PREDOC_00447 contract).

Keywords: Cylindrospermopsin, Microcystin, Neurotoxicity, Brain

4.14.P-Th463 Investigation of Anatoxin-a Uptake and its Possible Cytotoxic Effects in Different Cell Lines

***Cristina Plata Calzado**, Ana Isabel Prieto, Ana Camean and Angeles Jos, University of Sevilla, Spain*

Anatoxin-a (ATX-a) is a cyanotoxin involved in cases of animal and human poisoning reported worldwide. This cyanotoxin is classified as primarily neurotoxic; however, recent studies have described adverse effects on immune cells and at other levels following exposure to ATX-a. Despite this, the number of studies on the toxic effects produced by ATX-a in established cell lines is limited. Therefore, the aim of the present work is focused on the evaluation of the uptake and potential *in vitro* cytotoxicity of pure ATX-a in different established cell lines. Specifically, neuroblastoma (SH-SY5Y and N2a), liver carcinoma (HepG2), colorectal adenocarcinoma (Caco-2), and immune system (THP-1, Jurkat and L5178YTk±) cell lines were employed. ATX-a uptake by the cell lines was assessed by measuring intracellular and extracellular toxin levels using high performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS/MS) in cells exposed to 50 or 100 µg/mL ATX-a for 24 h. To evaluate cytotoxicity, the tetrazolium salt (3-[4,5-dimethylthiazol-2-yl]-5-[3-carboxymethoxyphenyl]-2-[4-sulfophenyl]-2H-tetrazolium) reduction (MTS) assay was performed after 24 h exposure of cells to pure ATX-a (0-200 µg/mL). Considering the amount of intracellular and extracellular toxin, ATX-a recoveries ranged from 61 to 104%, although ATX-a was only detected inside neuronal and immune cell lines (in a range of 1.9 and 13.1% of the total toxin added), while in Caco-2 and HepG2 cells the toxin only was detected in the extracellular fraction. Regarding to cytotoxicity, ATX-a only produced a decrease in viability in the cell lines THP-1 and Jurkat under the conditions employed, obtaining a median lethal concentration (LC_{50}) only in the THP-1 cell line. This could be explained by the low amount of toxin present inside the cells, being THP-1 the cell line with the highest % of ATX-a absorbed. Thus, these data suggest that ATX-a may require a specific entry mechanism at the cellular level not described to date. Further studies on the absorption mechanisms of ATX-a are necessary to adequately select *in vitro* experimental models for the evaluation of its toxicity.

Acknowledgement - The authors thank the Spanish Ministerio de Ciencia e Innovación (PID2019-104890RB-I00/AEI/10.13039/501100011033) for funding. C. Plata-Calzado is grateful for the financial support from the Junta de Andalucía (PREDOC_00447 contract).

4.14.P-Th464 Immunomodulatory Effects of Arsenic, Cadmium, and their Combinations with Cylindrospermopsin on the Human THP-1 Cell Line.

Antonio Casas Rodríguez, *Leticia Diez-Quijada, Silvia Pichardo, Angeles Jos and Ana Camean, University of Sevilla, Spain*

Cylindrospermopsin (CYN) is a cyanotoxin produced by cyanobacteria that is of increasing global concern due to its wide distribution, bioaccumulation capacity and toxic effects. Previous studies suggest an interaction between these toxins and other chemical contaminants that can be found together in nature. Therefore, the aim of this study was to evaluate the effects of arsenic (As), cadmium (Cd) and their combinations with CYN on the human THP-1 cell line. For this purpose, cytotoxicity assays were performed using the MTS assay. As and Cd significantly reduced cell viability after 24h exposure, with EC_{50} of 46.48 ± 0.17 and 55.09 ± 4.98 µM, respectively. The interactions between these contaminants and CYN were evaluated using the isobologram method, which revealed an antagonistic relationship with the toxin in both cases. The effect of the mixtures on the differentiation of monocytes into macrophages was studied after 24 and 48h. Both compounds and the mixtures with CYN significantly reduced the percentage of differentiated cells compared to the control. The mechanisms of cell death were also investigated. The results showed a concentration-dependent increase in the number of apoptotic cells after exposure to both binary mixtures. The number of necrotic cells did not vary significantly after 48h exposure. Finally, the effect on the mRNA expression of different interleukins (IL-2, IL-6, IL-8, TNF-α and INF-γ) was studied. Cd caused a significant increase in the expression of TNF-α and INF-γ, whereas exposure to As increased the expression of IL-8 and INF-γ. Exposure to the mixtures increased the expression of IL-8 and INF-γ, whereas the expression of TNF-α was decreased by the Cd + CYN mixture compared to the control. These results suggest that mixtures of toxicants have different effects than single toxicants, which should be considered for a proper risk assessment.

4.15.P Water-Related Problems in the Mediterranean Ecoregion and Their Environmental, Health and Social Impacts

4.15.P-Tu461 Soil-Aquifer Treatment with a Reactive Barrier for Contaminant Removal: a Strategy for Using Treated Wastewater as an Adaptation Measure to Drought on the Mediterranean Coast of Spain

Juan Cruz Carrizo[1], *Karen Paola Sepúlveda*[2], *Gerard Quintana*[1], *Lurdes Martínez-Landa*[3], *Cristina Valhondo*[4], *Cristina García - Aljaro*[5], *Jesus Carrera*[1], *Montserrat Folch-Sanchez*[6] *and Silvia Diaz-Cruz*[1], *(1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)University of Barcelona, Spain, (3)Tecnical University of Catalonia UPC, Spain, (4)University of Montpellier- CNRS, France, (5)Dept. Genetics, Microbiology and Statistics, Faculty of Biology; University of Barcelona, Spain, (6)Department of Biology, Healthcare and the Enviroment, University of Barcelona, Spain*

Addressing Mediterranean water scarcity demands innovative solutions like Managed Aquifer Recharge (MAR) through Soil-

Aquifer Treatment (SAT), effectively improving water quality by reducing Contaminants of Emerging Concern (CECs) through filtration, biodegradation, and sorption mechanisms.

Our study evaluated reactive barrier SAT systems' effectiveness in adsorbing CECs from urban Wastewater Treatment Plant effluents in Northeast Spain. Two SAT systems, S1 (100% sand, as control) and S2 (a reactive barrier composed of 50% sand, 30% organic matter, 10% biochar, 8% zeolite, 2% clay), underwent a 73-day winter recharge event. Using QueEChERS extraction and LC-HRMS analysis in positive mode processed by Compound Discoverer Software. A total of 1063 CECs were detected; 403 were found in S1, and 894 in S2, with an overlap of 234 CECs. To provide a comprehensive assessment, we introduced a variable called 'Total Area' (∑Area CECs),representing the sum of the area associated with all CECs.

Crucially, depth influenced S2 significantly, showing two distinct groups: one at 15 cm and the other at depths of 28, 41, and 54 cm. Higher Total Area and CECs were observed in the latter, attributed to the initial sand composition in the first 15 cm. Notably, from 28 cm onward, S2 exhibited increased CEC adsorption and potential removal, possibly driven by biodegradation through biofilm microorganisms fueled by organic carbon from the barrier. This convergence in biodegradation pathways likely contributed to reduced contaminant detection. However, the system's performance was sensitive to fluctuations in infiltrating water CEC loads, complicating interpretation.

Contrarily, S1 displayed a noticeable upward trend in CECs over time, suggesting potential accumulation, despite the unclear influence of depth on the samples.

System 2 shows significant potential in removing CECs through extended biodegradation enhanced by biofilm formation and increased adsorption facilitated by the reactive barrier materials. This sustainable solution addresses water scarcity, especially in arid regions, promoting water reuse and storage. Implementing this technology could establish vital pathways for mitigating water stress, contributing significantly to resource management in vulnerable areas.

4.15.P-Tu462 Identification, prioritisation and monitoring of the most relevant contaminants of emerging concern in a reclaimed water irrigation system

Dana Orlando Véliz[1]*, Manuel Garcia-Vara*[2]*, Pol Martin Chulio*[2]*, Rocío Inés Bonansea*[3] *and Miren Lopez De Alda Villaizan*[2]*, (1)Enviromental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Environmental Chemistry, National University of Cordoba, Argentina*

The reuse of regenerated wastewater emerges as a solution to address water scarcity, and its use for different purposes is subject to a legal regime that establishes permitted uses, basic quality criteria, and the treatments that must be applied. However, current treatments used in wastewater treatment plants (WWTPs) do not remove a wide variety of pollutants, such as pesticides, pharmaceuticals or industrial chemicals, which could represent a risk for the environmental and human health. To investigate this issue in an agricultural area where the irrigation water is a mixture of surface water and regenerated water, four locations (1.WWTP influent and 2. effluent, 3. reclaimed water discharged to the network of irrigation channels, and 4. water used downstream for irrigation) were sampled and analysed to identify the most relevant contaminants present in them with the application of a suspect screening (SS) workflow considering different parameters such as exact mass, isotopic pattern and fragmentation, and contrast of the data obtained with MS libraries. Subsequently, a prioritization of the top 25 compounds was conducted based on the semi-quantified Measured Environmental Concentrations (MEC) and the corresponding Predicted Non-Effect Concentrations (PNEC) in freshwater. Finally, a novel target method was developed and used to investigate the occurrence of these contaminants in the irrigation network of the agricultural area under study along one year and a final compound prioritization based on the parameters Frequency of Exceedance (FoE) and Extent of Exceedance (EoE) was performed. Galaxolidone, O-desmethyl-venlafaxine and venlafaxine appear as the compounds oh highest concern.

The SS showed a total of 158 contaminants present in at least one of the samples. The site-specific priority pollutants with the highest risk quotients were the metabolite O-Desmethyl Venlafaxine and its parent compound Velanfaxine, the personal care product Galaxolidone, plus others from various other categories. The year-round monitoring at different points of the network of irrigation channels also pointed to these compounds as those showing the highest concern.

4.15.P-Tu463 Role of Plastic Fragments in increasing permissiveness of E. coli towards Plasmids harboring Antibiotic Resistance Genes

Ifra Ferheen Phd [1]*, Lucia Cimarelli*[2]*, Stefania Marcheggiani*[3] *and Roberto Spurio Prof*[1]*, (1)School of Biosciences and Veterinary Medicine, University of Camerino, Italy, (2)University of Camerino, Italy, (3)Istituto Superiore di Sanità, Italy*

Plastic pollution in aquatic ecosystems provides a new 'hotspot' for the colonization of bacteria, accelerating the biofilm formation and exchange of genetic material. In this work, we determined the ability of bacteria to acquire plasmid DNA from an extracellular environment under laboratory conditions. The plasmid transformation frequency was tested by setting up a single species microcosm, in which different strains of *E. coli* individually were monitored to uptake plasmid in presence and absence of plastic fragments. In total, four plastic polymers and four incubation conditions were analyzed to go deeper insight into the transformation process, and the results were confirmed by using molecular tools, and colonization ability of strains was monitored by using LIVE/DEAD™ *Bac*Light™ Bacterial viability kit under the confocal microscope. Results illustrated that when all three ingredients (microorganisms, plasmids and plastic fragments) were incubated simultaneously, bacterial permissiveness towards plasmid was remarkably increased. Different polymers of plastic have different ability to adhere bacteria, hence Polypropylene and Polyethylene were proven to be the most efficient plastic polymers for allowing bacteria to colonize as compared to the polyethylene terephthalate and polystyrene. The microcosm models are promising tools to mimic natural events to understand the dissemination of Antibiotic Resistant genes via HGT. Our results depict the risk of plastic pollution present in soil and water environments in promoting the distribution and spread of plasmid DNAs and their associated ARGs.

4.15.P-Tu464 Bioactive Contaminants along Tyrrhenian coastal areas and their bioaccumulation in the Mediterranean endemic seagrass Posidonia oceanica

*Jasmin Rauseo[1], Francesca Spataro[1], Edoardo Casoli[2], Anna Barra Caracciolo[3], **Ludovica Rolando**[4], Tanita Pescatore[5], Paola Grenni, PhD[6], Sara Ardenti[7], Luisa Patrolecco[1] and Federica Franco[8], (1)National Research Council- Institute of Polar Science (ISP-CNR), Italy, (2)Sapienza University of Rome, Italy, (3)CNR-IRSA, Italy, (4)Italian National Research Council (IRSA-CNR), Italy, (5)National Research Council (CNR), Institute of Polar Science (ISP), Italy, (6)Water Research Institute (IRSA), National Research Council (CNR), Italy, (7)Ecology, Sapienza University of Rome, Italy, (8)Department of Environmental Biology, Sapienza University of Rome, Italy*

Various anthropogenic activities affect the Mediterranean ecoregion, including intense cargo traffic, cruises, beach tourism, and port and industries. This basin is also subjected to significant riverine runoff transporting contaminants from cities and rural areas. The combination of these pressures and its peculiar characteristics, such as being a relatively shallow and semi-enclosed basin with no tides and weak coastal currents, makes the Mediterranean Sea an accumulation sink of several pollutants. Among contaminants, pharmaceutical and personal care products (PPCPs) and phenolic endocrine-disrupting compounds (PEDCs), have gained considerable attention for their designed bioactivity, and mutagenic and/or carcinogenic properties for organisms, causing a potential risk to ecosystem and human health. Despite this, studies reporting the occurrence and concentration of these pollutants in the Mediterranean marine ecosystems are still scarce and incomplete. In this context, the present work aims to evaluate the presence of selected PPCPs and PEDCs in two Italian coastal areas with different degrees of anthropogenic pressure. The first one is the Marine Protected Area of Rome Municipality 'Secche di Tor Paterno', located in the Central Tyrrhenian Sea, off the coasts of the Lazio region (Italy) few miles southern from the River Tiber mouth. The river flows through the city of Rome, and during flood events, its estuary causes low water transparency and inputs of anthropogenic contaminants into the coastal seawater. The second study area is the small town of Giglio Porto (Giglio Island in the Tuscany Archipelago, Italy,), a popular summer touristic destination. *Posidonia oceanica* meadows (L. Delile 1813) develop on seabed shallower than 40 m in both areas. Surface seawater and *P. oceanica* (rhizomes and leaves) were collected to investigate the occurrence of pollutants and to evaluate the potential application of the seagrass as a bioindicator of PEDCs and PPCPs contamination. Based on the measured concentrations of these bioactive pollutants in seawater, an ecological risk evaluation was also performed. PPCPs were found at higher concentrations than PEDCs in the study areas and bioaccumulated in *P. oceanica*, suggesting that this plant can be a suitable bioindicator of organic contamination. The risk analysis indicated that the selected contaminants can pose a high risk to the marine ecosystem.

4.15.P-Tu465 Exploring the occurrence of emerging contaminants in a coastal environment: the Mar Menor lagoon – Campo de Cartagena aquifer case study (SE Spain)

***Nonito Ros Ros Berja**[1,2], Valentí Rodelles Sr[3], Steven Morales[4], Marisol Manzano[4], Josep Mas-Pla[1,5] and Meritxell Gros[1,6], (1)Catalan Institute for Water Research (ICRA), Spain, (2)Catalan Institute for Water Research (ICRA), Girona, Spain, (3)Institute of Environmental Science and Technology, Autonomous University of Barcelona, Spain, (4)Dept. de Ingeniería Minera y Civil, Universidad Politécnica de Cartagena, Spain, (5)Grup de Recerca GAiA-Geocamb, Department de Ciències Ambientals, Universitat de Girona, (6)University of Girona (UdG), Spain*

Coastal aquifers are important sources for water supply both for humans and for the environment. They are relevant groundwater-associated ecosystems offering valuable ecosystem services, and their performance can be influenced by groundwater dynamics. Meanwhile, groundwater quality is affected by land use, especially by agricultural, residential, industrial, and mining uses. These pressures lead to the presence of emerging contaminants (ECs) such as pesticides, pharmaceuticals (PhACs), and industrial chemicals, among others. The Mar Menor lagoon and its related aquifer of Campo de Cartagena (SE Spain) is a paradigmatic example of coastal lagoons where agriculture, urban development and mining use has produced an impact of huge hydrogeological, ecological, and socio-economic implications.

This study evaluates the occurrence of ECs, including PhACs, and some of their transformation products (TPs) and metabolites, endocrine disrupting compounds (EDCs) and pesticides in shallow groundwater discharging to the Mar Menor lagoon through the submerged beach. This exploratory assessment aims to expand the understanding on the occurrence of ECs in coastal ecosystems in vulnerable and hot-spot areas of contamination. This survey is part of the Spanish national project *REMEDIATE*, which aims at assessing the viability of inducing in-situ groundwater denitrification in coastal aquifers discharging to lagoons, as a complementary tool to reduce nutrient and ECs input.

The survey was conducted in April 2023, including 37 sea and groundwater samples that discharge onto the lagoon. 13 widely used pesticides, 45 PhACs, 9 TPs and metabolites, and 32 EDCs were screened for using Ultra-High-Performance Liquid Chromatography (UHPLC) coupled to tandem mass spectrometry. Several ECs were identified, including the pesticides atrazine, simazine, carbendazim, terbuthylazine and irgarol, the PhACs hydrochlorothiazide, valsartan, ibuprofen, acetaminophen, erythromycin, sulfamethoxazole, enrofloxacin, flumequine, clarithromycin, clindamycin, carbamazepine, citalopram, venlafaxine, the TPs epoxy carbamazepine and metoprolol acid, and EDCs like methylparabens.

These results characterize the extent of ECs occurrence in the shallow groundwater discharging to the Mar Menor from the Campo de Cartagena coastal aquifer, which is crucial for understanding the potential environmental impact and act as a support to targeted remediation efforts.

4.15.P-Tu466 First Assessment of Microplastic Contamination in Wild Specimens of Gelatinous Zooplankton From the Northern Adriatic Sea (Italy)

Valentina Ferrari[1,2]*, Luca Marisaldi*[3]*, Andrea Ferrari*[3]*, Daniela Prevedelli*[1] *and Elisa Bergami*[1,4]*, (1)Department of Life Sciences, University of Modena and Reggio Emilia, Italy, (2)Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, Italy, (3)TAO, Turtles of the Adriatic Organization, Italy, (4)Nbfc, National Biodiversity Future Center, Italy*

The Mediterranean Sea is one of the most affected regions in the world by the accumulation of microplastics (MPs; < 1 mm). Due to their small size, MPs are bioavailable for a wide range of marine organisms, leading to significant negative effects to marine biodiversity. Gelatinous zooplankton is abundant and widely distributed in the Mediterranean Sea, being a major food source for secondary consumers and providing important but overlooked ecosystem services in coastal areas. Recently, this group of marine organisms has been reported as able to internalize marine litter. However, information on how such interaction occurs is still limited. The present study aims to evaluate the MP content in key Mediterranean gelatinous zooplankton, focusing on both Scyphozoans and Ctenophores species.

Specimens of *Rhizostoma pulmo*, *Cotylorhiza tuberculata* and *Mnemiopsis leidyi* were hand-collected using a cotton net between August and September 2023 along coastal area of the northern Adriatic Sea (Italy). Field blanks were placed to quantify contamination from the operators and the environment, and surface seawater samples were collected to monitor background MP concentration. In each site, a *visual census* of floating litter was also performed. Once collected, samples were stored at −20°C individually or as pools. To extract and detect ingested MPs from samples, a suitable enzymatic and thermo-oxidative treatment was adopted, followed by a flotation step using the low cost and environmentally friendly canola oil. Then, MPs were concentrated onto glass fiber filters, counted and classified based on shape, colour and size, *via* optical digital microscope. Sub-samples were then analysed by µRaman spectroscopy to identify the different MP polymers.

The recovery-effectiveness of the extraction method was validated by spiking samples with a known number of MP fragments, reaching acceptable recovery rate (83.3 ± 7.6% for polyvinyl chloride and 88.3 ± 12.6% polystyrene). Scanning Electron Microscopy analysis showed that the reagents used in the extraction protocol caused no detrimental impacts to the reference polymers tested, nor changes in particle weight, size and colour. Overall, the results presented on MP intake in wild gelatinous zooplankton populations will provide insights into the use of these organisms as bioindicator for MP pollution within Mediterranean pelagic communities, disclosing potential new pathways for MP entrance in marine food webs.

4.15.P-Tu467 Effect of Land Use decisions on the abundance of Multi drug resistant bacteria and Antibiotic-Resistant in Bracciano Lake

Ifra Ferheen Phd [1]*, Olgalu Hernandez*[2]*, Aline Chiabai*[2]*, Marc Neumann*[2] *and Stefania Marcheggiani*[3]*, (1)School of Biosciences and Veterinary Medicine, University of Camerino, Italy, (2)BC3 Basque Centre for Climate Change Klima Aldaketa Ikergai, (3)Istituto Superiore di Sanità, Italy*

The rise of antibiotic resistance (AR) poses a significant and escalating global challenge for public health, mainly due to the increased prevalence of bacteria resistant to routinely administered antibiotics, undermining the efficacy of antimicrobial treatment. Current study focusses on the relationship between land use decisions and the abundance of multi-drug resistant bacteria (MDR) and antibiotic resistance genes in Bracciano Lake, utilizing Geographic Information Systems (GIS) for comprehensive spatial analysis. The research integrates diverse datasets, encompassing land cover, agriculture, urbanization, wastewater discharges, and the hydrological catchment area, to understand the holistic influence of anthropogenic factors on the lake ecosystem. Spatial analyses were conducted to identify patterns within the watershed and hydrological catchment area surrounding Bracciano Lake. The results revealed that the Bracciano lake is surrounded by the residential development, industries, and tourism making it prone to anthropogenic activities, which may contribute to increased pathogen risks through potential pollutants and human activities. Considering several factors such as surface discharge, soil erosion, and groundwater flow patterns, hydrological catchment maps depicted the potential routes of the pathogens transportation from terrestrial to freshwater bodies. Obtained results emphasizes the importance of a spatially informed approach to comprehend antibiotic resistance dynamics in aquatic environments. GIS integration aids in identifying high-risk zones, informing targeted mitigation strategies. The implications extend beyond Bracciano Lake, offering insights for sustainable land management practices to safeguard water quality and public health on a broader scale. The research contributes to understanding and addressing the complex interrelationships shaping antibiotic resistance proliferation in freshwater ecosystems.

4.15.P-Tu468 The Invasive Blue Crab Callinectes Sapidus (Rathbun, 1896) In Lazio Region (Central Tyrrhenian Sea): Updated Distribution And Possible Impacts On Shellfish Farming And Harvesting

Stefania Chiesa[1]*, Tommaso Petochi*[1]*, Maria Paola Campolunghi*[1]*, Laura Di Blasio*[1]*, Corrado Battisti*[2]*, Luca Gallitelli*[3]*,*

Massimiliano Scalici[3] and Giovanna Marino[1], (1)Italian National Institute for Environmental Protection and Research (ISPRA), Italy, (2)Torre Flavia" LTER (Long Term Ecological Research) Station, (3)Roma Tre University, Italy
The blue crab *Callinectes sapidus* (Rathbun, 1896) is native to Western Atlantic, from northern (Canada) to southern (Argentina) coasts. In its native range of distribution, the species is an important economic resource for fisheries industry. Introduced in the Mediterranean Sea in the mid of 1900s through ballast waters, the species is now spread both in eastern and western basin, representing a treat for biodiversity and affecting human activities, such as aquaculture and small-scale fisheries. The blue crab can colonize a huge variety of environments, such as coastal lagoons, saltmarshes, and freshwater habitats. It is an opportunistic predator capable to feed on fish, invertebrates (especially bivalves), detritus and macrophytes. The Lazio region, located in the Central Tyrrhenian Sea, hosts Natura 2000 sites and 19 marine aquaculture leases for shellfish farming, 9 of which are operational for mussel (*Mytilus galloprovincialis*) production. Moreover, natural bivalve banks have been registered along the regional coasts, a.g. for wedge clam (*Donax trunculus*) harvesting. Lazio also represents the second region at national level for marine fish farming production. On 2022, within the recent regional assessment of AZA (Allocated Zones for Aquaculture) carried out in the framework of the MSP (Maritime Spatial Planning) European Directive, identified a total of 354 km^2 suitable for shellfish farming were identified in Lazio region: approximately 68 km^2 with high suitability, 277 km^2 of medium suitability and the remaining 9 km^2 of low suitability. The monitoring of blue crab distribution in the region, obtained by both direct (field campaigns) and indirect records (local fishermen interviews and social media) showed that, until summer 2023, the blue crab occurrence was scattered and stable. Since then, a huge improvement of its abundance has been observed, together with new records in previously non- invaded locations.Since its voracious and aggressive predatory behaviour, the occurrence and the continuous spread of the blue crab in Lazio represent a serious risk not only for biodiversity, but also for local shellfish farming and harvesting activities. Therefore, monitoring, updating and mapping the species distribution with respect to aquaculture facilities and harvesting areas of natural banks of bivalve molluscs are fundamental to properly manage the species invasion and to avoid the huge impacts already occurred in other Italian shellfish production sites.

4.15.P-Tu469 Impacts of Shipping Discharges (Including Scrubber Water) in the Northern Adriatic Sea: Exploring Current and Future Environmental Exposure Using a Modelling Approach

***Loris Calgaro**[1], Elisa Giubilato[1], Manuel Aghito[2], Jukka-Pekka Jalkanen[3], Elisa Majamäki[3], Christian Ferrarin[4], Elena Semenzin[1] and Antonio Marcomini[5], (1)University Ca' Foscari of Venice, Italy, (2)Norwegian Meteorological Institute, Norway, (3)Finnish Meteorological Institute, Finland, (4)CNR-ISMAR, Italy, (5)Ca' Foscari University of Venice, Italy*
The Northern Adriatic Sea is a narrow and shallow basin, with a very short residence time (less than 3,3 months on average), and its physical properties and circulation dynamics are mainly determined by its low bathymetry, by atmospheric forcing, (e.g., wind stress and heat fluxes), tide, and by freshwater discharges mainly along the Italian coast. This leads to the presence of several different ecosystems for marine species, although they are under significant pollution pressure because this basin is surrounded by densely inhabited and highly urbanized areas. This pressure can be related to several land-based sources (e.g., effluents discharge, agricultural activities, transport of freights and people), but also shipping activities can represent a significant contribution to chemical pollution, especially near shipping lanes and ports.

In this work an exposure assessment for benzo(a)pyrene and fluoranthene accounting for both land-based sources and shipping emissions was carried out for the Northern Adriatic Sea. The modelling effort, realized within the H2020 "EMERGE" project, focused on the integration of several high-resolution predictive models to help exploring the implications of different abatement emissions techniques for shipping emissions (e.g., exhaust gas cleaning systems) for an improved management of environmental risks.

In detail, shipping-related emissions of pollutants were simulated with the STEAM (Ship Traffic Emission Assessment Model) model, based on Automatic Identification System data from 2018, as well as two different shipping development scenarios for 2050 regarding different fuel/scrubbers use options. Land-based emissions were quantified by combining daily river flow measurements with water concentrations from routinely monitoring of each tributary in 2018. The newly-developed ChemicalDrift model, a chemical transport module part of the open-source Lagrangian framework OpenDrift, was applied for these 3 scenarios using forcing data for the case study area from the SHYFEM model (ocean currents, temperature, and salinity) and Copernicus Marine Services (mixed layer depth and winds).

Results for a baseline (2018) scenarios and two future policy scenarios (in 2050) are illustrated and prove the efficacy of the proposed modelling approach to explore the implications of different shipping emissions control technologies and to identify the main sources of coastal pollution.

4.15.P-Tu470 Microcosm experiments to examine the antibiotic pollution in Mediterranean inland waters based on the response of aquatic primary producers

***Camilla Puccinelli**, Filippo Chiudioni and Stefania Marcheggiani, Environment and Health Dep., Istituto Superiore di Sanità, Italy*
Antibiotics pollution has been documented worldwide in surface waters and groundwater. They can affect negatively aquatic communities at different trophic levels, interfering with physiological processes. Primary producers, play an important role in aquatic ecosystems for the oxygen production and nitrogen fixation. Any alteration of these communities, may result in severe bottom-up effects on other organisms at higher trophic levels.

The aim of this work was to evaluate the response of primary producers, diatoms and macrophytes to Ciprofloxacin (CIP) exposure, listed in the third Watch list of Water Frame Directive WFD 2000/60/EC, through microcosm experiments.

Diatom species selected are widely distributed and representative of Mediterranean rivers: the planktonic *Cyclotella meneghianiana;* the benthonic slow moving, *Cocconeis placentula*; peduncolate and adhering to substrates, *Gomphonema parvolum* and motile *Nitzschia amphibia.* Their response to antibiotic contamination was evaluated analysing the increasing of teratological forms of their silica cell wall, called frustule.

We investigated the macrophyte's uptake capability of CIP, using the free-floating invasive species, *Lemna minuta*, widely distributed in Mediterranean slow-moving waters.

Species were exposed at three different CIP concentrations (0.1; 0.5; 1.0 mg/L) plus negative control, each tested in triplicate, in following growth conditions: temperature of 20 ±1°C, light intensity at 3000 lux (12:12 h light/dark cycle). After 30 days of exposure (diatom life cycle), diatom samples were treated to remove organic substances (with H_20_2 and HCl) and analysed at 100x microscope to investigate morphological alterations of frustule (i.e alteration in shape and outline). After 96 hours (short term exposure test) .*L minuta* growth solution samples were collected in order to analyse the remaining CIP concentrations*;* in addition *L. minuta* growth rate and tolerance were assessed.

Analysis are still in progress: preliminary results on *C.menenghiniana* showed an increase of 50 % teratological forms compared to the control at 0,5 and 1,0 mg/L with deformed frustule shapes, and changes in striae pattern.

The ongoing experiment on *L. minuta* has been showing no visible effect and a good tolerance to CIP concentration up to 1.0 mg/L

4.15.P-Tu471 A Comprehensive Review Of Metal(Loid) Bioaccumulation In The Invasive Blue Crab Callinectes Sapidus (Rathbun, 1896): The Influence Of Trophic Niche And The Possible Risks For Human Consumption
Stefania Chiesa[1]*, Laura Di Blasio*[1]*, Tommaso Petochi*[1]*, Giovanna Marino*[1] *and Massimiliano Scalici*[2]*, (1)Italian National Institute for Environmental Protection and Research (ISPRA), Italy, (2)Roma Tre University, Italy*
The blue crab *Callinectes sapidus* (Rathbun, 1896) is an important fishery resource along the native Western Atlantic coasts, where the species is native. The blue crab was accidentally introduced in the Mediterranean Sea through ballast waters and now occurs in all basin, where is considered a high invasive species affecting the native biodiversity conservation, but also aquaculture and traditional fisheries. In the light of containing its spread and impacts in the Mediterranean Sea, a valuable counteraction is represented by the direct fishing for both human consumption and for animal feed production. However, the blue crab has a wide ecologic niche, is an opportunistic predator and can colonize a huge variety of environments, such as coastal lagoons, saltmarshes, and even freshwater habitats, with different contamination levels. Therefore, the bioaccumulation of contaminants in blue crab, such as metal(loid)s, should be carefully evaluated to avoid any risk for its commercialization and consumption. The present review summarized the literature data collected both in native and non-native habitats of blue crab, highlighting its capability to bioaccumulate metal(loid)s, with reference to cadmium, nickel, mercury, iron, and zinc, depending on the investigated sites. Metal(loid)s bioaccumulation profiles were tissue-specific, with main concentrations found in hepatopancreas, liver and gills, and lower concentrations in the muscle tissues. Such differences observed in non edible and edible tissues should be considered in terms of risk for human consumption. Data also showed the role of its wide and variable trophic niche: the blue crab can accumulate elements in different chemical forms and concentrations, depending on their bioavailability in the different food resources occurring in the different environments during its entire life cycle. Therefore, the traceability of blue crab fisheries should be a priority, to avoid any risk that its collection will be carried out in contaminated sites, especially in the explosive phase of its invasion, when the resource is particularly abundant. Moreover, the metal(loid) bioaccumulation profiles must be carefully monitored in the different collecting areas, to avoid any risk for consumer's safety

4.15.PC Water-Related Problems in the Mediterranean Ecoregion and Their Environmental, Health and Social Impacts

Track 5. Life Cycle Assessment and Foot-Printing

5.01.A Circularity Strategies and Life Cycle Thinking: Ensuring the Way to Sustainability

5.01.A.T-01 A conceptual framework to enable the implementation of circular economy strategies in support of sustainable production and consumption

Stéphanie Muller[1]*, Ambroise Lachat, PhD Student*[1]*, Joana F Morgado*[2]*, Patrick Wäger*[3]*, Valentin Wewer*[4]*, Berend A Mintjes*[5]*, Elena Fernandez*[6]*, Evert A. Bouman*[7] *and Golnoush Abbasi*[8]*, (1)Bureau de recherches géologiques et minières, BRGM, France, (2)EMPA, (3)Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (4)Technical University Berlin, Germany, (5)Institute of Environmental Sciences (CML), Leiden University, Netherlands, (6)UNITAR, (7)NILU - Norwegian Institute for Air Research, Norway, (8)Norwegian Institute for Air Research (NILU), Norway*
In response to the challenge of limited supply of raw materials to rapidly adopt green transitions, the European Commission (EC) aims to minimize the loss of secondary raw materials and optimize their reuse across value chains. To achieve these goals, value chain actors need to be provided with the relevant information necessary to decide on the most appropriate Circular Economy (CE) strategy to be applied to a specific product. Gathering such information along the whole value chain is a challenging endeavour. As a concrete action, the EC is preparing general requirements for the establishment of digital product passports (DPP) that should help gathering information along the value chain. This work presents a conceptual framework that identifies indicators to monitor the progress in the implementation of CE strategies.

This conceptual framework allows the identification of CE solutions to maximize the use of resources in the economy while minimizing the associated environmental, social and economic impact. This framework presents a modular structure, where each module has a specific goal and list of questions to answer. To answer the questions adequate methodologies and indicators are defined. The first version of the conceptual framework consists of the following six modules: 1. A CE-criteria module that computes the ability of a product to enter a specific CE strategy; 2. A module computing the economic, social, and environmental impacts; 3. A module gathering the needed datasets from selected background databases; 4. An uncertainty module that estimates the level of confidence of the results; 5. An optimization module that provides recommendations on the best CE strategy to apply and 6. A conformity module that guarantees the robustness of the results and provides single indicators on sustainability and circularity.

The definition of this conceptual framework is one of the first steps of a 4-year project aiming to design, implement and test an information system useable by all actors in a product value chain. This conceptual framework defines a set of criteria, indicators and parameters, essential to inform value chain actors on optimal circular strategies enhancing the availability of secondary raw materials, including critical raw materials, in the economy. The corresponding information system, integrated with DPP solutions, enables implementation, measuring and monitoring of these circular strategies.

5.01.A.T-02 A Model to Assess Environmental and Economic Impacts of Waste Management in Europe

Paola Federica Albizzati[1]*, Gillian Foster*[1]*, Pierre Gaudillat*[1]*, Simone Manfredi*[2] *and Davide Tonini*[1]*, (1)European Commission - Joint Research Centre (JRC), Spain, (2)European Commission - Joint Research Centre (JRC), Italy*
The EU Monitoring Framework on Circular Economy includes mass-based indicators to assess the advancements towards a circular economy (CE) in EU27. Specifically for waste management, the proposed indicators are the overall recycling rate for municipal waste and the recycling rates for specific packaging waste streams. We argue that monitoring should go beyond physical mass flows by encompassing also the environmental and socio-economic impacts to understand the effects of the CE on the key dimensions of sustainability. Therefore, we propose a model that quantifies the impact of waste management at EU27 level and for each Member State in 16 environmental impact categories, internal, external and full environmental costs, as well as employment. The model is fed with EU data on municipal waste, for which a sound methodology is proposed to correct inconsistencies and ensure mass balance closure. Waste treatment technologies and processes are described with state-of-the-art data on efficiencies, consumptions and costs. Our results bring novel findings that are relevant for policy-making at national and EU level. First, we identify the inconsistencies or discrepancies in waste data reporting and propose solutions to improve reporting. We then show distance to targets at Member State level and quantify environmental impacts incurred by waste management. Last, we quantify financial and external costs, showing where the system incurs the highest benefits or costs. Our findings reveal that remarkable differences exist across EU27 in terms of environmental and economic performance in waste management, indicating the need for targeted efforts to fulfil the ambitions of the Green Deal.

5.01.A.T-03 Modelling the Environmental and Socio-Economic Impacts of Existing and Novel Technologies for Textile Waste Management in the EU: Methods, Data Sources and Hotspots

Martyna Solis[1,2]*, Dries Huygens*[3]*, Davide Tonini*[4] *and Thomas Fruergaard Astrup*[1]*, (1)Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark, (2)Technical University of Denmark (DTU), Denmark, (3)Joint Research Centre (JRC) - European Commission, Spain, (4)European Commission - Joint Research Centre (JRC), Spain*
The European Commission's "Strategy for Sustainable and Circular Textiles" has as a main goal that by 2030, all textile products on the EU market should be recyclable, be made as much as possible from recycled fibres, be free from hazardous substances and be produced in an environmentally and a socially sustainable manner. While textile waste recycling is currently

in its infancy, it is unclear what sustainability benefits could be achieved from textile recycling, or how individual textile materials should be prioritised relative to these technologies. Even though many studies have used a life cycle assessment (LCA) to evaluate the environmental impacts of textile waste management, no study offers an integrated assessment of environmental and socio-economic impacts from the perspective of future technology improvements. This study aimed at providing a state-of-the-art environmental and socio-economic assessment of all key existing and emerging textile waste technology pathways for a range of 6 selected textile waste fractions. Data sources included feedback from 220+ experts within the textile sector representing 150+ stakeholder organisations. Results indicate that reuse represents the most preferred management option across the investigated textile waste streams, under both current and future framework conditions. Environmental impacts varied between impact categories and could not be represented by a single grouping. Generally, internal costs (from -22 to 2030 EUR/t under current conditions) were much larger than external costs (from -1230 to 1230 EUR/t under current conditions), thereby dominating the socio-economic results. This illustrates the importance of shadow prices for societal costs: mechanical recycling was competitive relative to incineration, but only when CO_2 prices were modelled as significantly higher (at 344 and 498 EUR/t) than today. The differences in impact results between the assessed textile waste materials emphasised that the compositions of textile waste fractions are a critical part of decision-making when selecting preferred management options. It is concluded that both environmental and socio-economic perspectives should be taken into consideration when making strategic decisions. Depending on the societal priorities, the most preferred solution may be different. The study provided a basis for setting future regulatory targets for textile waste management in a European context.

5.01.A.T-04 How to reach an absolute sustainability and circularity in the building sector?

***Nada Bendahmane**, Mona Nasseredine and Mathilde Louërat, CSTB*

Mineral and metal resources present major environmental and socio-economic challenges, with the building sector emerging as their primary consumer. 96% of the material mass consumed in France's construction sector consists of mineral and metal resources, underscoring the urgent need for optimizing the use of these resources.

To tackle this challenge, regulatory texts referring to the circular economy are introduced in different countries. For example, in France, the Anti-Waste and Circular Economy Law was enacted in 2020. It introduces key principles for the construction sector, notably promoting reuse, encouraging the functional economy and establishing the Extended Producer Responsibility (EPR) system.

In this regard, this study aims to propose a methodology to support the building stakeholders in maximizing circular economy practices and minimizing pressure on critical natural resources.

The proposed method is inspired by the approach developed by Ryberg et al. (2018) by defining sustainable material budgets equivalent to a planetary limit for mineral and metal resources. These budgets, established at the most appropriate spatial scale for each material, are defined for the anthropogenic flows issued from reuse and for natural resources considering their criticality. These budgets are then used to estimate sustainability indicators related to the input flows of the building project.

Circularity indicators are also estimated to quantify how the studied project contributes to the circular economy through components targeted to reuse at the end of their life.

The method is structured around these following key steps:

1. Identifying the construction project's needs.
2. Estimating flows from reuse.
3. Calculating reuse material budgets assigned to the project.
4. Calculating primary material budgets assigned to the project based on their criticality.
5. Computing sustainability indicators by comparing the building needs with the assigned material budgets.
6. Computing circularity indicators at the end of life.

The proposed method can be used in the early stages of building design as well as in a prospective approach.

In this paper, the method is presented throughout a proof-of-concept case study related to the construction of building in France. This application serves to test, refine, and operationalize the method, showcasing its potential to support building stakeholders by maximizing circular economy practices and exerting minimal pressure on critical natural resources.

5.01.A.T-05 Assessing the potential of exergy as a thermodynamic material and energy efficiency indicator to guide the optimisation of industrial symbiosis projects

***Marie Lourioux**[1] and Guillaume Majeau-Bettez[2], (1)CIRAIG Polytechnique Montreal, Canada, (2)Chemical Engineering, Polytechnique Montreal, Canada*

To mitigate climate change and preserve resources for future generations, the economy is investing in a profound industrial transition. These transition efforts can be grouped into two broad categories: efforts to turn away from fossil-based energy sources with greater energy efficiency and efforts to use materials more efficiently. The development of industrial symbioses in which the energy and material waste flows of one industry are managed such that they serve as inputs to complementary industries constitute a promising avenue to potentially combine both energy and material efficiencies measures. But when trade-offs arise between increasing material efficiency or energy efficiency, or between energy and resources recovery, how should these choices be optimized? A case can be made that a single indicator of resource use should guide the design of industrial symbioses. There does exist a single indicator from thermodynamics that can quantify the “quality” of both material and energy resources by linking these to the notion of work: exergy. This approach has not commonly been used for several historical and fundamental reasons. Yet it seems important to find ways of communicating what thermodynamics has to say about the increasing consumption of resources and their dispersions. Is an exergy indicator relevant and practical in guiding the optimisation of an industrial symbiosis? Our study focuses on a tire production company. Through a material and energy flow analysis, the use flows and waste flows are quantified and translated into exergy flows. We represent the loss of exergy throughout the production cycle and end-of-life transformation. A linear optimisation model then selects the technological mixes and operation parameters that minimizes the total exergy losses. We conduct a comparative analysis between optimizing the industrial symbiosis using exergy, relative to using other sustainability and efficiency indicators. In our work, we provide a unified exergy indicator for energetic and material resources as well as an optimisation tool based on constraints which represents the reality of goods-producing companies in their environmental objectives, leading them to a more sustainable ecological transition. Our other aim is to furnish information to guide the target audience on the requirements needed to use the indicator. This method can then be used in any industry that aims to improve efficiency in resource use.

5.01.B Circularity Strategies and Life Cycle Thinking: Ensuring the Way to Sustainability

5.01.B.T-01 The Environmental Costs of Clean Cycles: Quantitative Analysis for the Case of PVC Window Profile Recycling in Germany

Sarah Schmidt[1]*, Thomas Gibon*[2]*, Tomás Navarrete Gutiérrez*[2] *and David Laner*[1]*, (1)University of Kassel, Germany, (2)Luxembourg Institute of Science and Technology (LIST), Luxembourg*

Plastic use in buildings has been steadily increasing in the past and has led to a significant stock of plastic materials in buildings and infrastructure, with polyvinylchloride (PVC) constituting the largest share of polymers in this sector. Although little plastic is yet recycled from construction and demolition waste, effective recycling schemes exist for instance for PVC window profiles. The latter are currently challenged by the presence of legacy contaminants in end-of-life (EOL) window profiles, in particular, lead-based stabilizers, which have been phased out in virgin PVC in Europe and are subject to use restrictions in new products. The long-lived nature of PVC window profiles may therefore threaten short-term circularity targets. In this study, the current and future level of lead contamination in EOL PVC window profiles in Germany is assessed and the effect of different market, restriction, and technology scenarios is quantified in terms of environmental impacts, material circularity, and lead phase-out. A dynamic material stock and flow model for PVC on the goods layer and lead on the substance layer was developed for window profiles in Germany from 1960 to 2100. The historic model is linked to prospective scenarios with and without restrictions on lead use in new PVC products. An LCA model is being coupled with the dynamic MFA model, to estimate environmental impacts associated with the treatment of window profile waste. The potential development over time is considered in 66 scenarios, including prospective foreground and background system scenarios. The dynamic stock and flow model revealed an increase in EOL PVC window flows by a factor of 1.7 between 2020 and 2050. Whereas a restriction of Pb in new PVC frames to 0.1% by 2034 (EU 2023/923) leads to an accelerated phase out of Pb in in-use stocks (factor 5 lower concentration by 2100), it also forms a barrier to recycling and results in additional global warming impacts of 6.9 million tonnes of CO_2-eq. between 2034 and 2100 compared to a non-restricted scenario. However, the assessment of scenarios on alternative treatment pathways for EOL PVC profiles, such as municipal solid waste incineration with recovery of hydrochloric acid or with carbon capture and storage, revealed that they can partially mitigate the trade-offs linked to the restriction. Comprehensive analyses are needed to identify environmentally preferable waste management concepts and to provide robust decision support.

5.01.B.T-02 Bioenergy with Carbon Capture and Storage as Catalyst for Carbon-Negative Products – A Life Cycle Assessment Case Study of Olive Oil Production

Ángel Galán Martín*, María del Mar Contreras and Eulogio Castro Galiano, University of Jaén*

The imperative for carbon neutrality and removing CO_2 from the atmosphere has led to a quest for resilient and sustainable production and consumption practices. In pursuit of these climate goals, Bioenergy with Carbon Capture and Storage (BECCS) stands out as a versatile solution, providing opportunities to convert biomass resources to meet the energy demands of diverse industries. The beauty of integrating BECCS into production systems lies in its potential to achieve a net-negative greenhouse gas emissions balance within the product system; in other words, it potentially allows for the production of marketable products while actively removing CO_2.

This study focuses on an illustrative case of integrating BECCS into the olive oil industry. By using Life Cycle Assessment (LCA), we evaluate the environmental implications of three scenarios, conventional virgin olive oil (VOO) production and two BECCS-integrated alternatives. The study follows a cradle-to-gate approach and the functional unit was defined as the production of a one-liter bottle of VOO. The SimaPro software and ReCiPe 2016 method were employed.

The carbon footprint (CF) of the baseline scenario was +1.89 kg CO_2eq per 1-liter bottle of VOO. The first BECCS-integrated scenario, which exploits only a portion of pruning residues to be energetically self-sufficient, reduced the CF by 34.46%. The second scenario that utilized all prunings generated at the olive tree cultivation stage, achieved carbon negativity up to -0.82 kg CO_2eq per 1-liter bottle). However, unintended environmental effects emerged, including terrestrial acidification, freshwater eutrophication, and ecotoxicity, driven by increased fertilizer use, biomass transportation, and the CCS system. Despite these challenges, BECCS integration substantially reduced damage to human health and ecosystem quality.

Our findings contribute valuable insights for the olive oil industry, serving as a catalyst for BECCS exploration in diverse sectors beyond food systems. This research aligns with the global pursuit of climate neutrality and provides a blueprint for integrating BECCS to promote sustainability and encourage active societal engagement in climate action by delivering products with a carbon-negative footprint for consumers.

5.01.B.T-03 Environmental impacts of reducing medication waste by redispensing unused oral anticancer drugs: a life cycle assessment
*Elisabeth M. Smale[1], **Anne Ottenbros**[2], Bart J.F. van den Bemt[3], Eibert R. Heerdink[4], Rosalie van Zelm[2], Jelle Verploegen[5], Toine C.G. Egberts[6] and Charlotte L. Bekker[1], (1)Department of Pharmacy, Radboud University Medical Center, Netherlands, (2)Radboud University Nijmegen, Netherlands, (3)Department of pharmacy, Sint Maartenskliniek, Netherlands, (4)Department of clinical pharmacy, University Medical Centre Utrecht, Netherlands, (5)Department of pharmacy, Radboud University Medical Center, Netherlands, (6)Division of pharmacoepidemiology and clinical pharmacology, Utrecht University, Netherlands*
Medication dispensed to patients for at-home use frequently remains unused after treatment continuation. Unused medication, like oral anticancer drugs (OADs), can be redispensed after quality check by the pharmacy. This study assessed the environmental impact of redispensing quality-assured OADs and explored how redispensing can be environmentally improved.

Environmental impacts of redispensing OADs were determined by a cradle-to-grave life cycle assessment, based on data from a one-year multicentre trial following 1,071 Dutch patients with cancer. Process burdens of quality-assurance materials (i.e., seal bag and time-temperature indicator) were calculated, as well as environmental impacts of a sample of six OADs used to extrapolate to all OADs used in the trial. Data on active pharmaceutical ingredient (API) production was based on patent data and scaled up to industrial scale. Impacts were quantified on human health, ecosystems, and climate change. Scenario analyses on quality assurance were conducted for optimisation.

Process burdens of the base case quality assurance procedure exceeded environmental benefits, mainly due to the time-temperature indicators used to assure product quality. When quality assurance materials were used selectively for temperature-sensitive OADs (i.e., maximum storage temperature: 25°C) environmental benefits for redispensing were obtained compared to producing new OADs. By using only visual quality checks, the environmental impacts could be optimised further.

This study showed that redispensing unused OADs can be used as suitable circularity strategy to, next to being economically beneficial, reduce waste and improve environmental sustainability of (cancer) treatment after process optimisation. In the presentation, results will be shown, as well as methodological challenges in performing the LCA on pharmaceuticals and circular strategies.

5.01.B.T-04 Life Cycle Assessment Case of Study: eAOP Applied to Commercial Scale Pd Recovery from Wastewater
***Gema Amaya Santos**, Chemical Engineering, University College London (UCL), London, United Kingdom*
This study compares the environmental performance of four pre-oxidation technologies for Pd recovery from pharmaceutical wastewater using ion exchange. The pre-treatment technologies are: (1) H2O2 addition, (2) anodic oxidation with BDD cells, (3) combined electrochemical oxidation and H2O2 formation in BDD cells, and (4) sole H2O2 generation in BDD cells. The reference process is incineration without Pd recovery. Life Cycle Assessment methodology is applied with a functional unit of treating 100m3 pharmaceutical effluent with 95% Pd recovery. The system boundaries include pre-treatment and ion exchange. Environmental impacts of acidification, climate change, ecotoxicity, human toxicity, and land use are calculated using the E.F. 3.0 methodology. Pd recovery is more environmentally favorable than incineration, except for land use impact when using electrochemical oxidation. Optimizing electrochemical oxidation could improve efficiency and reduce land use impact. Pd recovery from wastewater using ion exchange is more environmentally beneficial than incineration without Pd recovery. The most environmentally friendly pre-treatment technology is H2O2 addition, followed by anodic oxidation with BDD cells. The combined electrochemical oxidation and H2O2 formation in BDD cells and sole H2O2 generation in BDD cells are less environmentally friendly due to higher energy consumption. However, optimizing electrochemical oxidation could improve efficiency and reduce land use impact.

5.01.B.T-05 Synergies and Lessons: On-grid and Off-grid Solar Energy Systems in Kenya and Europe
***Gloria Moscatelli**[1], Anders Damgaard[1], Caleb Mireri[2] and David Mugendi[3], (1)Technical University of Denmark (DTU), Denmark, (2)Kenyatta University, (3)University of Nairobi*
Solar energy is hailed as a sustainable option however, concerns about circularity and waste in solar energy systems still persist. This research delves into the on-grid and off-grid solar energy systems of Kenya and Europe, seeking to uncover

insights for circular solutions. Unlike most previous studies, the entire solar energy system, including inverters, cables, and batteries is assessed in this work. Key questions include: What is the influence of geographical and temporal factors on the life cycle assessment of solar energy systems? What are the main barriers to the transition to a circular economy for these systems, and how do these barriers vary across different regions?

This study adopts the Life Cycle Assessment (LCA) methodology to evaluate major environmental hotspots and proposing circular approaches based on considerations regarding regulatory compliance, local infrastructure, on-grid/off-grid dynamics, and socio-economic factors. A unique aspect of our approach is the emphasis on the "second life cycle" of solar components, addressing challenges in maintaining material quality during prolonged product lifespans.

In Kenya, data collection involved two months of face-to-face meetings with over 20 stakeholders, providing a complete understanding of the local scenario. European data, sourced from meetings and literature reviews, complements this procedure, ensuring a well-rounded perspective. The gathered data are then utilized to simulate current and proposed scenarios in Kenya and Europe using the EASETECH software from the Technical University of Denmark.

Preliminary results emphasize the importance of closing material cycles, especially in electronic waste management. In Kenya, a concerning trend of lower quality and durability in off-grid systems leads to increased replacements, contributing to environmental impacts. Batteries instead, a critical component, see significant refurbishment or recycling, while circular challenges emerge for motherboards, often sent abroad for recycling, highlighting the crucial importance of implementing Extended Producer Responsibility (EPR) schemes for supporting in-situ treatment. Solar panel recycling is inadequately addressed in both Kenya and Europe, with panels accumulating in storage or landfills. This poses environmental and health risks due to hazardous substances leaching into the soil.

5.01.P Circularity Strategies and Life Cycle Thinking: Ensuring the Way to Sustainability

5.01.P-Th467 Allocation of by-products: A multi-sector Life Cycle Assessment of low carbon steel and cement production in the United Kingdom

Jacob William Whittle[1]*, Madeline Rihner*[2]*, Brant Walkley*[2]*, David I Fletcher*[3] *and Lenny S.C Koh*[4]*, (1)Department of Mechanical Engineering, University of Sheffield, Sheffield, United Kingdom, (2)Department of Chemical and Biological Engineering, University of Sheffield, United Kingdom, (3)Department of Mechanical Engineering, University of Sheffield, United Kingdom, (4)Management School, University of Sheffield, United Kingdom*

Energy intensive industries, such as the steel and cement sectors, are facing profound pressures to decarbonise through novel and innovative solutions. Within the United Kingdom (UK), the cement sector utilises supplementary cementitious materials, such as steelmaking by-products, to produce low carbon blended cements. However, the steel sector has begun a transition toward electric arc furnace steelmaking, which allows for a higher proportion of steel to be recycled. Whilst this enables a more effective use of the circular economy principle, it does not produce the co-products currently utilised in the cement sector to create lower carbon products. Life Cycle Assessment (LCA) is a standardized method to evaluate a wide range of environmental impacts throughout a product’s life cycle and has become a critical lever within industrial decarbonization strategies. It has been found in existing academic literature that, currently, the allocation of by-products has not been assessed on a cross-sector level. Similarly, industrial literature would indicate that allocation procedures are chosen to minimise environmental impacts of their product. Through a novel cross-sector analysis, this research aims to conduct an LCA that can provide a holistic view on the environmental impact of BFS across the steel and cement sectors through a detailed investigation of by-product allocation procedures. Early-stage findings indicate that the allocation procedure selected has a significant effect on the environmental impact generated for a product. These results will be used to further consider how changes in UK steel production may have an impact on the production of low carbon blended cements, including assessing the effects of increased GGBFS importation due to the transition to EAF steelmaking through modelling various by-product allocation scenarios.

5.01.P-Th468 Comparison of Different End-of-Life Modelling Approaches for an Environmental Life Cycle Assessment of Agrivoltaic Systems in Austria

Theresa Krexner*, Alexander Bauer and Iris Kral, Institute of Agricultural Engineering, University of Natural Resources and Life Sciences (BOKU), Austria*

Agri-photovoltaics (agrivoltaics, APV), i.e., the parallel use of agricultural land for food/feed and electricity production using photovoltaic (PV) modules, is currently a popular research topic due to its higher land use efficiency and alternative energy source. In a previous study by the authors, the environmental impacts of two APV systems were assessed using the life cycle assessment (LCA) method and further compared with selected mono-uses of agricultural land, either for agricultural production or electricity production using PV-modules. For a holistic assessment of APV systems, a system expansion approach was used to evaluate both outputs, the agricultural goods and the PV electricity. So far, system boundaries have only been set from cradle-to-gate as to be comparable with most literature studies. However, in order to conduct a comprehensive LCA covering the whole life cycle, the end-of-life phase is now the main focus in the proposed work. Due to the many different methodological approaches for end-of-life modelling, especially for recycling, the aim of this study is to evaluate different approaches, to assess advantages and disadvantages and to demonstrate the applicability of these approaches to a multi-output product system, for which a system expansion approach has already been applied. In particular, the circular footprint formula, the cut-off approach as implemented in the Ecoinvent database and other options, e.g., end-of-life allocation based on a closed-loop assumption will be evaluated. These approaches will mainly be applied to the steel and PV modules, as these are the most important hotspots and can be recycled in a potentially efficient way. The software openLCA v1.10.3 with the ecoinvent cut-off database 3.8 will be used; Austria is assumed as the case study region to use country specific data for e.g., steel recycling. A comparison of the results of the end-of-life modelling, but also an assessment of overall performance will be conducted. The results of the study will help to evaluate different end of life modelling options and which fit best to model APV systems.

5.01.P-Th469 Environmental Impact Effect of Food Loss Reduction by Automated Ordering System

Tomoya Hachiman[1]*, Kazuhiko Okamoto*[2]*, Itsubo Norihiro Dr*[3] *and Hiroki Ookubo*[1]*, (1)Tokyo City University, Japan, (2)Sinops CO.,Ltd, Japan, (3)Waseda University, Japan*

In recent years, there has been growing concern regarding food loss that is thrown away when it could be eaten. To reduce food loss, it is necessary to optimize distribution volume in the retail and wholesale industries, which are located further upstream. According to previous studies, optimization of purchasing by optimizing orders is estimated to be the most effective way to reduce environmental impact. However, the validity of this estimate has not been verified. Therefore, in this study, we quantified the environmental impact reduction effect when supermarket ordering is optimized by an automatic demand forecasting ordering system using primary data. The environmental impact of the following 16 items covered by the automated ordering system was quantified for each store at the production and disposal stages. The results showed that in most stores, the system contributed to reduce food loss and environmental impact. On the other hand, it was found that some stores did not fully benefit from automated ordering depending on the type of store location, regional characteristics, and specific product items.

5.01.P-Th471 Identification of Environmentally Optimal Process Design for a Large-Scale Cellulose Nanocrystals Production

Polina Yaseneva, PhD[1]*, Zhimian Hao*[2] *and Wadood Hamad*[3]*, (1)Cambridge Institute for Sustainability Leadership, University of Cambridge, United Kingdom, (2)Department of Chemical Engineering and Biotechnology, University of Cambridge, United Kingdom, (3)Impossible Materials AG*

Nanocrystalline Cellulose (CNC) is a highly promising class of materials due to its favorable functional properties and its green credential as biobased material. CNC’s unique properties make it suitable for a broad range of end-use applications, including pigments, packaging, electronics, medicine, etc; and there is a growing interest in scaling up its production. Today’s most common method of CNC manufacturing is sulfuric acid hydrolysis of Kraft pulp. As in any other process, there exist several design options for the overall CNC production process. Recycling of sulfuric acid (as a major process input) is generally seen as a pathway for more circular and sustainable CNC production design. However, chemicals recycling processes are often energy intensive and pose trade-offs in achieving environmental benefits. Hence to ensure improved sustainability, decisions on adoption of a specific plant configuration should be based on the economic as well as the environmental data from the life cycle assessment (LCA) perspective.

In this study we establish a benchmark LCA of a conceptual large-scale CNC manufacturing process based on sulfuric acid hydrolysis. We then employ the benchmark process model to explore several plant configurations under different acid recycling scenarios. The outcomes of LCAs that incorporate energy intensive processes are highly sensitive to the type of energy mix and consequently to specific geographies of production. Our analysis of CNC production’s environmental impacts for a benchmark case study in Quebec, Canada revealed the following key findings: (1) without acid recycling environmental impacts are dominated by input materials; (2) introducing circular design through acid recycling shifts environmental impacts from input materials to energy consumption: thus, complete acid recycling requires ∼ 14 times more energy; (3) based on the LCA study we recommend optimizing plant configuration through partial acid recycling for a balance between materials and energy consumption. For improvement of climate change impact, regions with abundant low-carbon energy, like Quebec in Canada and Sweden, favour high acid recycling, while fossil-dominated regions benefit from limited acid recycling. When several environmental impact categories are considered, exact optimal process configuration, such as per cent acid recycling, will require multi-criteria decision analysis, considering the product specification and energy mix of the plants’ location.

5.01.P-Th472 Homogeneous Green Conversion of the Bio-Based Platform HMF (5-Hydroxymethylfurfural) into BHMF (2,5-Bis(hydroxymethyl)furan): Synthesis and LCA (Life Cycle Assessment)

Eleonora Rossi*, Alessandro Messori, Andrea Piazzi, Nicolò Santarelli, Giulia Martelli, Massimiliano Curcio, Francesco Calcagno, Ivan Rivalta Prof, Fabrizio Passarini Prof, Daniele Cespi and Rita Mazzoni Prof, Industrial Chemistry, University of Bologna, Italy*

The global imperative to shift away from fossil-based products has highlighted the pivotal role of biorefinery in harnessing biomasses as a source for alternative chemicals, prominently featuring 5-hydroxymethylfurfural (HMF) among its derivatives. HMF, extracted from biomasses, emerges as a versatile compound capable of undergoing several transformations.

This compound’s intriguing structure opens pathways for various chemical alterations. Such transformations pave the way for HMF and its derivatives to replace conventional fossil-based chemicals across an array of applications, spanning polymer production, pharmaceuticals and biofuels.

Of particular interest is the reduction of HMF, leading to the production of 2,5-bishydroxymethylfuran (BHMF), an important compound for the polymer and flavor industries. However, the conventional production of BHMF typically involves heterogeneous systems operating at high temperatures and pressures. A homogeneous catalyst that has led to excellent results is the Shvo system, an organo-ruthenium compound[1].

However, the environmental impact of the catalyst (in particular of the Ru) cannot be overlooked. The extraction, processing, and disposal of ruthenium present considerable ecological concerns. This aspect highlights the ongoing need for exploration and development of new systems that balance effectiveness with reduced environmental impact to further enhance the environmental sustainability of bio-based chemical production.

In this study, the synthesis of BHMF was explored using an iron-based catalyst, presenting comparable outcomes to the Shvo catalyst synthesis while prioritizing sustainability. Iron was chosen for its accessibility and reduced environmental impact.

To evaluate the environmental implications of this reaction, a life cycle analysis (LCA) was conducted across multiple impact categories. As the technology remains in its early stages at TRL 4, an environmental assessment was carried out to represent both laboratory conditions and a prospective analysis for potential industrial application, known as an Ex-Ante LCA. This type of study anticipates the future maturity of lower scale technologies studied at present. The objective was to calculate the overall environmental impacts, considering not only climate change but various other impact categories. Additionally, an economic feasibility assessment and a preliminary Life Cycle Costing (LCC) were performed.

1- doi.org/10.1002/cssc.202200228

5.01.P-Th473 Eco-design Approach for the Steel Circularity: a Case Study of a Steel Radiator Manufacturing

***Riccardo Paoli**[1], Maksims Feofilovs[2] and Francesco Romagnoli[2], (1)Riga Technical University, Latvia, (2)Institute of Energy Systems and Environment, Riga Technical University, Latvia*

The production of steel as a raw material has a significant environmental footprint stemming from the extensive utilization of primary resources, substantial waste generation, emissions, and a high energy demand. Therefore, an eco-design approach supported by the Life Cycle Assessment (LCA) methodology is necessary to introduce the idea of sustainability and underline the importance of using secondary or recycled material within a concept of resource circularity. The eco-design process can be applied either during the selection of primary materials or in a more comprehensive manner that encompasses the entire production chain. This may involve considerations such as enhancing energy efficiency, minimizing waste, and optimizing production sourcing. The current study aims to perform an LCA study for the production of a steel radiator and compare different eco-design approaches in order to understand their benefits. The circularity approach involves the creation of three scenarios featuring varying percentages of scrap steels. Additionally, a fourth scenario has been developed to examine the production of "*carbon-free*" steel, aiming to introduce a sustainability concept encompassing the entire supply chain (cradle to gate). The production of "*carbon-free*" steel involves modifying the energy resources employed throughout the entire production stages, from the extraction of raw materials to the alloy processing. This adaptation included the utilization of green technologies, such as green hydrogen and electricity sourced from renewable sources, as substitutes for traditional fossil fuels like coal, diesel, and natural gas. The LCA study was conducted with *SimaPro 9.5* software and data from the *Ecoinvent 3.9* database. The environmental impacts are assessed according to the EN 15804 method. The findings highlight the climate change indicator as critically sensitive in steel production. To mitigate the overall environmental impact, employing the "*carbon-free*" steel provides notably positive results, achieving a reduction of over 50% in impact. These study outcomes can be leveraged as valuable insights or serve as a foundation for subsequent investigations within the environmental labeling domain, fostering stakeholder awareness of the enhanced value associated with products embracing an eco-design approach.

5.01.P-Th474 Environmental Assessment of Steel Slags Ball Milling Carbonation a Carbon Capture, Utilization and Storage Material

***Ponnapat Watjanatepin**[1], Laura Steinwidder[2], Anthony de Schutter[1], Giuseppe Granata[1], Sara Vicca[2], Tom Van Gerven[1] and Karel Van Acker[1], (1)KU Leuven, Belgium, (2)University of Antwerp, Belgium*

The steel industry is one of the most concentrated anthropogenic point sources on the planet. In addition to the emissions, steel slags are also generated as a by-product of the manufacturing process at between 15 to 25% of the crude steel mass produced. Given the current emphasis towards a carbon reduction of 80-95% of the steel value chain by 2050 as part of the European Green Deal on Steel, there is an urgent need to adopt circular economy strategies to the current value chain. Presently, the latest research pointed to the potential to generate stable carbonates and silicates from steel slags via mineral carbonation. The process utilizes the carbon dioxide in the flue gases to form stable carbonates and silicate layers in the slags for permanent carbon sequestration. Mineral carbonation could be a potential solution to generate values from both the carbon emissions and the steel slags, thereby, enhancing a circular economy approach to waste management within the steel manufacturing industry. Subsequently, carbonated slags can be designated as a carbon capture, utilization and storage (CCUS) material as the carbonated steel slags could be applied in the construction and agricultural sectors. Ball milling carbonation is a recent technology which employs the use of milling beads to reduce the size of the steel slags which consequently increases the surface area for the carbon dioxide to be sequestered onto the slags. Nonetheless, it is important to determine whether the benefits of carbon dioxide sequestration outweigh the emissions resulting from the carbonation process. To this end, this study has an objective to perform a life cycle assessment on the ball milling steel slags carbonation in order to (1) evaluate the environmental impacts of the ball milling carbonation, (2) identify the process hotspots for further future optimization and (3) calculate the optimum tradeoff point between the amount of carbon dioxide sequestered and the emissions during the ball milling carbonation process. The results obtained from this study can aid in the promotion and adoption of mineral carbonation of steel slags as a CCUS. Furthermore, mineral carbonation can also improve the industrial symbiosis between different manufacturing processes within and around the steel industry in such a way that promotes a circular economy value chain as well as advancing the transition towards a more environmentally sustainable steel manufacturing value chain.

5.01.P-Th475 State of the art on the environmental sustainability of aluminum foundries based on Life Cycle Assessment: a systematic literature review.

Federico Rossi*, Monia Niero, Chiara De Bernardi and Marco Frey, Sant'Anna School of Advanced Studies, Italy*

The metals sector represents one of the most impactful industries from an environmental point of view. Overall, metals production determines around 7% of the global energy demand and 8-10% of global greenhouse gas (GHG) emissions. In this sector, virgin aluminum production represents the most energy-intensive activity; for instance, the production of each ton of aluminum requires about eight times more energy than steel and iron. Not surprisingly, aluminum production is therefore responsible for about 3% of global GHG emissions. In addition, several hazardous wastes and contaminants, such as the so-called “red mud”, are produced by aluminum foundries.

On the other hand, recycling scraps can cut the energy demanded by aluminum production by 90%, but only a third of the aluminum is currently produced from secondary sources. Furthermore, secondary aluminum production and refining potentially imply relevant environmental burdens related to pollutants in off-gases, dust, slags, and dross. These issues can be, to some extent, turned into opportunities by recovering valuable materials from the by-products of both the primary and secondary aluminum industry. Moreover, innovative technologies like inert anodes are investigated by researchers to mitigate aluminum environmental burdens.

Therefore, depending on the materials' circularity and the technologies employed in metal foundries, the environmental impacts of aluminum products can be highly variable and time-dependent. Furthermore, a variety of methodological approaches and assumptions in Life Cycle Assessment (LCA) are applied in literature, especially concerning end-of-life modeling, thus affecting the variability of the results. In light of the evolution in technologies and LCA methodology, significant changes can be observed in scientific literature since the most recent review in the field was published in 2012.

This study highlights the main outcomes of a systematic literature review that is focused on the aluminum industry and LCA in a circular economy context, also remarking on perspectives and research directions in the field. This study is carried out under the framework of the “*GRINS - Growing Resilient, INclusive and Sustainable*” project, founded by the “*NextGenerationEU*” program and by the Italian Ministry of Education, University and Research. According to the aim of the GRINS project, the LCA publications related to the Italian aluminum industry are under the spotlight of our literature review.

5.01.P-Th476 Leveraging Life Cycle Thinking to Select Sustainable Circular Materials for Highly Demanded and High-Performance Grout Production

Nadine Riiashi[1] *and Angélique Léonard*[2]*, (1)University of Liège, Belgium, (2)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium*

To ensure a sustainable future, the construction sector is moving towards a circular economy, offering a promising pathway to limit environmental impacts while cultivating economic growth. C-GROUT research project under the ‘REMIND’ portfolio (Reverse Mineral Industry in Wallonia), focuses on assessing the environmental impact, performance, and feasibility of structural concrete grouts for energy market applications, where the product must withstand hard conditions. A critical aspect in this context is ensuring circularity by designing products that are safe, long-lasting, and circular. The assessment of specialized concretes in this sector uses life cycle thinking to advance circular material strategies.

The main challenge of this study is integrating secondary mineral materials available in Wallonia (Belgium), such as quarry fines, glass calcine, and various local mineral waste products, into the formulation of low, high, and ultra-high performance concrete grouts. The investigation assesses these materials during the manufacturing process, looking for ways to reduce natural resource consumption and landfill deposition to achieve equal or superior properties while having minimal environmental impacts.

Industrial partners of the project are set to conduct standardized tests to validate the technical efficiency, with the University of Liege lending its support by employing a life cycle thinking approach. This collaboration aims to unveil the environmental benefits of the resulting materials. Life Cycle Assessment (LCA) method from cradle to grave, following EN15804+A2 standard specifically, will stand as a decision-making tool to support eco-design and facilitate strategic alternative choices. Furthermore, an upscale strategy will be adapted to the potential market of the region.

The strategy is expected to result in new energy and resource efficient products, and business opportunities that will shape Wallonia's economic landscape.

This study endorses circular economy's principles, emphasizing the integration of wastes as a resource, mindful material sourcing, and creating innovative business strategies. The research highlights the significance of robust sustainability assessments that will direct the business toward products that are cost competitive. Furthermore, these new construction formulations with their minimal environmental impact point the way for future initiatives that will make a significant impact on the environment, society, and economy.

5.01.P-Th477 MaIsoVi Project: Vacuum Insulation Materials, Innovative Approach for Windows in Construction and Renovation

***Sylvie Groslambert**[1], Axel Hemberg[2], Bruno Riche[3], Thomas Lescot[4], Thibaut Van Hoof[5] and Angélique Léonard[6], (1)University of Liège, Belgium, (2)Materia Nova, (3)Menuiserie Riche, (4)AGC Glass Europe SA, (5)Cenaero, (6)PEPs-Chemical Engineering Research Unit, University of Liège, Belgium*

The building sector is responsible for almost 36% of CO_2 emissions in Europe and 40% of energy consumption. This underlines the need to develop new solutions to support the strategy of reducing the energy needs of housing.

The objective of the MaIsoVi project (GreenWin n°8653) is to offer the construction and renovation market for the residential and commercial (tertiary) segment:

- A vacuum glazing (tempered FINEO) demonstrating the same or better energy efficiency than triple glazing but with the same weight as double glazing and the thickness of single glazing.
- A wooden window equipped with this FINEO and using a minimum of materials while guaranteeing the best performance over a maximum extended life span.

The implementation processes and the design of these products will be optimized to obtain a lower environmental footprint than the state of the art (triple glazed wooden window). The life cycle assessment (LCA) of the products and their processing is conducted during all the steps of the project to ensure the completion of this objective.

The tempered FINEO glazing is produced in the Walloon region at AGC site in Lodelinsart. The wooden frame is manufactured at Menuiserie Riche in Mariembourg, and the FINEO window will be marketed in Belgium, a large part of France and neighbouring countries. Two research centers, Materia Nova and Cenaero, support the development and characterization of the new products, and Liège University is in charge of the LCA.

The first step of the LCA is the specific modelling of the woods based on both primary and background data, and from this, the evaluation of the footprint of the wood window especially (eco)designed for the FINEO glazing, with different wood combinations and innovative solutions for an easy repair/replacement/refurbishing. The FINEO life cycle assessment, on its side, is based on primary data. The resulting product is to be compared to the usual commercial equivalent windows with triple glazing.

This project is supported by the GreenWin Competition Clusters and subsidized by the Walloon Region (BE).

5.01.P-Th478 R3PANOT: Rethinking the tile of the future of Barcelona city

***Carolina Villa González**[1], Irene Rafols Ribas[1], José Jorge Espí Gallart[1] and Gerard Faneca Llesera[2], (1)Fundació EURECAT, Spain, (2)ESCOFET 1886 S.A*

The R3Panot project, a collaborative effort stemming from the 21st-century Panot Challenge initiated by BitHabitat and Barcelona City Council, stands as a transformative endeavor aimed at redefining the iconic pavement design that has shaped the city's aesthetic for over a century. This pioneering project, developed by a consortium comprising Escofet, Promsa, and Eurecat, seeks not only to pay homage to the historical significance of the Panot ("tile" in catalan) but also to chart a sustainable course for its future iterations, becoming a strategic reference for subsequent generations.The project is a comprehensive exploration of sustainable practices, innovative technologies, and meticulous eco-design considerations, with the overarching goal of minimizing environmental impact while ensuring the Panot's continued cultural and historical significance.

The resulting tile from the competition proposal, with dimensions of 20x20x4.5cm, symbolize the culmination. Key among these is the use of low-emission cement formulated with steel slag, ushering in an 80% reduction in CO_2 footprint compared to conventional cement. Exhibiting improved mechanical resistance, the tiles additionally extend their lifetime. Furthermore, the develovep tile, boast a 71% reduction in carbon footprint compared with de conventional one, includes a 30% recycled material content, mitigating the demand for primary resource extraction and an innovative recovery and repositioning system.

A significant and distinctive feature of the project is the incorporation and emphasis on the Life Cycle Assessment (LCA) as a tool for eco-design and continuous environmental improvement. Furthermore, the commitment to circularity is highlighted by the Panot's 100% recyclability at the end of its life cycle. This feature ensures that the product can be reintegrated into the production process, minimizing waste and reducing the demand for new raw materials.

In conclusion, the R3Panot project serves as a beacon of sustainability, blending tradition with innovation. By incorporating recycled content, responsible material sourcing, innovative business models, and placing a strong emphasis on LCA for continuous improvement and recyclability, the project not only reimagines the Panot for the 21st century but also sets a strategic precedent for sustainable practices in future urban design and infrastructure projects.

5.01.P-Th479 Environmental performance of end-of-life scenarios of Electric Vehicles (EV) batteries following a life cycle approach

Susana Leão[1]*, Meritxell Rovira*[2]*, Hatice Kübra Güney*[3]*, Caroline Mir*[4]*, Ronja Wagner-Wenz*[5] *and Marta Escamilla*[2]*, (1)Leitat Technological Center, Barcelona, Spain, (2)Leitat Technological Center, Spain, (3)Ford OTOSAN, (4)Renault Group, (5)IWKS Fraunhofer*

Energy storage is essential for the decarbonisation of the electricity grid and the transport sector. Batteries are likely to play an important role in meeting the need for short-term electricity storage in the grid and enabling electric vehicles (EVs) to store and use energy on demand. However, the use of critical raw materials (CRM) and the upstream environmental impacts of manufacturing, as well as end-of-life (EoL) management, are often cited as a drawback to the widespread use of rechargeable batteries. More efficient use of resources and efficient recycling processes are needed to reduce EU import dependency and contribute to ambitious climate targets by 2030.

It is estimated that over 80% of all energy product-related environmental impacts are determined during the design phase. Given this, special attention should be paid to the initial stages of battery design, considering the entire life cycle, with the goal of minimizing environmental repercussions. End-of-life management is of great importance and is strictly linked to the design phase. If the battery at end-of-life cannot be repaired, reused, or recycled due to an initial design constraint (e.g., disassembly problems) it will be disposable, leading to considerable environmental consequences.

In the framework of the EU Horizon Europe BATRAW project, two innovative pilot systems (TRL6-7) are being developed for sustainable end-of-life management of EV batteries, contributing to the generation of strategically important secondary CRM streams (e.g., Li, Co, Ni and Mn). In the project, an eco-design guide for battery packs is also being developed for battery pack providing recommendations at conception and manufacturing level. The BATRAW concept follows a circular approach, from collection and transport of waste battery packs, to dismantling, reparation, reuse, recycling, and sourcing of raw materials back into the EV battery manufacturing value chain. The Life Cycle Assessment methodology has been used to assess the potential environmental impacts associated to the life cycle of the BATRAW system and EoL scenarios under study (2nd life and repair of the battery pack, and recycling for the recovery of valuable materials). A comparison of the environmental profile of BATRAW with conventional production routes for valuable raw materials and traditional battery manufacturing will be presented. This project has received funding from the Horizon Europe programme under the Grant Agreement No 101058359.

5.01.P-Th480 Life Cycle Assessment of Electric Traction Machine Considering Novel Recycling Processes for Permanent Magnet Circularity

Lea D'amore[1]*, Joachim Jusselme*[2,3]*, Maeva Lavigne Philippot*[1]*, Tom Bauer*[2] *and Maarten Messagie*[1]*, (1)ETEC Department, Vrije Universiteit Brussel (VUB), Belgium, (2)Arts et Métiers, CNRS, Université de Bordeaux, France, (3)AMVALOR, France*

The electrification of the fleets targets the objectives of decarbonisation of the transport sector. However, while Electric Vehicles (EV) do not emit exhaust emissions during the use phase, effects of the resource’s extraction, electricity and vehicle production, maintenance and up to End-Of-Life (EoL) treatment can damage the environment. In this study, the focus is on electric traction machines (ETM). The use of strategic raw materials especially in the permanent magnets (PM) have raised concerns related to environmental performances as well as regarding the mineral resource depletion impacts. While the use of such resources helps to optimise the performance of ETM and still represents the common design for ETM, circularity strategies should help to reduce the environmental impacts of the product.

The objective of the study will be to analyse the environmental impacts of a full ETM considering a specific EoL treatment for the permanent magnet components. Such treatment consists of novel recycling processes of rare earths permanent magnets and reuse for ETM in EVs. This treatment is assessed within the context of an ETM ecodesign project called MAXIMA. Data collected for this will therefore be primary data. The idea is to understand the potential of the recycling processes considered to reduce the environmental impacts of the machine. The ETM will be used as a reference machine to which the new design will be compared during the project.

To assess the ETM, the method used will be Life Cycle Assessment (LCA), from a cradle-to-grave approach. The system boundaries will consider the ETM including the raw materials extraction, production, use phase and EoL treatment. A comparative LCA will be carried out between two scenarios: the ETM with a standard EoL treatment and the ETM including the recycling processes of PMs. The study will develop more precisely the method and allocations to consider for the systems and the approach to include recycling and circular strategy.

The results will present the impacts on all life cycle stages of the system. The goal is to show the sources of the main burdens on the environment of the ETM with a focus on the effect of improving circularity. It should give insightful information to this specific improvement in MAXIMA where the overall goal is to develop a more efficient ETM with a reduced use of resources.

Acknowledgement - This project received funding from MAXIMA projects through grant agreements numbers 101096097

5.01.P-Th481 Sustainable Design for Electric Vehicle Battery Packs: An Integrated Eco-Design Methodology

*Violeta Vargas-Parra[1], José Jorge Espí Gallart[2], **Carolina Villa González**[2] and Frederic Clarens[1], (1)Eurecat, Spain, (2)Fundació EURECAT, Spain*

Advancing towards a circular economy requires a concerted effort in designing products with sustainability at their core. This research introduces an innovative methodology for eco-design applied in the MARBEL H2020 project in the design of a battery pack.

Acknowledging challenges in existing Design for Circularity (DfC) methodologies, our approach seeks to provide clarity and practicality. Rooted in the ISO 14006 standard and embracing the life cycle concept, this framework harmonizes environmental and economic considerations.

The methodology is adaptable to a wide variety of products and processes. A four-step iterative cycle, aligned with the PDSA approach, forms the core of the methodology: 1) Identification of Hotspots and Life Cycle Stages, 2) Definition and Setup of Eco-design Strategies, 3) Re-adaptation of Technological Procedures, and 4) Definition of Concrete Eco-design Actions. Stakeholder engagement ensures a comprehensive understanding of diverse perspectives, contributing to informed decision-making.

For an objective prioritization, the integrated Analytic Hierarchy Process (AHP), fosters a robust decision-making tool. All relevant stakeholders, including product designers actively participate achieving a holistic coverage of all life cycle stages. The outcomes of the application of this methodology include minimized material and resource consumption, improved functionality, enhanced environmental performance, ease of disassembly, and increased potential for recycling—all without compromising technical efficiency and considering economic aspects.

In conclusion, our work specifically addresses the application of the DfC methodology in the design of an electric vehicle battery pack, offering significant contributions:

- Identification of key environmental challenges related to LIB batteries in electric vehicles, providing the basis for targeted strategies.
- Development of a collaborative ecodesign approach, yielding 10 generic strategies and 14 specific actions tailored to the unique challenges of battery pack development.
- Provision of an initial concept design for a sustainable battery pack, encompassing all key components.

This research introduces a transferable and adaptable methodology, fostering sustainable practices in the development of battery packs and contributing to the broader goal of creating more circular and environmentally aware electric vehicles.

5.01.P-Th482 To Mix or Not to Mix? Life Cycle Assessment of Critical Raw Material Recovery From Lithium-Ion Batteries by Hydrometallurgy

***Yvonne Kaye Perocillo**[1], Thibaut Lavis[2], Eric Pirard[3] and Angélique Léonard[4], (1)University of Liege - Chemical Engineering, Belgium, (2)Chemical Engineering, University of Liège , Liège, Belgium, (3)University of Liège, Belgium, (4)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium*

The focus of the world right now in decarbonization has disrupted global material flows, highlighting the so called critical raw materials (CRMs). Among these CRMs are materials like cobalt, lithium, manganese, nickel, etc. which are crucial in the production of batteries, the energy storage devices considered to be the key in the decarbonization of the electricity and mobility sectors. It is quite clear that since they are considered as CRMs, supply of these materials is imbalanced i.e., for the European Union (EU), most of these are supplied by other countries through processes that contradict the sustainability goals that these technologies are supposed to address. As the EU finds its footing in securing primary resources for these materials, keeping these materials in the loop through reuse and recycling becomes vital. Several researchers around the world are specially focusing on the recovery of CRMs from Li-ion batteries, a type of rechargeable battery first used on portable consumer electronics and now in electric-powered vehicles (EVs). Most of the processes that are advanced and improved are hydrometallurgical processes as they provide flexibility and are argued to have better recovery than other metallurgical approaches. However, these processes are known to be water and chemical reagent intensive due to the several steps required to ensure process efficiency. Thus, there is a need to reduce the number of separation steps and one proposed solution is to keep the CRMs together. The logic behind this is the fact that these materials are mixed to create the active materials required during battery production. The downside to this though is that the materials produced are not necessarily battery grade and would still actually need further refining, incurring additional associated impacts. This case study aims to analyze these different hydrometallurgical approaches of recovering rechargeable battery materials (e.g., Li, Ni, Co, Mn, Al, Cu, etc.) by using simulation-based LCA in hopes of gaining insight into the best possible approach of keeping these critical metals in the loop. Specifically, the purpose is to shed light between keeping the CRMs mixed or separating them out into individual materials for reuse as battery precursors would make sense in an environmental perspective.

5.01.P-Th483 Development of a Methodology for Assessing Circularity at Company Level

*Antonio Sellitri[1,2], Lisa Pizzol[2], Silvia Breda[3], Alex Zabeo[2], Angela Bonfà[3], Martina Menegaldo[2,3], Giulia Meneghin[3], Sarah Devecchi[2,3], Petra Scanferla[3] and **Elena Semenzin**[1], (1)Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice, Italy, (2)GreenDecision S.r.l., Italy, (3)Fondazione Università Ca' Foscari, Italy*

As stated by the new European Circular Economy Action Plan, circularity is an essential part of a wider transformation of industry towards climate-neutrality and long-term competitiveness. To implement circular strategies within their business models, circularity assessment is a key step for organizations to target concrete actions and pursue achievable objectives. However, standardized methodologies for assessing circularity performances at company level are still under development.

The objective of this contribution is to present an indicator-based methodology for assessing circularity at the micro level (i.e., the organization/product/service level) in the context of contaminated sites remediation which is compliant with the latest standard regarding circularity assessment (i.e., UNI/TS 11820).

The methodological development started with an in-depth analysis of the indicators included in UNI/TS 11820 and their data requirements to identify if they were suitable for their application in the field of contaminated sites remediation processes. This was followed by the setting up of a working group of experts with interdisciplinary expertise in remediation technologies design, Life Cycle Assessment, and Multi-Criteria Decision Analysis. Initially, each expert worked individually to evaluate the indicators, based on the SMART (Specific, Measurable, Achievable, Relevant and Time-bound) criteria. The outcome of this initial evaluation consisted in a preliminary selection of possibly suitable indicators and provided the necessary basis for supporting the discussion among the working group members during the second phase of the selection process. In the second phase, the working group members worked together to refine and finalize the indicators selection process. In doing so, two additional criteria have been identified: site-level applicability and respect of priority topics for remediation (use of resources, energy, water, and waste production). The identified indicators suitable for the circularity assessment of remediation processes will be presented along with the methodology to integrate them.

The developed methodology for circularity assessment of the contaminated sites remediation processes aims to be a useful tool for stakeholders and decision-makers to address problems and opportunities that can rise when implementing circular strategies in the field of contaminated sites remediation.

5.01.P-Th484 Digitalisation for a Sustainable Circular Economy: the DaCapo (Digital Assets and Tools for Circular Value Chains and Manufacturing Products) Project

***Valeria Acevedo García**, Rocio Pena and Lucía Alonso Ferreira, AIMEN, Spain*

The fourth industrial (digital) revolution can drive the transformation to a more sustainable circular economy (CE). Introduction of digital technologies have the potential to reduce resource use, pollution and facilitate circular systems. Digitalisation enables transparent access to data concerning products' resource consumption and makes it possible to optimise their life cycles, which allows more efficient processes, helps minimise waste, extends the product life cycle and minimises the transaction costs, thus promoting sustainability and circularity.

The goal of the DaCapo project is to define a new set of human-centred digital tools and services to enhance the adoption of CE strategies along manufacturing value chains and products lifecycle. These tools and services will substantially improve the sustainability, efficiency, and use of imported and critical raw materials in manufacturing, driving a new paradigm of digital-enabled EU industrial sustainability and resilience.

DaCapo will be based on the following key digital developments: Digital Product Passport (DPP), Modular Digital Thread, Digital Twins (DTs) and Circular Economy Decision Support System (CE-DSS).Three different sustainability tools (Life Cycle Assessment (LCA), Life Cycle Costing (LCC), and Social Life Cycle Assessment (s-LCA)) will be used to verify that the digital tools developed in DaCapo meet the sustainability and CE objectives regarding environmental, economic and social and socio-economic impacts, respectively.

DaCapo will develop digital tools and demonstrate how digitalization could be implemented in high-impact applications in critical EU manufacturing sectors in order to contribute to sustainability and circularity, by improving their environmental footprint while achieving not relying on imported and critical raw materials. To ensure its commercial and replicability potencial 3 case-studies were selected. First, Extending sustainable manufacturing and repairability approaches for aeronautic value chains based in Addictive Manufacturing (GKN Aerospace). Second, Eco-design, diagnosis and maintenance for modular mobile phones (Fairphone).Third, Elimination of bottlenecks in the warehouse industry by rethinking and renewing their logistics thanks to R-cycles in material flows for warehouse design, construction and operation (PESMEL).For this purpose, the change from a linear to a circular business model will be carried out to enhance circularity and sustainability.

5.01.P-Th485 Can LCA Support the Circular Economy? Evidences From Recent Scientific Literature

Caterina Barbiero[1] *and Anna Mazzi*[2]*, (1)Industrial Engineering, University of Padova, Padova, Italy, (2)Industrial Engineering, University of Padova, Italy*

The decreasing availability of resources and the continuous production of waste is one of the main causes contributing to climate change. To overcome this problem, a series of environmental, social and economic actions are required, including moving to a Circular Economy (CE) model. The application of Life Cycle Assessment (LCA) to the CE can be useful to gain a broader view of product and organisational impacts. The aim of this paper is to investigate the application of LCA to the CE, even if it was designed to be applied from cradle to grave. This paper also wants to investigate how much scientific literature is dealing with it, with a focus in waste application.

A systematic literature review on the application of LCA to the CE was performed. Keywords 'Circular economy' and 'Life cycle assessment' were searched for in English-language scientific articles published from 2020 to 2023. To better underline the use of LCA in case of different strategies for sustainable waste management, the words ‘reduce’, ‘reuse’ and ‘recycle’ were searched in the titles and keywords of these articles.

Research results demonstrate great interest on combining LCA and CE: almost 1600 papers have been published in the last four years. The large number of publications shows that the use of LCA to support the research in the field of CE is increasing today and characterizes different economic sectors and different research areas. From this review, main interest of scientists about the sustainable waste management is focused on recycling, while reduce and reuse are not frequently analysed: this contradicts the international policy recommendations that push for the minimization of waste.

In conclusion, LCA seems to be considered by scientists as robust methodology to investigate the convenience of recycling options; otherwise, reduce and reuse solutions to implement the CE still appear little analysed by LCA scholars. It would be important to further investigate the interest of scientists on reduce and reuse options of CE using other impact assessment methodologies, different to the LCA. Moreover, it would be interesting to search within the scientific papers recommendations and guidelines to correctly apply the LCA in case of CE options.

5.01.P-Th486 Towards Cascading Use of Wood in Switzerland: Material Flow Analysis as the Basis for Circular Economy

Nadia Ilaria Malinverno[1]*, Kealie Vogel*[2]*, Bernd Nowack*[3]*, Gustav Nyström*[4]*, Claudia Som*[1]*, Simon Buschor*[4] *and Francis Schwarze*[4]*, (1)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Swiss Federal Laboratories for Materials Science and Technology (EMPA), St. Gallen, Switzerland, (3)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (4)Empa, Switzerland*

Our society is facing environmental challenges such as climate change, energy availability, and resource efficiency. In this context, net-zero targets should be reached with a transition to a decarbonized society and enhancement of a bioeconomy. Forests and wood utilization are expected to contribute significantly to this goal by sequestering CO_2 in biomass, storing CO_2 in materials, and substituting energy sources. Wood, being a versatile material, plays a significant role in various industries and is a key resource for the bioeconomy, circular economy, and cascading use of material. Our study focuses on Switzerland with the aim to categorize and harmonize wood flow information for a detailed understanding the potential for a material cascade use of wood in order to support net zero targets and a circular economy. We achieve this aim by conducting a material flow analysis for the whole life cycle, from wood extraction from forest to being burned in different incineration types, of wood in Switzerland. This research addresses methodological challenges of wood as a versatile material which changes its form and composition along the life cycle. We offer a systemic view of the wood flow system, and provide insights into biomass conflicts within the wood value chain. Moreover, wood flows will be analyzed based on defined criteria (e.g., the treatment of wood) for cascading use (including reuse or recycling) in new valorization streams as a prioritized use before being burned for energy generation (as is done at the moment). The results will contribute to a bioeconomy strategy in Switzerland, while ensuring the durability, recycling, and multi-reuse of products for a circular economy, while also considering Safe and Sustainable by Design (SSbD) aspects.

5.01.P-Th487 Urban Mining Riches: Unveiling the Economic Value in Electronic Scrap Material for Enhanced Recycling Strategies

Ole Klein[1]*, Tristan Zimmermann*[2] *and Daniel Pröfrock*[2]*, (1)Inorganic Environmental Chemistry, Helmholtz Center Hereon, Germany, (2)Inorganic Environmental Chemistry, Helmholtz-Zentrum Hereon, Germany*

In our modern society electronic devices and their application have become heavily integrated in our everyday lives. This results in an ever-rising amount of electronic waste material as those materials are challenging to recycle due to their complex and heterogeneous composition. Especially for technology critical elements (TCEs), like Ga, Ge, In, Nb, rare earth elements, and Ta, an improvement in the life cycle is strongly demanded by the European Union to gain independence from possible supply risks. In this context, printed circuit boards (PCBs), light-emitting diodes (LEDs), or lithium batteries (LiB) gained increasing interest in the scientific but also recycling communities. The potential of environmental impacts by increasing electronic waste streams, but also the promising opportunity of urban mining are the key factors for the publicity of those three materials.

In this study end of life PCBs, LEDs and LiB were analyzed for their elemental mass fraction of 58 elements to set a standard for analytical methods for such complex matrices, thus helping the recycling industry to obtain initial estimates of the economic value of such materials.

Applying an optimized digestion protocol (microwave-assisted, 1 mL HCl, 3 mL HNO_3, 1 mL HBF_4) together with an improved ICP-MS/MS detection method using N_2O as reaction gas, recoveries ranging from 76% to 123% for the certified reference material BAM 505a were achieved. Mass fractions of the end-of-life materials (PCBs, LEDs and LiB) ranged from 5 µg kg^{-1} ± 17 µg kg^{-1} (Ho) to 119 g kg^{-1} ± 23 g kg^{-1} (Fe) resulting in economic values between 5.71 € kg^{-1} and 16.14 € kg^{-1} considering all measured element mass fractions. Comparing the mass fraction to the yields of commonly mined minerals or ores, the analyzed scrap materials may possess orders of magnitude higher mass fractions of TCEs resulting in enrichment factors of up to 580 (Pd). As a result, the urban mine clearly holds high potential to generate great economic value.

5.01.P-Th488 Production and use of biofertilizers from organic waste for sustainable agriculture

Cynthia Wong Arguelles, PhD[1,2] *and María Graciela Orduña y Hernandez*[3]*, (1)Ingenierías, Tecnologico Nacional de Mexico campus Ciudad Valles, Mexico, (2)Posdoctorante, El Colegio de Veracruz, Mexico, (3)Maestria en Desarrollo Regional Sustentable, El Colegio de Veracruz, Mexico*

The abuse of chemical fertilizers, herbicides and other substances in conventional agriculture causes damage to the environment and nature, generating ecological and social crises. It is important to look for more sustainable alternatives such as biofertilizers where their production through semi-continuous biodigesters is efficient, economical and their assembly-handling is simple. Anaerobic digestion is a biological process that uses microorganisms to biodegrade organic matter in the absence of oxygen, produces energy in the form of biogas and has biol and biosol as by-products that can be used in agriculture as organic fertilizers. Two formulations with a fermentation period of 45 to 75 days under controlled conditions were determined. A formulation was made with various raw materials (cow excrement, molasses, ash and whey); 87% of the material that entered the biodigester was transformed into biol; which serves as a stimulant for germination and plant growth, which was proven with a phytotoxicity bioassay. The biofertilizers obtained (F1 and F2) have a neutral pH (7.77 and 8.76). Formulation 2 is the one that presents the best results in terms of macronutrients (0.04% N, 0.01% P, 0.28% K) and formulation 1 for micronutrients (21.9 ppm Fe and 3.96 ppm Mn). In both bioles, the germination index (GI) was identified through phytotoxicity tests, integrating the relative percentage of germination and the relative growth of roots. The objective of this research was to obtain an enriched biofertilizer and evaluate its agricultural use to reduce environmental impacts and promote sustainable agriculture among small producers.

5.01.P-Th489 Sensitivity Analysis of a Life Cycle Assessment for Biochar in an Italian context

Simone Marzeddu[1]*, Andrea Cappelli*[2]*, Riccardo Paoli*[3]*, Andrea Ambrosio*[1]*, María Alejandra Décima*[1]*, Rosaria Boni*[1] *and* ***Francesco Romagnoli***[4]*, (1)Dicea, Sapienza University of Rome, Italy, (2)Dicma, Sapienza University of Rome, Italy, (3)Riga Technical University, Latvia, (4)Institute of Energy Systems and Environment, Riga Technical University, Latvia*

Due to its diverse applications in bioenergy production, coproducts (bio-oil and syngas), global Due to its versatile applications in bioenergy production, coproducts (bio-oil and syngas), global warming mitigation, sustainable agriculture, pollutant removal, and other fields, biochar has attracted interest worldwide. Implementing soil-based biochar for carbon sequestration could not only mitigate emissions but also enhance soil quality, creating opportunities for bioenergy production. However, to comprehensively assess the environmental and energy impacts of the production cycle and validate the myriad benefits of biochar, Life Cycle Assessment (LCA) stands out as a reliable evaluation tool.

This study builds upon the work of Marzeddu and Cappelli (Marzeddu S., Cappelli A. et al., 2021) to delve into the environmental impact of an energy-biochar chain involving an Italian gasification plant. In the previous LCA, which characterized biochar used as a soil conditioner, aspects such as soil carbon sequestration, nitrous oxide emissions, fertilizer usage, and water consumption for irrigation were considered. The findings indicated that employing gasification for energy and biochar production presents an appealing strategy for mitigating environmental impacts, particularly in terms of climate change, with a net decrease of approximately -8.3·103 kg CO2 eq.

However, the preceding study lacked a sensitivity analysis. Therefore, this study introduces a sensitivity analysis to consistently evaluate the environmental trade-offs associated with biochar and amended soil. Specifically, sensitivity is addressed for upstream processes by considering alternative types of woodchips. For the core process, variations in packing material are explored, and a cradle-to-grave perspective is taken by optimizing logistics, supply chain distances, and selecting the Best Available Technology (BAT) for transportation vehicles.

This research underscores strategic developments that collectively identify potential environmental trade-offs and thresholds in utilizing biochar, particularly as a soil conditioner.

5.01.P-Th490 Unlocking the Technical, Economic and Environmental Implications behind a Multiproduct Biorefinery from Exhausted Olive Pomace

Deborah Perez Almada[1] *and* ***Ángel Galán Martín***[2]*, (1)Department of Chemical, Environmental and Materials Engineering, Jaen University, Spain, (2)University of Jaén*

Recent advancements in bioconversion technologies have opened up exciting possibilities for extracting valuable compounds from biomass waste material. For example, the conversion of residue from olive pomace oil production has been the subject of numerous investigations, most of which concentrated on particular aspects of the procedure at the laboratory scale [1]. Filling this gap, this case study presents new insights into the valorisation of exhausted olive pomace from laboratory experimentation [1] to simulation at an industrial scale. In particular, we combined process simulation tools with Life Cycle Assessment to conduct a techno-economic and environmental analysis of a multi-biorefinery system designed for the extraction of antioxidants, lignin, and bioethanol. We defined five different scenarios which vary in the electricity source powering the processes (wind, photovoltaic, or the existing mix) and heat/cooling source either from fossil natural gas, synthetic natural gas (generated from Sabatier reaction of CO_2 from direct air capture and electrolytic H_2) while one scenario integrates carbon capture and storage (CCS). The simulation, executed through Aspen Plus serves as a basis to generate the mass and energy balance to carry out the economic and environmental assessments using SimaPro software. The functional unit (FU) of choice is "1 kg de bioethanol + 0.487 kg de antioxidants". In terms of cost distribution, regardless of the scenario, capital expenditures (OPEX) outnumber the operational ones (CAPEX) representing around 80% of the total cost, followed by utilities (the operating heating and cooling costs) which vary greatly across the scenarios. Concerning global warming, the scenario integrating CCS (and relying on synthetic natural gas with H_2 generated from wind power) emerges as the most environmentally favourable option, showing the lowest carbon footprint (9.35 kg CO_2eq/FU) compared to other scenarios. However, our findings also demonstrate nuanced trade-offs associated with burden shifting in these scenarios, worsening other environmental categories beyond climate. Overall our research sheds light on the broad implications of large-scale deployment of biorefineries and can guide future endeavours towards the optimization of biorefineries, fostering a resilient and eco-friendly bio-economy.

5.02 Innovations in LCA: Bridging Temporal Dynamics and Advancements in Inventory Data Modeling

5.02.T-01 FineChem2: An enhanced deep-learning model for estimating carbon footprints of chemicals

***Dachuan Zhang**[1], Zhanyun Wang[2], Christopher Oberschelp[1], Eric Bradford[1] and Stefanie Hellweg[1], (1)ETH Zurich, Switzerland, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Millions of chemicals have been designed and registered to contribute to the global efforts toward accelerating the transition to sustainable chemistry; however, their product carbon footprints (PCF) are often unknown, leaving questions on their own sustainability. This general lack of PCF data is because the data needed for comprehensive environmental analyses are generally not available at early design stages. Several predictive tools have been developed to estimate the PCF of chemicals, which are only applicable to a narrow range of common chemicals and have limited predictive ability. Here we propose FineChem 2, which is based on a Transformer framework and first-hand industry data, for accurately predicting the PCF of chemicals. Compared to previous tools, FineChem 2 demonstrates significantly better predictive power, and its applicability domains are improved by ~75% on high production volume chemicals, daily chemicals, and chemical additives in food and plastics. The better interpretability from the attention mechanism enables FineChem 2 to successfully identify PCF-intensive substructures and critical raw materials of chemicals, providing insights into design of sustainable molecules and processes. Therefore, we expect wide application of FineChem 2 for chemical PCF estimations, leading to advancements in sustainable chemistry.

5.02.T-02 Inventory estimation for chemical processes from the reaction stoichiometry by decision trees

***Tim Langhorst**, Moritz Tuchschmid, Benedikt Winter, Dennis Roskosch and André Bardow, Energy and Process Systems Engineering, Department of Mechanical and Process Engineering, ETH Zurich, Switzerland*

The chemical industry aims to transition toward sustainability. For this purpose, decision-makers in research and development (R&D) require process-specific Life Cycle Inventory (LCI) data. However, during early R&D, only the reaction equation is available, and the missing information on energy and utilities is often filled with average proxy values. These proxies prevent process differentiation and decision-making, as they are equal for all processes. Here, we present a method to estimate process-specific LCI data based solely on data directly derived from the reaction equation and physical property data for the chemicals involved. The method employs the machine-learning method of decision trees, which is easily accessible.

Our method is based on training decision trees to estimate the demands for electricity, steam, natural gas, cooling water, and process water, the direct emissions, and a coefficient for the raw materials global warming impacts (GWI). The trees use information about the reaction stoichiometry, such as the number of reactants and products, and property data, such as boiling points, as input data. For training, we used LCI data of 409 chemical processes for 148 organic chemicals, including platform chemicals, intermediates, and consumer chemicals. The LCI data is based on the Process Economics Program (PEP) yearbook, which offers detailed in- and output flows derived from patents, company reports, and process simulations.

The proposed decision trees estimate inventory flows for organo-chemical processes from the reaction equation alone, reaching the same accuracy as established cost estimation methods. Decision trees resolve patterns between reaction and property data with raw material and utility demands. The prediction accuracy improved for the overall GWI and each inventory information predicted, with improvements of the mean absolute error between 8 and 24 % compared to the best available proxy values. The proposed decision trees enable the automated generation of LCI data and can be used to improve background databases and inform decision-making during R&D.

An open-access toolbox is prepared for easy access. By integrating the DIPPR database, we minimized the required inputs and increased the scalability of the tool. The decision tree LCI estimation tool can support decision-making in chemical R&D and help identify the path toward a cleaner future for the chemical industry.

5.02.T-03 Integrated Life Cycle Optimization of the Foreground and Background Systems using the PULPO Open-Source Python Package

Fabian Lechtenberg[1]*, Ioan-Robert Istrate*[2] *and Gonzalo Guillén-Gosálbez*[3]*, (1)Department of Chemical Engineering, Universitat Politècnica de Catalunya, Spain, (2)Leiden University, Netherlands, (3)Department of Chemistry and Applied Biosciences, ETH Zurich, Switzerland*

The interpretation phase in Life Cycle Assessment (LCA) is often carried out without applying any systematic method to reduce impacts. While the life cycle optimization and TCM approaches couple LCA with optimization, they do so without attaining full integration between the foreground and background systems.

To overcome these limitations, here we introduce PULPO (Python-based User-defined Lifecycle Product Optimization), an innovative open-source Python package that integrates LCA data manipulation and optimization model creation and solution. PULPO enables the dynamic feedback between the foreground and background systems, which is achieved through the integration of complete LCI databases as backbone for the optimization model. Our goal with PULPO is to furnish the LCA community with a powerful tool that enables advanced analyses very hard to perform otherwise.

The approach is exemplified in case studies optimizing a country's power mix and global methanol supply chains. Through these case studies, PULPO demonstrated its ability to find optimal decisions across complex supply chains that minimize environmental impacts and identify efficient production pathways under various constraints (e.g., production capacity and resource availability).

The package, accessible via GitHub, facilitates a more consistent and coherent approach to life cycle optimization, assisting LCA practitioners in complex studies and providing insights out of reach for standard LCAs. Overall, PULPO provides a computational framework for environmentally conscious decision-making, that is made easily accessible through an open-source Python implementation. From a broader perspective, we intend to build bridges between the process systems and industrial ecology communities so together we can more effectively tackle the challenging problems ahead in the quest for sustainable development.

5.02.T-04 Result variations due to dynamic life cycle assessment compared to result variations due to sensitivity analysis on static inventory data

Sibylle Duval--Dachary[1]*, Sandra Beauchet*[1]*, Daphné Lorne*[1]*, Thibault Salou*[2] *and* ***Arnaud Helias***[2]*, (1)IFP Energies Nouvelles, France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France*

Biomass is a promising raw material for both energy and chemical production and their decarbonisation. However, calculating the impact of biomass use on climate change is still controversial, notably in terms of how to account for differences in the dynamics of carbon storage by photosynthesis and releases at the end of life (ex: incineration). Applying dynamic life cycle assessment (LCA) is one of the answers, but it requires more data and increases the complexity of the calculation. To address its relevance, we have to answer if the variation in results induced by the dynamic characterisation of the impact on climate change is significant compared with the variations induced by the uncertainty in the inventory data. This question is explored through the present case study, including the biomass production (miscanthus or wood residues), the CO_2 production by biomass fermentation, the conversion of the CO_2 into a polypropylene bag and the bag incineration with carbon capture and storage. A sensitivity analysis is performed to compare the results depending on i) the type of modelling (dynamic or static), ii) the characterization method to evaluate climate change (absolute global warming potential, AGWP, or temperature change, AGTP) and iii) one key parameter (the amount of CO_2 emitted by soil organic carbon change during miscanthus production). The results reveal that variations induced by the dynamic modelling compared to the uncertainty on static inventory data are significant in the case of wood residues production and more significant when using AGWP than AGTP. Using AGTP rather than AGWP to assess the impact on climate change would thus improve comparisons between systems even without distributing inventories over time. Moreover, it would be useful to develop a method for assessing the relevance of carrying out a dynamic LCA, by precisely defining the flows that will benefit from being spread out over time. This method should consider as input data some time parameters such as the duration of the inventory or the time of the first emissions. It is important to i) keep time to improve the static inventory and perform sensitivity analyses and ii) limit the loss of information due to the cut-off included in the algorithm used to calculate a complete dynamic LCA.

5.02.P Innovations in LCA: Bridging Temporal Dynamics and Advancements in Inventory Data Modeling

5.02.P-Mo452 The Importance of Timeframes When Determining Marginal Heat Suppliers for Informed Decision Support

Lasse Krogh Poulsen[1]*, Timen M. Boeve*[2]*, Søren Løkke*[3] *and Iva Ridjan Skov*[2]*, (1)Aalborg University, Denmark, (2)Department of Sustainability and Planning, Aalborg University, Denmark, (3)Department of Sustainability and Planning, Aalborg University, Aalborg, Denmark*

When assessing the impacts of a decision, the timeframe for when the decision takes effect is crucial, as different marginal

heat-producing technologies will be affected in different points in time. This study will focus on how decisions, that impact heat consumption and production, can have different environmental impacts depending on when the effects of the decision take place.
For example, in 2022 the Danish government mandated that public buildings should not be heated to above 19°C. This mandate had an immediate effect on heat consumption, which affected the marginal heat suppliers at the time i.e., the production marginal. On the other hand, if it was decided to implement beter insulation of public buildings, the reduction in heat consumption would take effect when the insulation has been installed, affecting the marginal heat suppliers of the future i.e., the capacity marginal. The later case is the typical approach applied in consequential LCI modelling.
As heat-producing technologies change over time, these two decisions will affect different marginal heat suppliers, and will therefore have different environmental impacts, but this is not reflected in many LCA studies. It is therefore important to develop and popularise a methodology for determining the marginal heat suppliers at different points in time. Since heating grids are localised, the marginal heat suppliers will vary between the grids. This paper therefore proposes a tool that applies a consequential modelling method for determining the marginal heat suppliers in a localised grid at a specific point in time. By using data for district heating in Denmark, the short term affected suppliers are determined based on trends for the previous five years, while the longer-term suppliers are determined by identifying likely future technologies of the specific grids, which depends on political and planning decisions.
The findings of the study will help to inform decision-makers on which decisions will be most impactful regarding reduction of environmental impacts from heat consumption, while also communicating why the timing of decisions matter.

5.02.P-Mo453 Regionalizing the Supply Chain in Process Life Cycle Inventory with Multiregional Input-Output Data: Ecoinvent with EXIOBASE
*Sidi Peng and **Stephan Pfister**, ETH Zurich, Switzerland*
Life cycle inventory (LCI) databases like ecoinvent are essential in life cycle assessment (LCA) but lack country resolution in both the activity details and trades among regional activities in the supply chain. For instance, photovoltaic (PV) panel production has only Rest-of-world (RoW) and European (RER) datasets in ecoinvent, which consumes the same global production mix of PV cells as technosphere inputs, since it is challenging to identify the precise origins of technosphere flows for a regional activity. These global or continental activities and trade limit the utilization of the existing country processes in ecoinvent, like electricity production, and affect the accuracy and granularity of LCA results and relevant decision-making.

To address this issue, we disaggregated the global and continental unit processes in ecoinvent to country level and regionalized the trade relations among them by applying country-sector-specific consumption mixes of products generated from the multiregional input-output table (MRIO) EXIOBASE. The outcome is a consistently regionalized ecoinvent database at country level that links regionalized production impacts to regionalized consumption.

We compared the climate change impacts of all 195’708 non-market datasets in our regionalized ecoinvent with reference datasets in the original database. Overall, manufacturing sectors show more different impacts after the supply chain regionalization, since most impacts of manufacturing activities are embedded in background supply chains.

The case study of PV panel production reveals that RoW/RER proxies in the original ecoinvent for Chinese, Japanese, and German production would cause differences of climate change impacts between -24% and +1%, compared to disaggregated country processes, mainly due to different electricity mixes used by the upstream country-specific suppliers of PV components and silicon, which get lost in the low-resolution trade data.

Our study demonstrates the significant potential of integrating better trade information and region disaggregation in LCI databases for improving the accuracy and granularity of LCA results. While the combination of two databases inherently has limitations and strengths from MRIO (low sector resolution but complete economy) and LCI data (low country and trade coverage but high process detail), it allows to have more detailed results that can help to identify processes that need further attention for proper supply chain assessment.

5.02.P-Mo454 Fully dynamic carbon footprint of circular biobased systems – A framework with temporal life cycle inventory database (DyPLCA) tailored for forestry and wood products cascades
*Tomás Navarrete Gutiérrez[1], Thomas Gibon[1], **Thomas Schaubroeck, PhD**[1], Laurent Chion[1], Tianran Ding[1], Massimo Pizzol[2], Ligia Tiruta-Barna[3], Kíra Lancz[2], Eduardo Entrena[4], Ricardo Méndez[5], Tomas Vilhelm Rydberg[6], Josefin Neuwirth[6], Ellen Riise[7], Pernilla Cederstrand[7], Dieuwertje Schrijvers[8], Tamara Coello-Garcia[9], Alexandre Charpentier Poncelet[8] and Enrico Benetto[1], (1)Luxembourg Institute of Science and Technology (LIST), Luxembourg, (2)Department of Sustainability and Planning, Aalborg University, Denmark, (3)TBI, Université de Toulouse, (4)Contactica, Spain, (5)CONTACTICA, (6)Swedish Environmental Research Institute (IVL), Sweden, (7)Essity, (8)WeLOOP, France, (9)Cesefor*
Global concerns about climate change and its impacts induced by greenhouse gas emissions and processes make it crucial to understand its evolution over time. This is particularly relevant for biobased systems, which take up CO_2 during biomass growth, of which a part remains stored during the life cycle of products (considering possible recycling, reuse etc.), and there is an eventual release at the final end of life (e.g. via incineration). However, in the field of life cycle assessment (LCA) and carbon footprint analysis, a static view is still the dominant approach. Few studies have considered dynamic effects, and if so,

only by taking into account time differentiation for the foreground system. Therefore, it is only recently that a fully dynamic LCA has been applied (in this case, dynamic only implies temporal differentiation), in particular through the dynamic process-based LCA (DyPLCA) framework, tool and related temporal database. Yet, there are several aspects needing improvement, A framework has been developed to tackle these gaps, as specified in the next section.

First, the DyPLCA temporal database is a collection of temporal data for all ecoinvent 3.2 processes. Currently, ecoinvent 3.9 is available and contains updated information and new processes. Hence, a straightforward improvement we have done for this framework is the update of the DyPLCA database by LIST in the CALIMERO and LCA4BIO projects.

Second, in the respective DyPLCA database, the temporal flows of forestry systems, especially greenhouse gases, have been considered in a simplistic manner. Emission amounts and their temporal distributions are improved based on the outcomes of a flexible parametric model for a balanced account of forest carbon fluxes in LCA.

A third gap relates to the need to update the climate change impact assessment. INSA Toulouse has developed an advanced tool that already covers different types of effects over time and is compatible with DyPLCA outcomes. This tool and its dataset will be updated.

The final and fourth gap of concern is the limited tailored loop modelling for wood cascading systems in ecoinvent and DyPLCA. This is ameliorated by systematically incorporation useage processes with their durations, the possiblity to adapt number of loops and the handling of recycling/reuse.

An application to two cases of the CALIMERO project is envisioned: (1) one on laminated strand lumber (LSL) & (2) the Swedish pulp and paper sector.

5.02.P-Mo455 Carbon Flux Forest Model Extended to Multiple Species and Forest Management Practices: Data and Validation

*Massimo Pizzol, **Kíra Lancz** and Agneta Ghose, Department of Sustainability and Planning, Aalborg University, Denmark*

Drawing from the work of De Rosa et al. (2017) we present our study done to extend the modelling of forest management, and the calculation of life cycle inventories for forest products, to a wide range of forest plantations and species. The use of the model is intended for the modelling of biobased products, which is then enabled and enhanced by the extension of the model and associated input data.

The model allows to generate a time-specific, dynamic flux inventory of carbon flows for a specific forest and express this impact using different climate impact metrics (both Global Warming Potential – GWP and Global Temperature Potential - GTP). However, previous published and available versions of the model only allowed the modelling of two species: Spruce and Eucalyptus, a long-rotation and a short-rotation one respectively. The present work documents the effort made to extend the input data of the model. This allows model simulations of a wide range of plant species and those commonly cultivated in Europe, as well as management practices.

We show the approach used to fill data gaps, that were substantial as no database was found to consistently report information about growth rates, rotation times, and thinning practices of different species and these had to be retrieved and aligned manually. Furthermore, we show results of a sensitivity analysis performed on the model results obtained from the simulation of several species, indicating that not surprisingly carbon content, density, and rotation time are highly sensitive parameters. A validation of the model is also presented - for selected species. Finally, we present a discussion on the correct use of the results and the linking with LCA software, specifically for the choice of environmental exchanges to be considered when modelling biogenic carbon uptake and release. We also document the improvements made to the user interface, as part of the effort in making the model user friendly and enhance interoperability by enabling import of resulting inventories in common LCA software. The work was conducted as part of the ALIGNED project (www.alignedproject.eu) on harmonisation of LCA methods for the assessment of biobased products.

5.02.P-Mo456 Data Quality Assessment of Aggregated Life Cycle Inventory Datasets - A Case Study on Fossil-Based and Bio-Based Plastic Food Packaging

*Anna Carlesso[1], Lisa Pizzol[1], Antonio Marcomini[1] and **Elena Semenzin**[2], (1)Ca' Foscari University of Venice, Italy, (2)Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice, Italy*

In Europe, approximately 40% of food is packaged in plastics. This packaging is criticized as a symbol for make- use- dispose economy due to its rather short lifespan, its dependency on fossil fuels, and its contribution to marine litter. Environmental impacts resulting from plastic food packaging, made from both fossil-based (FB) and bio-based (BB) polymers are increasingly analyzed in LCA studies. However, the literature reveals significant variations in results up to the order of 400% for the same polymer within the same scope. To enhance the reliability of these assessments, Data Quality Assessment (DQA) plays a relevant role. Despite most of the LCA studies employing aggregated Life Cycle Inventory (LCI) datasets, in literature DQA methods for aggregated processes are not available. To fill this gap, in this study a DQA for aggregated LCI datasets is proposed and demonstrated through its application to 101 aggregated LCI datasets, extracted from Ecoinvent and GaBi databases. The DQA method has been developed by adapting and integrating the Pedigree Matrix and the Data Quality Ranking proposed by the recently published EC Plastic LCA method. The three Data Quality Indicators (DQIs) used are Technological (TeR), Geographical (GeR), and Time-related (TiR) representativeness. To each DQI a score is assigned according to a five-point scale, where 1 is the best (corresponding to an Excellent Data Quality level), and 5 is the worst (corresponding to a Very Poor Data quality level) achievable score. The application of this method exhibits an overall positive evaluation of the selected datasets with differences between Ecoinvent and GaBi and among the three DQIs. Moreover, it highlights the role of metadata structure in adequately supporting a robust DQA. Indeed, in the absence of a common framework that defines, assesses, and provides access to data quality information, transparency must be assured by the operator in the metadata interpretation and related assumptions along the DQA process. Finally, although the proposed DQA method was developed for the plastic sector, its application can be extended to LCI aggregated datasets relevant for other sectors, materials, and products.

5.02.P-Mo457 Assessing methodological choices in wood-based biorefinery LCA literature

Kíra Lancz*, Agneta Ghose and Massimo Pizzol, Department of Sustainability and Planning, Aalborg University, Denmark*

Bio-refining is a process (or several processes) that converts any biomass into multiple beneficial products. Bio-refining is complex and is rapidly transforming given the increasing demand for bio-based materials particularly to augment the functionality of biomass. Modelling a bio-refinery for an LCA study is equally complex, given that it needs to address issues related to multi-functionality, choice of appropriate functional unit, identify market for feedstock, modelling of biogenic carbon, etc. We present the results of a systematic literature review to understand how these issues have been addressed in previous studies related to biorefining of woody biomass. We used the standard EN 16760:2015 for LCA of bio-based products as a framework to structure the review. The standard particularly emphasizes the need to report spatial and temporal boundaries related biomass systems, biogenic carbon flows, water use and land use. 41 studies between 2015 – 2023 which included detailed LCA models of bio-refining woody biomass were reviewed. Given the emphasis on key factors from the standard, it was surprising to find that few studies addressed the temporal aspects of biomass feedstock or water use in bio-refineries but did not account for them in the inventory. Four studies reported the biogenic carbon flows, although only two studies accounted for the temporal aspects of biogenic carbon. Most studies considered accounting for biogenic carbon ambiguous or neutral. Furthermore, most studies handle multi-functionality using economic allocation or system expansion followed by mass and energy- based allocation respectively. However, the specific use of consequential inventory modelling was limited to three studies. There was no discussion of market factors influencing the availability of biomass. Whilst there are several LCA studies on bio-refineries, this review highlights the lack of consideration given to modelling approaches that can have a key influence on the results based on source and management of biomass. Current studies lack a holistic modelling approach that could support assessment of prospective technologies. The work was conducted as a part of the ALIGNED project (www.alignedproject.eu) on harmonization of LCA methods for the assessment of bio-based products.

5.02.P-Mo458 Bridging scales in lithium production: From site-specific studies to a global model

Vanessa Schenker[1] and ***Stephan Pfister[2]****, (1)Institute of Environmental Engineering, ETH Zurich, Switzerland, (2)ETH Zurich, Switzerland*

The build-up of energy storage, such as Li-ion batteries, necessitates a significant increase in lithium supply. Brine deposits are one of the two important deposit types as they contain ~2/3 of the known lithium resources worldwide. These deposits, however, vary in chemistry and environmental conditions, requiring tailored processing techniques for optimal lithium yield. The increasing importance of lithium extraction requires a detailed life cycle assessment to account for specific impacts and avoid environmental burden shifting. While site-specific life cycle assessments have been performed, they are limited to a small number of mines because required data is scattered in the literature making it a time-consuming endeavour. There is currently no global model available that incorporates site-specific conditions to evaluate the existing and future production of lithium. Based on our previous research, the Generative Pre-trained Transformer (GPT) is used to systematically assess the processing technology reported in technical reports and feasibility studies. Data in the scientific literature are used to train GPT to classify the available information in the reports. The GPT output includes all processes from pumping the brine to the surface until the final product is produced. This data feeds into a life cycle inventory model, which allows calculating life cycle impacts of 1 kg lithium carbonate. Significant variations in climate change impacts are found, ranging from 3.2 kg CO_{2eq}/kg lithium carbonate from Salar de Atacama to 50 kg CO_{2eq}/kg lithium carbonate from Salton Sea, mainly due to technology choices based on brine chemistry. Technologies, such as the ones used at Salton Sea, have a higher energy demand leading to these elevated impacts compared to the sites that use conventional extractive methods. The study underscores the need for tailored assessments for current and future production of lithium. Using AI through GPT supports the systematic collection of data from various sources and also allows for detailed modelling, while assessing a broad range of current and future sites. With regard to future mining sites, this study reveals the importance of life cycle assessment at an early stage to highlight life cycle impacts – especially, reduced impacts by decarbonizing energy supply. Site-specific assessments are crucial for policy-making, offering insights beyond the scope of generic models.

5.02.P-Mo459 LCA of the Italian Photovoltaic Mix for 2021 and 2030

Carmen Ferrara[1]*, Benedetta Marmiroli[2], Maria Leonor Carvalho[1] and Pierpaolo Girardi[3], (1)RSE SpA - Research on Energy System, Italy, (2)Sustainable Development and Energy Sources, RSE SpA - Research on Energy System, Milan, Italy, (3)Ricerca sul Sistema Energetico - RSE S.p.A., Italy*

Photovoltaic (PV) is one of the technologies at the base of decarbonising electricity production plans in Italy. PV industry is experiencing rapid growth, and the technological development of PV technologies is constantly evolving. Of course the datasets available in commercial database (e.g Ecoinvent 3.8) for the LCA modelling of Italian PV mix are neither updated nor representative of the national context; therefore, the environmental performances assessment of photovoltaic electricity production results not be reliable and underestimated.

To fill this research gap, the current study presents a detailed, updated, and representative LCA modelling of the Italian PV mix for 2021 and of that expected for 2030.

For both PV mixes, data provided by an Italian company operating on energy i.e. GSE (Gestore dei Servizi Energetici), and the annual reports of "International Technology Roadmap for Photovoltaic " of VDMA were used to obtain the values of PV electricity production and installed PV power at the end of 2021 as well as to estimate the percentage shares of that power in function of: type of PV module as mono- and multi-crystalline silicon, thin films etc; type of PV technology; and type of PV plant configuration as ground or roof installation. The same analysis was also carried out for the period from 2021 to 2030 using data from Integrated Climate and Energy National Plan. Task 12 reports of "Photovoltaic Power Systems Programme" of International Energy Agency, together with primary data from PV industry and PV technologies developer, were the main data source for the creation of new datasets for each type of module, technology, and plant configuration, obtained updating, replacing, or integrating the Italian PV datasets of Ecoinvent database.

Adopting the Environmental Footprint impact assessment method, the environmental performances of the modelled Italian PV mixes (for 2021 and 2030) were evaluated and compared with those of the Italian PV mix of Ecoinvent database in function of 1 kWh of electricity produced.

The new PV mixes showed a significant reduction in environmental impacts, always greater than 40%, for all impact categories. This was mainly due to: (i) higher equivalent hours of operation; (ii) higher modules efficiency (iii) updating of the inventory data for the production processes of all PV plants components; (iv) addition of new datasets about the innovative PV technologies which are not present in the Ecoinvent datasets.

5.02.P-Mo460 State of the Art, Challenges and Future Development of Environmental Assessments of Magnesia Supply Chain

Sarah Badioli[1,2]*, Marielle Dargaud*[1]*, Thibault Champion*[1] *and Angélique Léonard*[3]*, (1)PCR, Saint-Gobain Research Provence, France, (2)Chemical Engineering, University of Liège, Belgium, (3)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium*

The present study discusses the state-of-the-art environmental assessments of magnesia for refractory industry and highlights the key challenges to be faced for the development of a methodology able to support the progress towards sustainability. About ten studies were found calculating the Carbon Footprint or the Life Cycle Assessments (LCA) of dry-route processed magnesia. The lack of common approach and relevant inventories are considered the main weaknesses of the current situation. LCA scenarios for fused and sintered magnesia are proposed to support this conclusion and to fill some of the existing gaps. Two actions are suggested to improve the datasets: to include materials quality and to detail technical parameters. First, the quality of the materials along the supply chain plays a relevant role in the production design and in the functional value of the final product. As no complete tracking of the materials quality has been found in literature, its implementation in the LCA inventory is suggested as key future development. Besides, the expansion of the system boundaries towards the use phase is equally suggested, to directly connect the quality of the resources and the product functionality. This approach is expected to support the enhancement of the methodological challenge regarding resource depletion. Second, despite the well-known flowchart of magnesia production, many variations can occur in the choice of technologies and operating conditions, which result in different input/output flows for the product system, especially for energy consumption. A lack of transparency and completeness was encountered in literature, hence, a comparation of alternative production routes is not possible. The incomplete assessment of the existing routes makes the support to decision- and policy-making difficult and imprecise. LCA energy scenarios are proposed to show the dependence of the environmental burdens and the energy consumption. Concluding, the quality of dataset and inventory has been identified as limiting factor for the progress of the environmental assessment of the magnesia supply chain. An urgent effort is needed to improve data quality to gain a better understanding of the magnesia-related environmental burdens. The identification of the hotspots can orient the methodological research towards the most impacted environmental domains and those for which the largest variability is observed due to the low representativeness of the methodology.

5.02.P-Mo461 Comparative Life Cycle Assessment of Power Supply Units in Direct and Alternating Current

Sonia Longo[1]*,* ***Maurizio Cellura***[1]*, Alberto Affranchi*[2] *and Marina Mistretta*[3]*, (1)Engineering, University of Palermo, Italy, (2)Center of Sustainability and Ecological Transition, University of Palermo, Italy, (3)Information Engineering, Infrastructures and Sustainable Energy, University of Reggio Calabria, Italy*

Most of renewable energy sources (RES), electric loads and storage systems use Direct Current (DC), despite the electric grid is in Alternating Current (AC). For this reason, there are considerable conversions between AC and DC when RES are used. A photovoltaic panel, for example, produces electricity in DC that is converted to AC through an inverter; this electricity provides power to a computer that has inside a converter that turns AC to DC. This process causes at least two "useless" conversions, with consequent energy and environmental impacts. In addition, the AC devices usually include more materials than DC ones, which can increase the above mentioned impacts.

This work aims to verify if the use of DC instead of AC devices can reduce the energy and environmental impacts (in particular Global Energy Requirement - GER and Global Warming Potential - GWP) from a life cycle perspective. For this purpose, a comparative Life Cycle Assessment (LCA) is conducted for a computer's Power Supply Unit (PSU) such as model of typical electric load that converts AC to DC. A PSU was disassembled at the University of Palermo's "LCA and Ecodesign Lab", all components of the PSU were catalogued and weighed, with a focus on the printed circuit board, to create a bill of materials model of the AC PSU. Starting from literature data, a model of DC PSU was created by identifying the components to be removed to transform a PSU from AC to DC.

Focusing on the two above models, as hypothesis, the steel case, the fan, and the cables are the same in both PSUs, while the printed wiring board of the DC PSU includes less materials and its surface is 25% less than the AC PSU. The eco-profiles of the two PSUs were calculated considering a "from cradle to gate" approach.

The results indicate that the DC PSU causes 186.3 MJ of GER, that is 38.5% less impact than the AC model, and releases 10.5 kg CO_{2eq}, 37.4% less than AC PSU. The obtained results are valid for examined computer's PSU, but the approach can be extended to other electric loads to assess the energy and environmental advantages of using systems operating directly in DC.

Adopting DC technologies, integrated to RES and electronic loads, can be a key element for the ecological transition and can lead to the development of more sustainable and efficient DC microgrids with reduced environmental impacts.

The research is developed within the activities of the project LOV – Lowering Ortigia's Voltage, funded by PO FESR 2014/2020.

5.02.P-Mo462 Solving LCI data gaps for fine chemicals by retrosynthesis for industrially relevant reactions

Jonas Goßen[1] *and Raoul Meys*[2]*, (1)Carbon Minds GmbH, Germany, (2)RWTH Aachen University, Germany*

Life Cycle Assessment is a pivotal methodology for assessing and enhancing the environmental impact of products, processes, or services by analyzing material and energy flows within supply and value chains. Our study addresses a critical gap in the realm of Life Cycle Assessment (LCA) for chemical reactions, where challenges such as data scarcity, confidentiality concerns, and the quest for sustainable reaction routes hinder comprehensive environmental evaluations. These challenges are particularly pronounced in the fine chemical industry, exacerbated by the absence of crucial environmental emission factors and concerns about confidentiality. To overcome these hurdles, we introduced an automated approach that utilizes a three-step algorithm for retrosynthesizing relevant fine chemicals. By combining neural networks and forking the AIZynthfinder project, we tailored an algorithm to identify compounds within the industrial value chain. Our test set, comprising 5,551 'druglike' molecules, demonstrated the algorithm's efficacy in generating valuable LCA entries. The 182 solved retrosynthetic reaction routes need to be sanitized and used to generate forward reactions, which are then fed into the Carbon Minds database. This automated syntesis planning does not only addresses data scarcity but also accelerates the traditionally slower modeling approaches, providing a tool to streamline LCA for chemical reactions and facilitate informed decisions about sustainable and environmentally friendly production processes in the fine chemical industry.

5.02.P-Mo463 How highly specific LCA data can inform purchasing decisions that significantly reduce environmental impacts

Francesco Scalogna*, Carbon Minds GmbH, Germany*

To address the growing need for environmental sustainability, many companies, particularly in the chemical industry, are exploring strategies to manage the significant costs associated with reducing their environmental impacts. Interestingly, only a small portion of emissions come directly from a company's own operations or from energy-related emissions from purchased energy supplies. The substantial part of environmental impacts originates from the upstream and downstream elements of their supply chains. The lack of detailed information on the environmental impacts of potential suppliers' production processes, however hinders companies to make informed decisions. To enhance decision-making processes, a new regionalized Life Cycle Inventory (LCI) database has been developed, adhering to ISO standards for Life Cycle Assessment (LCA), specifically ISO 14040/44/67 and TfS. This database focuses on the chemical and plastics sectors and features data on approximately 1,000 chemicals and plastics, covering up to 190 regions. In a case study the climate change impact of polyproylene production is analyzed, showing that the carbon footprint of the polypropylene supplier with the highest carbon footprint in a region is 11 times higher than the supplier with the lowest carbon footprint in the same region. As a results, these emissions can be reduced by up to 90% by choosing lower impact suppliers. This shows the importance of regionalized and detailed databases for informed decision making.

5.02.P-Mo464 Advancing on the transition towards data interoperability: the Global LCA Data Access Network (GLAD)

Carl Vadenbo[1]*, Claudia Giacovelli*[2]*,* ***Simone Fazio***[3]*, Robert Jaroslav Reinhardt*[4]*, Koichi Shobatake*[5]*, Selim Karkour*[6]*, Umberto Eynard*[7]*, Tiago Braga*[8]*, José Paulo Savioli*[8] *and Oliver Kusche*[9]*, (1)ecoinvent Association, Switzerland, (2)United*

Nations Environment Programme (UNEP), (3)Agriculture, Ecoinvent Association, Switzerland, (4)UN Environment Programme (UNEP), Kenya, (5)TCO2 Ltd., Japan, (6)TCO2 Co. Ltd, (7)European Commission - Joint Research Center (JRC), (8)Brazilian Institute of Information in Science and Technology (Instituto Brasileiro de Informação em Ciência e Tecnologia – IBICT), (9)Oliver Kusche Research & Consulting
The restricted accessibility of LCA data presents a notable obstacle to its widespread adoption, making it a pivotal concern within the LCA community. The harmonization of LCA data is being actively pursued by the Life Cycle Initiative of the UN Environment Programme (UNEP) through the Global Life Cycle Data Access Network (GLAD) initiative. GLAD is an open source web application, which allows users to find and access and screen metadata information to identify the most suitable datasets for use in LCA, ensuring interoperability by making connected datasets available in multiple formats, with compatible nomenclature and complete metadata. The development of GLAD has leveraged resources, expertise, and gathered requirements from diverse stakeholder groups from around the world, including the European Commission (EC).With most of the global data providers participating in GLAD, the initiative has been instrumental in supporting a worldwide endeavor to scrutinize interoperability challenges across LCA software, LCI databases, and LCIA methods.The GLAD Nomenclature Working Group (NWG) developed a procedure and a set of criteria to map elementary flows among major nomenclature systems and reviewed bidirectional mappings. The mapping procedure involved an ad hoc software tool titled the "GLAD Mapper Tool," which is made available by the EC. The tool is fed with the source and target flow lists and a file containing the mapping criteria properly formatted. The four nomenclature systems mapped within the NWG are ecoinvent, Environmental Footprint, IDEA, and the U.S. Federal LCA Commons. The Mapper Tool proved valuable for LCA practitioners, achieving over 90% coverage after seven iterations, with unique substances (flow names) and environmental compartments having the greatest impact.The NWG's mapping activities may serve as a starting point towards defining a central hub for mapping LCIA methods and datasets, improving data accessibility and interoperability for the LCA community as a step towards defining a unified nomenclature system. Relatedly and building on the mapping exercise, the Life Cycle Initiative, through GLAD, is currently working on developing the blueprint for a global nomenclature governance system (a central system) to map the elementary flows (EF) lists from major LCA databases. This approach holds the potential for greater interoperability across the LCA community, underpinned by GLAD's commitment to openness, inclusiveness and collaboration.

5.02.P-Mo465 The global environmental footprint of metal commodities

Frédéric Lai[1]*, Stéphanie Muller*[1]*, Jair Santillán Saldivar*[1]*, Audrey Philippe*[1]*, Antoine Beylot*[1]*, Aurélien Reys*[1]*, Gaétan Lefebvre*[1]*, Mathieu Leguérinel*[1]*, Lígia da Silva Lima*[2]*, Lieselot Boone*[2]*, Jo Dewulf*[2]*, Gyslain Ngadi Sakatadi*[3]*, Gian Andrea Blengini*[3]*, Aina Mas Fons*[4]*, Anish Koyamparambath*[4]*, Guido Sonnemann*[4]*, Ioan-Robert Istrate*[5]*, Brenda Miranda Xicotencatl*[5]*, Bernhard Steubing*[5]*, Afsoon Mansouri Aski*[6]*, Christoph Helbig*[6]*, Stephen Northey*[7]*, Juliana Segura-Salazar*[8]*, Victor Balboa-Espinoza*[8]*, Ioanna Paschalidou*[9]*, Kwame Awuah-Offei*[9]*, Ryosuke Yokoi*[10]*, Kamrul Islam*[10]*, Masaharu Motoshita*[10]*, Shinsuke Murakami*[11]*, Felipe Cerdas*[12]*, Valeria Superti*[13]* and Thomas Sonderegger*[13]*, (1)French Geological Survey (BRGM), France, (2)Ghent University (UGent), Belgium, (3)Politecnico di Torino, Italy, (4)University of Bordeaux, France, (5)Leiden University, Netherlands, (6)University of Bayreuth, Germany, (7)University of Technology Sydney, Australia, (8)University of Queensland, Australia, (9)Missouri University of Science and Technology (MST), (10)National Institute of Advanced Industrial Science and Technology (AIST), Japan, (11)University of Tokyo, Japan, (12)Institute of Machine Tools and Production Technology, Chair of Sustainable Manufacturing and Life Cycle Engineering, Technische Universität Braunschweig, Germany, (13)Ecoinvent Association, Switzerland*
The increasing demand for metal raw materials raises concerns as to the environmental burden of their production. This calls for a comprehensive, representative and reliable quantification of the environmental footprint of these raw materials in a life cycle perspective, based on up-to-date life cycle inventories (LCIs). However, current life cycle assessment (LCA) studies are often restricted to small-scale case studies that cover a relatively limited share of the global production. Thus far, only the study from Nuss and Eckelman '*Life Cycle Assessment of Metals: A Scientific Synthesis'*, published in 2014, provides LCA results for metal raw materials at a global scale. Yet, the latter study builds on market and LCI data prior to 2010, which is not representative of current mining/refining industry conditions. As a follow-up, this study aims at providing an up-to-date overview of the global environmental footprint of metal commodities, through the development of market-representative global LCA models for 62 different metal substances.

The development of these models follows a three-step approach based on:

i) A market analysis, to identify the main commodities and production routes associated with each substance;

ii) A review and analysis of existing LCI data in the literature and ecoinvent database, to select the most suitable LCI datasets in terms of market coverage, quality and representativeness;

iii) LCA modelling, which combines the selected LCI datasets and market data to develop market-representative global models.

The approach is showcased using tungsten (W) as a case study. The LCI review and analysis eventually led to the selection of three LCI datasets covering three production routes: two primary routes relative to W mining and tungsten carbide (WC) production, respectively in China and North America; and one secondary route relative to ammonium paratungstate (APT)

recycling from hardmetal scrap. Based on these data, a first model was developed for the global primary production of WC, which is the main W commodity. The carbon footprint of the global primary WC production is calculated to amount to 73.3 kg CO_2-eq/kg WC, driven in particular by the consumption of electricity and liquid nitrogen in the Chinese production route.

This preliminary W model needs further improvement. Moreover, beyond the W case, the approach is currently being replicated for the remaining 61 substances, for which updated LCI datasets will eventually be delivered.

5.02.P-Mo466 PLIM-WIND: A Parameterized Life-Cycle Inventory Model to Assess the Impacts of the European Wind Turbine Fleet

***Miquel Sierra Montoya**, Joan Muñoz Liesa, Ramin Soleymani and Cristina Madrid López, Autonomous University of Barcelona (UAB), Spain*

The European Union aims to achieve an installed wind power of 510 GW by 2030, doubling the current capacity within eight years. This underscores the pivotal role of wind energy in European transition plans to sustainable energy sources. Currently, the assessment of the sustainability of wind energy deployment primarily relies on Life Cycle Assessment (LCA). However, a big challenge lies in the scarcity of updated open and accessible data concerning the technical aspects of wind turbines. For instance, widely-used LCA databases like Ecoinvent rely on wind technology data from 2001 to 2007. At the same time, recent inventories mainly cover 1-2.5 MW turbines, far from current market trends of installed power in Europe. This data mismatch highlights the challenge of improving the representativity of wind turbine life cycle inventories through modelling.

In this study, we present a novel parametric model, PLIM-WIND, designed to generate customized life-cycle inventories for wind turbines, encompassing both individual turbine and wind park scales and based on power and design. The comprehensive inventories span all life-cycle stages, from material extraction to end-of-life, incorporating not only the turbines but also other components such as cables, transformers and access roads. This model facilitates the integration of technological, temporal, and geographical parameters that influence wind park installation and electricity production, enabling a nuanced analysis. To prove the validity of the tool, we characterized the material requirements and land use of the European wind fleet up to 2021. In addition, we also computed the aggregated environmental impact indicators derived from Life Cycle Impact Assessment ReCiPe method and assessed the viability of the fleet. All in all, this model contributes with new inventories to better evaluate the sustainability of highly renewable electricity mixes like the one the European Union is aiming for.

5.02.P-Mo467 Validation of New Technology for Sustainable Recovery of Materials in the Non-Ferrous Metallurgical Industry: RECOPPs Project

***Laura Mayor Pérez**[1] and José Jorge Espí Gallart[2], (1)Eurecat, Spain, (2)Fundació EURECAT, Spain*

The RECOPPs project aims to validate a new technological solution, scaling it from a Technology Readiness Level (TRL) 5 to a TRL 7. The aim is for the developed processes to recovering of added-value raw materials Bismuth (Bi) and Antimony (Sb) as well as the removal and inertization of Arsenic (As) from residues and by-products generated during the pyrometallurgical production of Copper (Cu) in the industry.

The management of mining industry waste is a relevant issue in today's society. This is of high importance because, on the one hand, there are substantial quantities of critical raw materials that are currently essential for the development of new materials and technologies. Regarding this project, bismuth is crucial for use in the pharmaceutical and cosmetic industries, and antimony serves as a useful catalyst in the production of polyethylene terephthalate and flame retardants amongst other uses. On the other hand, toxic elements such as arsenic are also present, and its removal is essential to prevent its dispersion across various environmental compartments and to avoid potential adverse effects on ecosystems and human health.

Through life cycle analysis, the aim is to validate this new technology, identify potential areas for improvement, and demonstrate its viability considering both environmental and economic perspectives. This assessment will quantify the environmental impacts of the different routes developed for the recovery of Bi and Sb as well as the inertization of As, while assessing the environmental benefits provided by RECOPPs strategies. Additionally, aims to conduct a comparative assessment against the current situation of the management of waste streams from a pyrometallurgical industry located in Spain. To perform the LCA, the recovery of 1kg of Bi and Sb will be addressed as functional unit. Regarding the system boundaries, all the inputs and outputs of material and energy are shown, as well as the processes that conforms the treatment of the eluate. Furthermore, the specialised software SimaPro v9.1 will be used, along with the LCA database Ecoinvent v3.6 for the inventory of the system and the method chosen to calculate the environmental impacts will be ReCiPe 2016 Hierarchist v1.1.

This approach emphasizes the principles of the circular economy by reintroducing to the market secondary resources with significant added value generated within the industry.

5.02.P-Mo468 The Grand Unifying Theory of Hybrid Life-Cycle Assessment

***Michael Philipp Weinold**[1,2] and Guillaume Majeau-Bettez[3], (1)Technology Assessment Group, Paul Scherrer Institute (PSI), Switzerland, (2)ETH Zurich, Switzerland, (3)Chemical Engineering, Polytechnique Montreal, Canada*

The reduction of truncation errors, the inadvertent omission of relevant emissions along the supply chain, remains an unsolved problem in life-cycle assessment (LCA). Hybrid life-cycle assessment (HLCA) has long been proposed as a powerful solution to removing the truncation error and thereby improving the accuracy of (LCA) studies. In HLCA, data from economic input-output (IO) tables are combined with specific process-data from an inventory database. However, the complete hybridization of both the foreground and the background inventory would require a complete matching of processes to their corresponding economic sectors. While some authors have used a set of heuristics for matching, others have suggested the use of machine-learning (ML) algorithms for greater flexibility.

Despite the promises of HLCA, its application remains limited in scope. Even more importantly, the contested designation of different methods and the lack of a common notation means that the majority of case-studies claiming to use some form of HLCA cannot be reproduced. This is largely the result of wide-spread confusion concerning the implementation of HLCA.

Today, four distinct HLCA methods are recognized in literature: "Matrix Augmentation", "Integrated", "Tiered" and "Path-Exchange". While recent publications have attempted to compare these, the advantages and drawbacks of each method remain entirely obscure. What is more, in the "path-exchange method", where the use of ML was most recently suggested, the original authors in 2017 completely changed the underlying mathematical definition while claiming to adhere to their original 2009 publication.

In our work, we provide mathematical proof that three of the established methods are mathematically equivalent. We further show evidence that should strongly discourage the use of the "Path-Exchange" method due to the lack of connection between the process-based supply chain and the IO-system. We further extend the mathematical proof with a formal system of visual representations, allowing practitioners to quickly compare different methods. Finally, we lay out a pathway to the use of different ML algorithms for process matching in this new framework of HLCA, enabling the complete hybridization of LCA databases.

This work represents an important step towards the wide-spread use of automated HLCA for higher-accuracy LCA results, which will become more relevant as further environmental footprinting policy is implemented around the world.

5.03.A LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Informed Decision-Making

5.03.A.T-01 Methodology for the Life Cycle Assessment of Various Process Design Options in Alternative Fuel Production
Julia Weyand[1]*, Simon Maier*[2] *and Ralph-Uwe Dietrich*[2]*, (1)University of Stuttgart, Germany, (2)Deutsches Zentrum für Luft- und Raumfahrt e.V.*
Sustainable transport fuels provide an essential alternative to fossil fuels when aiming to reduce greenhouse gas emissions in the EU transport sector, especially for the transport that is difficult to electrify. The production can be achieved via multiple process routes and even different process designs within one route. Hence, the question arises how to easily and comparably assess such a variety of process designs from a techno-economic and ecological perspective.

Within DLR the in-house tool TEPET$^+$ was developed to perform semi-automated techno-economic analyses (TEA) as well as life cycle assessments (LCA) of chemical processes and technologies. Both TEA and LCA build upon a rigorous energy and mass balance of an Aspen Plus® simulation. By combining TEA and LCA in one tool a consistent assessment (same boundary conditions, functional unit etc.) of different process designs is enabled and economic and ecological trade-offs can be quantified. The application of the tool and methodology regarding the LCA and combined evaluation is demonstrated for a Biomass-to-Liquid process with two biomass sources (bark and straw) and three process configurations.

While there are slight differences in environmental impact between the two biomass types, the variances between configurations are more prominent. In dependence of the major impact contributors the configuration without external electricity demand or the one with a lower biomass input to product output ration has the lowest impact. The combination of economics and ecology in the greenhouse gas abatement cost reveals a trade-off that favours the configuration with the lowest cost but medium global warming potential.

Semi-automated LCAs enable the easy and comparable assessment of multiple process designs while the combination of LCA and TEA in one tool allows for a consistent sustainability assessment from both an economic an ecological point of view. Although this methodology was only illustrated for one sustainable fuel production process, it can be applied for various other chemical processes as well.

5.03.A.T-02 Exploring the integration of Risk Assessment and Life Cycle Assessment in the context of the Safe and Sustainable by Design framework
Elisabetta Abbate[1,2]*, Ad M. J. Ragas*[2]*, Grazia Maria Cappucci*[1]*, Jiaqi Wang, MSc*[2]*, Leo Posthuma*[3]*, Mark Huijbregts*[2] *and Serenella Sala*[1]*, (1)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy, (2)Environmental Science, Radboud University Nijmegen, Netherlands, (3)National Institute for Public Health and the Environment (RIVM), Netherlands*

Approaches to safety and environmental impact assessment are pivotal for protecting environment and human health and ultimately for sustainability assessment. However, over time, the development of the approaches to safety and sustainability has been mostly independent leading to different fields of expertise, e.g. risk assessment (RA) and life cycle assessment (LCA). The evolution of decision making needs for sustainable chemicals, materials and products is now requiring the integration of safety and sustainability considerations, supporting ex ante assessments, capitalizing on the knowledge generated by the different approaches, including the identification of trade-offs and the evaluation of impacts at different scale (from local to global). The integration of RA and LCA has been widely discussed in literature, but the complete operationalisation of the approaches in tandem is challenging.

The Safe and Sustainable by Design (SSbD) framework for chemicals and materials as recommended by the European Commission pushes for an integration of the two approaches. The ultimate goal of the SSbD framework is to promote innovation towards safer and more sustainable chemicals/materials. It can be applied in the chemical design phase or to compare existing chemicals. Integration of RA and LCA aims at addressing the assessment needs streamlining the practical steps. Among the possible integration options identified by previous studies (e.g. results combination, RA into LCA, LCA into RA, etc.), the core challenge is to identify the one that is most suitable in the context of the SSbD framework..

The present study explores the extent to which safety and environmental sustainability assessment should be integrated. To this end, we firstly understood the terminologies used under the umbrella of this integration. Secondly, we performed in parallel RA and LCA following the steps of the SSbD assessment and we detected a number of preliminary data and assumptions to be harmonized, for instance the ones already embedded in the methods and models used for the assessment. The introduction of a preliminary step that clearly defines the study goal, here proposed, would improve the SSbD assessment by collecting information that will be used by both assessments, especially when different assessors perform the two assessments in parallel.

5.03.A.T-03 Human toxicity assessment in LCA and as element in Portfolio Sustainability Assessment

***Peter Saling*[1]*, Wibke Lölsberg[2] and Peter Kölsch[2], (1)CDS/S, BASF SE, Germany, (2)BASF SE, Germany*

Although regulatory requirements are in place to ensure the safe use of chemicals in their application, the ambition to reduce the environmental impacts of products along their life cycle is often combined with an ambition to identify and reduce hazards and exposures. As there is currently no methodology available to compare hazard and exposure performance along the lifecycle and identify priorities for improvement, requirements are often based on purely hazard-based lists for priority substances without evaluating their risk in specific applications.The new TripleS approach (Sustainable Solution Steering) was published in 2023.

The new method contains updates reflecting simplifications in the segmentation process, increasing transparency of the process and allowing for automation. Furthermore, changes in chemicals legislation have been reflected, ensuring the functionality as an early warning system for portfolio management. The purpose of this manual is to document the process for BASF’s TripleS approach. The manual aims to describe the segmentation methodology and relevant processes, including roles and responsibilities of participants involved. The TripleS process, as presented hereafter, fulfills the following quality criteria, based on the International Standard on Assurance Engagement (ISAE) 3000.

As an additional element of Triple S LCA elements can be integrated to quantify the overall environmental impact of products along the life cycle but the models for toxicity impacts are focussing on the indirect impact of chemicals emitted into the environment. As a performance-based indicator for the application in LCA; ProScale assesses hazard and direct exposure potentials from chemicals along their life cycle. It can be integrated in LCA to compare human toxicity potentials of alternatives.

The presnetation shows elements of the TripleS method and how it helps to meet the needs of customers, value chains, governments and society. TripleS was introduced at BASF with the aim of increasing our portfolio of innovative and sustainable solutions and the sustainability performance of the value chains we serve. By assessing key drivers and issues in our customers’ industries, we strive to identify the sustainability contribution of each of our products in its specific application. To do so, solutions in their respective application and region are assessed in terms of defined sustainability criteria evaluating the value chain from cradle to grave.

5.03.A.T-04 Integrating nutritional aspects and planetary boundaries in food LCA

***Merja Saarinen*[1]*, Venla Kyttä[1], Paula Torán-Pereg[2], Tiina Pellinen[3], Anne-Maria Pajari[3], Anna Kårlund[4] and Marjukka Kolehmainen[5], (1)Natural Resources Institute Finland (Luke), Finland, (2)BCC Innovation, Technology Center in Gastronomy, Basque Culinary Center, Donostia-San Sebastián, Spain, (3)University of Helsinki, Finland, (4)University of Eastern Finland, University of Turku, Finland, (5)University of Eastern Finland, Finland*

Intentions to include nutritional considerations in life cycle assessment (LCA) of foods have increased. The main way to do so has been using nutritional functional units (nFU), and nutrient indices composed of several nutrients have proposed to be utilised. However, nutrient indices are initially intended for nutrition education to promote healthy diets and therefore are not necessarily the most suitable as nFUs directly in the comparisons of individual products in the context of LCA. Key questions are, should the different product groups be addressed more specifically, what product categorisation would be suitable and how the nutrients of each nutrient index should be selected. The aim of our study was to further develop a product group specific approach to include nutritional aspects in FU in several product groups and progressing to a methodological framework for defining sustainable food products. We developed nFUs to protein sources, carbohydrate sources, vegetables, fruits and berries group, fats, and meal drinks. We evaluated different strategies to select the nutrients to be included in the nutrient indices and conducted a validation study to evaluate the suitability of the strategies for the baseline use that refers to the current dietary situation. However, the selection of nutrients for the index is always closely related to the dietary context in which the results are to be utilised, so we applied the approach in two different dietary contexts, the Finnish and the Spanish. In addition, we developed a new method for combining the nutritional basis with planetary boundaries-based life cycle assessment (PB-LCA), and we applied it in the Finnish case. As a result of the study, there are two sets of product group specific nFUs that have been adapted to the diet that reflects the local food culture. Use of these nFUs brings important sustainability information to product selection situations. The study provides a sophisticated and compelling way for the downscaling of planetary boundaries to food products considering the different roles different foods play in providing nutrients. According to our results, a large part of the products will be defined as unsustainable. This challenges the food system and diets, but also raises the question of whether it is possible to reach the share of the planetary boundaries assigned to the food system or whether the share of food should be increased in the method of downscaling the planetary boundaries.

5.03.B LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Informed Decision-Making

5.03.B.T-01 Evaluating biofuel alternatives for passenger transportation through sustainability indicators

Richard Emmanuel Cabrera[1]*, Fatemeh Rostami*[2]*, Laureano Jiménez*[3]*, Gonzalo Guillén-Gosálbez*[4] *and Carlos Pozo*[5]*, (1)Institute for Chemical and Bioengineering, Department of Chemistry and Applied Biosciences, ETH Zürich, Switzerland, (2)Rovira i Virgili University (URV), Tarragona, Spain, (3)Universitat Rovira i Virgili, Spain, (4)Department of Chemistry and Applied Biosciences, ETH Zurich, Switzerland, (5)Departament d'Enginyeria Quimica, Universitat Rovira i Virgili, Spain*

Liquid biofuels are pivotal in driving the transition to a sustainable transportation sector, providing a pathway to decrease carbon emissions and seamlessly integrate with the current vehicle fleet and infrastructure.

Biofuels can be produced using different sources and processes, each of which generates different environmental impacts and achieves different engine performances. In this context, the identification of the most suitable biofuel production routes is a valuable piece of information so that researchers, policymakers, and companies can explore and promote these options.

This study explores 19 biofuel production routes as potential substitutes for diesel in passenger transportation, encompassing seven bio-oil feedstocks and three distinct biofuel production processes. We characterize the performance of these routes utilizing key indicators such as cost, water use, land use, and global warming potential, so as to comprehensively cover the three dimensions of sustainability: economic, environmental (based on life cycle assessment), and social. With these data at hand, we employ a multi-criteria decision making tool to systematically evaluate biofuel alternatives and rank them to identify the most promising options and draw general conclusions.

Notably, biofuels derived from waste, such as tallow, emerge as standout alternatives, boasting lower environmental impacts compared to others. Conversely, emerging technologies like microalgae exhibit less favourable performance. This research serves as a pivotal resource, offering valuable insights to shape policies and initiatives aimed at enhancing the sustainability of biofuel alternatives with improvement potential.

5.03.B.T-02 Is Corporate Growth Sabotaging Sustainability Goals? A Case Study of Photochromic Textiles

Kamal A. Kamali*, Bertrand Laratte and Guido Sonnemann, University of Bordeaux, France*

Constant revenue growth is a key indicator of corporations' success. As corporations adopt various growth strategies relying on innovation to expand their market share, they may inadvertently trigger an increase in environmental and social issues. For example, single use coffee capsules, foldable smartphones, and wireless chargers can be attributed to higher waste generation, shorter lifetime causing frequent replacements, or higher energy consumption, respectively. Moreover, the demand for high quality yet affordable products often drives companies to shift their production to developing countries. This decision is driven by the potential cost reduction associated with lower wages, reduced social security expenditures, and lower standards for health and safety of the workers, thus resulting in high social risk.

Climate change various detrimental impacts on the environment, economy, and human health led world governments to sign the Paris Agreement, However, we are currently off course and to limit global warming to below 2°C, a 30% reduction in greenhouse gas emissions is necessary by 2030. This necessitates conducting sustainability assessment on emerging technologies to ensure their environmental and social sustainability, ensuring that prioritizing reduced greenhouse gas emissions technologies does not worsen social well-being of different stakeholders.

The fashion industry known for its substantial market size and high compound annual growth rate, serves as a compelling case study illustrating how certain growth strategies can affect consumption habits, resulting in accelerating climate change, increasing social risks, and hindering progress towards the sustainable development goals. Therefore, a prospective environmental and social analysis of photochromic textiles, a type of fabric that changes color when subjected to UV light, is conducted.

This work investigates how the adoption of innovation driven business models prioritizing constant revenue growth can influence workers' well-being and the progress towards attaining the Paris Agreement targets. We aim to uncover the global warming potential and the potential social impacts of these textiles in 2030 when technological maturity has been reached. As a result of this work, it was evident that incorporating photochromic dyes in fabricating clothing fabric does indeed offset a part of the progress attained by shifting towards renewable energy production and cause higher potential social impacts.

5.03.B.T-03 Societal Life Cycle Costing for the definition of eco-design requirements of products: a methodological proposal

Chiara Magrini[1]*, Maria Gonzalez Torres*[2]*, Judit Rodriguez Manotas*[2]*, Vincenzo Senatore*[2] *and Viktor Kouloumpis*[2]*,*
(1)European Commission - Joint Research Centre (JRC), Spain, (2)European Commission - Joint Research Center (JRC)

Societal Life Cycle Costing (sLCC) assesses all costs associated with the life cycle of a product that are borne by anyone in society. It includes all external costs, whether soon to be internalised or not, expressed in monetary terms. For this reason, sLCC is especially relevant for public authorities interested in knowing the overall cost of a product, through the monetization of societal and environmental impacts, as well as the computation of indirect costs held by actors not directly involved within the product life cycle (Bianchi et al., 2021).

This contribution aims to present how sLCC is applied in the context of eco-design policies developed by the European Commission (EC). In particular, sLCC is part of a framework, which has the objective to set and prioritise eco-design requirements for specific product groups to improve their circularity, resource and energy performance and other environmental sustainability aspects. sLCC is combined with an analysis of environmental impacts, performed through a Life Cycle Assessment (LCA), and with a qualitative assessment of social impact and non-quantifiable aspects and policy objectives.

First, monetisation factors are discussed, focusing on those available for the monetary valuation of midpoint impacts according to the 16 impact categories assessed by the Environmental Footprint method (EC, 2013a, b and related updates). The factors are used in the weighting phase of LCA. Secondly, the procedure followed to subtract environmental taxes and subsidies is presented, so that these transfer payments are not included, as they do not lead to a net cost effect for society as a whole. Finally, future methodological developments are proposed.

5.03.B.T-04 Sustainability Assessment Framework for Innovative Technologies in Agriculture - Application to Algae Production as Alternative Feedstuff

Melanie Douziech*, Melf-Hinrich Ehlers, Alexandra Baumeyer Brahier, Mariluz Bagnoud and Gérard Gaillard, Agroscope, Switzerland*

Calls for technological innovations that contribute to sufficient, healthy and sustainable food are increasing. Comprehensively assessing the sustainability of novel agri-food technologies is however challenging because of their evolving character, uncertain social uptake, trade-offs between sustainability dimensions and impacts, the great variety of stakeholders affected, and the range of existing sustainability assessment methods. We propose a Life Cycle Sustainability Assessment Framework (LCSA) aimed at assessing the sustainability of novel agri-food technologies by providing guidance on choosing methods, ensuring stakeholder involvement, and linking social acceptability to social desirability as required by Responsible Research and Innovation (RRI). The proposed LCSA framework follows the four stages of life cycle assessment (LCA), considers the entire life cycle of the technology, and ensures multi-criteria evaluation. Stakeholders are involved in goal and scope definition, the description of the technical and reference system, the choice of impact categories, and data collection for the foreground system. Newly compiled lists of advantages and disadvantages of social and economic assessment method inform the choice of respective methods. LCA evaluates the environmental dimension. Stakeholder involvement is a central element of the method because literature supports its direct link to the social desirability aimed for in RRI. The pursuit of social desirability implies that stakeholder involvement in LCSA can contribute to the social acceptability of the technology. The developed LCSA framework guides an evaluation of the sustainability protein production for feedstuff from microalgae based on three vertical tubular photobioreactor systems (glass, silicone or polymethylmetacrylate). This case study illustrates the applicability of the developed LCSA framework. The comparison is at laboratory scale and the algae's suitability as input in a livestock diet is assumed, but not further investigated. The LCSA framework is usefully applicable to the production of microalgae as alternative feedstuff, while thorough stakeholder inclusion requires large resources and the comparison with the reference system requires substantial calculations.

5.03.P LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Informed Decision-Making

5.03.P-We400 Exploring the Environmental and Economic Sustainability of a Novel Light-Driven System for Wastewater Management

Mario Martín-Gamboa Dr[1]*, Vafa Feyzi Dr*[2]*, Javier Dufour Dr*[2] *and Diego Iribarren Dr*[2]*, (1)Chemical and Environmental Engineering Group, Rey Juan Carlos University, Spain, (2)Systems Analysis Unit, IMDEA Energy, Spain*

Among current CO_2 valorisation technologies, one promising approach is artificial photosynthesis for energy production/storage. However, technological development and robust analyses are required to ensure the sustainability of light-driven systems. This work presents a multi-dimensional analysis, combining ex-ante environmental life cycle assessment and life cycle costing methodologies, of a novel photoreactor system for simultaneous treatment of water pollutants and fuel production from sunlight. Given the exploratory nature of this work, two different functional cases were considered: (i) only wastewater treatment, and (ii) wastewater treatment combined with solar fuel production. System boundaries of the photoreactor system include the manufacturing of the cell, stack and prototype, as well as its operation. The life cycle inventory was obtained through direct communication supplemented by life-cycle and economic databases. The Environmental Footprint method was used for the life cycle impact assessment, considering municipal wastewater treatment (in the first functional case) and the production of fuels such as ethanol, methanol or ethylene (in the second functional case) as reference systems. Scenario analysis was conducted to assess different operational scales of the system varying the number of cells, the prototype's lifetime, and electricity consumption. In order to estimate the levelised cost, a bottom-up cost analysis approach was followed by considering capital, building, operational, material and labour costs of the system. Although the carbon footprint impacts of operating the photoreactor surpass those of their conventional counterparts in both cases, potential environmental viability could be achieved provided that the system is multifunctional (producing fuel at a rate > 100 g/h) and scaled up. Regarding the photoreactor fabrication cost, the cells would account for the highest contribution. Comparing the calculated levelised cost of wastewater treatment with the cost for a conventional wastewater treatment system, simultaneous fuel production (producing fuel at a rate > 200 g/h) would be necessary to make this system cost-competitive. Hence, the conclusions drawn from this study emphasise two key prerequisites for the future environmental and economic viability of such a novel photoreactor system: (i) it should be multifunctional, and (ii) scale-up in design and operation is vital.

5.03.P-We401 Evaluating Economic Sustainability in LCSA – Learnings from the International Round Table of Materials Criticality

Dieuwertje Schrijvers[1]*, Alexandre Charpentier Poncelet*[1]*, Naeem Adibi*[1]*, Milena Amaral*[2]*, Eduardo Entrena*[3]*, Klara Midander*[4]*, Tomas Vilhelm Rydberg*[4] *and* ***Thomas Schaubroeck, PhD***[5]*, (1)WeLOOP, France, (2)Neovili, France, (3)Contactica, Spain, (4)Swedish Environmental Research Institute (IVL), Sweden, (5)Luxembourg Institute of Science and Technology (LIST), Luxembourg*

Raw material criticality is often suggested as an aspect to consider in an economic sustainability assessment in the Life Cycle Sustainability Assessment (LCSA) framework. In parallel, the project IRTC (The International Round Table on Materials Criticality) has addressed the questions of how criticality can be best evaluated and mitigated – although not in the context of LCSA. This contribution aims to identify best practices identified in the IRTC project that merit an integration into current LCSA practices.

Within the IRTC project, a cause-and-effect diagram is established and implemented in a free web-based tool that links raw material data, supply-risk factors, a company's exposure to these three types of risk, and the effect of these risks, to economic damage, both at a company and societal level. Recent studies discussing the integration of raw material criticality into the LCSA framework are reviewed to identify to what extent the IRTC approach is aligned with the current LCSA framework, and whether mutual improvements could be considered.

In the comparison between the IRTC approach and the supply risk methods currently recommended for the LCSA framework, many parallels and distinctions can be observed. A focus is put here on one difference: the IRTC emphasizes that raw material criticality is stakeholder dependent: economic value is created throughout the value chain, and each value-chain actor may operate in a different regional economy, and have different options for substitution (at the raw material, component, or technology level). On the contrary, LCSA methods do not seem to give room for multiple stakeholder perspectives. The lack of identification of a specific economic stakeholder in LCSA-focused criticality approaches diminishes the value of the assessment for all economic stakeholders. To avoid this, we suggest applying a step-wise procedure in economic sustainability assessments, allowing for the identification of sources of potential economic instability and potential mitigation measures. An economic sustainability assessment following this approach is less quantified than an approach based on characterisation factors that calculates a final single score. However, it emphasizes the interplay between supply disruptions, life cycle costs, and mitigation measures, and applies a defined stakeholder perspective, allowing for the provision of information that can lead to concrete actions.

5.03.P-We402 Evaluating the Sustainability Level of Energy Storage Options

Fatemeh Rostami[1], Richard Emmanuel Cabrera[2], Laureano Jiménez[3] and ***Carlos Pozo**[4]*, *(1)Rovira i Virgili University (URV), Tarragona, Spain, (2)Institute for Chemical and Bioengineering, Department of Chemistry and Applied Biosciences, ETH Zürich, Switzerland, (3)Universitat Rovira i Virgili, Spain, (4)Departament d'Enginyeria Quimica, Universitat Rovira i Virgili, Spain*

The intensified focus on environmental sustainability necessitates a shift to cleaner, intermittent energy sources like solar and wind, challenging the stability of electrical grids. Energy storage is a solution to match the intermittency of renewables with fluctuating energy demand.

This contribution aims for evaluation of 25 energy storage options. First, we categorize the options into medium-term (nine technologies) and long-term (16 alternatives) choices, to ensure a fair comparison. Indicators like energy consumption, energy density, employment (indicating new job creation), global warming potential, and water usage, resulting from Life Cycle Assessment (LCA) studies, assess the performance of each option. The application of Data Envelopment Analysis (DEA), a linear programming method, allows to integrate these sustainability dimensions into a single efficiency score. Alternatives with an efficiency score of 1 are deemed efficient, while those with scores strictly below are considered inefficient. In addition, DEA provides quantitative improvement targets for inefficient alternatives that, if achieved, would make them efficient. This is a valuable piece of information to guide the efforts of technology developers.

We find that, in the medium term, nickel-cadmium, Li-ion, sodium-sulphide, and lithium-ferro-phosphate batteries show relatively higher efficiencies. Conversely, vanadium redox flow battery, zinc bromine flow battery, lead-acid, and sodium-nickel-chloride batteries exhibit lower efficiencies, necessitating further improvements. Improvement targets reveal that inefficient batteries need over 80% reduction in water usage and global warming potential, demanding intense research and development efforts.

Among long-term options, green ammonia from solar consistently demonstrates high efficiency, followed by green hydrogen from solar and wind, and green ammonia from hydropower and wind. Grey (fossil fuel-based) and blue (fossil fuel-based with carbon capturing) options exhibit relatively lower efficiencies due to elevated global warming potential and energy consumption. Notably, grey hydrogen alternatives, like coal gasification, water splitting, and steam methane reforming, have substantial improvement targets (over 80%) in energy consumption, water usage, and global warming potential. In contrast, green options need relatively lower improvements.

The study offers insights for policymakers, energy planners, researchers, and technology developers.

5.03.P-We403 Second Life of Batteries: Modeling Choices in Social Life Cycle Assessment

***Maeva Lavigne Philippot**, Joeri Van Mierlo and Maarten Messagie, ETEC Department, Vrije Universiteit Brussel (VUB), Belgium*

The increasing market of batteries and the need for a more circular economy entails the necessity to assess the potential of second-life batteries. Social life cycle assessment (sLCA) is not widely applied to batteries and only a few studies include their end of life, but without second life. This study aims to assess the social impacts of three batteries (from generation 2 to generation 4) and focuses on the methodology to include alternatives for a more circular battery over their entire life cycle.

This study is a type 1 sLCA using a reference scale approach and PSILCA. The system boundaries follow a cradle-to-grave perspective, comprising battery manufacturing from raw material extraction, use stage in Belgium, and end of life in Belgium. Second life is assumed to be in a domestic 4 kWp photovoltaic installation. The main modeling choice studied here is the functional unit (FU). FU1 is 1 kWh of electric energy delivered by the battery over its first life and credits from the avoided production of a new battery are included. FU2 is 1 kWh of electric energy delivered by the battery over its full lifetime (first and second life). Primary data for the batteries and their use stages was collected. Battery cells were tested under driving cycles. The costs of battery manufacturing are adapted from BatPac version 5.0. The battery manufacturing country is China and the component and active material are assumed to come from to the main respective producing countries.

The results show that in all cases, China is the main affected country, followed by Belgium. for FU1, the more advanced battery has lower impacts, and accounting for the avoided battery reduces the risks however as generation 3 also has less qualified batteries for second life, the credits from second life are lower. On the other hand, generation 2 with lithium titanate oxide as anode active material is a very long-lasting battery, explaining the high credits from second life. For FU2, almost the same conclusions can be drawn but the absolute values are up to twice lower than for FU1.

The modeling choices presented here allow us to conclude that second life reduces the social impacts of batteries. However, modeling an avoided battery production may not be recommended as it entails uncertainty around the choice of avoided battery and raises ethics concerns. In further steps, other modeling choices, such as allocations will be studied to confirm the potential benefits of circularity for batteries.

5.03.P-We404 Prospective life cycle assessment of organic redox flow batteries

Shan Zhang, *Department of Energy and Technology, Swedish University of Agricultural Sciences (SLU), Sweden*

Organic redox flow batteries are emerging as a promising stationary energy storage solutions due to their versatility in meeting power and energy requirements across various application scales, as well as their long lifespan, low self-discharge, heightened safety, and the avoidance of expensive minerals. Evaluating the environmental performance of technologies during their early development stages is crucial for identifying potential environmental impacts and guiding technology development. This study assessed the environmental performance of two emerging TEMPO-based redox flow batteries: an all-organic flow battery (OFB) and a hybrid flow battery (HFB), using life cycle assessment (LCA). The environmental impacts of the two batteries are benchmarked to the conventional vanadium flow battery (VFB). Two functional unit were considered: 1 kWh theoretical storage capacity and 1 kWh electricity delivered over the battery lifetime. This study constructed a battery deisgn model based on industrial data and design equations, calculating the required amount of battery materials. Additionally, a battery performance model was built to estimate the amount of electrolyte requried and the energy delivered over the battery's lifetime. Moreover, a global sensitivity analysis (GSA) was performaned to discover the relative contribution of input parameters to the total uncertinty. Overall, the results showed that OFB and HFB outperformed VFB in most impact categories, except for freshwater ecotoxicity and resource depoletion. Regaring the relative contribution of battery components, the energy subsystem are the biggest contributor to the total impacts regardless of the battery type, functional unit, and the environmental impact categories. This is associated to the high environmental emissions of the electrolyte. GSA highlighted that electrolyte capacity fade is the parameter affecting the results most , emphasizing the need for battery researchers to prioritize improvements in this performance parameter for the development of sustainable flow batteries.

5.03.P-We405 Combining Life Cycle Assessment and Planetary Boundaries for Sustainable Energy System Designs

Jan Marcus Hartmann[1], *David Y. Shu*[2], *Christian Zibunas*[1], *Nils Klinkenberg*[3], *André Bardow*[4] *and Niklas von der Assen*[5], *(1)RWTH Aachen University, Germany, (2)Energy and Process Systems Engineering, ETH Zurich, Switzerland, (3)Energy Trading and Dispatching, Currenta GmbH & Co. OHG, Germany, (4)Energy and Process Systems Engineering, Department of Mechanical and Process Engineering, ETH Zurich, Switzerland, (5)Institute of Technical Thermodynamics (LTT), RWTH Aachen University, Germany*

The global energy system is responsible for over 73% of global greenhouse gas emissions and is, thereby, the main driver of climate change. Hence, to mitigate climate change, energy systems must shift towards net-zero greenhouse gas emissions. However, the shift towards net-zero may be accompanied by a shift in the environmental burden of energy systems from climate change towards other environmental impacts, possibly compromising the absolute environmental sustainability of energy systems. Life Cycle Assessment (LCA) enables the identification and quantification of burden-shifting, but does not facilitate the assessment of absolute environmental sustainability. By integrating the planetary boundary framework into LCA, absolute environmental sustainability assessment of energy systems becomes feasible. Current absolute environmental sustainability assessments of energy systems solely focus on single-sector energy systems without analysing cross-sectorial interactions and fail to identify obstacles and enablers of absolute sustainable energy system designs. We employ an energy system modelling and optimisation framework with integrated LCA (SecMOD) for the case of Germany that encompasses multiple, coupled energy sectors, to assess energy system designs in terms of absolute sustainability, identify critical technologies preventing absolute sustainability of energy systems, and utilize multi-criteria optimization methods to span a design space for absolute sustainable energy systems. We find that an absolute sustainable energy system for Germany cannot be achieved by an autarkic and sector-coupled energy system if energy demand is not reduced. We disclose the main technologies in the German energy system's supply chain compromising absolute sustainability. To enable an absolute sustainable energy systems, we span a design space including energy imports and energy demand reduction, e.g. by increase of energy efficiency. For the obtained energy system designs, we also provide cost estimates. We emphasise the need for considering environmental impacts beyond climate change in the design of future energy systems, as environmental burden-shifting prevents the absolute environmental sustainability of energy systems. Additionally, we conclude that absolute sustainable energy system design can be achieved through energy demand reduction and energy imports.

5.03.P-We406 Life cycle assessment of future energy system flexibility – a methodological framework applied to Belgium

Dominik Huber[1], *Maeva Lavigne Philippot*[2], *Alex Felice*[2], *Muhammad Andy Putratama*[2], *Thierry Coosemans*[2] *and Maarten Messagie*[2], *(1)EVERGi Group, Free University of Brussels (VUB), Belgium, (2)ETEC Department, Vrije University Brussels (VUB), Belgium*

Future European energy systems are built based on a higher share of renewable energy technologies, such as wind and solar, requiring storage to match energy supply and demand. Simultaneously, transport decarbonization is expected to increase the share of electric vehicles (EV), which are currently only used around 5% of their total time. Hence, the remaining 95% of their time, the EV could be used to help to balance the electricity grid, known as vehicle-to-grid (V2G) technology. To reveal its environmental benefits, a framework is needed to understand first the provided electricity by V2G service for the grid at each given hour and to translate this into environmental impacts. Currently, no such metric exists for evaluation of environmental impacts of V2G service in a future energy system.

Thus, this paper proposes a framework to assess the environmental impact of V2G services by combining prospective life cycle assessment (PLCA) with an energy system model. In this study, the functional unit is selected to be one kilowatt-hour generated by the Belgium electricity market in 2050. System boundaries include a cradle-to-gate approach for all generating electricity assets. Additionally, prospective life cycle inventory databases are built for three Belgium energy scenarios in 2050. To obtain the hourly electricity supply mix, an internal developed design- and optimization framework, an optimal economic dispatch model used for small and medium energy systems, is upscalled to a national level. Furthermore, the Belgium EV fleet is simulated to supply V2G service. In a last step, the output of the hourly national dispatch model is reduced by the electricity supplied with V2G, the environmental impact of the new supply mix is calculated and compared to the impact of the current electricity mix.

The proposed framework is an example of integrating PLCA with an energy system model to evaluate the environmental impacts of an emerging technology. Results are presented at the SETAC meeting itself.

The proposed methodological framework and its application to Belgium can support policymakers to advocate for a broader application of V2G technology and faster adoption of bidirectional chargers and thus use the unused storage capacity of a growing EV fleet to integrate more renewable energy into the electricity grid. This framework can also be adjusted for other countries and thus be relevant for other researchers and policymakers outside of Belgium as well.

5.03.P-We407 Social Implications of Raw Material Requirements for Solar Photovoltaic Deployment on the Terawatt Scale

Mario Martín-Gamboa Dr[1]*, Ángel Galán Martín*[2] *and Diego Iribarren Dr*[3]*, (1)Chemical and Environmental Engineering Group, Rey Juan Carlos University, Spain, (2)University of Jaén, (3)Systems Analysis Unit, IMDEA Energy, Spain*

The urgent need to meet climate goals requires a massive expansion of renewable energy technologies, e.g., solar photovoltaics (PV). However, the large-scale deployment of solar PV presents challenges intricately linked to the availability of raw materials and its environmental and social implications. While previous studies have focused on resource constraints and environmental implications, social concerns remain largely unexplored. This study aims to fill this gap by assessing the social risks associated with the prospective material requirements for solar PV deployment. Initially, the prospects for solar PV in terms of global installed capacity were determined using the Integrated Model to Assess the Global Environment (IMAGE) for three specific years: 2030, 2050, and 2100. The study assumes that the solar PV technology mix will consist of 90% silicon (c-Si), 5% cadmium telluride (CdTe), and 5% copper indium gallium selenide (CIGS) solar PV. Eight raw materials were selected, and their material intensity per installed capacity was estimated based on a literature review. Two scenarios were defined to represent the minimum (best-case scenario) and maximum (worst-case scenario) demand for raw materials. Regarding the estimation of the social profile related to those materials, the study assumes that PV production is concentrated in East Asia and Southeast Asia. For these regions, two types of data were collected: i) the identification of the mining countries supplying materials to these regions based on the COMTRADE and USGS databases, and ii) the number of worker hours associated with mining. This information was integrated into the PSILCA database to ultimately derive the material-related social profile for the target years. The results for four selected indicators (child labour, frequency of forced labour, fair salary, and health expenditure) reveal that the large-scale implementation of PV capacity worldwide is directly associated with an exponential increase in potential social impacts in countries where raw material mining occurs. Efforts to improve efficiency in material intensity could reduce these social impacts by 9-16%. However, considering the nature of these impacts, it is crucial to aim for zero-risk targets in the medium-to-long term, monitoring and ensuring the respect of human and working conditions as a vital strategy within energy planning.

5.03.P-We408 Life Cycle Assessment of Emerging Hybrid Storage Systems for Maritime Sector

Maria Leonor Carvalho[1]*, Maria Anna Cusenza*[2] *and Pierpaolo Girardi*[2]*, (1)RSE SpA - Research on Energy System, Italy, (2)Ricerca sul Sistema Energetico - RSE S.p.A., Italy*

The electrification of transport has been emerging as one of the key strategies towards the transport decarbonisation pathways since it offers the possibility of replacing fossil fuels used in internal combustion engine with renewable energy sources.

Battery energy storage systems (BESSs) are the dominating storage technology for electric transport. However, heavy duty-cycles and high dynamic response typical of the maritime transport limit the employment of this technologies since oversized BESS are necessary. In this context, the adoption of hybrid storage systems (HSSs), combining BESS with either supercapacitors (SCAs), superconductive magnetic energy storage systems (SMEs), or both, is explored within the EU-funded V-ACCESS project to enhance the readiness level of HSSs and boost their implementation on electric propulsed vessels.

At this early stage of technology development, Life Cycle Assessment (LCA) is necessary to orient research towards the better compromise between technical/design requirements and environmental sustainability.

In this context, within the V-ACCESS project, the authors aim at investigating the environmental system-wide trade-off of HSSs against BESS in three types of vessels. In detail, the examined systems consist of (1) full electric ferry, (2) hybrid offshore supply vessel, (3) hybrid trawler. The analysis will be carried out through the LCA methodology. The selected functional unit is “1 kWh of the total electrical energy provided over the service life by the power system technology to perform a specific function”. The analysis will follow a “cradle-to-grave” approach. For each case study, detailed primary data (foreground processes) about SCAs and SMEs manufacturing processes and vessels operational profiles will be provided by the industrial partners involved in the V-ACCESS project, while the end-of-life treatments will be modelled based on the practice available at the commercial scale. The background processes will be modelled based on the Ecoinvent 3 database.

The study will allow to compare the implementation of HSSs against BESS based on a wide set of environmental data in accordance with the sustainability objective of avoiding burden-shifting among impact categories. Moreover, it will identify the "hot spots" and provide a useful support to industries towards the eco-design of the examined system. The obtained results can support decision-making processes towards the transport decarbonization pathway.

5.03.P-We409 Relevance of application and use-phase impact on Carbon footprint of Battery Energy Storage Systems (BESS)

***Luka Smajila**, KTH Royal Institute of Technology, Sweden*

One of the most mentioned aspects of battery installations today is their (often large) carbon footprint. Reported values mainly cover production phase and estimates for End-of-Life (EoL) associated impacts of Battery Energy Storage Systems (BESS). While studies show the significance of use-phase emissions in the BESS life-cycle, applications vary greatly and system boundaries (geographic and temporal) are critical for proper quantification. Hence, reflecting these differences and providing a complete value that can be comparable between systems is a challenge. The purpose of this work is to show preliminary quantitative characterisation of the use-phase associated impact and the differences that different applications can have within the same or at least similar local energy system boundaries. This was produced using different application specific models developed in Python and Excel. The models were developed to reflect capacity services (such as energy arbitrage, capacity firming) and ancillary services (frequency regulation). These models indicated the characteristics of BESS operation under different scenario constraints, as well as compared those to the StatusQuo reported carbon footprint values for similar systems. Furthermore, different location-specific rules and policy constraints are investigated and simulated to understand how such system behave in the real world in those location- & use-specific scenarios. Reported values by the models show that the use-phase associated emissions can significantly surpass the production and EoL phase values. Additionally, levelising the impacts across the system lifetime, a more accurate understanding can be produced to benefit different stakeholders, from industrial actors to policy makers. Findings show that understanding the location, time and service-specific is critical for adequate assessment of associated carbon emissions to a specific system. The term application-complete carbon footprint was coined to represent the final value that includes the use of system, and application-incomplete carbon footprint represents the previously reported values. However, both delineations can be shown to serve an important role in different contexts; from project/system design, optimisation, and decision-support; to limiting and/or allocating responsibility across the value chain of BESS. This produced understanding and implications can serve an important tole in policy and community/infrastructure planning as well.

5.03.P-We410 Comparative life cycle assessment of NMC 811 type Li-ion battery production using different electricity mix

***Thaiskang Jamatia**[1], Viera Pechancova[1], Debashri PAUL[2], Hüseyin Ersoy[3], Merve Erakca[4], Jens Buchgeister[3], Manuel Johann Baumann[5] and Petr Saha[6], (1)Centre of Polymer Systems, Tomas Bata University, Czech Republic, (2)Tomas Bata University in Zlín, Zlín, Czech Republic, (3)Institute for Technology Assessment and Systems Analysis (ITAS), Karlsruhe Institute of Technology (KIT), Germany, (4)Karlsruher Institut für Technologie (KIT) - Institut für Technikfolgenabschätzung und Systemanalyse, Germany, (5)Karlsruhe Institute of Technology (KIT), Germany, (6)Tomas Bata University in Zlín, Czech Republic*

The need for battery storage device is rising and with this, the demand for battery production is on the rise too. Previous studies on the environmental impact of lithium ion batteries (LIBs) revealed that cell production within overall value consolidates the most energy-intensive stage. In addition, the energy usage during this process contributes heavily to the environmental impacts too.

In this study, the energy consumption and GHG emissions related to the production of NMC 811 battery cell will be evaluated. Different European electricity mix will be considered for this study- the Czech Republic, Hungary, Poland and Slovakia. According to Bloomberg News Energy Finance (BNEF) 2022 ranking, these four nations featured in top 30 countries, globally, for contributing to the battery supply chain. In the report, China accounted for 77% of global battery manufacturing capacity and Europe stands at 14% of the global share.

For comparison purpose, a Norway electricity mix will be taken into consideration. It should be noted that the electricity mix generation of these countries are mostly reliant on non-renewable sources, whereas, about 98% of electricity mix generation in Norway comes from a renewable source. These countries, with variance in sources of electricity mix production will be analysed, evaluated and compared using life cycle assessment method. Thus, evaluating the environmental impacts from the NMC 811 cell production in its geographical context.

The regional variability analysis of the cell production step studied in this work will set the platform on the need to harness renewable energy for the generation of electricity which, in turn, will make battery production more sustainable. Additionally, the future directions will be identified for achieving carbon-neutrality in line with the European Union (EU) battery regulations.

5.03.P-We411 Life-Cycle and environmental impact assessment approach to support decision-making in hybrid Solar-Battery projects

***Luka Smajila**, KTH Royal Institute of Technology, Sweden*

Energy projects today are designed (and optimised) for economic constraints and objectives, such as minimising cost and maximising profit/short payback period. With sustainability targets, environmental constraints are becoming increasingly relevant to take in consideration. This poses a challenge of satisfying potentially competing objectives, where the a more profitable energy system could perform worse on environmental indicators than a less profitable alternative. With it comes an opportunity to apply the understanding of Life-Cycle Thinking and Life-Cycle Management approach in the methodological framework. With this addition, a more relevant context and support for decision making and energy project design can be achieved. This approach can also leverage Life-Cycle Assessment as a supporting methodology in early stages of project implementation and development, as it is usually used as a forensic tool after the project decision has already been made. For this purpose, a model representation of a Solar-BESS system was developed to assess and optimise system performance and design in above mentioned competing objectives. The identified trade-offs show the discrepancy between economics-oriented and environmental-oriented solutions. Extending to different scenarios and conditions, the produced information can support different stakeholders in the decision making process for different objectives/goals. Furthermore, it was showed how the produced information and insights vary depending on location-specific conditions. Reported values show that the use-phase associated emissions can significantly surpass the production and EoL phase values, even when levelised and accounting for necessary system replacement in the project lifetime. Furthermore, trade-offs in optimisation approach have been identified in the context of projected global (local) energy system development when in line with IEA sustainability target scenarios. Real trade-offs and consideration between economic performance and environmental footprint of the system should (and can) be taken in consideration when designing energy system. Furthermore, these trade-offs are highly scenario specific and should be assessed on a scenario-basis. Additionally, depending on the local regulatory environment, different cost & CO2eq attribution reduction can be identified. This can lead to promote adoption of such system, especially in fossil-fuel heavy (local) energy grids.

5.03.P-We412 Environmental impacts of photovoltaic integration in concentrated solar power plants

***Daniele Costa**[1], Sofie De Regel[1], Gabriela Espadas-Aldana[1], Hannes Laget[2], Ravi Kishore[3], Youri Meuret[3] and Filip Duerinckx[4], (1)Energyville-VITO, Boeretang 200, Belgium, (2)AZTEQ, Belgium, (3)Light and Lighting Laboratory, Department of Electrical Engineering (ESAT), KU Leuven, Belgium, (4)Imo-imomec, Imec, Hasselt University, Belgium*

Technological advances in photovoltaic (PV) and concentrated solar power (CSP) technologies are crucial in pursuing the Green Deal's climate-neutral objective of reducing greenhouse gas emissions by at least 50% by 2030. This study introduces the developments of the CSP+ project, which designed innovative hybrid power demonstrator plants that combine PV and CSP systems. This concept innovates by integrating PV cells within the mirrors of the structure. Due to their varying solar irradiation, the pilot plants were installed in Belgium and Spain.

Using the Life Cycle Assessment methodology, the preliminary assessment of the environmental impacts of the CSP+ plants was conducted from cradle-to-grave. The functional unit is the production of 1 kWh of electricity and 1 kWh of heat. A multi-physics simulation was used to simulate the production of heat and electricity. The impact assessment used the Environmental Footprint 3.1 method, focusing on climate change and abiotic depletion categories.

The results showed that PV cell production was the greatest contributor to climate change impacts (about 51% of the total impact), mostly due to electricity consumption in their manufacturing. The second largest contributor was derived from the structure of the plant due to the steel use (47%). For abiotic depletion, the largest contributor is the plant structure due to steel consumption (60%). For the absolute impacts, the plant in Spain performed 43% better in all impact categories due to the higher energy production derived from higher solar irradiation. It was shown that the environmental impacts can be optimized according to different production levels of heat and electricity in the plant.

The CSP+ plants present an innovative technology for renewable energy generation that allows heat and electricity production in a combined plant, reducing the total impacts compared to benchmark alternatives due to the integration of PV and CSP. The results addressed the trade-offs of the system's environmental performance based on its flexibility in heat and electricity generation towards better recommendations for decision-making for renewable energy production. In addition, the innovative technologies developed in the CSP+ plants supported economies of scale through plant integration and reduced land use, which will be further investigated in a life cycle costing assessment.

5.03.P-We413 Feasibility of Using Alternative Fuels in Steel Industry

***Siti NURLISA BINTI Ahmad**, University of Sheffield, United Kingdom*

Steelmaking is a critical sector responsible for 5-7% of global CO2 emissions. As a result, it has become a focus for sustainability efforts, with ongoing research aimed at reducing the industry's carbon footprint. In a blast furnace, coal in the form of coke is used as fuel and a reducing agent to reduce iron ore to iron. This study explores the feasibility of replacing traditional coal fuel in blast furnace ironmaking with alternative fuels such as subcoal, charcoal, and wood pellets. A risk assessment methodology evaluates each alternative fuel's efficiency, environmental impacts, and fuel economics to identify an efficient, sustainable, and cost-effective option.

The results of this study indicate that co-firing coal with charcoal at a composition of 20% coal with 80% charcoal is the most feasible alternative, followed by subcoal and wood pellets. While the conclusions are deemed reliable qualitatively, the methodology may require refinement to improve the quantitative results. Additionally, setbacks related to the use of charcoal, such as corrosion and alkaline ash deposition, must be addressed by employing low-ash charcoal. Higher charcoal prices can also be mitigated by implementing a higher carbon tax and stricter environmental legislation.

These findings can serve as a starting point for Tata Steel UK and other steel industries to initiate strategies towards achieving the Paris Agreement's goal of net carbon zero by 2050. Besides, this study emphasised the variability of alternative fuel options, specifically the potential use of subcoal and wood pellets after charcoal. These alternative fuels were identified as potential areas for further exploration in future research. In summary, this study provides valuable insights into the potential use of alternative fuels in the steelmaking industry. It highlights the need for further research to refine the methodology and address the setbacks associated with all alternative fuels. These findings can significantly contribute to developing sustainable and cost-effective strategies towards achieving net carbon zero in the steel industry.

For future work, this study will explore the feasibility of using hydrogen as an alternative fuel in the steel industry, conduct a life cycle assessment for all the alternative fuels considered, and refine the methodologies.

5.03.P-We414 ASSESSING ENVIRONMENTAL IMPACT AND MATERIAL CRITICALITY IN SCALING PEROVSKITE-SILICON TANDEM PHOTOVOLTAIC MODULES: A COMPREHENSIVE APPROACH

Roberto Magnifico[1]*, Angélique Léonard*[2] *and Antoine Boubault*[3]*, (1)University of Liège, Belgium, (2)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium, (3)BRGM, France*

This study introduces an integrated approach that combines Life Cycle Assessment (LCA) and Critical Raw Materials (CRMs). The analysis aims to address challenges in scaling up perovskite-silicon tandem photovoltaic modules within the PEPPERONI project, funded by the Horizon Europe programme. Perovskite solar cells have attracted significant interest from the scientific community, primarily owing to their promising properties, including high power conversion efficiency (PCE). The focus of the study is on sustainable production, emphasizing environmental considerations, raw material scarcity, and the nascent nature of the technology.

The LCA conducted in this study will analyse the entire life cycle of the modules, extending from cradle-to-grave. Encompassing tasks such as resource extraction, material production, cell and module manufacturing, pilot line operation, field operation, and end-of-life management. Acknowledging the uncertainties inherent in low TRL and the novelty of this photovoltaic technology, global sensitivity analysis will be employed, aiding data visualization and facilitating the construction of probability distributions for the expected environmental impacts. This approach enhances the robustness of the results, considering the dynamic landscape of emerging technologies.

The material criticality, a central focus of this research, will be assessed also through a multifaceted approach considering supply risk and vulnerability to a supply disruption. Economic indicators, substitutability, geological, technical, and economic accessibility will be evaluated at each step of the supply chain. A multicriteria analysis will be performed, considering resource abundance, producing countries' distribution, price volatility, and other indicators. The objective is to establish a link between LCA and criticality assessment methodologies to concurrently analyse the environmental impact and metal scarcity associated with this technology.

The synergy between LCA and CRMs analysis is paramount. The combination offers a holistic perspective, enabling informed choices that balance environmental sustainability, economic feasibility, and material resource resilience. The integrated LCA and CRMs approach is poised to contribute valuable insights to the sustainable scaling of emerging photovoltaic technology.

5.03.P-We415 Environmental Footprint of Labgrown and Germinated Plant-based Meat: A Life Cycle Assessment Study

Nichole Eunice Yanson Lalas[1]*, Harlene Baron Cardos*[2]*, Atsushi Izumi*[2]*, Koji Ochiai*[2]*, Hiroki Ookubo*[3] *and Norihiro Itsubo Dr*[4]*, (1)Department of Environmental Management and Information Studies, Tokyo City University, Japan, (2)DAIZ Inc., Japan, (3)Tokyo City University, Japan, (4)Waseda University, Japan*

In the ever-evolving landscape of sustainable food production, this research delves into the transformative potential of lab-grown and germinated plant-based meats. Developed through advanced methodologies, these alternatives not only offer enhanced nutritional profiles but also exhibit a significant reduction in environmental impacts. This study underscores the critical role of Life Cycle Assessment (LCA) in evaluating the sustainability and nutritional implications of lab-grown and germinated plant-based meats.

Utilizing LCA, this research conducts a comprehensive analysis of the environmental footprints of lab-grown and germinated plant-based meats throughout their life cycles — from raw material sourcing and production to distribution (cradle-to-gate). Building upon existing research, our findings highlight that both innovative methods notably enhance the nutritional attributes of alternative meats, simultaneously decreasing their environmental impact compared to conventional counterparts.

To provide a holistic view, this study integrates insights from existing literature and primary data from actual producers and researchers, showcasing LCA's versatility as an invaluable research tool for assessing alternative meat sustainability. Beyond the immediate scope, we aim to expand upon prior studies by systematically comparing and evaluating various production methods. This approach aims to assist researchers, companies, and the industry in developing eco-friendly alternatives and fostering informed decision-making for sustainable food production. It is also important to note the limitations of the study, acknowledging potential constraints and avenues for improvement most especially in data collection and standardizing boundaries for the comparative analysis.

In conclusion, this study offers a nuanced exploration of the sustainability and nutritional dimensions of lab-grown and germinated plant-based meats, utilizing LCA as a key analytical tool. By building upon existing research and recognizing its limitations, our work seeks to inform future research directions and promote the development of sustainable alternatives within the food industry. Future research includes the application of social LCA and economic LCA (LCC).

5.03.P-We416 Consequential Life Cycle Assessment of Various Geographical Adoption of the EAT-Lancet Diet
Aurore Guillaume[1,2]*, Lise Appels*[2]*, Vladimír Kočí*[1] *and Annemie Geeraerd Ameryckx*[3,4]*, (1)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic, (2)Department of Chemical Engineering, KU Leuven, Belgium, (3)Sustainability in the agri-food chain group, KU Leuven, Belgium, (4)Ethics@Arenberg, KU Leuven, Belgium*
The afri-food sector, while being responsible for a large part of environmental pollution and use of resources, is a key for transitioning towards a more sustainable system. Shifting to a plant-based diet is seen as one of the most efficient ways to mitigate one’s environmental footprint. Yet, the previous statement often ignores the market effects of international trade, which likely offset the expected environmental benefits. A multi or global adoption of a more sustainable diet could actually have the predicted mitigation potential. Here, we evaluate the environmental impacts and land use changes of different scenarios of a diet shift in various regions following the EAT-Lancet recommendations for red meat and legume calorie intake, additionally assessing their contribution to EU and international targets to stay within 1.5°C. A consequential life cycle assessment approach is used with the agrieconomic model CAPRI, a global agricultural model focusing on Europe and including bilateral trades. The scenarios assessed are a multi-adoption of the diet by the EU-27 and China, by 40% of the population (i.e., regions eating the most red meat) and by the global population. Compared to an adoption of the EAT-Lancet diet in the EU-27 alone, preliminary results show that, for all scenarios, the gap between demand and supply is closing up and even, in the case of the global diet adoption, becoming almost equal. Furthermore, adopting the diet in both the EU-27 and China already brings much higher environmental benefits compared to the EU-27 alone, both in terms of domestic footprint and at a global level. Surprisingly, the environmental benefits from an adoption of the recommendations by 40% of the population and at a global level are quite similar, suggesting that a diet shift for regions the most far from the EAT-Lancet guidelines can already make significant improvements. As compared with business-as-usual, significant environmental benefits in all impact categories at a global and local level could be achieved by a multi and global adoption of the diet and will be compared to policy targets. These outputs contribute to a better understanding of policies needed to transition to a sustainable food system and of the role of producers and consumers in sustainable consumption.

5.03.P-We417 Inclusion of environmental impacts into the formulation of pig diets: Reducing the climate change impact of pig feed at minimal added cost
Styrmir Gislason[1]*, Alberto Maresca*[2]*, Morten Birkved*[1] *and Thomas Sønderby Bruun*[3]*, (1)University of Southern Denmark, Denmark, (2)SEGES INNOVATION P/S, Denmark, (3)Husdyr, SEGES innovation p/s, Denmark*
Agricultural farm-gate emissions are estimated at 13% of annual anthropogenic greenhouse gas emissions, with an additional 7% attributable to land use changes. The low profit margins of the agricultural sector suggest that careful consideration must be made when considering potential environmental mitigation options. Inclusion of environmental considerations during feed formulations may provide substantially reduced environmental impacts of pigs with relatively small changes in the costs associated to feed. This study aims to investigate the environmental effects of changes towards feed formulations through inclusion of the climate change as a minimization objective. The new feed formulations are achieved with relatively small changes in costs for the pig farmer, while keeping the feed formulations balanced from a nutritional perspective for the pig. A cradle to farm-gate attributional life cycle assessment (LCA) methodology was applied for the assessing environmental impacts of nutritionally balanced pig diets. The Danish feed unit for fattening pigs (FEsv) of 1.05 MJ/kg was defined as our functional unit. Given the strong interconnection between land use changes and climate change impacts, we applied multiple land use change methods when generating the new feed formulations with reduced climate change impacts. Feed formulations included options of multiple common feed ingredients used in Danish pig production for satisfying nutritional constrains (e.g. crude protein, fats, amino acids, micronutrients). The new feed formulations were all nutritionally balanced, although differed in contents of ingredients. Agrisoft was used for formulation of pig feed, while OpenLCA 2.0.3 combined with Agri footprint 6.3 was used for construction of a life cycle inventory. We used the Recipe 2016 (h) impact assessment method to provide a broad range of midpoint impact categories and investigate potential burden shift from climate change to other impact categories. The results are intended to provide knowledge on the potential reductions in climate change impacts given relatively small changes in the costs associated with feed formulations.

5.03.P-We418 Life Cycle Sustainability Assessment of nano-enabled PFAS (Polyfluoroalkyl substances)-free anti-sticking coating for bakery moulds

Arianna Livieri[1], *Lisa Pizzol*[1], *Sarah Devecchi*[2], *Alex Zabeo*[2], *Magda Blosi*[3], *Stella Ivanova Stoycheva*[4], *Maria José Lopez-Tendero*[5], *Elena Badetti*[1] *and Danail Hristozov*[1], *(1)Ca' Foscari University of Venice, Italy, (2)GreenDecision S.r.l., Italy, (3)National Research Council (CNR), Italy, (4)Yordas Group, United Kingdom, (5)Laurentia Technologies SLL, Spain*
The European Green Deal policy ambitions identify the need for a Safe and Sustainable by Design (SSbD) approach to chemicals and novel materials. With the aim of making this operational, the JRC developed a framework for the identification of criteria for SSbD, the basis for a European recommendation, which specifically asks for a tiered approach depending on the data availability. This need has been addressed by the SSbD approach developed within the SUNSHINE project**,** which aims to develop and implement simple, robust, and cost-effective Safe and Sustainable by Design (SSbD) strategies for materials and products incorporating advanced multi-component nanomaterials. This approach aims to assess safety, sustainability, and functionality aspects at each stage of product development from a lifecycle perspective. This is achieved via a tiered approach that uses qualitative (Tier 1), and quantitative (Tier 2) assessment methods. Tier 1 consists of a questionnaire to assess safety, sustainability and functionality, and Tier 2 applies standard quantitative methods for sustainability assessment such as Life Cycle Assessment (LCA), Life Cycle Costing (LCC), and Social Life Cycle Assessment (S-LCA). LCA aims to quantify and compare the potential environmental impacts, LCC the potential economic impacts and S-LCA the potential social impacts. The present work focuses on the application of Tier 2 to one of the case studies within the SUSNHINE project: the Laurentia case study which is developing a nanocomposite coating composed of silica carbide and titanium dioxide (SiC@TiO2) to provide non-stick properties on its applications in bread baking trays. This innovative material is a substitute for Perfluoroalkyl and Polyfluoroalkyl Substances (PFAS)-based non-stick coatings, such as Teflon (Polytetrafluoroethylene or PTFE). The outcomes highlighted that under certain conditions, the innovative material outperforms the benchmark, while in other conditions, the benchmark performs better. The present work aims to highlight the relevance of applying Life Cycle Assessment, Life Cycle Costing, and Social Life Cycle Assessment to innovative products, since the design stage of development to support them in identifying hotspots, and to further improve the multi-component nanomaterial-material sector toward increasingly sustainable solutions.

5.03.P-We419 Environmental sustainability analysis of an industrial Italian Laundry Operations: a comprehensive Life Cycle Assessment

Valeria Mezzanotte Prof[1], *Riccardo Paoli*[2], ***Francesco Romagnoli***[3] *and Sara Venturelli*[4], *(1)University of Milano-Bicocca, Italy, (2)Riga Technical University, Latvia, (3)Institute of Energy Systems and Environment, Riga Technical University, Latvia, (4)Disat, University of Milano-Bicocca, Italy*
Industrial laundries, generating significant wastewater and posing toxicological concerns, threaten water bodies and contribute to environmental pollution. The lack of a detailed Life Cycle Inventory (LCI) on laundry detergent use compromises environmental assessments, relying on substitute products or proxy datasets. Laundries, known for high energy consumption, drive the need for a comprehensive LCI and Assessment (LCA). This paper aims to establish an LCI/LCA for an industrial laundry, offering an environmental profile based on an Italian case study.

Primary data for finalizing the LCI were directly obtained from an Italian industrial laundry, supplemented by literature, data from supporting databases (e.g., Ecoinvent 3.8), and information from the technical datasheets of detergents. The industrial laundry system encompasses the entire product supply chain, including the extraction and manufacturing of raw materials (including detergent), transportation and logistics, the industrial laundry process, wastewater treatment, recirculation packaging, and final disposal stages.

The calculated environmental profiles are based on the functional unit of 1 kg of linen washed through a standard washing cycle. The study's system boundaries cover the production stages, encompassing transportation for linen delivery and collection, raw material procurement, and the sanitization and washing processes. SimaPro 9.2 software and the ReCiPe 2016 H method were employed for the LCA study. A baseline scenario was compared with an alternative scenario introducing renewable energy technology, specifically solar PV panels.

The results indicate a total impact of 12.77 mPt, with the washing phase (4.62 mPt), ironing phase (4.29 mPt), and drying phase (1.56 mPt) being the most impactful activities. The washing phase's significant impact is attributed to detergent and washing product usage. Most impacts fall into categories such as 'Global Warming, Human Health,' 'Fine Particulate Formation,' 'Carcinogenic Human Toxicity,' 'Non-Carcinogenic Human Toxicity,' and 'Fossil Resource Scarcity.' The midpoint category with the highest impact is ‘Fine Particulate Formation’ at 5.18 mPt. The alternative scenario with renewable energy technology reduces the impact by 19.7%. Sensitivity analyses were conducted to evaluate the LCA model's uncertainty, focusing specifically on washing agents, raw material transportation, and energy consumption.

5.03.P-We420 Considering the evolution of the risk of natural and technological disasters while applying Life Cycle Assessment: a morphological analysis-based prospective method

Alejandra Cue Gonzalez[1], *Eric Rigaud*[2], *Paula Pérez-Lopez*[3] *and Philippe Blanc*[3], *(1)O.I.E., MINES ParisTech, France, (2)CRC, Mines Paris | PSL, France, (3)O.I.E., Mines Paris | PSL, France*
Comprehensive planning and decision-making activities are essential to sustainably develop human societies in the face of uncertainty, especially for critical infrastructure. Results from various decision-support tools often aid such activities. Environmental impact assessment tools are a fundamental part of this, and Life Cycle Assessment (LCA) is among the most widely accepted tools. However, LCA is usually applied to model systems according to their average operation conditions, and

deviations are not considered in the inventory (LCI) phase. If a natural or technological disaster affects an industrial facility, its production will be hindered until it is fixed. From an environmental impact perspective, repair and replacement tasks may have non-negligible impacts. To verify this, such factors could be considered in LCA. One solution is to develop a dedicated risk-based prospective LCI module. This research proposes a methodological framework aiming to develop a model of potential LCI flows associated with the evolution of the risk of natural and technological disasters on a territory, using the General Morphological Analysis (GMA) approach as a basis for scenario development. Here, scenarios mean a set of circumstances that represent the situation-at-risk the studied infrastructure is under, considering a set of defined variables which are linked to each other.

The first phase consists of defining the problem space through four profiles: 1) The risks profile characterizes the properties of events that may occur within a given scenario. 2) The infrastructure profile describes the properties of the studied technological solution. 3) The territory profile describes the characteristics of the territory studied. 4) The trends profile describes the different global variables to support the scenario definition. With the four profiles defined, the second phase involves building the scenario universe by applying GMA to define the relationships between the profiles' identified variables and ranges of values. The third phase involves analyzing relevant scenarios to identify the effects of shocks between risk events and the infrastructure studied.

The above-mentioned method has been applied to a case study about the development of the photovoltaic sector in the Alpes-Maritimes, France, towards a 2050 horizon, which aids to identify challenges, opportunities, and limitations of the proposed methodological framework, also paving the way for new LCA-related research.

5.03.P-We421 Incorporating the Risk of Zoonotic Disease into Life Cycle Assessments of Animal Agriculture
John Daniel Hader[1]*, Nadia Ilaria Malinverno*[2]*, Hyunjoo Hong*[3] *and Claudia Som*[2]*, (1)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (2)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)Empa, Switzerland*
Billions of animals are raised in agriculture worldwide for their meat, milk, and eggs as a source of food, and for their feathers, skin, and other byproducts for use in materials like clothing. To increase circularity across production systems, there is also ongoing research investigating how to utilize the molecular components of wasted side streams from animal agriculture as the building blocks for bio-based materials (e.g., utilizing the proteins from dairy whey to make aerogels). Life Cycle Assessments (LCAs) of animal-derived products are essential to understand their sustainability, and often consider environmental impacts like greenhouse gas emissions, eutrophication, and land use. However, such LCAs do not consider the impact animal agriculture can have on the emergence and spread of zoonotic diseases (i.e., diseases originally present in animals that mutate to infect humans). Different agricultural practices can increase or decrease the risk of new diseases emerging and spreading from farmed animals to people (and wildlife), with sometimes devastating consequences for humans (and biodiversity). For example, crowded conditions and low genetic diversity of farmed animals can enable rapid spread of viruses. Contact between multiple species in agriculture (e.g., chickens and pigs) can enable mixing and amplification of virus strains, and the possibility of contact with wildlife can be a vector for transmission either to or from non-agricultural animals. Against this backdrop, numerous diseases have emerged from animal agriculture in the past decades, with massive impacts on humans (as well as wildlife). For example, the H1N1 influenza virus emerged from North American pig farms in 2009, sparking the global "Swine Flu" pandemic. The aims of our study are to 1.) Identify and begin to quantify the risk factors associated with zoonotic disease emergence and spread due to different animal agricultural practices, and to 2.) Identify key knowledge gaps and methodological challenges that need to be overcome to develop a quantitative metric for zoonotic disease risk in Life Cycle Impact Assessment of animal products. Such a metric is needed to fully assess and compare the sustainability of different animal agricultural practices, and to support decision making towards a sustainable system of food and fiber generation.

5.03.P-We422 Determining the external costs of metals through risk indicators
Pia Heidak*, University of Applied Science Pforzheim , Germany*
The operation of mines can create a great deal of value for society by providing raw materials, increasing shareholder value and developing local communities. On the other hand, mines typically generate environmental costs that are often borne by civil society - they are externalised. There have been few attempts to determine these costs for metal mining, either for commodities or for specific assets. However, the results could support the development of appropriate tools for internalisation and as a risk and sustainability indicator for customers and investors. In addition, the results could be useful for mining companies in quantifying environmental risks in monetary terms and in prioritising environmental activities.

By reviewing existing studies, we are able to show which environmental impacts have been included in existing attempts to determine the external costs of metals and which have not, although they are considered to be highly important. Furthermore, by using the economic value of metals rather than their tonnage as a reference, we were able to provide an indication of which external costs of metals might be relevant from an economic perspective.

Based on these findings, we are currently developing a methodology to calculate the external costs of mines depending on their geological, technical and environmental characteristics. As a starting point, we are analysing different targets for determining external costs and combining these with different site-specific risk assessment methods to identify appropriate indicators and cost categories. This work is progressing and we would be happy to discuss the approach.

5.03.P-We423 Using GIS-methods in Life Cycle Methodologies: an application in two olive groves
Cristian Soldati[1]*, Giacomo Falcone*[2]*, Giovanni Gulisano*[2] *and Anna Irene De Luca*[2]*, (1)Department of Agriculture, Mediterranean University of Reggio Calabria, Reggio Calabria , Italy, (2)Department of Agriculture, Mediterranean University of Reggio Calabria, Italy*
Ecosystem services are benefits that contribute to human well-being: examples of these services are pollination, food provisioning, soil formation, and landscape aesthetics. Ecosystem services are increasingly included in policy decision-making, and in order to show the state of the ecosystem, it is necessary to apply quantification methods and models. Life Cycle Methodologies are a group of robust and proven methods that can help identify the hotspots where there is a decrease in ecosystem quality by assessing the entire life cycle of a product or a service. However, Ecosystem services are not included in this analysis. Some methods that can be included in Life Cycle Analysis are shown in combination with GIS data and results. The ESs analysed include "Fish and meat production capacity", "Growth capacity", "Production capacity of fruit and vegetables", "Crop growth capacity", which can be extrapolated from a LCA software like SimaPro or GaBi, "physicochemical filtration", "soil erosion regulation", which need the use of GIS software for their elaboration, and "pollination" which the method is recently developed. These methods were applied in two olive groves of the EU PRIMA Sustainolive project, whose objective was to increase the sustainability of the olive sector in the Mediterranean area. The two olive groves chosen have different agricultural practices: one uses agro-ecological principles such as the use of organic products, the integration of livestock, or the use of cover crops, and it is called Sustainable Technical Solutions (STS) while the other uses ordinary agriculture, which is called non Sustainable Technical Solutions (non-STS). The results show that, in general, more ecosystem services have less impact on STS olive grove than on non-STS olive grove: this is the case, for example, of pollinators or fruit and vegetable production capacity. However, for some categories, such as the Crop Growth capacity or the soil erosion resistance, the impacts are less for non-STS olive grove. From a methodological point of view, the results are sensitive to the input data: the physicochemical results, for example, show the same values for both olive farms because the input raster used for the soil data has a resolution of 1km x 1km (and this required a resampling of 100m x 100m) and both were included in the same Soil Map Unit with the same share of sand, clay, silt, and organic carbon.

5.03.P-We424 How to assess impacts on biodiversity of metal sources ? Providing indicators for decision-making
Anne Asselin[1]*, Gregoire Gaillet*[1]*, Iléane Lefevre*[1] *and Ambre Brizon*[2]*, (1)Sayari, France, (2)L'Oréal, France*
Metal mining and refining are known sources of impact on biodiversity, through land (and potentially sea) use change, pollution, and climate change. Impacts mostly occur at the two first steps of the value chain, namely ore extraction and smelting. Metal mining and refining happens in very diverse ecosystems and can have important effects on the local biodiversity in the three biotas: terrestrial, freshwater, and marine.

Building on existing literature, and based on a life cycle approach, we developed a semi-quantitative assessment method for metal sources, prioritizing the most important cause effect chains. As for the method, we i) first identified three metals of interest with diverse technical extraction practices ii) did a literature review, gathering information on main mining spots and practices, as well as on pressures on biodiversity caused by mining iii) identified the main drivers (land and water use, metal pollution) and built a semi-quantitative method based on cause-effect chain, with resulting rating on a scale from 1 (very bad) to 7 (very good) iv) completed our work with a quality assessment of the rating v) tested it on 15+ case studies.

Our method assessed impacts on biodiversity from water and land use, as well as from metal pollution and looks at terrestrial, freshwater, and marine biota. It combines the magnitude of each pressure with the receiving ecosystem vulnerability (using Global Extinction Probability combined with quality of governmental policies). We are currently testing it to a series of 15+ mining and refining sites, for copper, cobalt, and aluminum in Australia, Chile, China, and Congo (DRC). Those case studies present various challenges e.g., allocation between coproducts (in the case of copper and cobalt in DRC); scarce and incomplete data on metal pollution; specific vs generic data; aggregation of marine/freshwater/terrestrial impacts from heavy metals …

Project is still ongoing, results of testing (impact on biodiversity and quality assessment) will be presented at the conference. As specific data on pollution and resulting pressures on biodiversity is largely incomplete, we will also shed light on quality assessment and discuss how to combine it with results to provide actionable yet robust indicators for business decision-making.

5.03.P-We425 Measuring biodiversity impacts of salmon production: A case study for Norway
Pinar Kavak Gulbeyaz[1]*, Martin Dorber*[1]*, Johan Pettersen*[1] *and Francesca Verones*[2]*, (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway*
Aquaculture is an alternative protein source to land based farming for protein production and Norway is one of the leading countries that produce and export farmed salmon across the world. with a share higher than 50% in 2020. The production is expected to increase due to climatic suitability and economic development. While it creates value for Norway, the environmental impacts of the production need to be evaluated to mitigate the development of future strategies and to facilitate

decision making. There are many studies investigating the different aspects of aquaculture industry to improve the current practice. In terms of environmental impact assessment, currently available research for Norway mainly focuses on the evaluation of lice treatment options and climate change impacts. This study aims to present the impacts of aquaculture on biodiversity, by focusing on two production regions (North and South Trøndelag) to evaluate the potential differences at fine scale.

In this study, ex-post environmental impact assessment was conducted for the salmon production in Trøndelag, Norway for years between 2018-2021. The examined production processes include growth stages from hatchery to full grown salmon (grow-out) to be transported to slaughterhouse. In order to quantify the impact, functional unit was determined based on the weight of final stage of the system boundary, considering the unit grow-out mass (one kilogram) and impacts are quantified accordingly. The inventory data for the assessment was obtained in collaboration with the county municipality.

Environmental impacts were quantified by utilizing LC-Impact methodology for relevant impact categories: climate change, land use, water use, ecotoxicity, eutrophication/acidification. The impact values were calculated for each year separately to evaluate the temporal changes. Also, as lice is the main threat for the mass produced, different treatment option were evaluated to measure the environmental performance of each treatment option. The results of the study were utilized to investigate the synergies and trade-offs between treatment options and biodiversity conservation.

5.03.P-We426 Moving forward with the definition and assessment of positive biodiversity impact from financial investments using an LCA-based methodology

***Ana Judith Guerrero Esquivel**, PRe Sustainability, Netherlands*

Having an extensive biological diversity on earth is essential for the life of the planet. However, due to extensive deforestation (among others), more than one million species are threatened with extinction [1]. Under this scenario, it is necessary to limit activities that represent a threat to different ecosystems and promote those who can have a positive effect. The financial sector plays a crucial role on deciding which of these type of activities is executed, as this sector decides where money is invested or not. Thus, it is essential to bring biodiversity into the financial equation. The increasing regulatory pressure of the European Green Deal [2] and more, makes the protection and restoration of biodiversity a cornerstone of green finance.

The Biodiversity Footprint for Financial Institutions (BFFI) methodology, a method grounded on LCA, allows to quantify the biodiversity impacts of diverse economic activities. This year, for the first time, the BFFI methodology was applied to the ASN Biodiversity Fund which aims to create a positive impact by investing in activities aiming at restoring and protecting biodiversity [3] such as nature conservation areas [4] or agricultural projects with sustainable farming practices [5].

Applying the BFFI methodology in this context required defining a clear framework for what is positive and avoided biodiversity impact. Additionally, it required developing new approaches to include activities not assessed before with the BFFI methodology. As a result, a proposal was done on how to model investments in projects focused on: (1) Agroforestry & sustainable agriculture; (2) Land conservation; (3) Reforestation; and (4) Aquaculture. Additionally, a first assessment on these type of investments was performed.

These developments within the BFFI methodology and the subsequent first assessment of the ASN Biodiversity Fund contribute to understanding how investments in restorative projects could have a 'positive' impact on nature.

5.03.P-We427 Integration of environmental sustainability for decision support applying the SSbD strategy at the design stage of nanomaterials production

***Cristiana Gheorghe**[1], Jonathan D. Oldfield Prof[2], Georgia Melagraki[3] and Iseult Lynch[4], (1)University of Birmingham, United Kingdom, (2)1 School of Geography, Earth and Environmental Sciences, University of Birmingham, United Kingdom, (3)Chemoinformatics, Entelos Institute, Cyprus, (4)School of Geography, Earth and Environmental Sciences, University of Birmingham, United Kingdom*

Sustainability is one of the main cutting-edge topics of the 21st century, which the United Nations has defined as “meeting the needs of the present without compromising the ability of future generations to meet their own needs”[1] and to put it into practice, 17 United Nations Sustainability Development Goals (UN SDGs) were presented in 2015 as part of the 2030 Agenda for Sustainable Development. Life Cycle Assessment (LCA) is one of the most powerful tools for measuring the environmental impact of products (NMs and nanoproducts) over their entire life cycle, from the extraction of the raw materials, manufacture, distribution, use and waste disposal, and underpins progress towards the UN SDGs and supports the European Green Deal.

Over the past decade, the increasing development and production of nanomaterials (NMs) and nanoproducts and their widespread usage in a variety of industries including food, cosmetics, medicine, pharmaceutics, etc. have led to associated negative effects on the environment. As an area of high innovation, NMs and nanoproducts pioneered anticipatory assessment of safety at the early stage of design (so-called Safe(r) by Design), and thus offer an excellent case study for integration of sustainability also at the design stage, to achieve the goals of Safe and Sustainable by Design (SSbD).

To further embed sustainability assessment into the production and use of NMs and their associated products, identification of the hotspots of environmental impact during the NM and nanoproduct design phases, application of the Safe and Sustainable by design (SSbD) approach, in which LCA is embedded, will offer new insights. Coupling these with the application of the principles of green chemistry and green engineering should dramatically lower the environmental footprint of NMs and nanoproducts, whilst maintaining the desired functionality and safety profile. This poster demonstrates the application of this integrated approach to existing NMs synthesis roots, using the example of silver NMs applied in personal care and medical products. The output is a decision tree, implemented as a web application, to support SSbD of NMs and nanoproducts through optimisation of synthesis reactions and conditions via green chemistry and engineering principles.

5.03.P-We428 Integration of Robust Chemical Safety and Sustainability Assessment with Agent-Based Models Applied to the Energy Transition

Agnese Fuortes[1,2], *Carlos Felipe Blanco Rocha*[1], *Joris T.K. Quik*[2] *and Willie Peijnenburg*[1,2], *(1)Leiden University, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands*

The energy transition is a complex and dynamic process that has the potential to bring about significant environmental and social changes. The shift towards renewable energy sources may lead to a reduction in greenhouse gas emissions and air pollution, but it may also have unintended consequences such as land-use conflicts, water scarcity, and negative impacts on biodiversity. Life Cycle Assessment and Ecological Risk Assessment are powerful tools to identify possible unintended consequences. However, these assessments are inherently uncertain and do not take into account the complex network of actors involved in the energy transition, such as the government, companies, and citizens. Therefore, it is challenging to extract robust policy advice from these assessments. The objective of this research is to integrate existing knowledge on assessing chemical safety, human health, and sustainability impacts with techno-economic and behavioral modeling to offer a broader understanding in steering towards a more resilient energy transition. This integrated modelling approach has the potential to better explore the different dimensions of uncertainty linked with the complexity of the system, expose the emergence of unexpected consequences, and inform decision-making processes that account for the diversity of perspectives, values, and preferences in the transition towards a sustainable energy system.

To demonstrate the potential of an integrated modeling approach we examine a fundamental aspect of the energy transition: residential thermal comfort. We propose practical computational strategies to integrate Life Cycle Assessment and Ecological and Human Health Risk Assessment with Agent-Based Models applied to residential thermal comfort in the energy transition. Our approach incorporates uncertainty, social behavior, environmental and human health impacts in a probabilistic integrated model in an effort to embrace the complexity of energy transition-related challenges and gain insights from the integration of different prospectives and methods. At the same time the integration of such models enables us to leverage state-of-the-art methods in e.g. Global Sensitivity Analysis to largely reduce the complexity, streamline analysis and interpretation, and thus to apply such complex modelling for informing the decision-making process of policy makers.

5.03.P-We429 Integrating LCA and MFA with Linear Programming: Assessing Pathways of Energy Storage within the European Union

Léon Ferrari[1,2], *Maeva Lavigne Philippot*[3], *Maarten Messagie*[3] *and Fabrice Mathieux*[2], *(1)Free University of Brussels (VUB), Belgium, (2)Sustainable Resources Directorate, Joint Research Centre (JRC) - European Commission, Italy, (3)ETEC Department, Vrije University Brussels (VUB), Belgium*

To fulfil its net zero promise by 2050, Europe shall replace most of its passenger car fleet with only Zero emission vehicles (ZEV). Replacing the 270 million passenger cars with ZEVs, currently, battery electric vehicles (BEVs) are the most promising technology. The embedded energy storage system (ESS), will drive raw material (RM) demands and the RMs used currently (e.g. lithium, cobalt, nickel etc.) are known but in the future new chemistries involving new RM are to be expected.

How much cobalt will be needed in the EU in 2035 if cobalt chemistries are losing their domination? Could we have, under given technological evolution, an environmental advantage of recycling batteries earlier than their end of life?

In this work, the Python framework combines environmental life cycle assessment (E-LCA), material flow analysis (MFA), and linear programming (LP). This model traces the material flows, primary and secondary, and quantifies and locates their impacts within the value chain.). The integration will be operationalized using Python packages Brightway, Pyomo, lca_algebraic and HIGHS.

More precisely, bills of materials and LCA impacts of modelled processes will be accounted for in the optimisation model and used as the objective to minimize environmental impacts (EI) or RM consumption and within the set of constraints to enforce environmental targets or maximum capacity (e.g. Gigafactories built in 2030). We represent each process (i.e. in our case, extraction, refining, active material, cell manufacturing, battery manufacturing, use phase and recycling) as one decision variable(DV) per year, i.e. the production output (e.g. production per year). Each DV is linearly associated with their respective EIs. Stocks are also modelled (e.g. Use phase, dissipative losses). The processes are impacted over the years by the power supply mix and, hypotheses on battery technology or ore grade.
The results of this model give us the primary and secondary RM needed per year, the production volume and EIs per process.

These results will allow a future assessment of the security of supply, the benefits of circular economy strategies, and the impacts of key parameters on circularity or EIs. Eventually, this model should be able to support decisions considering various key performances of the overall systems.

5.03.P-We430 Development of a Novel 'Hub & Spoke' Framework for the Holistic Sustainability Assessment of Chemical Value Chains

***Alex James Kenneth Newman**, University of Sheffield, United Kingdom*

Sustainability assessment is a multifaceted research field, encompassing not just environmental considerations but also the interplay between economic and social dimensions. Current literature highlights the pressing need for a comprehensive approach that integrates these three 'strands' seamlessly. To date, research has focussed predominantly on isolated assessments—environmental, economic, and social—failing to capture both their interconnections and burden shifting. This fragmented approach to assessments leads to an incomplete understanding of problem spaces, potentially catalysing erroneous investment and R&D efforts.

The primary challenge lies in rectifying the remaining misalignments between environmental, economic, and social assessments. Social impact characterisation models, analogous to those seen in environmental studies, have consistently eluded practitioners, a consequence of the complexity and cultural specificity of impact pathways. To tackle this issue and deliver quantified and repeatable assessment results, a set of seven risk-based characterisation models has been developed as part of a proof-of-concept exercise; at completion, results are fully defined for 129 countries. In this, the social risk is quantified through the consideration of each impact indicator's stimulating and de-stimulating factors.

Integration of these social characterisation models within holistic assessments has also been demonstrated through a case study examining soda ash value chains in Asia. All three strands are shown to be aligned with the ISO 14040 standards, delivering the first fully quantified and integrated holistic sustainability assessment. Multi-criteria decision-making (MCDM) techniques are also employed in the form of hybrid AHP-TOPSIS, systematically aggregating impact indicator scores in parallel to the traditional objective assessment, delivering a bespoke ranking of the available value chain permutations.

The integration of these three strands holds significant promise, not only providing a more nuanced understanding of value-chain sustainability but also setting the stage for robustly informed industrial decision-making. By harmonising these assessments, organisations and institutions can realise a more strategic approach to sustainable development, quantifiably accounting for the interrelations between environmental preservation, economic viability, and social justice.

5.03.P-We431 Circular economy metric for the energy transition: a life cycle thinking approach

***Maria Anna Cusenza**[1], Alessio Novi[2] and Pierpaolo Girardi[1], (1)Ricerca sul Sistema Energetico - RSE S.p.A., Italy, (2)Sant'Anna School of Advanced Studies, Institute of Management*

The circular economy will play a key role in the energy transition pathway undertaken by the European Union (EU) in particular in decoupling the decarbonization of electricity generation from the demand for primary raw materials essential for renewable technologies. Planning effective strategies requires measurement systems to establish the position of the current system and monitor the progress towards quantifiable circularity objectives. Within such a framework, in the present work, the authors present a metric to measure the circularity of the electric generation system at the national level (macro-level analysis). The metric was developed based on a circular economy definition and principles customised for the electricity generation system, and it includes indicators related to policies supporting circularity, materials, energy and waste flows and specific indicators related to environmental sustainability, estimated applying the Life Cycle Assessment (LCA) methodology.

The identified indicators are clustered under four areas of analysis, "enabling factors", "configuration of the electricity power plants and operational phase", "end of life management" and "improvement of the environmental life cycle impacts".

The metric provides a synthetic circularity index through the aggregation of the scores assigned at each indicator based on a system of weights obtained according to the analytic hierarchy process. The circularity index can range from 0 (linear) to 1 (circular) and classifies the electricity generation system into four levels of circularity: “beginner”, “started”, “concerned” and “circular”.

The framework of indicators will be applied to the Italian electricity generation system in 2020 providing a baseline for tracking the progress towards a more circular energy system. In addition, from a monitoring perspective, a first application referred to 2021 and 2022 will be proposed. According to the Bellagio Declaration the EU and National official statistics, policy information, but also other information sources beyond official statistics will be used for indicators assessment.

The proposed framework is suitable for application to other Countries and can support the decision makers in planning strategies aimed at increasing the circularity of the electricity generation system at the macro scale identifying potential areas of improvement and providing reliable information for the allocation of the available financial resources.

5.03.P-We432 An Integrated Framework for Combining Environment, Health, and Sustainability Metrics: Zinc Case Study

***Eric Van Genderen**, International Zinc Association, International Zinc Association*

Increasing requests from stakeholders across mineral value chains demand information on various aspects of material composition, risk to health and environment, and emissions footprint. As a result, industry strategies to support measurable progress towards zero pollution and decarbonization are becoming increasingly sophisticated. While individual companies take specific measures to address customer and jurisdictional requirements, industry sectors are integrating decades of research and development to identify metrics and pathways towards achieving decarbonization and reducing environmental emissions. The development of credible systems for assessing life cycle impacts (ISO guidance, GHG Protocol) or chemical management (GHS CLP, risk assessment) considerations for products have been individually challenging. However, consumers now demand a full spectrum of Environment, Social, and Governance assurance from producers. Using decades of research from the zinc industry on material flow analysis and life cycle assessment (LCA), decarbonization scenarios were developed. In an additional step, environmental emission scenarios from zinc production and use (e.g., EU REACH dossier) were used to link source apportionment with risk assessment and abatement scenarios. A synergistic result of the analysis illuminated zinc’s “value in use” that can equate to massive intractable carbon emission reductions from steel and concrete sectors. Results demonstrated that an integrated framework for combining LCA and risk assessment enables innovation. This presentation will offer a framework assessing the spectrum of benefits and impacts for materials along a value chain.

5.03.P-We433 Sustainable future of peatlands: evaluation of peat extraction site restoration strategies from a life cycle thinking perspective

***Francesco Romagnoli**, Dace Araja, Agris Kamenders and Maksims Feofilovs, Institute of Energy Systems and Environment, Riga Technical University, Latvia*

Peatlands are a vital part of the ecosystems that have a critical role in carbon storage, preservation of biodiversity, and flood risk reduction. The environmental challenges posed by the industrial extraction of peat include an increased risk of a large amount entering the atmosphere with GHG emissions, mainly CO2, N2O, and CH4, over a long period of time. Latvia is one of the European states with the highest percentage of relative area cover of peat and peat-topped soils accounting for 1.2 million tons, representing 31% of horticultural peat used in the EU. The financial benefit of peat exports from Latvia has increased from 104 million euros in 2012 to 293 million euros in 2022. Several international policy planning documents have been issued requiring Member States to implement restoration measures for the peat extraction sites. However, it is not clarified how exactly to find and implement the restoration measures without having an adverse economic from closing peat extraction industry and social effect on communities involved. Therefore, this study aims to develop a novel evaluation framework for evaluating possible peatland restoration strategies in peat extraction sites within the three pillars of sustainability, environmental, economic and social. The framework is implemented in a quantitative assessment tool, which addresses the sustainability evaluation of restoration strategies for peat extraction sites in the form of a multi-criteria analysis within a life cycle thinking perspective. The selected indicators for life cycle sustainability assessment include environmental impacts, life cycle costing, social impacts of restoration strategies. The tool is tested and validated within local case study on existing peat extraction site. The results of the study show a valuable insight into the most sustainable peat restoration strategies for the extraction site managers and also, contributing to advising the policy planning for the implementation of the peat extraction site restoration measures based on scientifically sound methodology.

5.03.P-We434 Portfolio Sustainability Assessment incorporating ProScale for a holistic view on human toxicity portencial

***Peter Saling**[1], Peter Kölsch[2] and Wibke Lölsberg[2], (1)CDS/S, BASF SE, Germany, (2)BASF SE, Germany*

The Portfolio Sustainability Assessment, TripleS, was introduced at BASF with the aim of increasing our portfolio of innovative and sustainable solutions and the sustainability performance of the value chains we serve. By assessing key drivers and issues in our customers’ industries, we strive to identify the sustainability contribution of each of our products in its specific application. To do so, solutions in their respective application and region are assessed in terms of defined sustainability criteria.

The results derived from the evaluation of the value chain support business units by given them a clear picture of the sustainability drivers and concerns in their current and future portfolio. In this respect, the performance assessment serves as an early warning system. We aim to identify at an early stage those solutions that are likely to be affected by regulations and/or a negative market perception. Where deemed necessary, mitigation options for solving the sustainability issue(s) are developed. In addition, the TripleS tool serves as a steering instrument to trigger innovations that ensure differentiation in the markets through their contribution to sustainability and improved quality of life. Consequently, BASF has derived measures to use TripleS as a strategic steering tool for its portfolio development. The two segments of most sustainable products, Contributor and Pioneer, were defined as the basis. Through this KPI, the qualifiers for such most sustainable products are an integral guidance for our business development with the goal to grow this share of the business over proportionally.

To further enhance the assessment ProScale can be used to evaluate the human toxicity potential of substances in their application across the full lifecycle. The methodology allows to assess application specific exposure potential arising from direct exposure of hazardous substances in a product along its entire life cycle. Proscale scores can be calculated at different levels of aggregation, e.g., for an entire life cycle, a part of a life cycle or a specific unit process. A prectical example will be presented.

5.03.P-We435 Communicating life cycle global health impacts of addressing the plastic pollution crisis

Megan Deeney[1]*, Lorie Hamelin*[2]*, Claire Vialle*[3]*, Xiaoyu Yan*[4]*, Rosemary Green*[5]*, Joe Yates*[5] *and Suneetha Kadiyala*[5]*, (1)London School of Hygiene & Tropical Medicine (LSHTM), United Kingdom, (2)Toulouse Biotechnology Institute, Université de Toulouse, CNRS, INRAE, INSA, France, (3)Laboratoire de Chimie Agro-industrielle (LCA), Université de Toulouse, INRAE, France, (4)University of Exeter, United Kingdom, (5)London School of Hygiene & Tropical Medicine, United Kingdom*

Human health risks associated with emissions across the plastic value chain are a growing concern but limited quantitative evidence has been available to inform international decision-making. We combined Life Cycle Assessment with Material Flow Analysis, using the Plastics-to-Ocean model, to estimate the human health impacts associated with scenarios of global plastic management in 2040. Scenarios included: (1) *Business-as-Usual* (BAU) projections for plastic production, management, and waste, and (2) *System Change* (SCS) comprising reduced global plastic production, increased waste collection and disposal, recycling, reuse, and material substitutions. We applied Life Cycle Impact Assessment (LCIA) methods with characterisation factors for estimating Disability-Adjusted Life Years (DALYs), including 15 combinations of modelling assumptions, perspectives, and time-horizons from ReCiPe 2016, Impact World+, LC-Impact and USEtox. We compared estimates between methods to evaluate implications for interpretion, communication and decision-making in the context of plastic waste reduction and global health. In 2040, the BAU global plastic system was associated with between 58,000 and 120 million years of healthy human life lost worldwide, the burden of which was reduced by 2% – 83% in SCS, depending on the LCIA method. Climate change was an important driver of health impacts in both system scenarios (BAU: 6.80E+05 - 2.23E+06 DALYs, SCS: 3.78E+05 - 1.24E+06 DALYs, 100-year time-horizon). Climate-related DALYs were influenced by whether models included heat stress-induced cardiovascular disease and rising malnutrition alongside the health burdens of diarrhoea, malaria, and flooding risk. Though all LCIA methods showed virgin plastic production as the leading source of health impacts in 2040, we found significant differences in terms of the relative importance of climate-related DALYs versus reduced water availability leading to malnutrition. Different time-horizons, perspectives and inclusion of environmental stressors were associated with the scale and severity of health impacts associated with global plastic scenarios. Careful interpretation and communication of human health impacts is critical to informing decision-makers, ensuring health concerns are considered in policy and monitoring, and that measures are used appropriately and transparently in terms of their validity, precision and remaining ‘known unknown’ and ‘unknown unknown’ risks for global health.

5.03.P-We436 On the Readiness of Social Life Cycle Assessment for Integration in Life Cycle Sustainability Assessment and Safe and Sustainable by Design Frameworks

Nina van Dulmen[1]*, Carlos Felipe Blanco Rocha*[2] *and Jeroen Guinee*[2]*, (1)Leiden University, Leiden, Netherlands, (2)Leiden University, Netherlands*

Social Life Cycle Assessment (S-LCA) faces fundamental methodological barriers. Its increasing applicability, e.g., in frameworks as Life Cycle Sustainability Assessment (LCSA) or Safe and Sustainable by Design (SSbD), calls for a critical evaluation of S-LCA and its feasibility to adequately assess the social pillar within these product-centric frameworks. We explore key differences between general S-LCA impact assessment methods and evaluate the value-added of S-LCA in its current form, compared to more qualitative and organization-oriented approaches to assess social impacts over a product’s life cycle.

Using the 2020 UNEP Social LCA Guidelines as a starting point, with a particular emphasis on Reference Scale approaches, we compare five methods for evaluating social impacts of a textile garment. Two methods are based on the PSILCA social database (through datasets with and without an activity variable as scaling factor). Third, the Subcategory Assessment Method is evaluated as a more organization-centric and semi-quantitative approach to S-LCA. As fourth and fifth, two more qualitative social due diligence approaches, based on the OECD Due Diligence and UNGP Principles for Business and Human Rights and IFC Performance Standards, are evaluated

The absence of a standardized S-LCA approach fosters a problematic variety in methods being developed. Evaluating five methods highlights how each handles very different modeling structures, whereby results differ considerably in nature, length, and social topics covered. Product-oriented S-LCA, which can be performed using social databases, faces important limitations in being restricted to assess quantifiable aspects only. More qualitative and organization-centric approaches assess the social performance of entities within a product's value chain rather than establishing cause-effect relationships between processes comprising the product system and social indicators. Such organizational approaches can rather be used to conduct social due diligence of suppliers in the target organization's value chain.

We conclude that a product-focused approach for S-LCA using a functional unit and limited to including quantitative indicators only is best for integration into LCSA and SSbD. These assessments can be complemented by more qualitative approaches assessing value chain actors. We call attention to the equal importance—but fundamental difference in approach—between product-based S-LCA and organization-level assessment.

5.03.P-We437 Assessing Social Life Cycle Impacts of Power Technologies in the Spanish Electricity Mix
*Luisa Beridy-Segade, María del Prado Díaz de Mera, Miguel Ángel Reyes-Belmonte and **Mario Martín-Gamboa Dr**, Chemical and Environmental Engineering Group, Rey Juan Carlos University, Spain*
Power generation systems are at the forefront of national energy transitions in many countries, such as Spain, which stands as a notable example. However, this profound transformation could have multifaceted implications, leading to unintended consequences on society. Under these circumstances, the present work aims to shed light, for the first time, on the social impacts of the Spanish power sector and their supply chains by using the social life cycle assessment methodology. The functional unit is defined as 1 kWh of electricity produced in Spain in 2022, distributed across the following technologies: 23% natural gas combined cycle (NGCC), 23% onshore wind, 21% nuclear, 10% solar photovoltaics (PV), 7% cogeneration, 7% hydro dam, 3% coal, 2% concentrated solar, 2% biomass, 1% hydro run-of-river, and 1% incineration. A cradle-to-gate approach is taken encompassing the production of operational inputs (e.g., fuel or energy), operation and construction of the power plants, manufacturing of capital goods as well as extraction and refining of raw materials. To compile the social life cycle inventory, data collection encompassed: i) the identification of national suppliers along the value chains of power technologies, and ii) the quantification of working hours linked to each process within the predefined system boundaries. All of this information was integrated into the PSILCA database to ultimately derive the social profile of the Spanish electricity mix. Althoug the results in terms of four selected indicators (child labour, contribution of the sector to the economic development, frequency of forced labour and women in the sectoral labour force) reveals significant differences, three main social hotspots emerge from the analysis: i) the production of solar PV panels in East and Southeast Asia (solar PV plants), ii) the extraction and refining of natural gas in North Africa (NGCC and cogeneration plants), and iii) the construction and operation of hydro and nuclear plants in Spain. In the first two instances, impacts directly relate to the risk levels associated with the involved processes, while in the latter case, a relatively high number of working hours lead to the significant contribution of these technologies. Therefore, high renewable production in national electricity mixes doesn't guarantee a positive social performance, revealing the need of balanced environmental and social considerations in energy policy making processes.

5.03.P-We438 Proposal of a scalable product biodiversity footprint framework based on state-of-the-art methodologies for eco-design of cosmetic products
***Kaiwei Wang**[1], Jacques L'Haridon, PhD[2], Magdalena Czyrnek-Delêtre[3] and Anne-Claire Asselin[4], (1)L'Oréal, France, (2)L'Oreal Research & Innovation, France, (3)I Care by BearingPoint, France, (4)Sayari, France*
Today, within the sustainability program "L'Oréal For The Future", ambitious commitments have been set by the company to continue tackling environmental issues on climate change, water, resources as well as biodiversity. The tool to support product developers in contributing to these commitments is SPOT (Sustainable Product Optimization Tool), an eco-design tool for cosmetic products based on life cycle assessment. As the science around biodiversity footprinting continues to progress, it is essential for L'Oréal to develop an understanding of the biodiversity footprint methodologies at product level to support eco-design with aim of the preservation or even the promotion of biodiversity as well as to explore how it connects to commitments at corporate level.

In order to leverage the already, acquired knowledge and available life cycle inventories and methodology, the LCA-based approaches are prioritized when building a relevant product biodiversity footprint framework. A panel of methods have been reviewed and selected by L'Oréal based on existing literature. A product biodiversity footprint framework built on the state-of-the-art methodologies has been then proposed. It suggests i)the use of the current SPOT method for a first screening level of insights and ii) use of additional known LCIA methods in biodiversity footprint studies to provide more relevant information and results when needed. This framework is currently being tested and assessed.

This work will enable L'Oréal to formulate recommendations for strategic deployment and implementation of product biodiversity footprint assessment for different use cases :

- At-scale and streamlined biodiversity footprint screening studies, with key data and hypotheses, which could be applied to the entirety of L'Oréal product portfolio as well as innovation projects at different life cycle stages (sourcing, ingredient production, processes, end of life, etc.).

- Specific biodiversity footprint studies, with more refined and accurate data, applied to some products or relevant projects.
- Complete and robust studies, with data and hypotheses of high quality as well as peer-reviewed steps for a potential biodiversity claim at the product level.

A brief discussion on the articulation with the corporate biodiversity footprint metrics will also be presented to highlight the relevance of the proposed approach.

5.03.PC LCA and Beyond – Integrating Sustainability and/or Other Dimensions for a More Informed Decision-Making

5.04.A LCA in Policy, Decision-Making and Communication to Support the Transition Towards Sustainable Consumption

5.04.A.T-01 Environmental Footprint for product policy support: current status and challenges
*Esther Sanye-Mengual[1], Cecilia Casonato[2], Laura Garcia Herrero[1], **Susanna Andreasi Bassi**[3], Viktor Kouloumpis[3], Loredana Napolano[3], Fulvio Ardente[4] and Serenella Sala[5], (1)European Commission - Joint Research Centre (JRC), Belgium, (2)Department of Agricultural Sciences, University of Bologna, Italy, (3)European Commission - Joint Research Center (JRC), (4)European Commission - Joint Research Center (JRC), Italy, (5)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy*
The use of Life Cycle Assessment (LCA) in EU policy has increased over the last decades with life cycle thinking becoming central for the European Green Deal ambitions. In particular, EU product policy development has benefited from the systemic approach of LCA in order to enhance the environmental performance of products while preventing trade-offs among environmental issues or life cycle stages. In this context, the European Commission recommends the Environmental Footprint (EF) to ensure the robustness and comparability of environmental information provided in the EU market.

This work aims to review the current use of EF methods in EU product policy, while discussing advantages and challenges of the LCA implementation. In addition, further developments for the EF are explored. The analysis focuses on the following policy examples: EU Green Public Procurement (GPP) and Product labelling for environmental information. Other examples may include Ecodesign for Sustainable Products Regulation (ESPR) proposal or the Batteries regulation.

The EF method can support policy-making in different steps of the policy cycle. Examples during policy design includes the use of EF data for defining criteria or requirements. In the implementation of policies**,** the EF can support the development of methodologies to provide a robust and comparable framework, e.g., to inform consumers about the environmental impact of products. For policy monitoring, EF-based indicators or frameworks can be developed to support the quantification of the effects of product policy. While several advantages of the use of EF in policy support are identified, the EF faces some challenges associated to the current modelling requirements (inventory) and impact assessment methods. Most of these challenges are common to LCA and aligned with current discussions and advancements in the LCA community.

5.04.A.T-02 The Green Deal's New Call for Greenhouse Gas Data: A Daunting Task or Déjà Vu?
***Julian Baehr**[1] and Liselotte Schebek[2], (1)Technical University Darmstadt, Germany, (2)Technical University of Darmstadt, Germany*
To achieve the European Union (EU) overall net-zero emission target until 2050, the European Green Deal announces a variety of new reporting regulations pressuring companies to report greenhouse gas (GHG) emissions of their activities, assets and their organization as a whole. Therefore, companies do not only struggle to keep up with the latest reporting requirements but also experience increasing difficulties to manage through the jungle of accounting methodologies and data sources. This leads to an increased accounting workload as well as to methodological and practical accounting errors negatively affecting the reporting quality [1].

To this end, our study aims to identify data which is required within the scope of two or more reporting schemes. We hypothesize that the in-depth theoretical knowledge of these data synergies could significantly reduce the associated accounting workload and simultaneously increase the consistency of reported results. As a practical outcome our analysis shall serve as the basis of future GHG accounting and data management concepts in companies.

To validate our hypothesis, we perform a three step anaylsis: first, we perform a systematic review of current GHG disclosure obligations within public regulations, introduced in the past and within the European Green Deal. Second, we review and cluster existing GHG accounting methodologies and identify which methodology is used within a certain reporting regulation. And third, we characterize data sources needed to be consulted within the respective accounting methodology. Synergies are identified and discussed regarding their methodological relevance and their practical potential to reduce accounting workload.

Our results show that similar data is used across system boundaries for varying reporting obligations. Being aware of these data synergies indicates that new reporting obligations might not necessarily come with new accounting challenges. Instead, reporting companies should make use of these synergies to recognize common data sources, thus avoiding multiple consultation of the same data. This way, corporate GHG accounting could substantially be improved, while reducing the accounting workload.

[1] Klaaßen L, Stoll C. 2021. Harmonizing corporate carbon footprints. Nat Commun 12, 6149 https://doi.org/10.1038/s41467-021-26349-x

5.04.A.T-03 Eco-labelling in France, time has come for implementation and scale up !
***Vincent Colomb**[1], Pascal Dagras[2], Lisa Chenerie[2], Alban Fournier[2], Audrey Rimbaud[3], Grégoire Richard[1], Raphael Guastavi[1] and Jérôme Mousset[1], (1)ADEME, France, (2)French Ministry of Ecological Transition, France, (3)ADEME, Bioeconomy and Renewable Energies Division, France*
France is on the verge of finalizing an extensive ecolabeling initiative, beginning with food and textiles, initiated in 2009. This effort aligns with the "French Climate and Resilience law," responding to citizens' calls for improved environmental information. Amidst the emergence of many private initiatives, France positions itself as a "pilot country" in the EU. ADEME and the French Environment Ministry propose a voluntary ecolabeling scheme in 2024, set to become mandatory in 2025.

The ecolabeling methodology centers on Life Cycle Assessment (LCA), presenting a PEF-wise approach. While rooted in the PEF methodology, adjustments address critical limitations. Modifications include modification of toxicity indicators and weighting. An "ecosystem services module" is introduced, addressing some biodiversity aspects lacking in PEF. The textile sector integrates a microfiber indicator.

Operationally, a tiered approach allows flexibility in data collection, accommodating stakeholders' capacities. Background data relies on established databases for food (Agribalyse) and textiles (Base Empreinte). An open-source Ecobalyse tool supports method development, implementation, and ensures transparency in stakeholder discussions.

The success of the French ecolabeling scheme hinges on achieving acceptability across multiple dimensions: methodological robustness, operational feasibility, and stakeholder support. The proposal introduces a "cost for the planet" concept, utilizing a dedicated unit for environmental impact (mPt). In contrast to the A-B-C-D-E scale used by most private schemes, this approach emphasizes that every product has an environmental impact, addressing ecodesign, but also consumption levels and sobriety dimensions. It avoids complex categorization debates, threshold effects, and aligns with consumers' familiarity with comparing products based on financial costs.

The French ecolabel format, currently under development, will be presented at the SETAC conference. The scheme aims to provide clearer and more comprehensive environmental information to a broad market, bringing LCA knowledge into the households of millions of French citizens. It acknowledges LCA's limitations and proposes short-term fixes until academic consensus is reached, and LCA databases are more comprehensive. The communication and pedagogical aspects are deemed crucial, given the lack of shared understanding on environmental metrics and diverging interests among stakeholders.

5.04.A.T-04 Harmonization of LCA methods, rules and guides across sector boundaries: A shared responsibility of science and industry.
***Dr. Martin Baitz**[1], Magnus Piotrowski[1], Steffen Schoell[1], Maike Horlacher[2] and Yannick Bernard[2], (1)LCA Data Content, Sphera Solutions GmbH, Germany, (2)Consulting, Sphera Solutions GmbH, Germany*
Several scientific-industrial initiatives are working on guides or rules to sharpen requirements of Product Category Rules (PCR), LCA sector-guides and method specifications. All initiatives aim for collaboration among the entire value chain. Environmental Product Declarations Systems (EPD), Together-for-Sustainability (TfS), the Automotive Network Catena-X, Clean Vehicles Research (CLEVER), Sustainable Apparel Coalition (SAC) are examples. Whereas requirements are based on ISO, the initiatives aim sector-specific rules, beyond ISO. Goal is to define sector consistent rules and specifications enabling result reliability based on technological or supply chain differences, free of (hidden) methodological differences. Everybody in the supply chain (resource extractor, supplier, manufacturer, B2B customer, final user, recycler as well as policy maker) is expecting reliable results based on (real or natural) technological and supply chain differences, rather than (virtual or rule made) methodology. The aim sounds too well to be true. The sector initiatives are appreciated and supported. However, there is an issue, which is widely disregarded (or at best acknowledged and postponed), which can only be solved via constructive and responsible cooperation of involved industry, science and policy: Neither LCA nor the supply chain are sector-specific. The presentation will demonstrate concrete (and wherever possible quantified) practice examples where "sector specific rules" need to be harmonized into "intersectoral rules". Method requirements (e.g. by-product treatment, end-of-life assignment, data quality indication, life-cycle system boundary allotment, energy system choice, regionalization and technology specifications, data gaps handling) to improve results and consistency, need to be accepted by "providing or receiving neighbor sectors". We present quantitative figures concerning the (real) impact of certain differences in key method choices; based on overall LCA results of key products. It is aimed to provide more clarity on where existing general claims "like allocation is very important" should be specified into "allocation is important in these specific circumstances". The presentation provides information and background for future constructive and responsible cooperation of all involved stakeholders of industry, science and policy towards harmonized LCA application, rules and guides across sector boundaries, based on physical and practical evidence.

5.04.A.T-05 Combined Assessment of Absolute Sustainability performance and Life Cycle Damage of global consumption

Acosta-Izquierdo Santiago[1], Michael Hauschild[2] and ***Olivier Jolliet***[3]*, (1)Technical University Denmark, DTU-Sustain, Quantitative Sustainability Assessment, Denmark, (2)Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark, (3)Technical University of Denmark (DTU), Denmark*

LCA has been developed for determining impacts of products and services over their entire life cycle, assessing damages on human health (HH), ecosystem quality (EQ) and natural resources, with a focus on relative improvements of products. In parallel, Absolute Environmental Sustainability Assessments (AESA) assess the absolute sustainability performances of products and compare their impacts with limits fixed by planetary boundaries. Both frameworks continue evolving separately and there is a need for combining these approaches for sound decision making.

This study presents a framework to consistently perform a combined assessment of absolute sustainability and damages, to be simultaneously considered by decision-makers, and apply it to evaluate the impacts of world overall consumption. Using an Environmentally Extended Multi-Regional Input-Output Model to evaluate elementary flows associated with global consumption, Impact World+ to assess the corresponding Life Cycle Damages, and sustainable boundaries aligned with the LCIA metrics, we determine damage and absolute sustainability status for 18 specific impact categories affecting ´HH, and EQ areas of protection (AoP). An area-based graphic, enables us to visualize for each AoP both the exceedance fold of each impact category specific planetary boundary (Y-axis), and the corresponding damages (X-axis and total area).

Damages associated with global consumption are exceeding global sustainable levels for 50% and 62,5% of the HH and EQ impact categories. The exceedance does not directly relates to the damage *per se*, and are complementary representations. For example, the global consumption exceeds climate change planetary boundary by a factor 30, with a damage of 9.2E+7 DALY/y, whereas it exceeds the fine particulate boundary by a lower factor of 10, but with a higher impact of 1.3E+8 DALY/y. Similar contrasting tendencies are observed for ecosystem quality impacts contrasting high impacts and high exceedance factors associated with land use (2.6E+13 PDF-m2-y/y; exceedance fold of 39) and climate change (2.0E+13 PDF-m2-y/y; exceedance fold of 30). In contrast terrestrial acidification is below planetary boundaries (exceedance factor of 0.7) but still has a substantial impact (4.8E+12, PDF-m2-y/y). In conclusion, it is crucial to consider both planetary boundary and level of damages, damages being able to provide science-based weighting to the respective planetary boundaries in different impact categories.

5.04.B LCA in Policy, Decision-Making and Communication to Support the Transition Towards Sustainable Consumption

5.04.B.T-01 Assessing Environmental Impact Reduction Potential for Blue Ammonia: Navigating Complexities in Carbon Capture and Utilization Modelling

Mutaz Chahrour[1]*, Christina Wulf[2] and Petra Zapp[2], (1)Institute of Energy and Climate Research (IEK) - Systems Analysis and Technology Evaluation (IEK-STE), Research Center Jülich, Germany, (2)Institute of Energy and Climate Research (IEK) - Systems Analysis and Technology Evaluation (IEK-STE), Forschungszentrum Jülich GmbH, Germany*

Ammonia, an indispensable cornerstone in global chemical production, accounts today for approximately 2% of the total energy demand globally, with an overwhelming share of the energy stemming from fossil-based sources like natural gas and coal. This positions Ammonia as one of the most emission-intensive commodities produced by heavy industry and prompts the need for a more environmentally friendly alternative. Emerging short-term alternatives like Blue Ammonia use steam methane reforming with natural gas as a hydrogen source while simultaneously capturing and either storing or utilizing carbon dioxide (CO_2) emissions, presenting itself as a climate-friendly option. With more Blue Ammonia suppliers opting for CO_2 capture and utilization (CCU), the key question arises: which standards and guidelines must be followed to ensure a transparent representation of environmental impact reduction? This research focuses on assessing and discussing the most up-to-date guidelines that tackle Life Cycle Assessment (LCA) modelling of CCU, primarily the latest Together for Sustainability (TfS) guideline promoted by the chemical industry; notably, this approach contrasts with the broader and more holistic discussions prevalent in the scientific community. The goal is to put such guidelines to the test, enhancing their critical evaluation, and assessing their cascading effects throughout the supply chain. The preliminary findings, derived from modelling according to TfS guideline, indicate a carbon footprint reduction when transitioning from fossil-based to Blue Ammonia. Further dive into the details of the guideline showcase that employing system expansion via substitution of Direct Air Capture technology yields mixed outcomes. The impact of such substitution on the results is contingent upon several factors, mainly the region of operation and the subsequent energy mix selection. Alternative modelling approaches can result in no shared incentives between CO_2 producer and user, such as employing system expansion via substitution of Ammonia production without CCU. In such cases, the reported environmental impact reduction applies only to the user of captured CO_2, with no further credit incentives for Blue Ammonia user. This research not only evaluates the progress made in industry-specific modelling principles for LCA of CCU, but also underscores the considerable room for improvement in existing guidelines.

5.04.B.T-02 Sustainable Transition to a Circular Economy: Modelling Environmental and Socio-Economic Impacts of Regional and National Waste Management Systems in Europe

Josefine Hededam Sund[1]*, Paola Federica Albizzati[2], Davide Tonini[2] and Thomas Fruergaard Astrup[3], (1)Technical University of Denmark (DTU), Denmark, (2)European Commission - Joint Research Centre (JRC), Spain, (3)Environmental*

and Resource Engineering, Technical University of Denmark (DTU), Denmark
Waste is being produced at a faster rate than any other environmental pollutant and is expected to increase dramatically over coming years. In response, world leaders are increasingly embracing the idea of a circular economy, where materials are reused and regenerated rather than discarded. In this regard, the European Union (EU) has established regulatory targets that mainly prioritize recycling over incineration and landfill. This will inevitably lead to a range of technological developments and new product design requirements to facilitate recycling, reuse and refurbishment. However, rapid changes may pose challenges in adaptation. This could result in the mismanagement of waste, which, in turn, can have detrimental consequences on human health and the environment. Thus, it is imperative that the impacts of waste management systems are assessed to ensure resource circularity while avoiding adverse effects. In addition, the existing targets focus exclusively on municipal waste. It is important to evaluate not only the effectiveness of these targets and whether they appropriately target specific streams and sectors but also the necessity of setting targets for non-municipal fractions. Moreover, the environmental, economic, and social impacts of both the current waste management system and the potential consequences associated with future changes should also be assessed. However, currently, no studies provide a comprehensive and dynamic system-level model based on life cycle thinking that enables the consistent assessment of all waste streams occurring in the EU, addressing the three sustainability pillars, namely environmental, economic and social impacts. This study contributes to an ongoing EU project that provides a flexible modelling framework, that can assess both EU and country-specific waste management systems and is adaptable to changes in framework conditions, technology options, and regulatory focus. The model has the ability to assess different scenarios (e.g. imposing an environmental tax on a material to assess its effectivity, etc.) and produce results regarding recycling rates per waste stream, overall recycling rates, 16 environmental impact categories, internal costs, external costs, and employment. At the conference, the model set-up along with preliminary results will be presented to provide insight into how such frameworks can be leveraged in policymaking to ensure an efficient and sustainable transition towards a circular economy.

5.04.B.T-03 Supporting decision-making on municipal utility fleets decarbonization considering inventories and impact assessment dynamics

Susie Ruqun Wu[1]*, Anne de Bortoli*[2] *and Cecile Sophie Marie Bulle*[3]*, (1)ESG, CIRAIG, UQAM, Canada, (2)Génie chimique, Montreal Polytechnic, Canada, (3)UQAM, Canada*
Due to the dynamic nature of battery electric vehicles (BEVs), assessing their environmental impacts requires dynamic LCA (DLCA) coupled with dynamic life cycle inventory (D-LCI) data and dynamic life cycle impact assessment (D-LCIA) methods.

Unlike the abundance of studies focusing on impacts from passenger/freight transportation, municipal utility fleets (MUFs), however, have rarely been scrutinized. Using MUFs driven in Quebec, Canada as the study object, we incorporate both D-LCI and D-LCIA (focusing on Global Warming Potential (GWP)) to evaluate the potential impacts on electrification of Internal Combustion Engine Vehicle (ICEV) MUFs.

For D-LCI, we prepare dynamic foreground inventories and adopt premise-adjusted ecoinvent database as the background dynamic inventory. For D-LCIA, we propose a d-GWP_{SSPx} approach by integrating future projected climate scenarios, i.e., calculating d-GWP using the CO2 concentration under different Shared Socioeconomic Pathways (SSPx, x = 1/2/3/4/5). The DLCA is conducted to compare a conventional ICEV-diesel(-d) with a BEV garbage truck driven in Montreal, Quebec, Canada. For the BEV, two types of battery were tested: the currently commercialized lithium nickel manganese cobalt oxides battery (LIB-NMC622) and a promising lithium–sulfur battery (LSB). We averaged the vehicle lifetime impacts to a functional unit of vehicle-km (vkm). The methodological consistency is ensured. The LSB investigated are expected to be deployed only after 2030, under either SSP1 (taking the Green Road) or SSP2 (Middle of the Road) scenarios. We tested with two Integrated Assessment Models (IAMs), i.e., image SSP2-Base and image SSP2-RCP26.

Preliminary results provided us with unanticipated findings. Both LSB- and NMC-BEV received slightly worse (~9% higher impact score) as compared to ICEV-d in 2030. Overtime, the LSB-BEV improved by 6% and 23% as compared to ICEV-d in 2050 on climate change under image SSP2-Base and SSP2-RCP26, respectively.

The DLCA study showed us that electrification of a garbage truck does not necessarily yield positive climate change consequences, especially when new battery technology readiness level is still low. However, the conclusion is dynamically changing with the evolving foreground and background systems.

5.04.B.T-04 Consequential Life Cycle Assessment of Fuels for Shipping

Megan Roux[1]*, Massimo Pizzol*[2]*, Thomas Fruergaard Astrup*[3] *and Giovanna Croxatto Vega*[4]*, (1)Environmental and Resource Engineering, Technical University of Denmark (DTU), Denmark, (2)Department of Sustainability and Planning, Aalborg University, Denmark, (3)Ramboll, (4)A.P. Møller-Mærsk A/S*
While the maritime transportation sector is responsible for the movement of up to 90% of the world’s goods, it is also responsible for 3% of global GHG emissions. The awareness of the effects of these emissions has led to regulations on decreasing emissions from fuel combustion, and changing to low-carbon or carbon-free fuels has been identified as a critical

means of achieving these targets. A variety of alternative fuels for shipping have been identified as promising, although there is no consensus yet on what the future fuel mix looks like.

Life cycle assessments (LCAs) have been used to support decision-making in various sectors, and several life cycle assessments of maritime fuels have been conducted and published in scientific journals, with many of these focused on conventional fuel oils. Despite an increasing representation of alternative maritime fuel LCAs in literature, the existing literature is limited in its inclusion of critical elements and transparency in reporting methodological choices and assumptions. The diversity of fuel types and fuel production pathways, coupled with inconsistent LCAs on these fuels complicate decision-making regarding fuel choice.

In this work, consequential LCA is applied to a range of different maritime fuel scenarios, to demonstrate how to address the existing gaps in literature. The system boundaries include both production and combustion of the fuels. The function unit is chosen as 1 tonne of cargo transported 1 kilometer (1 tkm) to address differences in fuel energy density. Multiple literature sources of data are used to provide a range of potential impacts for several different impact categories.

Additionally, the results of the environmental life cycle assessment scenarios are contexualised with regards to regulatory frameworks and certification schemes for fuels, such as the EU's Renewable Energy Directive (RED) and the the Low Carbon Fuel Standard (LCFS).

It is expected that the outcomes of this study will provide guidance to LCA practitioners and decision-makers for i) how to conduct comprehensive LCAs of alternative maritime fuels, and ii) decision support regarding fuel choice and the expected ranges for the various fuels.

5.04.B.T-05 Lessons Learned From a Practitioner-Driven Project on the Sustainability Assessment of Regional Products

Barbara Madeleine Mejía*, Martin Stüssi, Eric Mehner, Gérard Gaillard and Melanie Douziech, Agroscope, Switzerland*

Quantitative evidence of the economic, environmental, and social sustainability of consumer products is difficult to find and scientific studies on the evaluation of Protected Designation of Origin (PDO) products are scarce. The one-year DurAOP project aimed at developing a methodological framework for the sustainability evaluation of PDO products and applying it to five Swiss PDO products. The aim of this work is to reflect on the lessons learned from the DurAOP project in terms of methodological development of the sustainability assessment methods, project co-creation, and communication challenges. The project was carried out in four main step: First, the development of the methodological framework, second, the data collection, third, the results generation and fourth, the presentation and interpretation of the results. Several methodological challenges arouse in the first three steps of the project, namely: (1) defining quantitative indicators able to reflect trade-offs for the social and economic dimension, (2) reflecting the specificities of regional production, (3) ensuring the quality and comprehensiveness of the collected data and the representativity of default data, and (4) allocating the impacts to the analysed product, or more generally going from a company/farm level to a product level. In addition, the communication of disaggregated results for several indicators across the three sustainability dimensions has proven difficult. We tried to tackle the methodological challenges by keeping the indicators of the social and economic dimension simple, ensuring a good overlap with the available data, and defining new indicators reflecting the regional character of the products' value chains. We further visited all the producers and conducted plausibility checks to increase the confidence in the collected data. Finally, allocation was avoided as much as possible by modelling only the processes relevant for the considered products. The combination of in-person meetings and streamlined results presentations aimed to facilitate the communication of the projects' outcome. In addition, a transparent communication of the study's strengths and limitations contributed to the confidence in the presented outcome. Overall, the DurAOP project allowed the development of a first methodological framework for the sustainability evaluation of PDO products and the evaluation of the sustainability of five Swiss PDO products.

5.04.P LCA in Policy, Decision-Making and Communication to Support the Transition Towards Sustainable Consumption

5.04.P-Tu475 A theoretically based approach to reconcile different types of GHG-accounting

Marco Rudolf*, Karlsruhe Institute of Technology (KIT), Germany*

Greenhouse gas (GHG) emission accounting plays a pivotal role in guiding climate actions and policy decisions. In the contemporary landscape, diverse objects, including countries, cities, regions, organizations, products, projects, and individuals, engage in GHG-emission accounting. The resulting accounts underpin critical decisions related to climate target comparisons, policy instruments, investments, and consumption choices. While global initiatives such as the GHG-Protocol and the International Standardization Organisation (ISO) have endeavored to standardize GHG accounting, these standards emerge from complex negotiation processes driven by diverse interests.

This study critically examines existing GHG accounting standards, revealing inherent conceptual challenges arising from the absence of a holistic, theoretically grounded foundation. The lack of unified definitions for central terms, inadequate consideration of interdependencies between GHG accounts, variations in handling temporal dimensions of accounting, and the failure to distinguish between different forms of double counting contribute to the fragmentation of current standards.

In response to these challenges, our work presents a theoretically based approach aimed at assessing the foundational principles of GHG emission accounting. By identifying conceptual challenges in existing standards, we propose solutions to facilitate the reconciliation of diverse GHG-accounting types. This research contributes to a comprehensive understanding of current GHG-emission practices, shedding light on the necessary steps to transform GHG accounting into a robust asset for addressing climate change.

The outcomes of this research hold significant implications for policymakers, practitioners, and researchers, offering insights that can inform the development of more coherent and effective GHG accounting standards. Ultimately, this work contributes to advancing our collective understanding of how GHG emissions are accounted for across different objects and lays the groundwork for enhancing the role of GHG accounting in the global effort to combat climate change.

5.04.P-Tu476 Alternative pathway for evaluating the environmental impacts of industrial plants with publicly collected data

Monika Vitvarová[1]*, Eliška Purkarová*[2]*, Aleš Paulu*[3] *and Vladimír Kočí*[3]*, (1)University of Chemistry and Technology Prague (UTC), Czech Republic, (2)Sustainability and Product Ecology Department, University of Chemistry and Technology Prague (UTC), Czech Republic, (3)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic*

Assessment of industrial plants and technologies at the level of only one environmental indicator, such as carbon footprint, can cause an insufficient view and negative environmental impacts at the local level, e.g. increased acidification, eutrophication, a decrease of mineral resources, etc.

It is necessary to update and expand the standard approach for evaluating new low-emission technologies and systems to include other environmental impacts to limit or avoid these negative aspect, thereby limit the potential adverse effect of shifting one environmental problem to another.

The paper will present a structure of designed alternative approaches for evaluating the environmental impacts of industrial plants in the Czech Republic, primarily developed for the public sector. Environmental assessment and indicators are determined using the life cycle assessment method (LCA) with the implementation of the European methodology, PEF 3.1, i.e., Product Environmental Footprint. The PEF 3.1

The developed methodology defines and establishes a set of environmental impact indicators that can be used for a comprehensive and transparent assessment of industrial operations at the level of the source, sector and even regions/the whole of the Czech Republic using data collected today by the public sector for statistical purposes, e.g. IRZ or E-PRTR, the database of the Statistical Office of the Czech Republic etc.

The alternative pathway is built on the structure defined by the European Investment Bank for the evaluation of new projects at the level of the value of the so-called carbon footprint. It expands it by other environmental indicators and the use or treatment of solid waste as alternative secondary raw materials for producing materials or products with the implementation of the so-called industrial symbiosis approaches.

Finally, the paper will show the results of using the proposed approach and environmental indicators to assess selected heavy industrial plants.

5.04.P-Tu477 A systematic review of the life cycle assessment of clothing

Toshiro Semba[1,2]*, Ryuzo Furukawa Dr*[3] *and Itsubo Norihiro Dr*[4]*, (1)National Institute of Technology, Tokyo College, Japan, (2)Tokyo City University, Japan, (3)Graduate School of Environmental and Information Studies, Tokyo City University, Japan, (4)Waseda University, Japan*

According to McKinsey & Company (2020), the fashion industry emitted about 2.1 billion tons of GHG in 2018, and there is an urgent need to address this issue. In addition, global clothing sales nearly doubled from 50 billion to 100 billion items from 2000 to 2015 due to the growth of the world population and the growing middle class; by 2050, it is estimated to be more than three times the current level. In addition, the exit disposal phase has all kinds of environmental impacts, with 73% of used garments going to landfill or incinerated at the exit of the global garment material flow, according to the Ellen MacArthur Foundation (2017). In this study, we surveyed the literature and attempted to identify representative clothing and their environmental impacts from fiber materials in the processes of spinning, fabric manufacturing, dyeing, and sewing. As a result, for cotton fiber, many data were reported up to cotton cultivation. However, it was found that there are only a limited number of reports that include the process of separating the cotton fiber from the seeds, known as ginning, after cultivation. GHG emissions per kg of cotton fiber ranged from 1.33-4.43 kg-CO_2e, with Cotton Inc.'s 1.33 kg-CO_2e being the most frequently cited. As reported by Prabod Munasinghe et al. (2021) and Baydar et al. (2015), the environmental impact of the wet process, including the dyeing process, was found to account for a high proportion of the cloting manufacturing life cycle. For jeans, a typical garment, we found that the report by Levi's is often cited and treated as a standard. Among those surveyed in this study, the range varied from 5.53-68.5 kg-CO2e per pair of jeans manufactured. Factors contributing to this included the use of utilities and steam in factories, and the country and method of manufacture.

5.04.P-Tu478 How Does Global Palm Oil Consumption Impact Indonesia's Biodiversity and Ecosystem Services?

*Shuntian Wang and **Stephan Pfister**, ETH Zurich, Switzerland*

Indonesia's economy heavily depends on palm oil production but faces significant environmental challenges, particularly regarding biodiversity and ecosystem service degradation. This study aims to analyze the tele-connected impacts of global palm oil consumption on Indonesia's biodiversity and ecosystem services through a sub-national landscape-scale analysis. We will first integrate the latest satellite remotely sensed earth observation datasets (e.g., high-resolution maps of oil palm plantations) with state-of-the-art landscape-scale biodiversity and ecosystem service models for impact assessment. Then, we will calculate the impacts of oil palm cultivation per unit area/unit production at the district scale. The above two steps will allow us to identify specific and overlapping environmental hotspots of oil palm cultivation with high spatial explicitness and, therefore, address the so-called double materiality of the oil palm industry (dependence and impacts on nature). Finally, we will link district-scale export supply chains with country-scale multi-regional input-output (MRIO) tables to track the tele-connected impacts from cultivation to consumption. Preliminary results show a direct link between global palm oil demand and the degradation of biodiversity, carbon sequestration, water purification, and intact forest landscapes in Indonesia. Our detailed results aim to provide policymakers and stakeholders with a thorough understanding of these interlinked impacts, which will be essential for developing strategies to mitigate the environmental impacts of palm oil production. This, in turn, can influence local and international policy decisions towards more sustainable consumption patterns. Furthermore, the presented approach can be extended to assess other commodities and sectors with high spatial details.

5.04.P-Tu479 Impact assessment of relocating and improving the recycling of scrap metal from end-of-life vehicles and waste electrical and electronic equipment in Wallonia, using the life cycle assessment tool.

***Thibaut Lavis**[1], Yvonne Kaye Perocillo[2] and Angelique Leonard[3], (1)Chemical Engineering, University of Liège , Liège, Belgium, (2)University of Liege - Chemical Engineering, Belgium, (3)University of Liège, Belgium*

In response to the rising production of vehicles and waste electrical and electronic equipment (WEEE) amid decreasing resource availability, the Wallonia region in Belgium has initiated "Reverse Metallurgy +" projects. These projects focus on circular economy practices (metal, battery, and mineral reuse, upscaling, and recycling) and low-carbon industry development to meet CO_2 emission reduction targets in metallurgy and construction.

Key challenges include relocating metal scrap treatment to Europe for a sustainable local recycling industry and enhancing recycling processes for high-purity, high-value metal streams. The aim is to optimize metallic material recycling for more circular metal production in Europe, assessed using the Life Cycle Assessment (LCA) tool.

Several projects from “Reverse Metallurgy +” are part of this approach for circularity in the metal supply chain. These include “CISTEMEEC” (in the field of light electric mobility with Li-ion, copper and rare-earth batteries); “ECWALI” (for high-purity sorting of aluminum alloys and stainless steels); “PYROTECNIC” (development of a pyrometallurgy industry and intelligent packaging techniques for the circular economy) and “REMADE” (valorizing recycled metals in very high value-added products by developing various production and utilization channels for metal powders, in particular for additive manufacturing).

In the “CISTEEMIC” and “ECWALI” projects, the aim is to estimate the impacts of a Belgium recycling site which uses innovative technologies and to compare these values with those in the literature in order to conclude on the various benefits. Once this recycling process has been estimated, it will then be possible to estimate the benefits of additive manufacturing in the “ECWALI” project.

There are no results yet, as we are still in the data-gathering phase. The impact of metal recycling, based on the literature, should be calculated by the time of the conference. The comparison with the impacts of the projects mentioned will depend on the availability of company data, which is also linked to their ability to isolate metal flows during recycling and production.

Ultimately, these projects seek to estimate the benefits of high-quality metal recycling in Europe, aiding companies in strategic decision-making for technology development to address climate emergencies and market demands.

5.04.P-Tu480 Using Life Cycle Assessment (LCA) to foster the renaissance of the European photovoltaic (PV) manufacturing industry

***Sabela Teixeira Taboada**[1] and Angelique Leonard[2], (1)Chemical Engineering, University of Liège, Liège, Belgium, (2)University of Liège, Belgium*

Solar energy has become a key player in the transition towards a cleaner energy system and its deployment is essential to achieve the climate targets set by the Green Deal.

The EU has ambitious plans to promote and accelerate the use of solar energy. At the moment, PV manufacturing industry is mainly retained in China. Diversifying supply chains and delivering more efficient and sustainable products is essential to ensure a secure and successful energy transition in Europe. However, the abrupt drop in prices of PV modules puts under imminent risk the renaissance of the European PV manufacturing industry. To tackle this critical situation, LCA could be a useful tool to show the environmental advantages of pushing for a resilient solar industry in Europe. Also, it can be used to highlight the main challenges that need to be addressed at each phase of the solar panel life.

To support the development of new photovoltaic technologies in Europe, a cradle-to-gate LCA is performed to study the hotspots of a potential mainstream technology: silicon heterojunction tunnel – interdigitated back contact technology and assist the eco-design phase. Hereafter, it will be extended to a cradle-to-grave LCA, to analyze the impacts during the use phase and the end-of-life. Different background scenarios are considered to compare the impact of importing Chinese panels with EU manufactured ones.

To perform the described analysis, Product Environmental Footprint Category Rules (PEFCR) for PV electricity are followed, and the E.F 3.1 impact assessment method is used. Primary data for the SHJ-IBC is collected from technology manufacturers and secondary data is mainly obtained from the inventories of the International Energy Agency. Ecoinvent 3.9.1 is used as database and the modellings are done in the software Simapro.

Results will show to what extent emerging PV technologies present an environmental advantage compare to imported modules. Also, the analysis of how the manufacturing location and technical characteristics make a difference to reduce the environmental footprint could make a shift to stop focusing only on the economic dimension and put more weight on sustainability aspects.

Ultimately, on this critical moment when European solar industry is at risk of disappearing, LCA can be used as decision-making tool to transform solar module panels "made in Europe" into a real sustainable technology that can lead the energy transition towards a cleaner and dematerialized society.

5.04.P-Tu481 Improving the Availability of High-Quality Environmental Impact Data for Key Food Items Through HESTIA

Matthew Anderson-Barker[1] *and Michael Cummins*[2]*, (1)The Waste and Resources Action Programme (WRAP), United Kingdom, (2)Defra, United Kingdom*

The availability of high-quality, granular, comparable, and representative environmental impact data for food items provides a number of important opportunities. However, many existing databases fall short on at least one of these requirements. We have been working to improve the data in this area with a focus on UK-consumed food. The work has involved: improving the quality of data available for high-impact food commodities; understanding the impacts of multi-ingredient food items and how their variability is distributed; and enhancing a model of the UK food and drink sector GHG footprint. The aim of the work is to build a comprehensive understanding of how UK consumption impacts the environment, how those impacts vary, and how uncertainty affects their variability, with implications for eco-labelling.

To obtain consistent, comparable data for on-farm impacts, the HESTIA platform was used to upload, recalculate, and store activity data from farm surveys and LCA studies. To analyse multi-ingredient food item impacts, information was obtained through the foodDB database, and then linked to the UK's National Diet and Nutrition Survey and to HESTIA data. Variability of impacts was analysed through Monte Carlo simulations. The outputs have been used within WRAP's GHG model of the UK food system to provide a holistic understanding of the impact of the production and consumption of food and drinks.

Our results show the power of using consistent data infrastructure to recalculate impact estimates in an automated way. It has the potential to transform the food data system, enabling transparency and comparability of data to aid decision-making. Monte Carlo analysis coupled with such data can help policy makers understand requirements for on-pack environmental impact information, and provide hotspot analysis to focus businesses' efforts most impactfully.

We plant to further develop this work by: embracing large datasets to accelerate HESTIA's data coverage; supporting integration of HESTIA infrastructure in businesses; scrutinising existing eco-label methodologies; and providing recommendations for how eco-labels can be developed with integrity. This is an opportunity to improve the availability of high-quality, granular, and representative data for food system transformation. Future partnerships between us, industry and academia can help make food LCA data available in a consistent and transparent manner to substantially reduce environmental impacts.

5.04.P-Tu482 Methodological Framework for Life Cycle Assessment of Hydrogen Production Technology via Non-Thermal-Plasma Methane Cracking

Isabella Bulfaro[1]*, Gabriela Benveniste*[2]*, Beatriz Amante*[3] *and Victor Ferreira*[2]*, (1)Energy System Analitics, Polytechnic University of Catalonia, Barcelona, Spain, (2)Fundacio Institut Recerca Energia Catalunya, Spain, (3)ENMA (Environmental Engineering), Universitat Politècnica de Catalunya (UPC), Spain*

Hydrogen (H_2) will play a key role in the economy sustainability challenge and energy transition.
In this frame Coldspark is a European project exploring the production of H_2 via non-thermal-plasma (NTP) methane cracking, which technology represents an innovative solution to produce high-pure H_2 and solid carbon at low temperatures and ambient pressure without the use of any catalyst and with no direct carbon dioxide (CO_2) emission.
The environmental sustainability evaluation of the technologies through the life cycle assessment (LCA) methodology represents a crucial step in early projects to help the researchers in selecting the most optimal technical solution. Therefore, a preliminary LCA of the process is a fundamental tool to assist the researcher in the process development and assure the technology alignment with the environmental sustainability criteria.
The LCA methodology supported by the ISO 1404/44:2006, involves a comprehensive evaluation of the potential environmental impacts of the product system through the life cycle stages, its development in the European context is represented by the ILCD handbook and by the definition of the European Environmental Footprint method (EF). Despite this guidance, the existing LCA studies in the H_2 sector have incorporated various methodological choices that significantly impact their findings and integrations. In this vein, different harmonization efforts were made through the development of more specific guidelines, such as the LCA protocol for fuel cell and H_2 energy systems elaborated by FC-Hy Guide. Additionally, specific greenhouse gas emission (GHG) calculation methodologies are defined and in development respectively for the renewable and low carbon H_2 classification in the European legislation frame. In this research the authors focused on the Hydrogen LCA methodological framework identifying common methodological aspects which will constitute the basement of the NTP methane cracking LCA model. The selected LCA parameters according to the unified recommendations and the technology specifics are: 1) Functional unit: 1 kg H_2 and 1 MJ H_2; 2) System boundaries: complete life cycle of H_2, covering production to disposal while excluding the use phase; 3) Multifunctional approach: system expansion.

5.04.P-Tu483 PEF-wise methodology for bio-based fertilisers: A first normative proposal, critical analysis, and further perspectives

Jorge Senan-Salinas Dr.[1]*, Karetta Timonen*[2]*, Pasi Korkalo*[2]*, Carlos Alberto Torres Guerrero*[3]*, Nancy Peña*[1]*, Joan Colon*[1]*, Hannele Heusala*[2] *and Daniel Egas*[1]*, (1)University of Vic-Central University of Catalonia, BETA Technological Center, Spain, (2)Natural Resources Institute Finland (Luke), Finland, (3)University of Vic - Central University of Catalonia (UVic-UCC), Spain*
Bio-based fertilisers (BBFs) promotion is a key element in the Farm-to-fork strategy and European Green Deal to reduce the dependency on mineral fertilisers. Mechanisms to promote the most environmentally effective products will maximise environmental benefits and prevent rebound effects. Life Cycle Assessment (LCA) is the most suitable tool. Nonetheless, one of the main criticisms is the divergent methodological decisions that hinder its reliability and comparability. The European Commission has developed the Product Environmental Footprint (PEF) initiative which aims to create a harmonised LCA method for products and provide a common way of measuring different sectors and products through the Product Category Rules (PCR). This work presents the first proposal for a PEF-wise PCR of BBFs. For its development, a review of the scientific literature, standards and guidances was done. Then, the methodologies were adapted to the PEF framework. Moreover, other normative frameworks, such as Environmental Product Declarations and specific PCRs were consulted. When developing a PCR, decisions are needed on the definition of the Functional Unit (FU), reference flow, system boundaries, allocation methods, and further specification of the use of the Circular Footprint Formula. This first proposal assumes that BBFs and fertilisers are intermediate products of agricultural systems and are embedded in other supply chains. Therefore, to propose a PEF-wise PCR from the raw material/biomass collection to the distribution of BBF at the biorefinery gate (Cradle-to-Gate). The application stage shall be included in other products' PCRs. Due to major differences in the nutrient content of the BFFs and their fertilization efficiency, no common FU could be derived. Thus, only the reference flow of the BBF (i.e., 1 kg) shall be given. However, this approach is acknowledged to be limited to the final aim of PEF which is the comparability of fertilizer products and guiding decision-making. Therefore, it is proposed to use complementary FUs and extend system boundaries to include the application stage as additional environmental information (as defined in PEF). Nonetheless, there are technical limitations, such as the variability of the application stage and agronomic performance indicators. Finally, a critical assessment of this normative adaptation reveals some constraints of the PEF framework in creating a suitable and useful mechanism for the emerging sector of the BBFs.

5.04.P-Tu484 Life cycle assessment framework for evaluating the environmental performance of refractories in the steel industry: the choice of magnesia-carbon bricks for steel ladle lining as a case study

Md Jubayed[1]*, Rinus Siebring*[2] *and Angélique Léonard*[3]*, (1)University of Liège, Belgium, (2)Ceramics Research Centre, Tata Steel, Netherlands, (3)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium*
Refractories are materials that can withstand at very high temperatures and are essential for any high-temperature operations across various industries. With no surprise, the iron and steel industry is the largest end user of refractories, with around 70% of the total market share. Few life cycle assessment (LCA) studies were found in the literature mainly focusing on the production of refractories or refractory raw materials, ignoring their use and end-of-life scenarios. Inconsistency in system boundaries, lack of data, multifunctionality, and uncertainty were identified as major challenges in conducting LCA, comparing different studies, and communicating LCA results with stakeholders. Therefore, methodological guidelines are necessary to address these challenges and communicate LCA results for decision support. In this study, a comprehensive LCA framework is proposed to assess the environmental impact of refractories within the steel industry and the utilization of magnesia-carbon (MC) bricks in the steel ladle lining is specifically examined as a case study. The investigation involves a cradle-to-grave LCA on MC bricks sourced from three alternative suppliers situated in China and Europe. Allocation and

system expansion approaches are applied to deal with co-products and account the benefits of recycling. Inventory data associated with the use phase and end-of-life management of refractories were collected from Tata Steel Netherlands. However, it was not possible to compile refractory production data from suppliers due to confidentiality constraints as inventory data often equivalent to their product recipe. Innovative techniques are developed to retrieve crucial inventory data from product data sheets received from suppliers. Preliminary cradle-to-gate LCA results highlight electricity as a major environmental hotspot, prompting the exploration of different scenarios, including variations in the electricity source. Acknowledging the inherent uncertainty in inventory data, Monte Carlo simulations are planned to be implemented at the inventory level to illustrate the distribution of LCA results. Furthermore, sensitivity analysis will be conducted to test the influences of significant uncertain parameters on results. The primary objective of this study is to provide a comprehensive LCA framework for refractories to enhance methodological practices and communicate LCA results for decision support in the steel industry when choosing refractories.

5.04.P-Tu485 Comparative Life Cycle Assessment of Combined Ethylene and Acetic Acid Production by Oxidative Dehydrogenation of Ethane

***Carolin Meier**[1], Desislava Tota[2], Martin Schubert[2], Sebastian Rehfeldt[1] and Harald Klein[1], (1)Technical University of Munich (TUM), Germany, (2)Linde GmbH*

Steam cracking is a central process in the petrochemical industry for the production of olefins such as ethylene and propylene. In this process, hydrocarbons are thermally cracked into short-chain hydrocarbons at high temperatures and short residence times with the addition of steam. Despite process optimization, the steam cracking process is not climate-friendly due to high process-related greenhouse gas emissions, especially from underfired reactor heating to achieve high process temperatures.

An alternative process is the oxidative dehydrogenation of ethane (ODHE). This is a catalytic, exothermic process that allows direct dehydrogenation of ethane with the addition of oxygen. The process is carried out at much lower temperatures and does not require underfired reactor heating. This can save a large amount of direct CO2 emissions in the production of ethylene. Another by-product of the catalytic reaction and an additional value product of the overall process is acetic acid. Linde GmbH developed a commercial-scale process based on the ODHE, the EDHOX™ process.

In the context of this work, the potential of the novel process for the ODHE to avoid climate-relevant emissions in the production of basic chemicals will be investigated in a comparative life cycle assessment (LCA).

The EDHOX™ process is compared to a conventional steam cracking process for the production of ethylene. To solve the multifunctionality problem of the EDHOX™ process, the steam cracking process is extended by means of system expansion with a conventional production process for acetic acid. In addition, further potentials are being investigated for making both the EDHOX™ process and the existing processes more sustainable, for example through energy integration or successive electrification of subprocesses. Thus, future decarbonization strategies in chemical industrial processes are investigated and included in the comparative LCA.

5.04.P-Tu486 Challenges and Insights in the LCA of Perovskite PV at Low TRL

***Afzal khan Peerukhan**, Angelique Leonard and Sylvie Groslambert, University of Liège, Belgium*

The European Union has positioned itself at the forefront of the global effort to transition from fossil fuels to renewable energy sources and curb greenhouse gas emissions, with a specific focus on achieving climate targets by 2030. Notably, the photovoltaic market for electricity generation has witnessed substantial growth in recent years, driven by the imperative to address climate change.

Perovskite photovoltaics (PV) has emerged as a notable subject of interest among researchers in the photovoltaics field. In laboratory settings, perovskite PV exhibits distinct advantages, including reduced thickness, cost-effectiveness in production, and higher efficiency compared to other photovoltaic technologies. Researchers assert that the efficiency of Perovskite PV can reach up to 25%, with stability demonstrated over several thousand hours. The lightweight nature of perovskite PV has opened up diverse applications in aerospace, automotive, and other industries.

Recognizing the environmental implications of this technology, conducting a life cycle assessment (LCA) is imperative. Unlike many previous LCA studies that focused on specific stages like production or end-of-life, this study aims to conduct a comprehensive attributional LCA of perovskite PV, covering its entire life cycle from cradle to grave. Key obstacles hindering the extensive adoption of this study involve issues with data quality, inadequate inventory data, absence of a dedicated LCA methodology, and significant scale-up issues.

In this LCA study, Primary data have been gathered from project partners, supplemented by secondary data from Ecoinvent v3.9.1. The LCA study is done according to the ISO 14040/44 standards and also followed by PEFCR and International Energy Agency(IEA) Guidelines and harmonized with other PV projects across Europe to ensure methodological rigor. Additionally, sensitivity and uncertainty analyses are incorporated to assess the reliability of the data and address uncertainties. This final study contributes in understanding how the Perovskite PV impact varies in different environmental impact categories throughout their life cycle.

5.04.P-Tu487 Environmental assessment of producing fossil and bio-based polyurethane foams: a review

*Raquel Silva[1], Ana Barros-Timmons[2] and **Paula Quinteiro**[3], (1)Department of Chemistry, aCICECO, Aveiro Institue of Materials and Department of Chemistry, Portugal, (2)University of Aveiro, Portugal, (3)CESAM, University of Aveiro, Portugal*

The global polyurethane (PU) market projections indicate growth will continue up to 27.61 million tons in 2026. Their environmental impact is a matter of significant concern as so far, the production of PUF is essentially dependent on fossil materials, namely isocyanates and polyols. European Green Deal aimed at reducing greenhouse gas (GHG) emissions and decoupling economic growth from resource use, therefore, urgent action is needed to find alternative raw materials and optimize manufacturing processes. In line with that, the use of renewable polyols is already a reality in the PUF industry, namely vegetable oils, recycled polyols, and CO_2-based polyols. However, this only contributes in part to the total polyol used in some formulations in various industrial-scale applications. Even though there are other potential renewable polyol counterparts such as lignin, as well as alternative synthetic routes to produce PUF including variations of the so-called via Non-Isocyanate Polyurethane (NIPU), there are still several limitations compared to the conventional manufacturing processes involving petroleum-derived raw materials. For that reason, most of these alternatives are not yet available. Furthermore, the possible benefits of these potentially greener alternatives need to be compared with the environmental performance of well-established conventional processes. Yet, only a few life cycle assessment (LCA) studies exist on PUF. Moreover, a comparison of impact results between different LCA studies is only possible whether the methodological choices and assumptions of each study are equivalent.

This review work presents the results from a systematic literature analysis regarding LCA studies on PUF produced using a variety of raw materials, classified as four different feedstocks in this work. This timely work identifies the main trends in methodological choices, including functional unit, system boundaries, multifunctionality, impact assessment methods, and sensitivity analysis, and enables the understanding of their effect on the environmental sustainability of PUF, namely in the most evaluated impact category- the climate change (CC). A wide range of CC variation was observed, ranging from 2.95 $kgCO_2eq/FU$ for a fossil-based to 7.67 $kgCO_2eq/FU$ for a recovered fossil polyol. The main issues for this high variability are addressed, highlighting the need for further harmonization and consistency in data collection and methodological choices used in LCA studies.

5.04.P-Tu488 Environmental impacts of alternative dross utilization from primary and secondary aluminium production

*David Nováček[1], Monika Vitvarová[2], Umay Cinarli[3], Ahmet Turan[3], Ilyada Ozbag[3], Frantisek Pticen[2], **Kamila Milnerova**[2], Onuralp Yucel[4] and Selcuk Kan[4], (1)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic, (2)University of Chemistry and Technology Prague (UTC), Czech Republic, (3)Yeditepe University, Turkey, (4)Istanbul Technical University (ITU), Turkey*

Dross in context of the aluminium production is a mixture of both metallic and non-metallic materials which forms mainly due to the rapid oxidisation of molten aluminium upon contact with air. The loss of aluminium and the formation of aluminium oxide is unwanted from both economic and technological perspective. The formation of dross has also significant environmental impact and wrongly attended dross poses substantial threat to surrounding biosphere. Around 5 million tons of aluminium dross is produced yearly. Despite noticeable progress over past decades in both the minimalization of the dross production as well as the further utilization, significant amounts of mainly black dross are still being deposited.

The goal of the presentation is to identify and assess of potential environmental impacts or benefits of novel pathways and improvements of dross utilization developed in ABTOMAT project. In addition, the effects of the implementation of the proposed solutions on the environmental footprint of aluminum will be analyzed.

Environmental impacts and indicators are evaluated using the Life cycle Assessment (LCA) approach based on Product Environmental Footprint (PEF 3.1) methodology. The analyses is focused primarily on the operation phase. The evaluation is performed by Expert for LCA software with specific databases (Sphera – 2023, Ecoinvent 3.9, ILCD, EF).

5.04.P-Tu489 Life Cycle Assessment to Support Bioenergy Integration in Tissue Paper Production

*Ricardo L. Carvalho[1], Cristina N. Marques[2], Raquel A. Bértolo[2], Ana M. Carta[2], Luís M. Machado[2] and **Ana Cláudia Dias**[1], (1)University of Aveiro, Portugal, (2)RAIZ – Forest and Paper Research Institute, Portugal*

The consumption of tissue products such as toilet paper, napkins and kitchen towels is increasing globally, leading to increased environmental impacts. The integration of pulp and tissue paper production in the same industrial site arises as a strategy to decrease these impacts. This integration allows the transfer of slush pulp (in water suspension) to the tissue mill displacing market pulp (dried and sold in bales), avoiding pulp transport and drying. Furthermore, it enables bioenergy transfer from the pulp mill to the tissue mill replacing energy produced from fossil fuels. However, the environmental performance associated with this strategy remains unclear. In this study, life cycle assessment was applied to support decision-making regarding the implementation of bioenergy integration in a typical industrial site in Portugal producing eucalyptus pulp and tissue paper.

Two scenarios differing in the sources of steam and electricity consumed in the tissue mill were analysed. In the scenario without bioenergy integration, steam is produced on-site from natural gas and electricity comes from the national grid. In the scenario with bioenergy integration, steam and 33% of the electricity are produced on-site in the biomass boiler of the pulp mill, and the remaining electricity comes from the national grid. A cradle-to-gate perspective was adopted using primary data based on real operations. The ReCiPe 2016 impact assessment method was applied as default and the Environmental Footprint (EF) method was used in a sensitivity analysis.

The results show that the integration of bioenergy in tissue production leads to a decrease in the environmental impacts of up to 20% with the ReCiPe method except for the categories of marine eutrophication and mineral resource scarcity. Marine eutrophication increases by 22%, whereas mineral resource scarcity remains similar. The application of the EF method results in similar trends, except in the case of marine eutrophication which has similar results in both scenarios.

In conclusion, bioenergy integration in tissue production contributes to a better environmental performance of tissue products, but additional measures are required to achieve improvements on marine eutrophication and mineral resource scarcity. These results are paramount to support decision-making concerning processual changes in the pulp and paper industry and also for authorities in charge of defining environmental policies, incentives and tax regulations.

5.04.P-Tu490 Lowering Laundry and Dishwashing Environmental Impacts in Europe from a LCA perspective
***Jasmin Martinez**, Procter & Gamble, Belgium*
Climate change exerts a significant and far-reaching influence on the global environment, economies and society. It is imperative for all stakeholders, including manufacturers and consumers, to proactively engage in understanding and mitigating their environmental impact. The findings presented in this study reveal the outcomes of three Life Cycle Assessments carried out by Procter & Gamble in European markets, aligning with ISO standards, to comprehensively evaluate the environmental footprints of laundry, automatic dishwashing, and hand dishwashing detergents. The primary goals were to pinpoint key impact areas and compare prevailing consumer practices with more sustainable product usage.

Across the three product categories, the use phase emerged as the most significant contributor to the carbon footprint, constituting 60% for laundry detergents, 73% for automatic dishwasher detergents, and 90% for hand dishwashing detergents. Moreover, the use phase dominated in various other impact categories, including water scarcity, fine particulate matter, and fossil resource scarcity. This dominance is intricately tied to the energy required for heating water during the washing process, influenced by the energy composition of each country- be it fossil fuels, renewable sources, or nuclear power. As a consequence, the carbon footprint varied across different markets, with lower emissions observed in nations boasting a higher proportion of nuclear energy (e.g., France) or renewable energy (e.g., Sweden). Nevertheless, future scenarios for laundry detergents suggest that, despite the anticipated greening of the electricity grid by 2030, the use phase will remain the primary driver of environmental impact for these product.

The scenarios of sustainable product usage underscored that reducing energy consumption by employing lower wash temperatures in laundry and hand dishwashing or adopting energy-efficient short cycles in dishwashers, holds the most significant potential for carbon footprint reduction (16% for laundry, 60% for hand dishwash, and 33% for automatic dishwash). These study results emphasize the necessity for a holistic approach in evaluating the environmental impact of detergent products and guiding informed actions and business decisions. This involves considering various aspects, including sourcing, formulations, packaging, and promoting sustainable usage through product innovation and consumer education to foster environmentally conscious habits.

5.04.P-Tu491 What Are We Missing in the Climate Crisis? A New Role for Healthcare Systems
***Walter Cristiano**[1], Chiara De Marchi[2], Kevin di Domenico[1], Ornella Punzo[1], Aurora Mancini[3] and Laura Mancini[1], (1)Environment and Health, Italian National Institute of Health, Italy, (2)Public Health and Infectious Diseaes, La Sapienza University of Rome, Italy, (3)Law, Roma Tre University, Italy*
Healthcare systems (HSs) play a crucial role in providing support and care to populations worldwide, yet they demand a considerable amount of energy to fulfill their responsibilities. Specifically, HSs directly contribute to global warming and environmental footprint, accounting for up to 5% of global net carbon emissions. This impact can be classified into three scopes based on the source type: scope 1 emissions originate directly from healthcare facilities and vehicles, scope 2 emissions result from purchased energy sources, and scope 3 emissions encompass all other indirect emissions triggered by the healthcare supply chain. This evidence highlights a paradox where HSs while maintaining their role in health protection, may increase risks to collective health. In this scenario, health prevention is at risk of failure, and achieving the zero-carbon dioxide (CO_2) emissions targets set by the Paris Agreement in 2015 by 2050 seems unlikely without limiting the impact of HSs, alongside other industries, on climate change. This study aims to reconsider the role of HSs and propose a shift during health prevention. We conducted a rapid scoping review, searching all PubMed databases and selecting only peer-reviewed quantitative studies that delve into direct and indirect CO_2 emissions attributed to HSs. To date, the available data is limited, though a slight increase in recent years offers some hope. Most emissions appear to stem from the supply chain on which HSs rely to perform their tasks. In addition, the analysis of the impacts that HSs have on the carbon footprint varies among countries. Less economically developed countries are underrepresented, and even in economically developed countries, most studies come from English-speaking countries. Our literature search underscores the need for a more concerted effort in investigating healthcare sector emissions. Furthermore, given the global nature of the issue, shared guidelines should be implemented among

HSs of different countries to collectively reduce emissions and reorganize procedures for less impactful actions while maintaining high-quality care. As healthcare sector professionals, we advocate for promoting more sustainable ways of working and emphasize that health workers and policymakers cannot ignore the inherent environmental implications of HSs activity concerning climate change and related health issues.

5.04.P-Tu492 Which LCA methodology for hydrogen-based policies?

Alessandro Arrigoni[1]*, Francesco Dolci*[1]*, Marco Buffi*[2]*, Oliver Hurtig*[2] *and Romain Besseau*[3]*, (1)Joint Research Centre (JRC) - European Commission, Netherlands, (2)European Commission - Joint Research Center (JRC), (3)Mines ParisTech, France*

EU policies rely more and more on life cycle assessments for the green transition. For instance, the carbon border adjustment mechanism (CBAM) will rely on LCAs to determine the taxation for goods entering the EU market. Another example is the renewable energy directive, which provides an LCA methodology to determine whether a fuel can be considered renewable or low-carbon. Hydrogen is interested by both policies, since it can be a renewable or low-carbon fuel, and it will be traded under the CBAM rules. Depending on the LCA methodology, the carbon footprint of hydrogen can vary significantly. For instance, depending on the multifunctionality approach adopted the carbon footprint of hydrogen produced via chlor-alkali electrolysis can be as low as 1 kg CO2e/kg H2 or as high as 11 kg CO2e/kg H2. This could create inefficiencies and market distortions. Another potential source of discrepancies is the way the carbon intensity of the electricity input for hydrogen production is determined: e.g., if the additionality criterion is considered when renewable electricity is used, or if the production- or consumption-based mix are considered when electricity is sourced from the grid.

Our work explores how the carbon footprint of hydrogen can vary depending on the approaches adopted in the LCA methodologies used by the EU policies. The goal is to understand which approaches should be adopted in LCA-based policies to maximise their objectives: i.e., to foster the green transition and minimize the environmental impact generated by the hydrogen consumed in the EU. Preliminary results suggest that potential consequences outside the boundary of the system investigated should be included in the methodology to avoid unintended outcomes. For instance, if the additionality principle is not included in the LCA methodology, hydrogen produced from non-additional renewable hydrogen could not lead to a net reduction of the overall emissions. This because the renewable electricity would be simply taken away from an existing user. The same applies to the consumption vs production mix: a consumption-based mix should be considered to actually reflect the carbon intensity of the electricity consumed for the hydrogen production. Overall, more research is needed to understand the best approaches to adopt in LCA methodologies for policy purposes.

5.04.P-Tu493 Consequential LCA of the mineral fertiliser consumption patterns in Europe for policy making.

Jorge Senan-Salinas Dr.[1]*, Massimo Pizzol*[2]*, Laia Llenas*[3]*, Serena Molina*[4] *and Junkal Landaburu-Aguirre*[4]*, (1)University of Vic-Central University of Catalonia, BETA Technological Center, Spain, (2)Department of Sustainability and Planning, Aalborg University, Denmark, (3)BETA Technological Center, University of Vic-Central University of Catalonia (UVic-UCC), Spain, (4)IMDEA Water Institute, Spain*

Fertilisers have guaranteed food security and human demographic growth in the last decades. Nonetheless, agriculture systems have been pointed out as one of the most relevant in the alteration of the nitrogen (N) and phosphorous (P) cycles promoting several environmental threats for humanity such as climate change and water body eutrophication. The European Union has deployed a range of policies such as the Farm-to-Fork strategy and the European Green Deal to mitigate their use by at least 20%. To assess the environmental changes in the demand, consequential life cycle assessment has been pointed out as one of the most suitable tools. However, current databases use consumption average mixes and do not resolve properly the multifunctionality of compound fertilisers. On the contrary, consequential LCA uses marginal suppliers' mixes. That means the identification of the technologies or products that could be affected by a change in demand. In this case, the identification of the fertilisers that could be affected by the reduction of N, P and K demand.

This analysis aims to assess the environmental performance of mineral fertiliser consumption patterns in Europe and the consequences of the potential changes in the as consequence of the policy mechanisms. For that purpose, in this study, different algorithms and linear models have been applied to the database of consumption patterns of the International Fertiliser Association. To improve the robustness of the results a sensitivity analysis has been done considering the time-series length. As a result, the marginal mixes of the 3 nutrients (NPK) sectors were obtained. The inventories included the whole life cycle of the mineral fertilisers. For that, the identified inventories of the marginal mixes were coupled with the different emissions factors to model fertiliser-induced impacts in the application. These factors include the NH3 volatilisation factors from the EEA, the direct and indirect production of N20 from the IPCC as well as other factors for the leakage to groundwater. The inventories were modelled with Brightway 2.5 and Ecoinvent database 3.9 and uncertainty was included. The results allowed the ranking of countries where the political measures can have more rebound impacts on the environment in fossil and mineral resource depletion, climate change, and eutrophication categories as well as correlation with national economic statistics.

5.04.P-Tu494 The impact of implementing strategies in the upstream supply chain on the environmental footprint of a pharmaceutical

Amelie Verlinden[1]*, Lieselot Boone*[1]*, Wouter De Soete*[2] *and Jo Dewulf*[3]*, (1)Ghent University (UGent), Belgium, (2)Janssen Pharmaceutica NV, Belgium, (3)Green Chemistry and Technology, Ghent University (UGent), Belgium*

Greenhouse gas emissions from pharmaceutical production contribute significantly (e.g., 20 % in England) to the total healthcare emissions. As pharmaceutical supply chains are complex systems many activities that contribute to the environmental impact of pharmaceuticals are outside the direct control of the company and are therefore scope 3 emissions. Hence, it is important to manage these activities to reduce the environmental impact. In this study, the life cycle stages and parameters contributing to the carbon footprint of a pharmaceutical are identified. Additionally, the benefits of implementing environmentally friendly strategies in the upstream supply chain of the pharmaceutical are analyzed. To determine the environmental impact, a life cycle assessment was performed in accordance with the ISO 14044 standard. The IPCC GWP 100 method is used to determine the carbon footprint of the drug product, expressing the impact per blister pack (60 x 500 mg tablets). A cradle-to-grave analysis was executed, considering all life cycle stages from raw material extraction up to end-of-life. To analyze different supply chain strategies, scenarios were developed in which both the solvent procurement strategy and the electricity mix were altered and compared with the reference (current situation). Considering the impact of one blister pack, it appeared that the production of the active pharmaceutical ingredient (API) had the highest contribution (94 %) to the carbon footprint. Zooming in on this production, results show that the highest share of impact can be assigned to the production of the intermediates of the API and to the solvents used in the further production of the API. Comparing the reference with a worst-case scenario, i.e., assuming electricity sources and solvents with a high carbon footprint (due to origin) used for the intermediates and API production, resulted in an increase of carbon footprint with 32 %. However, implementing a best-case solvent procurement strategy and green electricity mix resulted in a decrease of the carbon footprint with 16 %. Therefore, it could be concluded that implementing a best-case solvent procurement with solvents originating from production processes or countries that result in a lower carbon footprint of the solvent and the implementation of a green electricity mix in the production of intermediates (upstream supply chain) and APIs could significantly reduce the total carbon footprint of a pharmaceutical.

5.04.P-Tu495 Organizational climate impact accounting – moving from blame distribution to towards accounting for action

Timen M. Boeve[1]*, Søren Løkke*[2] *and Jannick Schmidt*[1]*, (1)Aalborg University, Denmark, (2)Department of Sustainability and Planning, Aalborg University, Aalborg, Denmark*

In order to reach the Paris Agreements climate target, urgent reductions of GHG emissions are needed. Therefore, there is no time for suboptimized reduction initiatives, and a need for evidence-based decision support. This paper explores how consequential LCA can provide this evidence-based decision support to organizations in order to make decisions that matter. The paper proposes a shift from traditional climate accounting to climate *impact* accounting, in order to quantify the potential impacts of decisions and assess the system wide impacts of a potential decisions, avoiding burden shifting and suboptimal reduction initiatives. Aalborg University is used as case study for this approach, and climate impact accounts from 2018 to 2022 have been developed. The study will investigate how decision makers at AAU understand and utilise the results from traditional guidelines and the new approach presented in this paper. The paper proposes potential improvements to more traditional accounting guidelines such as the Green House Gas Protocol and compares the climate impact accounts with traditional climate accounts based on the GHG-P. An example of an improvement proposed, is how to account for buildings, as traditionally the construction is only accounted for in the first year and maintenance and operations are accounted for in all remaining years. This traditional approach has two downsides, first it means that a building would be climate neutral if no maintenance or operations are conducted for a given year, secondly it disregards the impact of occupying said building. When an organization utilises its buildings they are removed from the market for buildings, which results in the construction of new buildings for other expanding organizations, whereas if an organization reduces their building mass, they release new building to the marked, in turn displaces the construction of new buildings of the same type. This new proposed approach of impact accounting presents a new challenge, namely that the results and methods need to be clearly communicated to the relevant decision makers, so that they understand on which premises their decision are based. This issue is addressed through transparency both in how the emission intensities are calculated and a short but comprehensible description of how to interpret what these intensities represents.

5.04.P-Tu496 ECOSCORE for Vehicles Procurement in Belgium: an Update in the Methodology to Integrate Life Cycle Assessment Approach

Lea D'amore[1]*, Maeva Lavigne Philippot*[1]*, Maarten Messagie*[1] *and Tobias Denys*[2]*, (1)ETEC Department, Vrije Universiteit Brussel (VUB), Belgium, (2)VITO/EnergyVille, Belgium*

In Belgium, a tool called Ecoscore has been developed to help both for a more environmentally friendly procurement from consumers' side and for policy making. Ecoscore rates the environmental performance of vehicles based on a well-to-wheel approach. An Ecoscore between 0 and 100 is attributed to every vehicle. The closer to 100, the more environmentally friendly the vehicle is. All cars from the Belgian fleet have an Ecoscore. The current methodology was created in 2006 when most of the fleet were thermal passenger cars and only a few electric vehicles existed. Hence the choice for a well-to-wheel approach was sufficient to answer the goal of the score to rank the different cars of the Belgium fleet based on environmental performances. Currently, with the electrification of the fleet, the score methodology needs to be improved. This update is discussed with a steering committee composed of different stakeholders: university, research institute and the environmental agency per region of Belgium.

This study presents the challenges and work done to adapt the methodology of a tool that is used for consumers' procurement and policy making. Several alternative scores were assessed through different criteria such as ease of interpretation, completeness of impacts and differentiation of EVs (comparison between the score of a small city car and a large SUV). Some scores kept the same methods but added new life cycle stages inventories (i.e., battery production, glider production). Then, other scores were considering all life cycle stages with a change in the methodology (i.e., ReCiPe 2016 or Environmental Footprint (EF) 3.1). The preferred method was EF 3.1 as it is the one preconized by the European Commission.

However, one main issue arises with the proposed methodology of using EF3.1. The main strength of Ecoscore is indeed that the database for exhaust emissions comes from homologation tests. It means that only for certain pollutants for the damage categories of EF3.1, the exact measures for every car in Belgium are available. For this reason, it has been decided to adapt the EF 3.1 method to only emissions included already in Ecoscore and their impacts on the corresponding damage category from EF 3.1.

Therefore, the new score is based on an adapted EF3.1 methodology. Further research will consist of validating the new method. The representativity and relevance of it will be assessed, especially regarding the effect of normalization and weighting choice.

5.04.P-Tu497 Improving the robustness of freshwater ecotoxicity impact assessment of cosmetic products in life cycle assessment: summary and illustration of the work conducted by the EcoBeautyScore Consortium

Florence Bohnes[1], Alessio Aufoujal[2], Laurent Gilbert[3], Mathilde Kolenda[2], Monica Lam[4], Sacha Laruelle[5], ***Jacques L'Haridon, PhD***[3]*, Olena Onyshchenko[6], Jennifer K. Saxe[7], Pascal Seel[8], Harald Streicher[9] and Jad Zoghaib[3], (1)Unilever R&D Colworth, United Kingdom, (2)Quantis, France, (3)L'Oreal Research & Innovation, France, (4)Procter & Gamble, (5)LVMH Recherche Parfums & Cosmétiques, France, (6)Henkel AG & Co. KGaA, Germany, (7)KENVUE, (8)Environmental Strategy & Human Rights, Beiersdorf, Germany, (9)Beiersdorf, Germany*

Life Cycle Assessment (LCA) has been recognized by the European Commission (EC) as the most effective method to assess the overall environmental footprint of products and services. The EC initiated the Product Environmental Footprint (PEF) project in 2013 to harmonize application of LCA for the determination of environmental footprints of products on the European market. The PEF guidance is considered today as the reference measurement system in Europe regarding environmental footprint assessment of consumer products.

The EcoBeautyScore (EBS) Consortium, grouping more than 70 companies or professional associations of the cosmetic industry at worldwide scale, was launched in 2021 to develop a common environmental footprint measurement and scoring system for cosmetics, based on LCA and aligned with the PEF method, enabling communication to allow consumers to make more environmentally informed purchasing choices. However, Consortium members acknowledge that the PEF as a reference method is not fully workable for the Beauty sector, improvements being needed for cosmetics regarding methodology. One of the key topics subject to adjustments from PEF in the EBS method is the impact assessment method for freshwater ecotoxicity.

The PEF method prescribes the use of the USEtox© 2.1 model adapted by the Joint Research Center (EC) for freshwater ecotoxicity impact. There is a consensus within the EBS Consortium on some limitations of this adapted USEtox model for freshwater ecotoxicity and the corresponding characterization factors (CF) (as part of the EF 3.1 method package) needed to generate robust environmental scores of cosmetics suitable for the main objective of the Consortium, *i.e.* meaningful differentiation between products. The actions achieved within the EBS Consortium to tackle these limitations and improve the robustness of the freshwater ecotoxicity CF will be presented along with practical cases showing their relevance for application to cosmetics. A particular focus will be placed on: (1) the alternative method proposed to calculate the Effect Factor of CF based on the Most Sensitive Species approach, considered as more robust than the Species Sensitivity Distribution approach for cosmetic ingredients having a small number of ecotoxicity data on different aquatic species, (2) updated CF using more recent ecotoxicity data and (3) replacement of inconsistent CF of the EF method package with improved ones.

5.04.P-Tu498 Will digital memory technologies decrease their environmental impacts? The memristor’s environmental footprint

Angela Lao Zea[1]*, José Carlos Pérez Martínez[2], Juan Bautista Roldán[3], Antonio Urbina[4] and Lucía Serrano Luján[5], (1)Department of Computer Science, King Juan Carlos University, Spain, (2)Department of Applied Mathematics, Materials Science and Engineering and Electronic Technology, Universidad Rey Juan Carlos, (3)Department of Electronics and Computer Technologies, Universidad de Granada, Spain, (4)Department of Sciences, Universidad Pública de Navarra, (5)Department of Computer Science, Universidad Rey Juan Carlos*

The use of digital technologies is a daily practice in human lives. According to one of the latest reports of the International Energy Agency, data centers and data transmission networks are responsible for 1% of energy-related GHG emissions. The Waste Electrical and Electronic Equipment European Directive regulates the end-of-life of the devices and obliges companies and public institutions to treat, reuse, recover and recycle electrical and electronic devices. The European Commission identified servers and data centers as environmentally concerning fields, and compiled standards that estimate their energy consumption.

The next generation of digital non-volatile memory devices, memristors, has a strong position to replace current technologies in the future due to their scaling potential, similar retention times, lower power consumption and faster latency. In this study, we show the results of applying Life Cycle Assessment (LCA, complying with standards ISO14040 and 14044) to three different memristor technologies, i.e., halide perovskite memristors (Ps-M), TiO_2-based memristors (Ti-M) and hafnium-oxide-based memristors (Hf-M).

The report shows their cumulative energy demand and ReCiPe methodology results for several impact categories per memristor area and functional unit (FU). FU consist of a combination of their figure of merits, i.e., area and energy required for a device (memristor) capable of storing 1 bit, considering a switching time of 1.5 x 10^{-4} seconds per storage cycle and per second. The main conclusions are: 1) Electricity and direct emissions during manufacturing are the primary factors driving life-cycle impacts. 2) Regarding Ps-M, the gold layer and the photolithography process have the most significant impact. 3)Ti-M has a more straightforward manufacturing process, and its most significant impact is observed in the semiconductor layer. 4) Hafnium-oxide memristors are the ones with the lowest environmental impact and promising features. 5) Ps-M and Ti-M memristors are produced at a laboratory scale and still exhibit low retention times to be competitive in the market. 6) More retention times and cycles would be required to compete with Hf-M ones.

5.04.P-Tu499 Life Cycle Assessment applied to novel solar modules' encapsulants

Angela Lao Zea[1]*, Antonio Urbina*[2] *and Lucía Serrano Luján*[3]*, (1)Department of Computer Science, King Juan Carlos University, Spain, (2)Department of Sciences, Universidad Pública de Navarra, (3)Department of Computer Science, Universidad Rey Juan Carlos*

The assembly of photovoltaic (PV) modules requires a significant amount of materials, with the cover glass contributing considerably to the environmental impacts and to the overall economic cost. The currently prevailing cover material for PV modules is 3-mm-thick glass, representing 10% to 25% of the total cost. It is essential to enhance the mechanical properties of glass for PV modules to achieve a thickness reduction below 3mm. This decrease will directly influence the total weight of PV modules, which typically range from 20-25kg for a standard module. Glass accounts for approximately 75% of the weight in a framed crystalline silicon module and exceeds 95% in a frameless thin film module. Reducing weight is crucial for facilitating the transportation, installation, and decommissioning of PV modules. Therefore, there is a need to reduce the thickness of the glass cover while simultaneously improving the service lifespans and efficiencies of PV modules.

The strength and toughness of flat glass are primarily influenced by surface properties rather than the bulk characteristics of the glass. Reducing thickness is accomplished through reinforcing and incorporating flexibility in the glass. There are three fundamental approaches to enhancing glass's toughness and fracture energy. These basic strategies include thermal or relaxational toughening, chemical (ion-exchange) toughening, and intrinsic toughening.

Adding of ions is crucial for glass's mechanical and optical enhancement for PV applications. Using iron oxides incorporated into the glass for UV filtering functions unavoidably results in absorption in the visible (Fe^{3+}) and near-infrared bands (Fe^{2+}). In contrast, outcomes with bismuth (Bi_2O_3) show promise, demonstrating effective UV filtering capabilities while maintaining the glass free from absorption in both UV and IR bands. The production cost is two to six times higher than conventional thermally toughened glass.

The report presents an application of the Life Cycle Assessment methodology to determine if strengthening Soda-Lime-Silica (SLS) glass through Na^+/K^+ ion exchange, and to include Bi_2O_3 for a more efficient UV filtering and durability is worthwhile from economic and environmental perspectives. Although this process is more expensive, it could be beneficial in the long run as the glass becomes more resistant, potentially lasting longer over time and exhibiting improved efficiencies by enhancing its optical properties.

5.04.P-Tu500 Environmental Impact of Municipal Wastewater Management System Based on Life Cycle Assessment (LCA) in Indonesia

Teguh Adhitia Suyadi[1]*, Ryuzo Furukawa Dr*[2]*, Kentaro Hayashi Dr*[3]*, Itsubo Norihiro Dr*[4]*, Takashi Onodera Dr*[5]*, Kazuya Nishina Dr*[5] *and Shinsuke Kyoi Dr*[3]*, (1)Tokyo City University, Japan, (2)Graduate School of Environmental and Information Studies, Tokyo City University, Japan, (3)Research Institute for Humanity and Nature, Japan, (4)Waseda University, Japan, (5)National Institute for Environmental Studies (NIES), Japan*

Water quality in an area has an important implication on human and environmental health. Urbanization and lack of proper municipal wastewater treatment coverage has left the water condition in Jakarta, Indonesia in a heavily polluted condition. Proper municipal wastewater treatment, so called Centralized Wastewater Treatment Plant (WWTP), has a low treatment capacity coverage in Jakarta. Based on the data from UNICEF in 2017, only around 7% of domestic wastewater in Indonesia that has been treated with proper method [1]. Septic Tank is the most often used municipal wastewater treatment, installed personally by each household. Wastewater leakage from the septic tank is a common issue due to the lack of maintenance. Water pollution is getting worse since open defecation or direct discharge activity is still happening although at the low percentage. Based on the information from the World Bank in 2022, still there are around 4% population in Indonesia that is still practicing open defecation [2]. Environmental impact assessment for each municipal wastewater treatment: Centralized WWTP, Septic Tank, and Open Defecation (direct discharge) should be carried out in Jakarta. The result of the environmental impact assessment can be used as the basis for policy making in terms of municipal wastewater management in Jakarta. In this study, the evaluation is conducted for three types of municipal wastewater treatment method: Centralized WWTP, Septic Tank, and Direct Discharge. The simulation was carried-out with SimaPro using the ReCiPe2016 model. Greenhouses Gasses (GHG) was chosen as the impact category to be analyzed with since it gave the significance environmental impact in terms of municipal wastewater management.

5.04.P-Tu501 Systematically Assessing Environmental Impacts of Pharmaceutical Products – Lessons Learned

Lowik Pieters[1]*, Martijn van Bodegraven*[1]*, Susanne Waaijers-van der Loop*[1] *and Rosalie van Zelm*[1,2]*, (1)Centre for Sustainability, Environment and Health, National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Radboud University Nijmegen, Netherlands*

During the life cycle stages of healthcare processes and products, many emissions and resource extractions occur that can have negative health and environmental effects. If one person is cured today, at the expense of making other people sick tomorrow, healthcare becomes counter-productive. Safe and sustainable pharmaceuticals can contribute to a healthy healthcare system. To understand the environmental consequences of pharmaceuticals, Life Cycle Assessments (LCAs) can provide valuable input. However, it is not clear to what extent these studies are complete (i.e. covering all life cycle stages and important environmental impacts), representative for global pharmaceutical production and consumption, and accurate for impact prediction, accounting or monitoring.

Therefore, the goal of this work is to review scientifically published LCAs of pharmaceutical products, to come to recommendations for complete, representative, reliable, and accurate application of LCA to pharmaceutical products. We do this by presenting the current state of the science of LCAs of pharmaceutical products whereby methodological choices, knowledge gaps and challenges are identified. We conclude with recommending solutions on how to deal with challenges, strengths and limitations in pharmaceutical LCAs.

LCAs of 143 pharmaceutical products with a known active pharmaceutical ingredient (API) and 6 with an unknown API have been retrieved during literature screening. The LCAs on pharmaceutical products showed varying scopes, approaches and data quality. This limits comparisons and applications in broader environmental sustainability assessments.

Common inconsistencies in performing LCAs for pharmaceutical products are missing life cycle stages, unspecified inventories, a limited life cycle impact assessment, due to missing impact categories or characterization factors, and missing interpretation steps. To allow for complete and representative LCAs, comprehensive functional unit and system boundaries are needed. Transparent life cycle inventories lead to greater reliability, while complete impact assessments and interpretation contribute to representativeness of the LCA study. This presentation will show how identified solutions can be put into practice to aid decision-making.

5.04.P-Tu502 Environmental Impact Assessment of Paint Production and its Distribution

Elisa Jazmin Arteaga Prieto*, KU Leuven, Belgium*

Current societal pressure to have sustainable resource use and products reaches every economic sector. In the chemical sector, paint industries are not an exception. In past years, these industries changed their production processes and primary inputs to have non-toxic, safe products with an special focus on reduction of volatile organic compounds as concerns on human health raised. Concerns have extended to environmental aspects, making industries invest on innovation aiming to produce paints with lower carbon footprint, less resource use and biocompatibility. Achieving these aims requires deep understanding of how materials and processes across the value chain generate impact. In previous assessments of paint environmental impact, aspects included were: production of primary materials, their transportation to production plan, and production of paint, including aggregation of raw materials and packaging process. This assessment provides an insight on the most environmentally impactful decisions, focused on primary materials, leaving transportation and packaging aside due to their lower impact in comparison. Nevertheless, this assessment lacks the inclusion of stages once the product leaves the production plant. Aspects to be considered are the impact arising from paint that is discarded before reaching to the consumer (around 20% of paint produced), and the impact produced by the paint which reaches the consumer but is not fully used and spoils in houses (around 10% of paint produced). This discarded paint contaminates water and affects ecosystems. During this study we propose to extend the LCA to the entire supply chain, with the aim of finding the impact of waste paint and therefore propose suitable strategies to avoid this spoilage. Currently, discussions about biocides are in place, given that they can extend the lifespan of paints and prevent spoilage, but there is concern about their possible effects on biodiversity and health. Therefore, one scenario is created to investigate how the inclusion of biocides contribute to avoiding waste paint and if a trade-off is created between lifespan extension and effects on biodiversity. Additionally, the inclusion of a circular business model is investigated due to their potential to reduce waste. The findings will provide information for decision makers in companies and policy, so that they can push for right strategies in this sector and contribute to the decrease of gas and water emissions due to paint use.

5.04.P-Tu503 Life cycle analysis for Environmental impact assessment of cavitation assisted valorization of keratin waste

Vikram Chatake[1]*, Aniruddha B Pandit*[2] *and Dr. Chandrakant Ramnath Holkar*[3]*, (1)Chemical Engineering, Institute of Chemical Technology (UICT), India, (2)Chemical Engineering, Institute of Chemical Technology, India, (3)Biological Sciences and Biotechnology, Institute of Chemical Technology (UICT), India*

In recent years, Acoustic cavitation and hydrodynamic assisted processes are the prominent techniques used for process intensification in various industries such as textile, pharmaceuticals, polymer, food, agricultural and petroleum. In various studies, researchers have reported the reduction of energy consumption due to cavitation assisted processes (CAP) compared to conventional processes (CP) indicating that CAP could be considered as a “sustainable” alternative. However, the environmental impacts of these processes have not been compared. Indeed, till now very few studies have reported results to indicate the effective reduction of environmental impacts of CAP, generally considered as green, in comparison to CP. Thus, it needs to be evaluated at early development stages through environmental assessment tool i.e. life cycle assessment (LCA). Performing LCA will provide a better understanding of factors with environmental impact associated with both CAP and CP at early development stages. The aim of this work is to elucidate the potential of cavitation for reducing environmental impact associated with the cavitation assisted valorization of keratin waste and its comparison with the conventional processes. For this purpose, a gate-to gate LCA analysis is carried for the processes without and with cavitation. Different categories of environmental impact considered in the current study includes greenhouse effect, eutrophication, acidification, ozone layer depletion, ecotoxicity and human health. The results of the current study will enable the quantification of potential environmental impacts of CAP and hence their sustainability before they can be industrially up-scaled.

5.04.P-Tu504 Environmental impact of alternative red mud utilization for metal extraction

Monika Vitvarová[1]*, David Nováček*[2]*, Camila Barreneche*[3]*, Adela Svobodova*[4]*, Shareq Nazir*[5]*, Pedro Souza*[5]*, Vladimír Kočí*[2]*, Arif Karaca*[6] *and Sergei Preis*[7]*, (1)University of Chemistry and Technology Prague (UTC), Czech Republic, (2)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic, (3)Diopma, Universitat de Barcelona, Spain, (4)Public University of Navarre, Spain, (5)KTH Royal Institute of Technology, Sweden, (6)ETI Aluminyum, Turkey, (7)Laboratory of Environmental Technology, Tallinn University of Technology, Estonia*

Red mud is the alkalic suspension waste of red to brown colour created during the primary aluminium production process. With the typical pH range about 10 to 13, red mud is considered hazardous waste and high amounts of acids are needed for the neutralization process. The suspension contains particles of size lower than 10 micrometres which resolves in extremely low sedimentation rate and long-time deposition in specially designed sedimentation reservoirs. The particle size poses also a significant problem for further processing. Per 1 ton of primary aluminium there is 1.6 to 3.7 tons of red mud produced. In 2020 worldwide production of red mud was about 175 megatons. Fe_2O_3, SiO_2 and Al_2O_3 are representing most of the weight of red mud. CaO, TiO_2 and Na_2O also usually accounts for significant weight percentage.

While several solutions to the red mud treatment were introduced in laboratory scale none of them has been adopted by the aluminium industry. The main reason being the unfavourable economics of invented processes. ABTOMAT project aims to extract Fe from red mud through the gasification process and to extract REEs, Sc, Ti, Fe, V and alkali metals from the after gasification red mud residue. The red mud samples from the ETI Aluminium plant in Seydişehir, Türkey were used in this study as input materials. The XRD analysis of input red mud identified around 30% of the weight as Hematite (Fe_2O_3) and more less the same percentage as Quartz (SiO_2), around 15% of weight as Calcite ($CaCO_3$) and similar content of Alumina (Al_2O_3).

This paper is focused on the life-cycle assessment of the red mud utilization for extraction of valuable metals and environmental impacts of experiments with red mud utilization involved in ABTOMAT project. Environmental assessment and indicators are determined using the life cycle assessment method (LCA) with the implementation of the European methodology, PEF 3.1, i.e., Product Environmental Footprint. The PEF 3.1

The goal of the study is assessment of environmental impacts of current situation of red mud management and calculating the impacts with implementation of the utilization using gasification. By using modelling software and data calculations we identified crucial processes and flows. We established potential added value of the new utilization in the treatment of aluminium red mud and were able to compare it with present situation as base level.

5.04.P-Tu505 Human toxicity emissions produced by copper supply chain: A comparison between different productor countries

María-Pilar Martínez-Hernando*, Sofía Mares Rueda, David Bolonio, María Jesús García Martínez and Marcelo Ortega, Energy and Fuels, Universidad Politécnica de Madrid, Spain*

Copper stands as a pivotal metal in modern industry due to its electrical and thermal properties, ranking third in global metal utilization. Key sectors relying on copper include construction and equipment manufacturing, accounting for more than half of worldwide copper consumption. Meeting the global copper demand primarily depends on deposits concentrated in Latin America, notably in Chile and Peru, totaling 271 million tons by 2023. As global copper production continues to rise, driven by population growth and the economic advancement of previously industrializing nations, the study's objectives are to assess countries deeply involved in copper activities and to comprehend the global copper flow. Additionally, the study aims to compare countries to identify the one with the most significant impact on human toxicity in copper production. The methodology employed for Life Cycle Assessment (LCA) relies on input-output matrices, an economic tool measuring the impact of changes in demand for goods and services. This matrix serves not only as an economic tool but also finds application in life cycle analysis. The chosen methodology, "Environmentally-Extended Multi-Regional Input-Output Analysis (EEMRIO)," allows for a comprehensive study of the origin of impacts. According to United States Geological Survey (USGS) data, Chile leads in copper mining production, while China dominates copper metallurgy. Analyzing human toxicity emissions from major producers in each region (Chile in South America, the United States in North America, Poland and Spain in Europe, Congo in Africa, China in Asia, and Australia in Oceania), the results indicate that China has the highest impacts on human toxicity in both mining and metallurgy. Spain, in contrast, boasts the lowest emissions in mining, while for metallurgy, Congo has the lowest cancer emissions, and Poland has the lowest non-cancer emissions.

5.04.PC LCA in Policy, Decision-Making and Communication to Support the Transition Towards Sustainable Consumption

5.05.A Life Cycle Impact Assessment – Advances in Modelling and Application

5.05.A.T-01 Biodiversity Impact Assessment for the Financial Sector: Guiding Investments and Policies

*Viktoras Kulionis[1], **Stephan Pfister**[2] and Jeanne Fernandez[3], (1)Pictet Asset Management, (2)ETH Zurich, Switzerland, (3)Pictet Group*

Biodiversity loss, driven by human activities, significantly affects the environment, human societies, and economies. This study examines the role of financial institutions in addressing these challenges. Using the Environmentally-Extended Multi-Regional Input-Output Assessment (EEMRIO) and LCA techniques, we offer insights into how these methodologies can be used to inform financial decisions related to biodiversity focusing on three key aspects: biodiversity impacts, ecosystem service dependency, and net impact. Our method combines spatially explicit characterization factors from LC-impact with the GLORIA database to estimate biodiversity impacts. As a case study we assess the biodiversity impact of the MSCI ACWI stock index which consist of about 3000 large and mid-sized companies, from 23 Developed and 24 Emerging countries. The results demonstrate most of the biodiversity impact is caused in the Americas, followed by Asia, despite its low representation in the index's country weight (6%). Europe shows the least impact. These results emphasize the need to account for global supply chain linkages as products sold in one country might have significant biodiversity impacts elsewhere due to sourcing of production inputs. Secondly our results identify the main determinants of the index's impact: land use, followed by water stress and climate change. Although a majority of the impact is localized in few sectors, the distinct characteristics of these sectors require industry-specific mitigation approaches. We also analyse dependencies on ecosystem services by coupling ENCORE data with GLORIA in order to analyse double materiality. The combined analysis shows both, the influence companies have on biodiversity and the reciprocal effects. Companies neglecting these impacts risk financial setbacks, making it a crucial concern for investors and policy makers.

5.05.A.T-02 Linking freshwater ecotoxicity to species loss in life cycle impact assessment

***Susan Oginah**[1], Leo Posthuma[2,3], Jaap Slootweg[2], Michael Hauschild[1] and Peter Fantke[1], (1)Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Department of Environmental Science, Radboud University Nijmegen, Netherlands*

Linking predicted ecotoxicity impacts to damage on ecosystem quality as an area of protection in life cycle assessment (LCA) involves using a severity factor that converts 'affected' into 'disappeared' fractions of exposed species. A relationship of 1:1 has been reported between predicted effects (msPAF: multi-substance Potentially Affected Fraction of species) and observed impacts (PDF: Potentially Disappeared Fraction of species) calculated from acute EC50 effect concentrations. However, the recent adoption of a 20% effect threshold for use in LCA ecotoxicity characterization requires a PAF-to-PDF linkage at the $HC20_{EC10}$ level (HC20: hazard concentration at which 20% of species are affected above their chronic EC10 effect concentration). To address this gap, we introduce a systematic approach that consists of a stepwise procedure to calculate mixture toxicity pressure (msPAF) at the level of chronic EC10 equivalents (msPAF-EC10eq), to evaluate non-collinearity with other abiotic factors and to characterize the observed "lost fraction" of species at 20% msPAF change. Our approach is used to derive data-driven severity factors for LCA at $HC20_{EC10}$ as a 'working point'. We started from an extensive Netherlands freshwater (bio-)monitoring data set and first calculated msPAF-EC10eq of ambient mixtures for all sites. Second, we established low variance inflation factors between toxic pressure and six other abiotic factors, suggesting that we can derive the PAF-to-PDF link with no or limited bias. Third, we visualized raw invertebrates' data patterns for biodiversity metrics. Fourth, we established PAF-to-PDF relationships through stepwise evaluation, binning msPAF data into 10 groups, excluding opportunistic species, calculating Observed Disappeared Fraction (ODF) of species and delta msPAF between groups, taking group 1 (i.e., 'pristine' water) as reference, and finally using a generalized additive model to predict the PDF at a 20% change in msPAF. Results show varied mixture toxic pressure (0 to 0.75) across sites, independent of other abiotic factors. The GAM model shows that a 20% change in msPAF-EC10 covaries, with 19% of initially-present species disappearing. Thus, we determined a consistent extrapolation factor of a near 1:1 relationship between predicted effects and actual damage required for different decision-support tools, such as LCA.

Keywords: mixture toxic pressure; species loss; life cycle impact assessment

5.05.A.T-03 Towards a Unified Spatial Framework to Quantify Biodiversity Effects in Life Cycle Impact Assessment

***Sharon Janssen**[1], Koen Kuipers[2], Mark Huijbregts[2] and Rosalie van Zelm[1], (1)Radboud University Nijmegen, Netherlands, (2)Environmental Science, Radboud University Nijmegen, Netherlands*

With the increasing concern about global biodiversity loss due to increasing pressures on the environment, it is crucial to accurately characterize biodiversity effects in Life Cycle Impact Assessment (LCIA). Currently available multi-pressure LCIA methods, including the widely used ReCiPe and LC-IMPACT methodologies, quantify biodiversity loss per pressure-impact pathway independently and at various spatial scales, challenging consistent aggregation of pressure-specific impacts to total biodiversity impacts. Although LC-IMPACT harmonizes pressure-specific biodiversity loss at various (local to regional) spatial scales to a global potentially disappeared fraction of species, no method quantifies combined effects of pressures harmonized to local, regional, and global biodiversity loss.

We propose a consistent framework that quantifies combined effects of various pressures on terrestrial biodiversity loss on the local, regional, and global scale, to be implemented in the ReCiPe methodology. As a first step in the framework, the local biodiversity loss is quantified as the product of the local potentially disappeared fraction of species (LPDF) of the different pressures per grid cell. Subsequently, the LPDF can be scaled to the level of the ecoregion using a multi-pressure species-area relationship. As a third step, the regional PDF (RPDF) values of the different ecoregions are used to calculate the global PDF (GPDF) using endemism richness. At each scale, the biodiversity loss can be disaggregated based on the relative contribution of each pressure to the combined biodiversity loss. Finally, pressure- and scale-specific effect factors are calculated based on the pressure-disaggregated biodiversity loss per scale and the pressure magnitude.

In the presentation, we will show the application of the proposed modelling framework in which the combined effect of both land use and global warming on terrestrial biodiversity are quantified on three spatial levels. Characterization factors will be presented in terms of local, regional and global PDF per area of land use and kg of greenhouse gas emission. Finally, the presented study will highlight the differences in characterization factors between the new proposed method and the method currently used in ReCiPe and other LCIA methods.

5.05.A.T-04 Operational Accounting of two Major Drivers of Marine Biodiversity Loss in Life Cycle Assesment (LCA) of Seafood Products

*Aurore Wermeille, Gregoire Gaillet and **Anne-Claire Asselin**, Sayari, France*

The latest global assessment report of the Intergovernmental Panel for Biodiversity and Ecosystem Services (IPBES) identifies 5 main drivers of biodiversity loss for terrestrial, freshwater, and marine ecosystems. For marine ecosystems, the driver “Direct exploitation of biotic resources” is the largest, followed by “Land- and sea-use change”, “Climate change”, “Pollutions”, and “Invasive alien species”. Up-to-date methods of resource depletion (Hélias et al., 2023) and seabed impact assessment (Woods and Verones, 2019) have not been applied to case studies other than their respective proofs of concept.

We included those two pressures in an operational method, accounting for Resource Depletion and Seabed Impact on ecosystems. We applied it to a business case study, and we identified key parameters and data driving results. Our goal was to determine if it was feasible to include these key drivers of marine biodiversity loss – Direct exploitation and Sea-use change – in the biodiversity impact assessment of seafood products over their value chain and for the three biota (terrestrial, freshwater and marine). A prescriptive framework was also included to collect data and determine their quality.

The method encompasses four drivers of biodiversity loss calculated with LCA. Climate change and pollution were assessed with LC-Impact while direct exploitation and sea-use change were calculated using respectively Hélias et al. (2023) (resource depletion indicator) and Woods and Verones (2019) (seabed impact indicator). Field data provided by companies enabled us to apply it to a practical case study on frozen saithe fished in the North Sea, at landing. Seabed impacts were spatialized based on logbook.

The application of the resource depletion indicator highlighted the great role of bycatch species which, when vulnerable to fishing, may account for the majority of impacts despite low catches. Regarding seabed impact, case study highlighted two main parameters influencing impacts of a fishing métier: i) the trawled area (in m²) and ii) the vulnerability of marine ecoregion. Case study highlighted different orders of magnitude between pressures. Seabed impact indicator is dominant in our case study and more generally should be dominant for fisheries targeting sustainably managed resources with active bottom fishing gears. In the perspective of aggregation of pressures, homogeneity between PDF units must be achieved, through further research.

5.05.B Life Cycle Impact Assessment – Advances in Modelling and Application

5.05.B.T-01 Regionalized Characterization Factors for Microplastics Emissions in the Marine Environment

*Anne-Marie Boulay[1], **Carla Hajjar**[2] and Cecile Sophie Marie Bulle[3], (1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)Chemical Engineering, CIRAIG-Ecole Polytechnique de Montreal, Canada, (3)UQAM, Canada*

Keywords: microplastics, marine environment, life cycle impact assessment, characterization factors, regionalization

Microplastics (1 μm–5mm) concentrations in the marine environment are increasing throughout the years. Consequently, their potential impacts on marine biota are becoming more important. These include, internal and external wounds, false satiation, and even mortality. Therefore, it is important to assess these impacts in the holistic approach of life cycle assessment (LCA).

Previous initiatives have developed characterization factors (CFs) to be implemented in the life cycle impact assessment (LCIA). These initiatives lacked the consideration of various marine sub-compartments, and different fate mechanisms responsible for the distribution of MPs within the sub-compartments. In order to refine fate modelling necessary for the development of CFs, most influencing parameters on the fate of MPs were identified as an initial step. Along with the physical properties of the particles (size, density, shape), environmental and oceanographic variables were proven to be influencing. Therefore, regionalization is important to account for the spatial variability of these factors, which is the aim of the present study. For 8 different polymers of three different shapes and five size classes, a rate **K** matrix [day^{-1}] is developed. Within the matrices, compartment-specific sedimentation rates, for 20 riverine emission points along the global coastline, are quantified using a 3D tracking model (TrackMPD). Other mechanisms are quantified based on equations and models from the literature. Fate factors (FFs) [kg per $k_{emitted}$/d] are then obtained from the **K** matrices. CFs are then obtained by multiplying the FFs with water and sediment exposure-effect factors for micro/nanoplastics potential physical impacts on marine environment. They are expressed in PAF.m^2.year/$kg_{in\ compartment}$ for the LCIA impact category "physical impacts on biota". Using MP input data from polluting rivers into the ocean, site-specific CFs are aggregated to obtain continental CFs. Consequently, continental CFs are aggregated into a global CF to represent the global impacts of MP emissions in the marine environment. These regionalized CFs are an improvement to already existing factors. They take into consideration the physical properties of the particles along with the spatial variability of environmental factors within various marine sub-compartments.

5.05.B.T-02 Spatial assessment of the environmental sustainability impacts of pesticide use across Europe

***Farshad Soheilifard**, Yuyue Zhang and Peter Fantke, Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark*

To get a broader understanding of pesticide impacts on human health and the environment at the regional or country level, data representing pesticide use beyond specific farms are required. A systematic comparison of the environmental impact performance of different pest control options based on actual country-level data and factors to scale between farm-level and country-level data, putting a special emphasis on the direct field-application impacts of pesticides, is currently missing. To address this aspect, we adopted a spatially explicit environmental fate model and integrated it with widely applied life cycle toxicity characterization models. To characterize national-level impacts of pesticide use, actual pesticide use data are combined with physico-chemical substance databases to assess emissions of applied pesticides to crops at different crop growth stages and via different application methods to different environmental media. Resulting emissions are coupled with results from spatial multimedia modeling for environmental fate, using additional physico-chemical substance data, and spatial data for atmospheric, aquatic and terrestrial environments. The results are coupled with information on exposure and effects for humans and ecosystems as implemented in the global scientific consensus model USEtox. Concentration maps and related impacts were determined for Europe. On average, 5 tonnes of pesticides per year were applied per country, with a cumulative mass of 53 tonnes. For glyphosate, we reached high-end steady-state concentrations of 25 mg/m³ in freshwater, while overall highest concentrations were found in agricultural soil, reaching ~100 mg/m³ for several pesticides. Human toxicity impact of considered pesticide use sums up to ~2 million disability-adjusted life years, with France, Italy and Spain as main contributors, and with terbuthylazine, prothioconazole, prosulfocarb, metconazole and metiram contributing jointly to >83% of total human toxicity impacts. Ecotoxicity impact sums up to 80 million species-years lost over the considered land area, again with France, Spain and Italy dominating. Across countries, spriroxamine, pendimethalin and azoxystrobin contribute jointly to ~75% of ecotoxicity impacts, with highest impact in agricultural soil ecosystems. Our findings on the substantial damage from pesticide use show that urgent action is required to replace chemical pesticides with more sustainable alternatives across EU-countries.

5.05.B.T-03 Highly Resolved Life Cycle Impact Assessment of Global Industrial Air Pollution

***Christopher Oberschelp**, Stephan Pfister and Stefanie Hellweg, ETH Zurich, Switzerland*

Health impacts due to particulate matter (PM) air pollution present a major threats to human well-being, but are difficult to capture accurately with life cycle assessment due to their highly regionalized characteristics. Drivers of PM air pollution are a number of criteria air pollutants such a primary fine particulate matter (PM2.5), sulfur dioxide (SO2), nitrogen oxides (NOx) and ammonia (NH3), which are dominantly being emitted from energy-intensive industrial sectors. This study consistently links state-of-the-art regionalized life cycle impact assessment (LCIA) with a broad range of emission measurements for these substances with site-specific technical data, emission models, and atmospheric fate and effect models to quantify health impact reduction potentials at nearly all global fossil power plants, steel mills, oil refineries and cement plants.Thus, emission hotspots and reasons for regional human health can be identified, which allows for targeted policy inteventions. The results highlight the key role of emission abatement at coal-consuming industrial sites, especially in densely populated areas of Asia (Northeastern India, Java in Indonesia, Eastern China) and Western Europe (Germany, Belgium, Netherlands) as well as in the US. One of the global top priorities is the high amoun of SO2 emissions in India, which are caused by lack of flue gas treatment and contribute a particularly high share of local health impacts despite a limited number of emission sites. At the same time, the massive infrastructure and export capacity build-up in China in the recent years is a cause for major regional and global health impacts related to cement-making and steel manufacturing and thus requires more stringent regulation than in the rest of the world due to unfavorable environmental conditions and high population densities. The level of detial in this study shows how highly resolved LCIA methods and emission inventories can be combined to provide very specific reduction suggestions for environmental impacts. Furthermore, such work can also enhance standard LCA and carbon footprinting by informing the development of background LCI databases and by adding further depth to the analysis of existing studies.

5.05.B.T-04 Incorporating Ecosystem Services in LCIA - Recommendations from GLAM 3

***Tim Grant**[1], Valeria De Laurentiis[2], Rafael Horn Mr[3] and Laura Debarre[4], (1)Life Cycle Strategies Pty. Ltd., Australia, (2)European Commission - Joint Research Centre (JRC), Belgium, (3)Fraunhofer IBP, (4)CIRAIG - Ecole Polytechnique de Montreal, Canada*

Current Life Cycle Assessment (LCA) practice has struggled to include Ecosystem Services (ES) in its life cycle inventory or into impact assessment.

As part of the third Global Life Cycle Impact Assessment Methods (GLAM) project, a task force was established to propose impact methods and endpoints for potential impacts ecosystem services and over the last 3 years the project has developed recommendations and build on existing methods to propose a common endpoint and recommended characterization factors.

After and extensive review six midpoint categories and four endpoint categories have been recommended. The midpoints categories included are Soil Organic Carbon(SOC) deficit, erosion resistance, groundwater regeneration, mechanical filtration, physiochemical filtration and soil salinization.

Endpoints were calculated for 4 of these pathways SOC deficit, erosion resistance, groundwater regeneration, mechanical filtration using economic valuation of ecosystem service loss compared to potential natural vegetation.

The method was normalized against annual global land occupation and transformation and established a total value of ecosystem service damage of $1.7 trillion international dollars which compares to total value of agriculture in the world of approximately 4.4 trillion US dollars. Land occupation accounts for most of this impact with SOC deficit (0.97 Trillion) and ground water regeneration (0.58 Trillion) being the main contributing ecosystem services.

The paper has demonstrated a pathway for including an important group of ecosystem service impacts associated with land occupation and transformation. By finding a common endpoint for 4 of the indicators a practical summary indicator for including in ES impacts in the LCIA framework which is suitable for LCA based on existing data.

5.05.P Life Cycle Impact Assessment – Advances in Modelling and Application

5.05.P-Mo469 Opening the Pandora’s box of Soil Biodiversity in LCA: a First Attempt to Model the Impact of Human Activities on Earthworms

Valeria De Laurentiis[1]*, Alberto Orgiazzi*[2] *and Serenella Sala*[3]*, (1)European Commission - Joint Research Centre (JRC), Belgium, (2)European Dynamics, (3)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy*

Current Life Cycle Impact Assessment (LCIA) methods are still lacking the assessment of the impacts of human activities on soil biodiversity. Recent estimates see soil organisms as the major component of global biodiversity accounting for nearly 60% of the planet’s life (Anthony et al, 2023). For this reason, while evaluating the impacts of human activities on biodiversity, soil ecosystems should not be overlooked anymore. In this context, earthworms may represent a first good proxy for soil biodiversity, especially in relation to human activity impacts, as their sensitiveness to anthropic stressors is well known (Conrado et al., 2023).

The objective of this work is to present a first attempt at filling the identified knowledge gap by developing a life cycle impact assessment model to quantify the impact of land occupation and transformation on earthworms’ diversity, compatible with the nomenclature system of the Environmental Footprint (EF) and aligned with the framework to assess the impacts of land use activities in LCIA established by Koellner et al. (2013). This work will build on progress made over the last years to assess the distribution of soil organisms at global scale.

The model developed will be fully regionalized, and in addition aggregated characterization factors (CFs) will be provided at country level and global level. The calculation of the CFs will be based on a number of global datasets, including maps of earthworm diversity (Phillips et al., 2019), land cover maps, and maps of climate regions and soil types. The developed CFs will be fully operational and compatible with life cycle inventories developed with the EF nomenclature. Examples of their application will be provided.

5.05.P-Mo470 Using Species Sensitvity Distribution to capture ecosystem scale fisheries impacts on biodiversity

Chloe Stanford-Clark[1]*, Eleonore Loiseau*[2]*, Cecile Sophie Marie Bulle*[3] *and* ***Arnaud Helias***[2]*, (1)National Research Institute for Agriculture, Food and Environment (INRAE), France, (2)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (3)UQAM, Canada*

Fishing is one of the main drivers of global marine biodiversity loss. The impact of fishing on ecosystem quality is a newly established impact pathway characterising impacts on individual stocks, but overlooking broader ecosystem-scale damages.

This work enhances impact characterisation by integrating indirect impacts on target and non-target species in the ecosystem. The new approach draws inspiration from the USEtox method of constructing Effect Factors for ecotoxicology impacts, using Species-Sensitivity Distributions (SSD) to fisheries pressure to quantify the ecosystem-scale impacts in a single Characterisation Factor (CF) value per target catch.

FAO regionalised catch data and the dynamic ecosystem model Ecopath with Ecosim model the cause-effect relationship between fishing pressure, trophic interactions and the proportional abundance of each fish stock present. Akin to the effect-concentration curves that determine toxic effects of contaminants, biomass depletion curves reflecting the species-specific responses to increasing fishing pressure are compiled. SSDs per target species are constructed based on a threshold depletion value, to generate ecosystem-scale impact values in Potentially Affected Fraction of species (PAF) units.

The depletion curves are computed relative to a reference state: the carrying capacity of the stock- representing a hypothetical pristine state from which biodiversity loss can be measured. CFs are ultimately derived from the PAF curves per target species, following the USEtox approach but using current catch pressure to establish a “HC50 equivalent” point.

In contrast to contaminant effects, depleting a target species can positively affect other species in the ecosystem by altering predation pressure. Defining a dual threshold analogous to the (single) EC20 in ecotoxicology allows both negative and positive population changes relative to the reference state to be considered within the potentially affected fraction of the population.

To validate this new approach, 41 novel midpoint CFs are computed for Functional Groups in the Adriatic Sea.

The methodology offers significant improvements by accounting for indirect impacts via altered ecosystem dynamics, capturing both over-exploitation and over-expansion of populations resulting from fishing, and using Functional Groups to broaden representation of ecosystem effects, demonstrating a more comprehensive assessment of fishing impacts on biodiversity.

5.05.P-Mo471 Towards a consistent assessment of potential impacts of human activities on the instrumental value of natural systems in life cycle assessment
Laura Debarre[1], *Titouan Greffe*[2], *Cecile Sophie Marie Bulle*[3], *Manuele Margni*[1], *Jérôme Lavoie*[1], *Jana Schluenss*[4] *and Catherine Lalongé*[5], *(1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)Montreal Polytechnic, Montreal, Canada, (3)UQAM, Canada, (4)Institut des sciences de la forêt tempérée, Université du Québec en Outaouais, Canada, (5)CIRAIG, Institute of Environmental Sciences, UQAM, Canada*
The concept of "ecosystem services" (ES) encompasses the “benefits populations derive, directly or indirectly, from ecosystem functions”. Recent ES classifications includes both services offered by living systems and geodiversity.

Integrating ES into policy and decision-making processes is imperative to prevent their erosion. Integration of ES into Life cycle assessment can be done within the impact assessment phase. However, there is no harmonised framework for assessing potential impacts on resources and ES, leading to inconsistent development of characterisation models, partial coverage and/or double counting. This research addresses this challenge and provides a conceptual framework for characterizing the potential impacts of human activities in terms of changes in natural systems’ instrumental value. It builds on the research of the ES community and provides a consistent framework that intertwines resources within ES and clarifies the terminology. The position of impacts on ES in relation to other more common AoP (e.g. Human health and ecosystem quality) is discussed.

A conceptual framework is presented to depict potential impact mechanisms on natural systems' instrumental value. The framework is derived from existing LCIA frameworks and incorporates the cascading nature of ecosystems. Human interventions can induce modifications at various levels of the cascade model. Adaptation and non-adaptation responses lead to two new Areas of Protection (AoP). The *Ecosystems and resources’ services (ERS)* AoP accounts for the potential loss of nature’s instrumental value if deployed adaptation measures are inadequate to balance the loss of service. The *Human assets* AoP accounts for the monetary valuable assets used to avoid a loss of service (adaptation or replacement costs), or due to the loss of valuable socio-economic assets (e.g damage on infrastructures). Insufficient adaptation can induce potential impacts on human health and ecosystem quality. A monetary unit is proposed to quantify damage, adaptation, and replacement costs. However, these scores cannot be summed due discrepancies between monetary valuation methods.

The framework reconciles impact modelling for resources and ES, clarifying terminology, promoting consistency, and guiding future LCIA developments. It emphasizes the complexity of ES and their interconnectedness with other AoP, providing a comprehensive approach for assessing human activities' potential impacts on nature’s instrumental value.

5.05.P-Mo472 Weighting Factors for LCA – A New Set from a Global Survey

*Ayşe Bayazıt Subaşı[1], **Cecilia Askham**[2], Erlend Dancke Sandorf[3], Luis Dias[4], Danny Campbell[5], Itsubo Norihiro Dr[6], Elçin Filiz Taş[1], Christine Betty Nagawa[7], Christine Mugumya Kyarimpa[8], Mamadou Djerma[9], Bazoin Sylvain Raoul Bazie[9,10] and Marco Cinelli, PhD[11], (1)Department of Architecture, Istanbul Technical University (ITU), Turkey, (2)NORSUS AS, Norway, (3)School of Economics and Business, Norwegian University of Life Sciences (NMBU), Norway, (4)University of Coimbra, Portugal, (5)Faculty of Economics, Economic Division of Management School, University of Stirling, United Kingdom, (6)Waseda University, Japan, (7)Department of Forestry, Biodiversity and Tourism, College of Agricultural and Environmental Sciences, Makerere University, Uganda, (8)Department of Chemistry, Faculty of Science, Kyambogo University, Uganda, (9)Sustainable Water and Environment Expertise and Technologies (SWEET), Burkina Faso, (10)Centre Universitaire Polytechnique de Manga/Université Norbert Zongo, Burkina Faso, (11)Decision Engineering for Sustainability and Resilience Laboratory, Leiden University College, Faculty Governance and Global Affairs, Leiden University, Netherlands*

The Weighting subtask of the United Nations Environment Programme (UNEP) Life Cycle Initiative's "Global Guidance for Life Cycle Impact Assessment Indicators and Methods" (GLAM) project work will be presented. This work provides global weights (weighting factors) for the three endpoint impact categories (Areas of Protection, AoPs) human health (HH), ecosystem quality (EQ), and natural resources and ecosystem services.

Methods A Discrete Choice Experiment (DCE) elicited the preferences of respondents through interviews and a web survey. Responses were obtained from a subset of countries pertaining to each income level defined by the World Bank (i.e., low, lower-middle, upper-middle, and high) and used to calculate adimensional (between 0 and 1) weights using two different approaches: econometric and Multiple Criteria Decision Analysis (MCDA). The econometric approach is grounded in random utility theory and its weights are obtained by transforming the estimated preference parameters from a multinomial logit model. The MCDA approach is grounded in deterministic value theory and its weights represent the vectors that best reconstitute the choices of each individual, using linear programming to fit an additive value function.

Results The weights calculated are presented and discussed, including income group population share adjustment of the weights. Recommendations for the use of these weights are also provided, as well as comparison with other existing weights. The econometric and MCDA disaggregation approaches give similar weights. For high income countries EQ has the highest weight; for upper-middle-income countries EQ and HH have the same weights using the econometric approach, while in the MCDA approach HH is weighted higher than ecosystem quality. For the two lower income country groups the priority is given to HH with both approaches. The sets of weights presented in this paper are also related to existing LCA and environmental science and economics frameworks.

Conclusion Weighting is an optional, subjective part of LCA methodology. The weights proposed in this paper can coexist with other weighting proposals; they do not represent an objective truth, but reflect the results obtained from the large scale survey described in this paper. The weights are offered as an option for problem-owners or researchers who wish to use weighting to synthetize their LCA results, but do not have the resources to calculate them through other means.

5.05.P-Mo473 Recommended model for the endpoint assessment of mineral resource use in GLAM3 project

***Masaharu Motoshita**[1], Ryosuke Yokoi[1], Titouan Greffe[2], Olivier Jolliet[3], Rodrigo Alvarenga[4], Antoine Beylot[5], Johannes Drielsma[6], Tom Huppertz[7], Manish Kumar[8], Stephen Northey[9], Mikolaj Owsianiak[10], Amandine Pastor[11], Charlotte Pradinaud[12], Stephan Pfister[13], Rita Schulze[14] and Tim Grant[15], (1)National Institute of Advanced Industrial Science and Technology (AIST), Japan, (2)Montreal Polytechnic, Montreal, Canada, (3)Department of Environmental and Resource Engineering, Quantitative Sustainability Assessment, Technical University of Denmark, Denmark, (4)ERM, (5)French Geological Survey (BRGM), France, (6)Drielsma Resources Europe, (7)RDC Environment, (8)Indian Institute of Science, (9)University of Technology Sydney, Australia, (10)Technical University of Denmark (DTU), Denmark, (11)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (12)INRAE, (13)ETH Zurich, Switzerland, (14)DECHEMA e.V., (15)Life Cycle Strategies Pty. Ltd., Australia*

The GLAM project led by the UNEP Life Cycle Initiative has been dedicated to developing guidance for Life Cycle Impact Assessment models based on international consensus. During the 3rd phase of the project, experts gathered to develop recommendations on LCIA indicators for all AoPs. A taskforce on natural resources (TF) aimed to describe generic impact pathways for natural resource use and recommend an impact assessment model, based again on review of existing models.

The generic framework of impact pathways from the previous study was revised, and a set of 23 models shortlisted for feasible fit with the generic framework. Two of the methods selected for evaluation are LCI methods, which enable classification (JRC-LCI, ARP) and inclusion (JRC-LCI) of some dissipative flows. The shortlisted methods were evaluated using a four-way rating against the following seven criteria, each with their own acceptance threshold based on priority and significance in the scope of GLAM3 project.

For mineral resources use, we updated FWL CFs using latest available market price data together with a measure of market price uncertainty. The FWL model uses the difference between social and market discount rates applied to market prices as a measure of damage to mineral resources. Market price is a most influential parameter of the CFs. While CFs for different natural resources range from 32,960 USD/kg to 0.00180 USD/kg, by comparison the range of uncertainty of the CFs is small. The timeframe of assessment is, however, a most influential parameter of the CFs if it is set to less than 300 years. As for the normalization values derived from multiplying the CFs with the annual production of minerals, the CFs of fossil fuels are smaller than those of metals, but fossil fuels account for 72% of the normalized total due to faster extraction.

Application of the FWL CFs to inventory flows of mineral resources extracted from ground is currently the most practical approach due to the availability of these flows in standard LCI datasets. However, the values of minerals will not be lost when they are extracted but will be lost when they become inaccessible. The TF is also investigating application of FWL CFs to the dissipative mineral resource flows indicated in the generic framework of impact pathways through new classification approaches and adaptation of life cycle inventories.

5.05.P-Mo474 Refining the Modelling Approach for Terrestrial Acidification in Life Cycle Impact Assessment
__Marion Naia Lebrun__[1], Andrew Henderson[2], Francesca Verones[3] and Martin Dorber[1], (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Eastern Research Group, Inc., (3)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway
Terrestrial acidification, driven predominantly by anthropogenic activities, poses a threat to ecosystems by altering soil pH and impacting biodiversity. This study addresses the critical need for an updated modelling framework to generate spatially differentiated characterization factors (CFs) for terrestrial acidification.

The approach, based on the fate-effect framework from Rosenbaum et al. (2007), and more specifically on the work from Roy et al. (2014), quantifies global species richness decline of vascular plants, expressed as Potential Disappeared Fraction species (PDF) per kilogram of acidifying substance emitted.

Fate factors ($FF_{i,j,p}$) account for dispersion, chemical reactions, and transportation of pollutants (NO_x, NH_3, SO_2) from emission to reception, generating source-receptor matrices (Roy et al., 2012b). Sensitivity factors ($SF_{j,p}$) estimate soil pH changes due to a marginal increase in the deposition rate of acidifying substances (Roy et al., 2012a), while effect factors (EF_j) depict regional vascular plant species loss following a pH decline (Gade et al., 2021). Regional CFs, adjusted with Global Extinction Probability weighting, assess biodiversity loss globally (Verones et al., 2022).

Results provide regionalized CFs for 867 ecoregions and 206 countries, expressing the global loss in species richness due to marginal emissions of acidifying entities. Fate factors reflect expected patterns with highest values near emission sources (Roy et al., 2012b). Effect factors vary significantly at ecoregion level, influenced by vegetation types (Gade et al., 2021). As for sensitivity, soil pH responses to additional deposition can be linked to soil composition and local climate conditions.

This comprehensive modeling framework enhances assessments of regional and global impacts, marking an important step towards consistent evaluations of ecosystem quality.

5.05.P-Mo475 Biodiversity Loss by Water Consumption in Global Watersheds: Effects on Riverine Fish Species
__Kamrul Islam__[1], Eleonore Pierrat[2], Yuichi Iwasaki[1], Wataru Naito[3], Francesca Verones[4], Stephan Pfister[5] and Masaharu Motoshita[1], (1)National Institute of Advanced Industrial Science and Technology (AIST), Japan, (2)Envionmental Engineering and Resources, Denmark Technical University, Denmark, (3)Riss, Natil Inst of Advanced Industrial Science and Technology (AIST), Japan, (4)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway, (5)ETH Zurich, Switzerland
Human activities in the Anthropocene have caused a four-fold increase in global water demand, severely impacting freshwater ecosystems, and leading to an 84% decline in the global population of freshwater species. Despite covering only 0.01% of the Earth's surface, freshwater ecosystems host 9.5% of globally recognized animal species. In water ecosystems, persistent threats include flow modifications and alterations in river discharge. About 65% of global river discharge faces moderate to high threats, with a limited focus on biodiversity conservation due to data limitations. Within the context of life cycle assessment (LCA), the evaluation of biodiversity loss and ecosystem quality is a continuous effort. For this purpose, numerous methodologies have been dedicated to addressing factors like land use shifts, climate variations, environmental contamination, and water utilization. Another aspect involves evaluating environmental impacts on freshwater ecosystems due to water consumption, utilizing methods such as habitat simulation for LCA. In this study, the aim is to assess the impact of water consumption on global riverine fish species using characterization factors developed for this purpose in combination with detailed, spatially explicit inventory time series, from 2000 to 2016. The watershed level water consumption data is obtained from the WaterGAP 2.2d hydrological model. The impacts are calculated using both, the weighted average and maximum values of water consumption, to discuss the uncertainty in the results. This investigation seeks to contribute insights into the impacts of human freshwater use on riverine fish species and identify realted hotspots of species loss.

5.05.P-Mo476 Enhancing Local Biodiversity Assessment: Similarities and Differences Among Methods Applied to Agribalyse Datasets
Melissa Cornelus[1,2], Audrey Rimbaud[3], Aurore Wermeille[4], Gregoire Gaillet[4], __Arnaud Helias__[1] and Anne-Claire Asselin[4], (1)ITAP, Univ Montpellier, INRAE, Institut Agro, France, (2)National Research Institute for Agriculture, Food and

Environment (INRAE), France, (3)ADEME, Bioeconomy and Renewable Energies Division, France, (4)Sayari, France
Primary drivers of biodiversity collapse, as identified by the Intergovernmental Platform on Biodiversity and Ecosystem Services, include land-use change, climate change, pollution, natural resource use, and invasive species. This work specifically addresses the "land use change" pressure on biodiversity associated with agriculture. The work addresses one of the REVALIM roadmap priorities. It assesses agriculture's impact on local biodiversity using case studies from the French Agribalyse database. Four methods (HCF (Kuipers et al. 2021), LUIS (Chaudhary and Brooks 2018), BVI (Lindner et al. 2019), BSS BioSyScan) were chosen from a qualitative assessment based on environmental relevance, completeness, transparency, reproducibility, acceptability, and feasibility. They were more thoroughly reviewed, and twenty crop and animal production datasets from conventional or organic agriculture were selected to test them.

The methods exhibit differences in approach, metrics, and specificity. HCF, LUIS and BVI methods are based on a classic LCA framework, and study the (potential) biodiversity variations linked to the product. HCF and LUIS methods rely on species richness, BVI uses the concept of hemerobia on a unit area for a time unit, while BSS determines unitless biodiversity points. Divergence occurs in biodiversity evaluation scales. HCF aligns with GLAM 1, proposing regional or global assessments, while LUIS proposes only a global level. HCF method introduces the Global Extinction Probability, combining species richness, vulnerability, and endemism. Consideration of habitat fragmentation, transformation and land management practices varies among methods. Geographical location proves significant in some methods, with considerable differences depending on the sub-criteria taken into account endemism, species vulnerability, roadless area, ... HCF and LUIS methods are easily applicable to Agribalyse, requiring minimal information, while BVI and BSS pose challenges due to limited agricultural practice data.

The study acknowledges biodiversity's multidimensional nature, highlighting the complexity of capturing it with a single indicator based on current methodological developments. It underlines the need for multiple biodiversity indicators in LCA to comprehensively represent product and supply chain impacts on biodiversity. It also highlights the current lack of inventory data, especially at landscape level (eg. SNH field size, ...), needed for BVI and BSS methods.

5.05.P-Mo477 New Effect Factors for Freshwater Ecotoxicity of Pharmaceuticals

Tolga Ayeri[1]*, Jiaqi Wang, MSc*[2]*, Rosalie van Zelm*[2] *and Ad M. J. Ragas*[3]*, (1)Radboud University Nijmegen, Nijmegen, Netherlands, (2)Radboud University Nijmegen, Netherlands, (3)Environmental Science, Radboud University Nijmegen, Netherlands*
Pharmaceuticals play a crucial role in protecting and improving human health, but their release into the aquatic environment has raised significant concerns. Unfortunately, limited information is available regarding the risks of pharmaceuticals for the environment, mainly due to lacking data on the ecotoxicity of pharmaceuticals.

Life cycle assessment (LCA) is a widely used method to quantify the environmental impacts of products or and services. In LCA, Life Cycle Impact Assessment (LCIA) is the third step that quantifies and assesses the magnitude and importance of the potential environmental impacts of a product system. For this, Characterization Factors (CFs) are used, transforming the life cycle inventory data into environmental impact scores on various impact categories such as freshwater ecotoxicity. The calculation of CFs involves the effect factor (EF), translating ecosystem exposure concentrations into a measure for the potentially affected fraction (PAF) of exposed species. The derivation of EFs depends on the availability of ecotoxicity data, which is limited for pharmaceuticals. As a consequence, CFs have only been derived for less than 150 pharmaceuticals. This study aims to refine the approach to derive EFs for freshwater ecotoxicity of pharmaceuticals by optimizing the use of available ecotoxicity data. The method is illustrated by deriving new EFs for 217 pharmaceuticals, thereby significantly expanding the application domain of LCA for pharmaceuticals.

Our approach uses hazardous concentration HC20 from the species sensitivity distribution curve of chronic No Observed Effect Concentration (NOEC). Three main steps are followed to derive EFs: collecting all NOEC data, constructing the SSD with chronic NOEC and (iii) calculating the EFs. The database includes 217 pharmaceuticals from three sources.

Six of the top ten pharmaceuticals with the highest EFs, indicating the lowest HC20 values, are hormone-based. Among 11 pharmaceuticals with literature EFs, 9 have higher EFs in our approach, consistent with the expectation that chronic NOEC values are lower than EC50 values.

The present study proposes a refined approach to derive effect factors EFs for freshwater ecotoxicity, tailored to pharmaceuticals. New EFs were calculated for 217 pharmaceuticals. This will enable a more comprehensive evaluation of pharmaceuticals in LCA.

5.05.P-Mo478 Are We Overestimating Marine Eutrophication Impacts in LCA? – A Temporal Approach to Assessing Nitrogen Emissions

Montserrat Nunez*, IRTA, Spain*
No research has focused so far in LCA on studying the temporal dynamics of the processes that mediate in marine eutrophication. Temporality is important to predict intra-annual peaks of potential impacts due to use of nitrogen (N) fertilisers

and other N sources and introduce corrective measures in the timing of N emissions accordingly. Here, I show how I included temporality in state-of-the-art characterisation factors (CFs) for marine eutrophication impacts, which I derived at watershed level for the world and per quarterly periods in a year. CFs are for dissolved inorganic nitrogen (DIN) emissions. DIN is the largest fraction of N in rivers, particularly in human dominated watersheds and is also the most readily fraction of N assimilated. The CFs build upon fate factors of the state-of-the-art marine eutrophication model (Cosme et al.). They express the amount of time the fraction of the original DIN emission will be in the coasts each quarter of the year, which is the period within which DIN can be transformed in new algae and lead to biodiversity loss. I modelled three emission pathways: DIN to soil (to characterise emissions from fertiliser application), DIN to freshwater (to characterise any inland emission different than fertiliser application), and DIN to the coast (to characterise emissions to coastal waters). My CFs model the same fate, transport, and retention processes as the current state-of-the-art model plus DIN retention in lakes. Furthermore, I greatly improved the robustness of coastal water residence times and DIN removal in coasts. I achieved this by replacing old data from scattered studies and expert judgment used in Cosme et al. by recent and coherent data drew from a coupled global ocean physical-biogeochemical simulation model at monthly time scale. Results show that annual quarters with higher rainfall and cooler temperatures lead to higher DIN export to the coasts, contributing to higher CFs. At the coast, cooler winter temperatures reduce denitrification rates, leading to higher CFs particularly in lower latitudes. My CFs tend to be lower than those of the most advanced method, meaning that the latter might be overestimating impacts. Further major work is the introduction of airborne emissions and transport pathways from air to coasts. My CFs allow as of now for the integration in decision making of the timing of application of fertilisers and of any other DIN emission source to reduce marine eutrophication impacts.

5.05.P-Mo479 REsource Services Depletion Assessment (RESEDA): a parametrized life cycle impact assessment method of dissipative flows

Titouan Greffe[1]*, Guillaume Majeau-Bettez*[2]*, Manuele Margni*[3] *and Cecile Sophie Marie Bulle*[4]*, (1)CIRAIG, UQAM, Canada, (2)Chemical Engineering, Polytechnique Montreal, Canada, (3)CIRAIG - Ecole Polytechnique de Montreal, Canada, (4)UQAM, Canada*

Abitioc resources provide multiple services (e.g. mobility, conditioned living space) to society through their use in multiples products (e.g. vehicles, buildings). However, there are some problematic losses of abiotic resources that threaten the provision of those services. These are called dissipative flows, which ends in stocks much more difficult to access than the ones they were initially extracted from. We present RESEDA (Resource Services Depletion Assessment), a parametrized life cycle impact assessment model that quantify the additional efforts for society to meet demand of resource services to compensate dissipative flows. Its objective function is to minimize the cost associated with the extraction of resources. One of its constraints is to meet the demand of services such as mobility, worldwide instantaneous communication or conditioned living space. The demand of services can differ from one scenario to another, therefore we run RESEDA for three different scenarios of demand. It regards (i) the Decent Living Standard, (ii) a business-as-usual scenario on the demand side following production pathways towards Net Zero by the International Energy Agency and (iii) Shared Socio-Economic Pathway 2. At each time step, RESEDA derives the flows of resources from extraction to fabrication of materials to in-use stocks and then to recycling. Dissipative flows are computed considering losses occuring at each life cycle stage. For each scenario, RESEDA is run once with dissipation and then without dissipation. The difference between the two resulting cost for society at a given time horizon enables to determine the marginal cost for society due to the dissipation of a kg of resource (e.g. copper, zinc). It integrates the evolution of future demand, substitutability between functionnally equivalent resources, global processing capacity and byproduct production linked to host metals. We developed scenario-based set of characterization factors for 64 abiotic resources. We will present the governing equations of the model as well as the three sets of characterization factors of abiotic resources including both fossils, metals and non-metallic mineral resource such as phosphate.

5.05.P-Mo480 Characterizing Human health Impacts of physical activity in sport and transportation LCAs

Jacob Namovic[1]*,* ***Olivier Jolliet***[2] *and Marko Taino*[3]*, (1)Eastern Research Group, Inc., (2)Department of Environmental and Resource Engineering, Quantitative Sustainability Assessment, Technical University of Denmark, Denmark, (3)Finnish Environment Institute (SYKE), Finland*

Physical activity is an important component to consider within various lifestyle determinant (PA, nutrition) when studying the life cycle environmental and human health impacts of various activities such as transportation or sport activities. However, direct use phase impact are presently not included, thus the need to provide factors characterizing the benefit of such activities per km or per hours of different PA types. This presentation aims to address this need by focusing on the following objectives and using the following approach: 1) develop a framework and common parameterization of available dose-response relationships between relative risks of health outcome incidence and physical activity intensities; 2) map dose-response data disease categories to Global Burden of Disease (GBD) background morbidity and mortality rates; 3) compare weighted average health outcomes of PA according to individual disease; and 4) extend the findings to 825 physical activity categories to obtain the hours of healthy life gained per hour of activity as a function of the activity intensity.

Using a meta-analysis of physical activity dose-response data and harmonized relationships for 22 disease and mortality outcomes, the human health impacts of physical activity were expressed as the product of the physical activity level expressed in marginal metabolic equivalent of task (MET) - and a characterization factors in DALY or hours of healthy life saved per MET-hour of activity. Impacts of physical activity on health is substantial, reaching 7 hours of healthy life gained at 10 MET-h/Week, and up to 10 hours of healthy life gained at 40 MET-h/week.‘Coronary Heart Disease Fatal & Non-Fatal’; ‘Stroke

Fatal & Non-Fatal'; and 'Diabetes Fatal & Non-Fatal' see the greatest reduction in DALY with higher quantities of physical activity weekly. Starting at 7h at 10 MET-h/Week, reaching as high as 10 h at 40 MET-h/week. For transport related LCA, health benefits per km amounts to between 0.1 and 0.4 hour gained per km biked, and to between 0.25 and 1.1 hour of healthy life gained per hour walking or running. These benefits are up to 20 time higher than the absolute value of the life cycle impacts on human health of around 7E-3 hour lost per km driven in a gasoline car. This study confirms the importance to consider the impacts of physical activity when performing the life cycle assessment of sports activities or transportation over limited distances that involve physical activities.

5.05.P-Mo481 Spatially and taxonomically explicit characterisation factors for greenhouse gas emission impacts on biodiversity

Cristina-Maria Iordan[1], *Koen Kuipers*[2], *Francesca Verones*[3], *Bo Huang*[4], *Xiangping Hu*[4] *and Francesco Cherubini*[5], *(1)Climate and Environment, SINTEF Ocean, Trondheim, Norway, (2)Environmental Science, Radboud University Nijmegen, Netherlands, (3)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway, (4)Industrial Ecology, Norwegian University of Science & Technology (NTNU), Norway, (5)Norwegian University of Science & Technology (NTNU), Norway*

In life-cycle impact assessment, currently available characterisation factors (CF) for climate change impacts on biodiversity are highly simplified and do not consider spatial and taxonomic differentiation of species or local climate variability. We develop the first spatially and taxonomically specific CFs for the impacts of 20 GHGs on biodiversity considering 26,648 species across terrestrial and marine ecosystems. Generally, CFs are higher in the tropics, and marine species are affected more severely than terrestrial ones. When global GHG emissions from 2020 are assessed in a scenario with a global temperature rise of 3 °C by 2100, an average of 0.25%, 0.15% and 0.03% of species are negatively affected in 2100 from CO_2, CH_4, and N_2O emissions, respectively, across the globe. The new CFs can be used at different levels of spatial and taxonomic aggregation to quantify co-benefits for biodiversity of climate change mitigation in tools such as life-cycle assessment, input-output analyses, or integrated assessment models.

5.05.P-Mo482 LCA for financial institution's investment and loan portfolio -Biodiversity Damage Assessment Using LIME3-

Nishitani Naoki[1], *Hiroki Ookubo*[1], *Itsubo Norihiro Dr*[2], *Hirokazu Masuoka*[3] *and Shuichiro Kajima*[3], *(1)Tokyo City University, Japan, (2)Waseda University, Japan, (3)The Norinchukin Bank*

In March 2022, the importance of nature conservation was globally recognized, and nature-related financial disclosure was made mandatory; the GBF was agreed at COP15, requiring financial institutions to disclose natural capital and biodiversity risks. In this study, we analyzed the FY2021 portfolio of the The Norinchukin Bank using Japan's LIME3, utilizing EORA to calculate the amount of activity, considering economic spillover effects by country and region. LIME3 is then applied to quantitatively analyze the biodiversity damage assessment. In the portfolio assessment, the amount of activities such as GHG emissions and land use were obtained, and biodiversity damage (EINES) was evaluated. A detailed analysis of the results by country and industry was conducted. The contribution and impact of specific financial institutions is clearly indicated. An assessment of the environmental impact of financial institutions' portfolio data using LIME3 was conducted. In the future, detailed calculation of activity volumes and analysis by industry will be pursued, with the aim of improving the consistency of the methodology and contributing to the formulation of future regulations.

5.05.P-Mo483 A Highly Regionalized Biodiversity Economic Value Database for Life Cycle Impact Assessment

David Font Vivanco, *Eco Intelligent Growth, Spain*

Genetic, species, and ecosystem biodiversity provide critical provisioning, regulating, and cultural services to humanity, yet the planet has lost 58% of its biodiversity since 1970 and it is estimated that up to 30% of existing species will be extinct by 2050 with current consumption and production patterns. To reverse this critical trend, it has been argued that the economic valuation of biodiversity can be fundamental for its sustainable use and conservation. While biodiversity is rather unevenly distributed across the world, existing valuation methods are generally context-specific or offer very poor detail, which can lead to sub-optimal decision-making. To address this challenge, we have developed a novel economic valuation method and a database which retains spatial detail to the extent possible. The method departs from the native potentially disappeared fraction of species (PDF)-based characterization factors by elementary flow provided by the Impact World + 2.0.1 database (IW+), with an up to 0.5 x 0.5 degree grid cell resolution for some impact categories. To assign an inclusive economic value to each of these factors, we use an approach based on the total economic value (TEV) of ecosystem services, which covers both use and non-use values. This approach is based on the Ecosystem Services Valuation Database (ESVD), which contains 9,500 value records, as monetary unit per area, from over 1100 studies distributed across all biomes, ecosystem services and geographic regions. Specifically, it is assumed that the future TEV of a given area for a given biome and region is a function of a given additional impact expressed as PDF. Using the land occupation impact category as an example, eliminating all secondary vegetation from an area of a Tropical and Subtropical Dry Broadleaf Forests biome would decrease the value of such area by 22% according to IW+, and so on for the rest of elementary flows until all its value is lost. To account for the elementary flow carrying capacity of each area (e.g., area of secondary vegetation), various additional sources are used, such as global vegetation maps. Uncertainty is comprehensively considered by accounting for different types of uncertainty, such as alternative TEV-PDF functions (e.g., linear and exponential) and economic valuation methods (e.g., damage cost avoided and restoration cost). This database could help practitioners to adequately value biodiversity impacts during the weighting step.

5.05.P-Mo484 A Landscape-scale Biodiversity Impacts Analysis of Côte d'Ivoire's Cocoa Cultivation Along Export Supply Chains

*Shuntian Wang and **Stephan Pfister**, ETH Zurich, Switzerland*

Agricultural land use for export commodities leads to significant biodiversity impacts. Enhancing transparency in these commodities' production and supply chains is crucial for assessing and implementing effective mitigation policies. Using cocoa cultivation and exports in Côte d'Ivoire as an example, we present a novel framework that combines earth observations, enhanced landscape-scale biodiversity models, and sub-national export supply chains to track the land-use-related biodiversity impacts. Our findings indicate that cocoa cultivation accounts for ~13% of the country's land-use-related biodiversity impacts, with ~87% attributable to cocoa exports. The top ten importing countries account for ~84% of these impacts. Our method offers improved spatial detail compared to existing approaches, facilitating the identification of biodiversity hotspots. Furthermore, we discovered that the land-use-related biodiversity impacts of agroforestry cocoa cultivation are not consistently lower than full-sun cocoa, largely depending on the region's contextual biodiversity importance. Finally, we identified a disparity in biodiversity impacts between global and local perspectives: cocoa cultivation in departments like Guiglo can account for up to 43% of local impact share, while other departments are more important from a global impact perspective. Our transferable framework provides a comprehensive understanding of biodiversity footprint and promotes informed decision-making for sustainable agricultural production, trade, and processing.

5.05.P-Mo485 How to better reflect biodiversity impacts within the Environmental Footprint method? A comparison analysis following a consultation approach

*Laura Garcia Herrero[1], **Valeria De Laurentiis**[1], Fabrizio Biganzoli[2], Fulvio Ardente[2] and Serenella Sala[3], (1)European Commission - Joint Research Centre (JRC), Belgium, (2)European Commission - Joint Research Center (JRC), Italy, (3)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy*

Biodiversity plays a fundamental ecological role in important economic sectors such as agriculture, forestry and fisheries requiring thus comprehensive attention. The Environmental Footprint (EF) framework includes impact categories associated with biodiversity loss, such as climate change, land use, water use, acidification, eutrophication, ozone depletion, photo-oxidant creation, and ecotoxicity. The IPBES has identified several key drivers of biodiversity loss which are Land Use Change, Direct Exploitation of Organisms, Climate Change, Pollution, and Invasive Alien Species. These drivers frequently intersect and their effects can accumulate, resulting in intricate and extensive ramifications for biodiversity and ecosystem services. Additionally, the impacts of different land management approaches remain insufficiently differentiated and not capturing all aspects. It is noteworthy that land use impact categories currently embedded in the EF framework predominantly concentrate on soil quality and fail to encompass a wider diversity of land use approaches required for a comprehensive assessment of biodiversity, particularly in terms of land management practices.The primary objective of this work was to delineate previously unaddressed impacts on biodiversity as a distinct impact category within the EF. Additionally, it involves revisiting the relevant impact categories in the EF, particularly those associated with land use. This evaluation also seeks to explore the medium- and long-term requirements for other methods, including climate change, ecotoxicity, eutrophication, and others. The outcome could be either a differentiation and complementing of the current EF LCIA framework (e.g. by separating out a biodiversity sub-indicator composed of biodiversity-related currently covered midpoints plus additions of yet unconsidered ones) or a complete further development, as main but not only potential solutions. The proposed method will be interim, and the EF group will keep following the advancements of several platforms.

5.05.P-Mo486 Land-Use-Based Biodiversity Impact Assessment Methods in food LCA

*Venla Kyttä and **Merja Saarinen**, Natural Resources Institute Finland (Luke), Finland*

Agricultural land use presents a substantial threat to global biodiversity. To comprehensively evaluate the biodiversity impacts of food, it is imperative to systematically incorporate the country of origin for each product. Beyond the production site, the quantities of consumed products also hold relevance in the assessment of food-related impacts. Therefore, diet level assessments are ideal when identifying hotspots and finding measures to decrease the biodiversity impact of food consumption.

In this study, we employed two recent land-use-based biodiversity life cycle impact assessment methods (Chaudhary and Books, 2018; Kuipers et al., 2021) to assess the biodiversity impacts of five dietary scenarios, including the current Finnish diet and four alternatives gradually reducing animal-origin food intake. The assessment utilized the previously developed FoodMin model, which evaluates climate impact and nutritional quality of diets based on 90 food product groups. For the biodiversity impact assessment, the countries of origin and the land use, as well as land-use changes, associated with each product category in those countries were assessed utilizing national import data and international statistics on yield and land-use change.

The study revealed substantial variability in biodiversity impacts, with a 60-fold difference in magnitude depending on the assessment method. Land-use change, particularly associated with feed production, emerged as a primary driver of impacts, reducing the dietary impacts with the intake of animal-origin foods. At the same time, particularly for beverages, sugars, and sweets, occupation impacts were higher than the impacts originating from land-use change.

An analysis of the two assessment methods revealed that absolute comparisons of results obtained with these methods are inappropriate. On a product-level basis, also different relative results were obtained, influencing which products appeared most burdensome.

The results emphasize the critical importance of tracking the production locations of each product in biodiversity impact assessment, and the necessity of considering both land-use change and occupation impacts. Future research should focus on developing biodiversity impact assessment methods, especially on addressing impacts on a local scale, improving land-use change methodology accuracy, and analysing the impacts of diverse agricultural management practices.

5.05.P-Mo487 Sustainability in Wheat Farming: A Critical Examination of Fungicide Practices in Belgium Through Life Cycle Assessment.

Delphine Lina, Nelly Cerica[1] *and Angélique Léonard*[2]*, (1)Chemical Engineering, University of Liège, Belgium, (2)PEPs-Chemical Engineering Research Unit, University of Liège, Belgium*

Fungicide treatments represent a critical concern in Belgian wheat farming due to the prevalence of diseases such as fusarium, septoria, and yellow rust, which exert significant pressure on yields. The optimization of fungicide programs is essential, requiring the strategic use of multiple substances with distinct modes of action to mitigate resistance development. This challenge is further exacerbated by regular adjustments in fungicides regulations and the introduction of new compounds.

Despite the crucial role of fungicides in agriculture, there is a notable scarcity of Life Cycle Assessment (LCA) studies addressing their environmental impacts. However, decision support systems for fungicides application already exist, and integrating LCA into these tools could provide an additional valuable criterion for decision-making, promoting more sustainable agricultural practices. This research aims to address key challenges surrounding the environmental impacts evaluation of fungicides use, focusing on wheat production in Belgium. These challenges encompass limitations of field emissions modelling in current Life Cycle Inventory (LCI) databases and the assessment of potential toxic effects on human health resulting from the consumption of residues on plants.

In this context, the framework developed by the OLCA-Pest project is applied in order to model field emissions of fungicides and estimate the characterization factors for human toxicity associated with the fungicidal substances currently employed in Belgian wheat farming. This preliminary analysis focuses on a specific two-step program, involving triazole, SDHI, and multi-site fungicides. Initial results reveal significant environmental impacts on toxicity categories, with notable variations across different substances. The outcomes of this analysis will serve as a benchmark for the LCA of alternative fungicide programs, including innovative sustainable pest control solutions currently under development within a project funded by Belgian public authorities.

This approach aims to provide valuable insights into the environmental and human health impacts of fungicide programs in Belgian wheat farming. Integrating such LCA studies into local decision support tools holds promise for refining fungicides use strategies, ultimately contributing to a more sustainable and resilient agricultural sector in Belgium.

5.05.P-Mo488 Environmental Assessment of Bio-based Fertilizers: adaptability of the non-LCA methods into LCA

Carlos Alberto Torres Guerrero[1]*, Jorge Senan-Salinas Dr.*[2]*, Nancy Peña*[2]*, Ilkka Leinonen*[3]*, Joan Colon*[2] *and Daniel Egas*[2]*, (1)University of Vic - Central University of Catalonia (UVic-UCC), Spain, (2)University of Vic-Central University of Catalonia, BETA Technological Center, Spain, (3)Natural Resources Institute Finland (Luke), Finland*

Bio-based fertilizers (BBFs) are crucial for reducing dependency on mineral fertilizers and developing a circular economy. Life Cycle Assessment (LCA) is the primary tool for measuring BBFs environmental impacts. However, no specific adapted methods exist to evaluate some key impacts such as biodiversity, carbon sequestration, or pathogens presence. Thus, the incorporation of complementary models (non-LCA) can lead to the development of a comprehensive evaluation with more robustness that can mitigate the main challenges of representativity, regionalization, and modeling in the LCA framework.

This work aims to identify the most cited environmental burdens caused by BBFs, the methods the scientific community has used to assess them, and their possible coupling with the LCA framework. A preliminary screening to identify BBF's main environmental concerns was conducted using a two-step literature review. A comprehensive search was conducted to review the available modeling, tools, indicators, and methods. Then, we collected the most representative case studies in which these models were applied coupled with the LCA approach. We developed an integral analysis of the strengths and weaknesses of each one of them.

Our results indicate that the most critical environmental concerns of BBFs were the effects on soil properties, the soil organic carbon dynamics (sequestration/sink), biodiversity, and the presence of heavy metals. For example, the biogenic carbon accounting in LCA uses two possible criteria: i) the uptake-release accounting or ii) the exclusion approach employed in the Product Environmental Footprint methods (PEF). For the biodiversity assessment, a method that covers the drivers causing pressure and includes evaluating ecosystem services along value chains seems the most effective. Also, in this case, a critical evaluation of the differences in the LCA results with midpoint and endpoint indicators is recommended. Finally, risk assessment is the most widespread and commonly used method to evaluate the potential toxicity of heavy metals in human health, crops, or soils.

LCA still has aspects/fields in which further development and research are needed. Still, coupling methodologies outside of the LCA approach can represent advantages to determine and evaluate more precisely the environmental impacts of BBFS, obtaining robust, reliable, and comparable results. Moreover, they can help minimize the lack of specific standardized LCA guidance.

5.05.P-Mo489 Biogenic Carbon – Challenges For Product Life Cycle Assessment and Opportunities for Streamlined Carbon Tracking

*Sam Hinton and **Rachel Jobson**, Ricardo Energy & Environment, United Kingdom*

Chemical manufacturers are utilising life cycle assessment to report the environmental impacts of their products. These are usually cradle-to-gate assessments under methodologies such as Together For Sustainability (ISO14067). One challenge for manufacturers performing assessments to ISO14067, is applying a -1/1 methodology to carbon flows. Under this methodology, CO_2 sequestered in a product is characterised as -1 $kgCO_2e/kg$, while biogenic CO_2 emissions are characterised as 1 $kgCO_2e/kg$. This contrasts with 0/0 methodologies that are utilised in the Product Environmental Footprint method and characterisation models such as IPCC 2021 GWP 100a (excluding uptake) where all biogenic carbon flows are characterised as 0. LCA modelling platforms allow practitioners to switch between -1/1 and 0/0 methods. However, background datasets e.g., ecoinvent, used by platforms apply allocation, which doesn't always align to the physical allocation required for carbon flow modelling.

We have observed that when applying a -1/1 calculation method, individual ecoinvent processes' biogenic emissions do not balance with their carbon uptake. While this is *possible*, it is improbable, unless the carbon is released in the form of CH_4, rather than CO_2. Likewise, we observed that some processes result in carbon uptake so much higher than biogenic emissions, that the carbon content of the product would have to be in excess of 100%. This could lead to practitioners drawing inaccurate conclusions particularly when undertaking comparative LCA.

We have sought to address this by creating a calculation to characterise and balance carbon flows. We tested this calculation on 26 food datasets and observed that at the extreme, datasets possessed up to five times as much carbon uptake as biogenic emissions.

Through our assessment we were able to identify where the imbalance occurred and automatically propose a correction. This calculation could be applied to any ecoinvent material process and would enable users to report GWP impacts under a -1/1 method that balance carbon flows. This should help avoid inaccurate assessments under systems like ISO14067.

5.05.P-Mo490 ProScale-E - an easy-to-use scoring approach for ecotoxicity potential assessment.

***Tomas Vilhelm Rydberg**[1], Richard van Gelder[2], Athanasios Gkrillas[3], Maja Halling[1], Martin Klatt[2], Peter Saling[4], Pearl Németh[5], Triranta Sircar[1], Rosella Telaretti Leggieri[1] and Hannah K Wagner[2], (1)Swedish Environmental Research Institute (IVL), Sweden, (2)BASF SE, Germany, (3)DOW, (4)CDS/S, BASF SE, Germany, (5)Anthesis Group*

This abstract presents ProScale-E, a hazard classification based scoring approach for ecotoxicity potential assessment suitable for, for example, LCA in the SSbD context in early innovation phases. The ambition for the current ProScale-E model was to a) obtain a similar hazard banding model as in ProScale-H, for substances classified according to ecotoxicity (hazard classes in the H400 family) thereby accounting for the severity of impacts, b) accounting for potency of substances, and c) facilitating inclusion of release, fate and degradation of substances. A task force consisting of experts from member companies of the ProScale consortium has worked through a series of meetings organised with 2-3 weeks interval and with various aspects of the model elaborated in between these meetings. During this time period, the Task Force representatives have discussed with internal experts in order to come up with an agreeable classification and scoring scheme. The topics covered were divided into three factors: 1) environmental release, 2) environmental transformation and fate, 3) environmental hazard. A preliminary scoring system for eco-toxicity hazards based on a grouping of hazard statements from CLP is now in place. Comparing with the hazard banding model of the suggested SSbD framework, there are similarities between the displayed ProScale-E scoring model and the Levels as suggested in the SSbD framework, but there are also mportant differences. In particular the introduction of significance to the M-factor is a key aspect of ProScale-E, as the M-factor is based on EC50 values, and therefore introduces the potency of a substance into the scoring.

5.05.P-Mo491 Methods to Determine Freshwater Aquatic Toxicity Effects Factors and Their Influence on Product Environmental Footprinting

***Jennifer K. Saxe**[1], Naveen Reddy[2] and Sagar Thakali[1], (1)KENVUE, (2)KENVUE, India*

The potential for a chemical substance to elicit adverse effects to aquatic ecosystems can be represented by a single toxic potency value. The value is derived from the database of controlled, empirical aquatic toxicity studies and sometimes from predictive models. The distillation of numerous study and model results of varying quality for a broad range of standard and non-standard test species to a single value is scientifically challenging. To support consistent and reproducible potency estimates, researchers and regulators have undertaken numerous efforts to create regimented systems for translating aquatic toxicity databases to single potency values. In product environmental footprinting (PEF) for environmental sustainability assessment, the consensus method is to determine the hazardous concentration to the most sensitive 20% of aquatic species tested (HC20) using a probabilistic model that simultaneously accounts for all valid study results – a species sensitivity distribution (SSD). These HC20 values are a critical element of the freshwater ecotoxicity characterization factor used to compare among alternatives for PEF. Regulatory environmental risk assessment uses a similar approach. Here, SSDs are used, but with prescriptive guidelines, varying by jurisdiction, that require an extensive minimum data set in terms of study quality and breadth of species diversity. The HC5 is generally used as an absolute level of environmental protection desired. However, because of the stringent data requirements for SSDs in regulatory settings, it is more common for potency to be characterized using a single test result associated with the most sensitive species/endpoint tested modified by an “assessment factor” to account for uncertainty. This presentation explores the implications of solely using SSDs in PEF, regardless of database robustness. First, we simulate the variability expected among data-poor SSDs by using subsets of data from data-rich substances to calculate “pseudo-data-poor” SSDs and compare the results. Second, these results are compared using the most sensitive species test result according to regulatory guidelines as an alternative estimate of potency. The pragmatic and scientific pros and cons of each method and recommendations for appropriate use cases are presented.

5.05.P-Mo493 Including non-linearity in life cycle impact assessment: a case for GWP and energy transition scenarios
Cristina Madrid López[1], *Miquel Sierra Montoya*[1], *Alexander de Tomás Pascual*[1], *Romain Sacchi*[2], *Tomás Navarrete Gutiérrez*[3] *and Chris Mutel*[2], *(1)Autonomous University of Barcelona (UAB), Spain, (2)Paul Scherrer Institute (PSI), Switzerland, (3)Luxembourg Institute of Science and Technology (LIST), Luxembourg*
Life cycle impact assessment relies on fixed characterization factors. These fixed factors implicitly assume a constant relationship between biosphere flows, the condition of the receiving Earth compartment, and the resulting impact. However, environmental impacts depend on both the pressure and the state of the environment, implying that fixed characterization factors may be misleading in the calculation of impacts and the activities they inform.

A notable example of adaptation to changes in compartments is the Global Warming Potential (GWP) indicator. For certain emissions, GWP characterization factors have been adjusted; for instance, methane, which was once considered 25 times more impactful than CO2, is now considered 28 times more impactful. These adjustments are contingent upon the concentration of greenhouse gases in the atmosphere. The higher the concentration, the greater the relative impact.

Life Cycle Assessment (LCA) is frequently employed to evaluate the impact of technological changes in future renewable energy scenarios. However, the characterization factors used for scenario assessments in years 2050 or 2030 often do not account for anticipated changes in the atmospheric concentration of various gases . These concentrations are typically estimated using climate models.

In this study, we propose a dynamic evolution of GWP characterization factors aligned with IPCC scenarios. We used PREMISE to calculate structural changes in the Ecoinvent inventories based on different scenarios and integrated assessment models. Subsequently, we developed a dynamic LCIA method within Brightway2 and integrated it into the ENBIOS tool. We conducted an ENBIOS assessment for various energy transition scenarios in Europe.

Our findings support the notion that estimated impacts will be higher than those derived from a linear definition of GWP as shown in the figures below. As these changes are currently not considered in energy modeling, the prevailing designs for energy pathways may not be the most suitable options for achieving a truly sustainable energy transition.

5.05.P-Mo494 Life Cycle Impact Assessment with ReCiPe
Rosalie van Zelm[1], *Koen Kuipers*[2], ***Sharon Janssen***[3], *Chrysoula Karetta*[4], *Mark Huijbregts*[2] *and Anne Hollander*[5], *(1)Radboud University Nijmegen, Netherlands, (2)Environmental Science, Radboud University Nijmegen, Netherlands, (3)Animal Sciences and Aquatic Ecology, Radboud University Nijmegen, Netherlands, (4)Department of Environmental Science, Radboud University Nijmegen, Netherlands, (5)RIVM, Netherlands*
ReCiPe is a multi-impact life cycle impact assessment method available for practitioners. It is a comprehensive LCIA methodology, which provides a harmonised implementation of cause-effect pathways for the calculation of both midpoint (18 categories) and endpoint (3 areas of protection) characterization factors (CFs). To our knowledge, it is one out of only two methods that are currently available that provide both mid- and endpoint factors. Another unique feature is that in ReCiPe, different value choices were grouped into a limited number of scenarios or perspectives. The individualist perspective is based on short-term interest, impact types that are undisputed, and technological optimism regarding human adaptation. The hierarchist perspective is based on scientific consensus regarding the time frame and plausibility of impact mechanisms. The egalitarian perspective is the most precautionary perspective, considering the longest time frame and all impact pathways for which data are available. Review articles on LCA case studies show that ReCiPe has been one of the most used LCIA methods since its release in 2008.

Despite its unique features and high level of use, ReCiPe also has some shortcomings that need to be addressed in a next update. The most important shortcomings are listed below.

For the area of protection ecosystem damage, biodiversity loss is currently determined in different ways, depending on (data available for) the impact category. While for land use local biodiversity loss is quantified, for global warming global biodiversity loss is quantified. Furthermore, some impact pathways are currently not included, such as microplastic impacts on ecotoxicity, and nitrogen impacts on freshwater eutrophication.

For the area of protection human health damage, an important shortcoming is the lack of archetype-specific CFs for particulate matter formation. Research has shown that the emitting sector and region are important factors that determine the magnitude of the CFs, which is not reflected in the currently available country-specific factors.

Finally, to improve applicability and representativeness of the CFs, the factors need to become available for input-output modelling, and a plan to address uncertainty in the CFs is needed.

The goal of this work is therefore to develop new methods to be implemented in a ReCiPe update, to provide the user with a high-level method for future LCAs. In the poster, foreseen updates will be outlined and discussed.

5.05.P-Mo495 Improving substance coverage for more accurate ecotoxicity normalisation factors – A Consortium-based approach

Florence Bohnes[1,2]*, Mathilde Kolenda*[2,3] *and Jad Zoghaib*[2,4]*, (1)Unilever R&D Colworth, United Kingdom, (2)EcoBeautyScore Consortium, (3)Quantis, France, (4)L'Oreal Research & Innovation, France*

Normalisation and weighting are used to aggregate the results of multiple impact categories into a single score in life cycle assessment (LCA), allowing an easier interpretation of the results and empowering the use of LCA in decision making. While some weighting approaches, such as the one recommended by the Product Environmental Footprint (PEF), are based on panels' opinions, the normalisation step is based on empirical data associated with uncertainty and variability. This additional layer of transformation of the results means that the uncertainty of a single score is increased by the uncertainty of normalisation factors. It is therefore crucial to continue working towards improving normalisation factors.

Specifically, normalisation factors of toxicity/ecotoxicity impact categories are known to be particularly uncertain, due to the inherent complexity of these impacts: as any substance can be associated with ecotoxicity/toxicity impacts, the number of substances to be characterised and included in these methods is enormous, which makes the collection of inventories to build normalisation factors especially challenging. In the EF 3.0 method package, the three USEtox impact categories were given the lowest grade of III for both 'Inventory coverage completeness' and 'Inventory robustness' by the European Commission. This is explained partly by the fact that some sectors are not covered at all by these inventories, such as the cosmetic sector for which close to no ingredients are included.

In this work, we investigate the magnitude of inaccuracy of the ecotoxicity normalisation factor (EF method) and present ways to improve it for the cosmetic sector. We took advantage of the EcoBeautyScore Consortium to gather data about global usage of beauty and personal care products across many companies and deduced missing inventories of substances emitted to the environment related to that sector. We report how to improve normalisation factors more generally, draw recommendations for future practitioners and illustrate the benefits of data-driven, industry-wide collaborations.

5.05.P-Mo496 Earth System Functioning as a Separate Area of Protection for Life Cycle Impact Assessment

Jan Matuštík*, Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic; Charles University Environment Centre, Czech Republic*

The impact categories in Life Cycle Assessment (LCA) are developed to capture potential environmental impacts, on midpoint, endpoint, or damage level. For several decades now, the considered impact pathways predominantly aim for one of the three principal Areas of Protection (AoP): Human health, Ecosystem quality, and Resources. These AoPs determine which elementary flows are considered, which environmental processes are included, and how the impacts are evaluated. Conversely, the flows, processes, and impacts not directly relevant to the AoP are not considered. While the three AoPs dominate, others have been proposed over the years, for example ecosystem services. Yet another environmental issue and another dimension of sustainability research is related to Earth System (ES) functioning. According to the field of Earth System Science, planet Earth can be viewed as one complex adaptive system which provides the unique conditions which allow flourishing of life on Earth. In the geological epoch of the Anthropocene, human activity now competes with natural regulatory mechanisms and affects the stability and functioning of the ES. I propose ES functioning as additional unique AoP to capture this crucial area of environmental science. ES functioning is inherently intertwined with the other AoPs. From one perspective ES stability and functioning can be seen as a vital precondition to human health, ecosystem quality, and resource provisioning, hence a midpoint in those impact pathway. But at the same time ecosystems and humans are inherent parts of the ES and affect its functioning, thus ecosystem quality and human health to a degree could be seen as midpoints to the ES AoP. In the same way, ecosystem quality is necessary for human health. While there are many common elements with the current AoPs, the perspective, and thus the considered impact pathways, would often differ. Specific impact assessment models and midpoint and damage-level impact categories could be developed to capture this AoP. In fact, the process has already started with impact assessment models targeting the Planetary Boundaries framework. Indeed, the issues and formulations presented in the Planetary Boundaries, or Earth System Boundaries, could provide an apt starting point and guidance on which impact pathways should be considered. Establishing ES functioning as a unique AoP would provide a useful addition to the comprehensiveness of LCA studies.

5.05.P-Mo497 Choices Mechanism in Models Construction for Life Cycle Impact Assessment of Natural Resources.

Camille Chabas*, Montreal Polytechnic, Canada*

Life Cycle Assessment (LCA) is a widely used tool for assessing the environmental impact of products and processes. Like any other decision-support tool, LCA characterization models contain numerous so-called value judgments (whenever the modeler makes a subjective choice between two modeling options that cannot be objectively distinguished). The presence of subjective choices in LCA has been a source of controversy within the LCA community, but the debate remains unresolved. The assessment of natural resource depletion in LCA is a typical example of this controversy: there is no consensus on what safeguards subjects should be assessed through the impact category, and there are over 27 methods for assessing impacts in the "natural resources" category, each quantifying different elements. These variations produce differences in results that can influence decision-making. We need to understand modelers' decisions and model construction in LCA. This research aims to identify the various factors that influence modelers when building a new model, the contextual, epistemic, and personal influences leading to choices.

The methodology of this research combines a critical literature review of existing natural resource characterization methods with qualitative interviews and content analysis, aiming to identify the factors influencing modelers and understand the choice-making mechanisms inherent in the construction of life cycle impact assessment models for natural resources.

For now, 43 motivations were identified, classified in 8 categories such as pragmatism, feasibility, acceptability, LCA culture, modeling technique, colleagues or hierarchy influences, personal experience, literature, and data. Certain trends have been analyzed in greater detail, to show how the different motivations for a decision can interact.

The study found that modeling tends to be a collaborative effort. The study examined motivations for modelers' choices, driven by tools and team expertise, contextual values, like feasibility, available data, and acceptability. We conclude that models are not purely objective tools, but social constructs influenced by decisions meaning model results depend on the context, leading to the need for transparency in modeling procedures.

5.05.P-Mo498 Substitution in Circular Footprint Formula: feasibility showcase through nutrient recycling to secondary fertilizer

Zoe Chunyu Miao[1], *Vanessa Zeller*[2], *Liselotte Schebek*[1] *and Guido Sonnemann*[3], *(1)Technical University of Darmstadt, Germany, (2)Technical University Darmstadt, Germany, (3)University of Bordeaux, France*

In response to heightened sustainability awareness, regulations promoting resource recycling are exemplified by initiatives like nutrient recycling from wastewater/waste to produce secondary fertilizer. LCA has been applied in such cases to support decision-making.

Understanding various approaches that address multifunctionality, an inherent facet of recycling in end-of-life scenarios, is imperative, as it induces alterations in results and assigns different incentives. Circular footprint formula (CFF) is proposed as an alternative for end-of-life modeling, where avoided burden of primary material production combined with a Quality factor (Q), a typical approach often associated with consequential LCA (CLCA) approach, is presented. Yet, the applicability of CFF in the unique context of nutrient recycling to secondary fertilizers remains uncertain, as their composite nature entails nuanced quality and function-related properties. Only through a granular assessment at the nutrient level can these properties be adequately captured. Additionally, official documents failed to define "quality" as this term embodies a feature: despite the product can fulfil the same function, it can exhibit distinctions in emissions in later life phases.

A case study is presently underway to investigate the feasibility of CFF in terms of substitution and substitutability through Q factor. In total, six scenarios are designed in both attributional and consequential systems to demonstrate applications of 'standard' substitution and facilitate a comparative analysis with the CFF approach. Within this schema, considerations pertaining to the functional unit and system boundary will be expounded. Both well-established and emerging technologies with a production of organic and mineral secondary fertilizers are assessed. Both types of secondary fertilizers will offer distinct aspects in terms of Q factor and substitutability.

The objectives of this presentation are (i) to illustrate disparities between "standard" substitution and CFF in a specific case of secondary fertilizer production, (ii) to identify imperative parameters when calculating substitutability, and (iii) to examine the applicability of CFF. The results outlined in this presentation call upon researchers to dedicate increased focus to exceptional cases, fostering advancements in both CFF and substitution approaches.

5.05.P-Mo499 Comparing approaches for assessing Absolute Environmental Sustainability: a case study on the EU Consumption Footprint

Andrea Paulillo[1], *Esther Sanye-Mengual*[2], ***Susanna Andreasi Bassi***[3] *and Serenella Sala*[4], *(1)Chemical Engineering, University College London (UCL), United Kingdom, (2)European Commission - Joint Research Centre (JRC), Belgium, (3)European Commission - Joint Research Center (JRC), (4)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy*

Absolute environmental sustainability assessment (AESA) is an emerging approach that enables identifying those systems that are inherently environmentally sustainable by combining Life Cycle Assessment (LCA) with absolute limits, most commonly represented by the Planetary Boundaries (PBs) framework. The ability to assess the absolute environmental sustainability of a product system is paramount because although we are iimproving the environmental performance of individual products (i.e. the eco-efficiency), the total environmental impacts of our society continue increasing due to growing population and per capita consumption. For this reason, AESA is attracting increasing attention in academia and beyond, including for policy-makin.

One potential obstacle to the widespread uptake of AESA is the lack of a consensus methodology. In this work we focus on two key methodological aspects: i) how to harmonize LCA indicators with the Planetary Boundaries control variables, and ii) how to allocate the Safe Operating Space delineated by the Planetary Boundaries to individual systems. We compare existing literature approaches and investigate their qualitative and quantitative differences, using as a case study the EU Consumption Footprint developed by the Joint Research Center (JRC). The harmonization aspect is investigated via 3 approaches that address different steps of the life cycle impact assessment stage. The allocation aspect is explored via 4 alternative approaches, representing those that are most commonly adopted. The results of our study will enable developing recommendations for the application of AESA and potentially for the establishemtn of a consensus methodology.

5.05.P-Mo500 Limitations of the resource depletion assessment in the energy transition
***Benedetta Marmiroli**[1], Maria Leonor Carvalho[2], Carmen Ferrara[2] and Pierpaolo Girardi[3], (1)Sustainable Development and Energy Sources, RSE SpA - Research on Energy System, Milan, Italy, (2)RSE SpA - Research on Energy System, Italy, (3)Ricerca sul Sistema Energetico - RSE S.p.A., Italy*
There is a clear nexus between decarbonisation and resource consumption in the energy transition. However, while the methods to measure the climate change are well assessed, the way to assess resource depletion is still ongoing. The gaps are both due to Life Cycle Inventory limitations and LCIA methods. This study shows the variability in the results obtained across years, using one of the most common LCA database and the impact assessment methods suggested by the European Commission, and applying them to the Italian energy scenario at 2030. The analysis of the Italian Energy scenario at 2030 was performed in different years, following the evolving decarbonisation goals in the energy sector. Meanwhile also the database used in the background changed (from Ecoinvent 2.2 to Ecoinvent 3.9.1) and the assessment method recommended by the European Commission moved from ILCD to EF. Even though the trade-off between decarbonisation and resource depletion was confirmed across the years, the variability among the depletion results were notable and not explainable with the differences in the energy scenarios. Analysing the changes in the results across different ecoinvent versions and LCIA methods, this study investigated the reasons behind this variability. On the inventory side, an intrinsic multi output sector such as the mineral one with coproducts originating from different processes across the production chain, makes it difficult to solve multifunctionalities with the classic allocation methods; this is particularly true for mineral resource flows. In the evolution of Ecoinvent database different options have been put in place to solve this problem: from resource correction factors (Ecoinvent 2.2) factor to resource flows entering the tecnosphere lower along the production chain instead of entering the extraction process (Ecoinvent 3.3). In the current version of the database (Ecoinvent 3.9.1) there is a pure economic allocation, and resource consumption does not reflect the mineral and metal content in the final product. If this allocation might be coherent with an intertwined sector such as the extraction sector, this economic aspect should be reflected also in the impact assessment method that evaluates the depletion of resources. For short-medium term goals such as the decarbonisation of the energy system, our suggestion is to use prices of minerals and metals as proxy of their availability.

5.05.PC Life Cycle Impact Assessment – Advances in Modelling and Application

5.06 Navigating the Complexity of Plastic Life Cycles: Interdisciplinary Challenges and Advances in Assessing Environmental Impact

5.06.T-01 A Meta-Analysis of LCA Studies and Global Warming Potential on Polylactic Acid
***Claudia Som**[1], Akshat Sudheshwar[1], Nadia Ilaria Malinverno[1] and Barbora Pinlova[2], (1)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)EMPA Technology & Society Lab, Switzerland*
Bio-based polymers are often perceived as a solution for sustainable plastic manufacturing. Frequently cited advantages include their potential lower carbon footprint compared to fossil-based polymers and alternative end-of-life pathways in case they are also biodegradable. This also applies to polylactic acid (PLA), one of the most advanced biopolymers on the market. Over 80 life cycle assessment and carbon footprinting studies of PLA have been performed since the early 2000s, with many including a comparison to fossil-based plastics. In this review, the results from these studies were collected and compared to clarify, whether an overall conclusion can be made about the advantages of replacing fossil-based plastics with PLA. The main focus was placed on global warming potential. When looking at cradle-to-gate (resin manufacture) scope, the median value for PLA was 1.63 kg CO_2 eq/kg PLA, which is indeed lower than the fossil-based polymers such as PET, PP, or PE. However, when the median values from cradle-to-grave studies were weighed up, PLA with a median value of 3.91 kg CO_2 eq/kg showed comparable results to the investigated fossil-based polymers. This discrepancy in the conclusions between the scopes is primarily a result of biogenic carbon accounting, where the cradle-to-gate results benefit from the CO_2 uptake by feedstock. A great variation was observed in the results for PLA between the different studies, stemming from the complexity of the LCA and the different choices made by the authors. Those include type of feedstock, electricity mix, end-of-life option, or aforementioned biogenic carbon accounting. It was noted that especially moving towards using renewable energy is beneficial in terms of reducing global warming potential.

5.06.T-02 A Life cycle Assessment with microplastic aquatic ecotoxicological impacts included.

Anna Schwarz[1]*, Sjoerd Herlaar*[1]*, Joris T.K. Quik*[2]*, Jan Harm Urbanus*[1]*, Quirine M. Cohen*[1]*, Milad Golkaram*[1]*, Mark Huijbregts*[3] *and Tim H.M. van Emmerik*[4]*, (1)TNO, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Environmental Science, Radboud University Nijmegen, Netherlands, (4)Hydrology and Environmental Hydraulics Group, Wageningen University & Research (WUR), Netherlands*

The environmental impacts from plastic pollution are typically not included in Life Cycle Assessment (LCA). As a result, an LCA performed from plastic products do not reflect the full impact spectrum of the product. In this study, characterisation factors (CFs) were developed for macroplastic (MaP, >5 cm) and microplastic (MiP, <5 cm) emissions related to freshwater ecotoxicity and marine ecotoxicity. These CFs were added to the ReCiPe2016 impact assessment method. To obtain the CF, environmental fate and ecological effects of MiPs were assessed. The environmental fragmentation of MaP to MiP were accounted for through a conversion factor. The developed CFs were applied to a case study LCA, which includes two consumer films, made from 3 different polymer types (PP, LDPE, PET). Mass loss estimates of MaP and MiP per functional unit were accounted for through adaptations of an existing plastic litter material flow analysis model (Schwarz et al., 2023). The CFs were obtained for the three polymers by assessing the Effect and Fate Factor. Effect Factor was kept constant for all three polymers and based on literature research. Fate Factor modelling was executed using Simplebox4plastics (Quick et al., 2023) for the three selected polymers. Incorporation of MiP in the case studies resulted in significantly higher ecotoxicity midpoint impacts, maximally >99% increase of impact, depending on ReCiPe2016s cultural perspective and polymer type. The endpoint indicator on ecosystem quality resulted in a limited increase, with a maximum increase of 3.3%. The results indicate the relevance of including plastic pollution in ecotoxicity impact indicators. The degradation rate of MiP played a key role in fate modelling. Improvement of Effect and Fate factors used to obtain the CFs is recommended for future research.

5.06.T-03 Modeling Environmental Impacts of Plastics in Life Cycle Assessment: Effects of Biodegradation

Felicitas Pellengahr[1]*, Elena Corella-Puertas*[2]*, Valerie Mattelin*[3]*, Anne-Marie Boulay*[4] *and Yvonne van der Meer*[5]*, (1)Aachen-Maastricht Institute for Biobased Materials, Netherlands, (2)Chemical Engineering, Montreal Polytechnic, Canada, (3)Ghent University (UGent), Belgium, (4)CIRAIG - Ecole Polytechnique de Montreal, Canada, (5)Maastricht University, Netherlands*

Plastic emissions to the environment and the rapid accumulation of plastic particles in different environmental compartments are posing a threat to ecosystem quality and human health. To determine the magnitude of their potential damage within the full life cycle of a product, it is necessary to include the quantification of potential impacts from plastic emissions in Life Cycle Assessment (LCA) modelling. To integrate plastic emissions into LCA, characterization factors are needed that commonly consist of three elements: a fate factor, an exposure factor, and an effect factor. In this context, fate factors quantify the distribution and longevity of plastics in the environment. However, research on these fate factors is still limited, especially for biodegradable polymers. Hence, the main objective of this research is to determine the fate factors of biodegradable polymers (polylactic acid, polybutylene succinate-co-butylene adipate, polycaprolactone) based on primary experimental data for the marine environment. In former research, fate factors were based on literature data, assuming that the degradation kinetics of macroplastics and microplastic particles would be similar. This work tests this assumption by comparing the degradation kinetics of macro- and microplastics under the same conditions. Although polymers are commercially used in different grades, most degradation data found in literature were assessed for pure polymers. In this work, the degradation kinetics of different grades of a commercial plastic (differing in molecular weight) are compared to explore whether this simplification is suitable. Furthermore, in this work, degradation at the ocean average temperature (4 °C) is compared to degradation at elevated temperatures (20 °C), as the latter conditions are often used in the literature on polymer degradation. The degradation data are obtained by monitoring the oxygen consumption, pH, and microbial growth over a period of six months in natural seawater, sampled at the coast of Oostend (Belgium). The determined degradation rates are combined with sedimentation rates to obtain fate factors, based on USEtox recommendations. These fate factors are subsequently integrated into LCA characterization factors. Resulting characterization factors are tested in an LCA case study of a synthetic sports shirt, allowing for an assessment of the relative importance of microplastic impacts compared to the rest of the life cycle.

5.06.T-04 Environmental assessment of emerging bio-based polymers: Integration of ex-ante and prospective LCA

Narie R.D. Souza *and Francesco Cherubini, Norwegian University of Science & Technology (NTNU), Norway*

Biomass is a promising renewable feedstock to defossilize the chemical sector, transitioning from a fossil linear economy to a circular bioeconomy. However, this transition has multiple challenges. The sustainability of bio-based technologies depends on biomass availability at lower risks of impacts to food security and nature conservation, and many of these technologies are still at a low technology readiness level (TRL), thereby hindering a fair benchmark with their fossil counterparts. To assess a more robust comparison of environmental performance of emerging bio-based polymers against their fossil alternatives, this study applies a combined framework integrating ex-ante and prospective life cycle assessment (LCA). The framework includes a stepwise approach to scale-up technology maturity (ex-ante) followed by an integration of the up-scaled inventories with future projections of background data (prospective). We assess the potential for climate change mitigation by substituting fossil polystyrene (PS), polymethyl methacrylate (PMMA), and polycarbonate (PC) produced in Europe (EU) with poly-isosorbide methacrylate (PIMA), an emerging polymer produced from lignocellulosic feedstock (LCF) that is at low TRL. To avoid competition with food production, the assessment explores biomass resource availability in EU to produce PIMA considering country-specific availability of LCF (i.e., agriculture and forest residues) for a sustainable supply potentials (i.e., at levels that soil carbon pools and nutrients are not depleted). In total, all necessary PIMA to replace the fossil polymers can be annually produced, using only 5% of the sustainable available residues in EU. The replacement of the fossil polymers using PIMA impacts at lab-scale results in emissions of 43 million tonnes of CO_2eq per year, as the lab-scale impacts are higher than the

fossil ones. The ex-ante LCA reduces total impacts by 80%, but this is insufficient to result in net mitigation relative to the fossil polymers. However, when combining ex-ante and prospective LCA, a net climate change mitigation of -7 $MtCO_2eq/yr$ is achieved (up to -6 $kgCO_2eq/kg$ polymer when PIMA replaces PC). This is about 12% of emissions from the chemical sector. The integration of ex-ante and prospective LCA has the potential to secure a more consistent assessment of climate change mitigation potentials in the EU chemical sector, and thus better guide research and development investments relative to conventional LCA.

5.06.P Navigating the Complexity of Plastic Life Cycles: Interdisciplinary Challenges and Advances in Assessing Environmental Impact

5.06.P-We439 Regionalized sourcing strategies of lignocellulose residues for a net-zero plastics industry
Jing Huo[1]*, Zhanyun Wang*[2]*, Pekka Lauri*[3]*, Juan Diego Medrano-Garcia*[4]*, Gonzalo Guillén-Gosálbez*[4] *and Stefanie Hellweg*[1]*, (1)ETH Zurich, Switzerland, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)International Institute for Applied Systems Analysis (IIASA), Austria, (4)Department of Chemistry and Applied Biosciences, ETH Zurich, Switzerland*
Climate change, biodiversity loss, and pollution are the three major environmental challenges that the world is currently facing. The primary cause of climate change is human activities, particularly the increasing use of fossil fuels. The chemical industry is the largest consumer of fossil fuels and the third-largest emitter of greenhouse gases, making it imperative to find sustainable alternatives. Bio-based plastics production is seen by the industry as a lever to reach net-zero greenhouse gas emissions. However, the availability and environmental impacts of biomass vary widely across regions and types, which are often oversimplified or ignored in previous studies. We provide a comprehensive assessment of low-impact lignocellulose residues as plastics feedstocks, considering their spatial distribution, quantity and environmental impacts.

We utilize the Global Biosphere Management Model (GLOBIOM) to project the availability of these residues on the grid-level. We estimate that 2.6–5.2 Gt dry mass of lignocellulose residues will be available in 2050, with Brazil, China, India and the United States accounting for half of the potential supply. Regionalized prospective LCAs are then conducted to demonstrate the future environmental implications of utilizing lignocellulose residues as chemical feedstocks. With the assessment of more than 600 country-feedstock combinations, this study emphasizes the regional difference in impacts related to biomass, especially concerning land use-related impacts. We find that forest residues have 85% lower climate change impacts but triple the land-use related biodiversity loss impacts compared to agricultural residues. The comprehensive LCA database generated in this study is open-sourced to bridge the existing gap between process-based LCAs with limited data coverage and system-wide analyses of the plastics industry that oversimplify biomass-related assumptions. A case study is provided to compare the impacts of the alternative feedstock-based plastics with the alternatives. This study serves as a foundational resource by offering valuable insights into the regional availability of biomass and the associated environmental impacts of its utilization. They play an important role in shaping the future development of global and region-specific, comprehensive net-zero strategies for the plastics industry.

5.06.P-We440 Methodology and case studies to address potential impacts of plastic emissions in life cycle assessment
Daniel Maga[1]*, Christina Galafton*[1]*, Jan Bloemer*[1]*, Nils Thonemann*[2]*, Aybüke Özdamar*[1] *and Jürgen Bertling*[1]*, (1)Fraunhofer UMSICHT, Germany, (2)Leiden University, Netherlands*
Products made of plastic often appear to have lower environmental impacts than alternatives. However, present life cycle assessments (LCA) do not consider possible risks caused by the emission of plastics into the environment. This study presents a new approach to address the environmental impacts of plastic emissions in life cycle assessments (LCA) by proposing characterization factors (CFs) to calculate the impacts of plastic pollution. The CFs expressed in plastic pollution equivalents are based on the residence time of plastics in the environment and take into account the precautionary principle.

The method developed focuses on defining and quantifying plastic emissions in LCA and estimating their fate in the environment based on their persistence. In the fate model, the fate of plastic emissions is influenced by the environmental compartment they are initially emitted to, their redistribution to other compartments, and their degradation speed. The specific surface degradation rate (SSDR), emission shape, and characteristic length of the plastic are key factors affecting its degradation speed. SSDRs were derived from a literature review, and uncertainty assessments were conducted using the pedigree matrix approach. The fate factor (FF), which represents the residence time, is calculated by determining the area below the degradation curve of an emission.

The results of this research include degradation measurements (SSDRs), a surface-driven degradation model, redistribution patterns, FFs based on residence time, and an uncertainty analysis of the proposed FFs. The FF values vary depending on polymer type, size class, shape, and initial compartment, with some values exceeding 1000. Polymer types were grouped into six clusters based on compartment-specific FFs and total compartment-weighted FFs. The proposed FFs can be used as CFs and can be further developed to integrate exposure factors and effect factors related to human or organism exposure and impacts on species.

The developed methodology aims to support product designers in making informed choices regarding materials, specifically plastics, by estimating potential risks associated with plastic emissions.

The method was already applied in various case studies e.g. focussing on PHB products, and different strawberry production methods. The latter case study will also be presented.

5.06.P-We441 Including Microplastics Emissions Impact in Sediments in Life Cycle Impact Assessment
Nadim Saadi[1]*, Jérôme Lavoie*[2] *and Anne-Marie Boulay*[2]*, (1)CIRAIG Polytechnique Montreal, Canada, (2)CIRAIG - Ecole Polytechnique de Montreal, Canada*
Washing and handling of synthetic fibers could be responsible for the release of 500,000 tons of microplastics (MPs) per year into marine ecosystems. When released, MPs first reach the water column where they can be ingested by pelagic species. MPs can then reach marine sediments, a potential sink, where they can affect benthic species. However, current life cycle impact assessment methods do not consider the impact in the sediments of MPs emissions.

This work builds on the MarILCA working group advances by including the *physical effect on biota* of MPs in the sediments sub-compartment. The fate of MPs in the marine environment is quantified by calculating the residence time of MPs in the water column and sediments sub-compartments, of different polymers, sizes and shapes. Further, a combined exposure and effect factor ($EEF_{sediments}$) for microplastics in sediments is also developed, allowing to obtain updated marine characterization factors (CFs) for MPs. To compute $EEF_{sediments}$, ecological endpoints (e.g. LOECs and EC_X) measured on a $weight_{MPs}/weight_{sediments}$ basis were gathered from the literature and converted to chronic EC10eq. The EEF developed is based on an $HC20_{EC10eq}$, following updated recommendations. To aggregate the $CF_{sediments}$ and CF_{water} obtained into *marine* CFs representing all marine species, two weighted aggregation approaches were proposed: 1-feeding behaviour weighting and 2-marine zones (i.e. pelagos, epi- and endo-benthos) species richness weighting.

High density polymers were found to have a larger residence time in sediments than in water due to their high sedimentation rate while low and medium density polymers have a longer residence time in water. The combined marine and freshwater $EEF_{sediments}$ was calculated using data from 17 species, belonging to 3 taxonomic groups. The $EEF_{sediments}$ obtained is 17.7 PAF.m^3/kg, significantly smaller than the EEF_{water} of 1067.5 PAF.m^3/kg. Obtained marine CFs range from 1.83 x 10^3 to 7.81 x 10^6 PAF.m^3.day/kg, representing the affected fraction of total marine species. Overall, sediments are a sink for high density MPs and is the location where most of their impact occurs. It is therefore an important sub-compartment to consider in LCAs of products emitting high density MPs. However, low and medium density polymers do not impact sediments as significantly but have larger marine CFs, as their fate is longer in the water column where organisms are more exposed to MPs.

5.06.P-We442 Plastic Litter in Life Cycle Assessment: Advances of the Marine Impacts in Life Cycle Assessment International Taskforce
Jérôme Lavoie[1]*,* ***Anne-Marie Boulay***[1]*, Ian Vázquez-Rowe*[2] *and Francesca Verones*[3]*, (1)CIRAIG - Ecole Polytechnique de Montreal, Canada, (2)Pontificia Universidad Catolica del Peru, Spain, (3)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway*
Even though marine litter, especially plastic, is viewed as one of the main threats for biodiversity, life cycle assessment (LCA) was late to implement any indicators allowing the consideration of this important hazard. After the publication of a first framework detailing the assessment of marine plastic litter in life cycle impact assessment, the Marine Impacts in Life Cycle Assessment (MarILCA) working group has made concrete advancements in various stages of the impact modelling. This research proposes an overview of the projects that were led on the topic as a way of providing clear indications about the nature of the tasks that are either realized, upcoming or that constitute the next priorities.

For microplastics particles, the development of effect factors and fate factors have led to the publication of the first recommended characterization factors (CFs) for physical effects on biota, which lead to impacts on ecosystem quality. In parallel, various other research projects are focusing on deepening the fate processes, while other specific case studies are being led to foster the development of the methodology. Furthermore, the case of other substances contained within plastic products have also led to the development of additive-specific effect factors. Impacts of macroplastics are also being tackled and the modelling of impacts of plastic litter on other areas of protection, like human health and socio-economic assets is also underway, or partially completed. CFs are available to quantify the abiotic depletion impact of marine plastic litter.

The addition of plastic impacts in LCA is not without its challenges. Access to data is an important issue in the field, as data is developed simultaneously as the impact metrics are developed. Important tasks remain, namely the fate of additives, and the ability of plastic litter to act as vectors for other pollutants. Yet, the developed metrics have been tested in case studies and provided the first look at how impacts from plastic litter may compare to other impact categories considered in LCA. Results from these have also allowed the identification of important remaining challenges. The past years have led to significant steps in the quantification of plastic litter impacts, mainly in the marine environment and it is expected that the next 2 years should allow to the completion of the main impact pathways identified within the first framework.

5.06.P-We443 Updated and Comprehensive Characterization Factors for Microplastics in Life Cycle Assessment Considering Multimedia Fate Modelling

*Juliette Louvet[1] and **Anne-Marie Boulay**[2], (1)CIRAIG Polytechnique Montreal, Canada, (2)CIRAIG - Ecole Polytechnique de Montreal, Canada*

Plastic litter released into the environment poses potentially significant threats to ecosystem quality, human health, and socio-economic assets. Yet even today, Life Cycle Assessment (LCA) does not properly consider these impacts which can adversely affect decision making regarding plastic use. To address this issue, the international research group MarILCA (Marine Impacts in LCA) has proposed a framework to integrate the impacts of plastic litter in LCA. While MarILCA has primarily focused on assessing impacts in the marine environment, microplastics may impact other ecosystems depending on their emission locations. This project addresses this complexity by investigating microplastic transfer among other environmental compartments and establishing updated and more comprehensive characterization factors for a new impact category, *physical effects on biota*, using effect factors for aquatic, terrestrial, and sedimentary ecosystems.

To achieve this, a fate model is developed, building upon the SimpleBox4Plastics model, and adapted to the USEtox methodology. The model covers 9 environmental compartments (air, natural soil, agricultural soil, lake water, freshwater, marine water, and their sediments) on continental and global scales. It illustrates the fate mechanisms of microplastics within and between the compartments from their release to their complete removal.

From this model, fate factors are computed, quantifying the distribution of plastic emissions in the different compartments. Subsequently, midpoint and endpoint characterization factors are established for 9 spherical microplastics types: EPS, HDPE, LDPE, PET, PLA, PP, PVC and TRWP, each associated with distinct sizes (1, 10, 100, 1000, 5000 µm) using effect factors for aquatic, terrestrial, and sedimentary ecosystems.

This model allows for the first time the integration in LCA of potential impacts of nine microplastics in all compartments including sediments. The fate factors will facilitate a more precise characterization of microplastics' pathways in the environment. They could also be employed in the future to evaluate the impact of microplastics on human health. The characterization factors can be integrated with emission inventories, complementing life cycle assessments of plastic products and empowering governments and consumers to make more informed decisions regarding plastic use.

5.06.P-We444 Development of an Effect Factor for Quantifying the Physical Impacts of Macroplastic Ingestion in Marine Ecosystems

***Ahmed Marhoon**, Marthe Høiberg, Oda Rosvoll and Francesca Verones, Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway*

Plastic has become an essential material for satisfying numerous human needs. Due to its versatility and affordability, this fossil-based material has found its way into a wide range of applications and products. Despite the large benefits it provides to our societies, plastic products are often mismanaged. Since plastic is a very persistent material under most environmental conditions, with degradation rates reaching up to thousands of years, this mismanagement has led to its omnipresence in the environment, and especially in the marine compartment that serves as the ultimate sink for plastic waste. The unceasing influx coupled with the continuous circulation of oceanic gyres have resulted in the formation of marine debris hotspots in the open ocean. A recent estimate showed that between 1.1 and 4.9 million tons of plastics are currently afloat in the global oceans, a trend that increased rapidly since 2005.

The presence of plastic fragments in the marine environment is responsible for tremendous impacts on ecosystems. Marine species have been documented to ingest plastic debris, with records dating back to as early as the 1960s. Since then, around 1300 marine species from different trophic levels have been reported to ingest plastic debris, with trends showing a steady increase in consumption over time. The intake of considerable amounts of plastic debris by species can cause physical impacts (e.g., through damaging or blocking the gastrointestinal tract) which often lead to harmful and even mortal effects. Despite the increasingly good documentation of these impacts in marine ecosystems, current Life Cycle Assessment (LCA) methods still lack models for ingestion impacts of plastics. In this study, we present an Effect Factor (EF) for quantifying the physical impacts of macroplastic ingestion by marine fauna. We use previous ingestion records, species range maps, species functional traits, and marine surface plastic concentrations to derive a spatially explicit and species sensitive model. Our model paves the way for developing characterization factors that can be used in future environmental assessments of plastic products.

5.06.P-We445 Examining the environmental benefit of the chemical recycling of polypropylene plastic waste

*Christine El Khoury[1], **Carlos Pozo**[2] and Laureano Jiménez[3], (1)Rovira i Virgili University (URV), Spain, (2)Departament d'Enginyeria Quimica, Universitat Rovira i Virgili, Spain, (3)Universitat Rovira i Virgili, Spain*

The escalating global utilization and production of plastics since the 1950s has resulted in a significant and increasing carbon footprint. Plastic waste management, with 80% directed to landfills, 12% incinerated, and only 9% recycled globally, highlights environmental concerns. Traditional recycling methods, primarily mechanical, fall short of achieving a closed-loop process, necessitating the integration of the circular economy concept into advanced recycling technologies. Chemical recycling, particularly pyrolysis, emerges as a promising solution, allowing the conversion of plastic waste into original monomers for a closed-loop process. This study focuses on polypropylene (PP), a widely-used thermoplastic, and evaluates the environmental advantages of chemical recycling, specifically pyrolysis. Using Life Cycle Assessment (LCA), we examine a scaled-up industrial process for the pyrolysis of sorted waste PP (wPP), considering two perspectives: waste treatment and propylene production. Energy integration, utilizing pinch methodology, addresses the process's energy intensity. The LCA, utilizing SimaPro with Ecoinvent v3.7.1 and ReCiPe Endpoint (H) V1.1 impact categories, assesses the cradle-to-grave scope. The first perspective analyzes pyrolysis as a waste treatment process, comparing it with incineration and landfilling, using 1 kg of wPP as the functional unit. Products obtained are considered avoided, and incineration heat serves as environmental credit. The second perspective evaluates pyrolysis as a propylene production process, comparing it with the business-as-usual (BAU) route. The functional unit is 1 kg of propylene, with credits for avoided wPP treatment. Results show positive attributes of pyrolysis in impact categories (human health, ecosystems, resources) due to environmental credits. Propylene and 1-butene exhibit the most positive influence. Incineration credits contribute to positive impacts. Landfilling poses threats to human health but minimal damage to ecosystems and resources. Comparing BAU propylene production with pyrolysis illustrates the latter's environmental advantages, even without considering credits. In conclusion, pyrolysis of waste PP proves a promising closed-loop alternative with environmental benefits. Further research into techno-economic aspects is warranted for widespread implementation.

5.06.P-We446 The Importance of Material Flow Analysis for Life Cycle Assessment of Microplastics

*Simon Alexander Saxegård[1], Valentina Helen Pauna[1], **Cecilia Askham**[2] and Mafalda Silva[2], (1)Norwegian Institute for Sustainability Research (NORSUS), Norway, (2)NORSUS AS, Norway*

Plastic pollution is a complex environmental problem that has gained interest from numerous fields of study. Given the persistence of plastic pollution in environmental compartments, impact assessment has become increasingly relevant. However, in order to carry out a comprehensive and holistic impact assessment using Life Cycle Impact Assessment (LCIA), the flows of plastic to and through environmental compartments must be understood. The challenge, however, is rooted in the inherent complexity in attempting to map plastic pollution sources and leakage pathways. It becomes increasingly clear that interdisciplinary work is required to accurately map plastic pollution. Therefore, we demonstrate the benefits of using material flow analysis (MFA) to populate the life cycle inventory (LCI) phase of LCA. By combining these methods, we were able to carry out an MFA of macro- and microplastic pollution from geotextiles, dollyropes and mulch film as well as a simplified LCIA of microplastics released from mulch film. The use of MFA allowed us to better understand macro- and microplastic leakage from relevant materials as well as highlight critical data and knowledge gaps that should be addressed in future research.

5.06.P-We447 The Life Cycle Inventory of an Innovative Biorefinery for Polyhydroxyalkanoates Production

***Martina Pelliconi**[1,2] and Serena Righi[2,3], (1)Department of Physics and Astronomy "Augusto Righi", University of Bologna, Bologna, Italy, (2)Interdepartmental Centre for Research in Environmental Sciences, University of Bologna, Italy, (3)Department of Physics and Astronomy "Augusto Righi", University of Bologna, Italy*

Petroleum-based plastics carry undoubted environmental burdens, thus, alternatives to fossil feedstock are sought. Biobased and biodegradable polymers, such as polyhydroxyalkanoates (PHAs), appear as a valuable substitute for conventional plastic. However, their environmental preferability over fossil plastics is greatly conditioned by the production process, whose high cost also hinders their market penetration. To be viable, solutions must consider both the cost and the environmental aspects. To overcome these challenges, an innovative PHA production process is proposed by the Horizon Europe-funded BioLaMer project, based on the valorization of food waste, through the food-eating black soldier fly larvae (BSFL, *Hermetia illucens*). The invariable chemical composition of the larvae constitutes a novel high-impact feedstock for the cost-effective production of PHAs and chitosan biopolymers. Life Cycle Assessment (LCA) is conducted from the very beginning of the proof of principle stage, to ensure the environmental sustainability of this innovative biorefinery and to provide a final product which is safe and sustainable by design. The project started in April 2023, and after the goal and scope definition, the Life Cycle Inventory (LCI) is now under development. Firstly, the main steps of PHA production will be here illustrated. The manufacturing process starts with the food waste to BSFL conversion, in a self-supporting larvae cultivation plant. Then, the BSFL exoskeleton is separated - for chitin extraction - from the protein and lipids fractions. These will be converted into PHAs through biorefinery. At the moment, various biopolymer synthesis pathways are trialed, comprehending both pure and mixed media cultures. As an accurate LCI is of primary importance to obtain reliable and strong conclusions, our first aim is to obtain a complete qualitative LCI comprising data on single-operation unit processes to the greatest extent, while minimizing black box unit processes. This not only allows easier reviews but also avoids multifunctionality problems as much as possible. Furthermore, while the quantitative data will vary as the production process is optimized, a detailed qualitative LCI is already relevant at this stage, to verify if available datasets exist for background processes. Moreover, it is also an essential base for the upscaling process, where lab-scale processes will have to be converted to pilot-scale plants.

5.06.P-We448 Life Cycle Assessment of the Electron Beam-Assisted Production of Thermoplastic Elastomers Based on Recycled Polyethylene and Polypropylene Waste

***Richard Zeumer**[1], Doina Constantinescu[2], Uwe Gohs[1], Kathrin Harre[1] and László Mészáros[3,4], (1)Faculty of Agriculture, Environment, Chemistry, University of Applied Sciences Dresden, Germany, (2)S.C. Monofil S.R.L., Romania, (3)HUN-REN-BME Research Group for Composite Science and Technology, Hungary, (4)3Department of Polymer Engineering, Faculty of Mechanical Engineering, Budapest University of Technology and Economics, Hungary*

Increasing production rates of rubber products combined with a lack of effective recycling methods have led to an exponential growth of rubber waste in landfills and incineration, inducing severe environmental problems. Due to the crosslinking of rubbers, recycling via melt processing cannot be used to process emerging rubber waste. One way to recycle cross-linked rubber is the mechanical recycling into rubber particles (ground vulcanized tire rubber waste, GTR). This elastic filler can be used to produce thermoplastic elastomers (TPE). These composites are prepared by melt mixing of a thermoplastic polymer and GTR particles. The mechanical properties of GTR particle filled thermoplastics decrease proportionally to the percentage of recycled GTR particles due to low interfacial adhesion between the composite components. Recent studies have shown, that surface activation as well as the application of gamma ray-induced interfacial crosslinking did not enable the multiple recycling of GTR based TPE while improving its comparably low mechanical properties. Hence, innovative methods are crucially needed to enable and strengthen circular economy. A promising way is the application of electron beam treatment to produce recyclable TPE based on recycled polyethylene and/or polypropylene as well as GTR particles.

In this study, life cycle analysis was done to compare the environmental impacts of the cascade of mechanical recycling of rubber and mixed polyolefin waste on the one hand, and the conventional production of virgin rubber and polyolefin on the other hand. Under application of the LCA software Umberto, real industry data was combined with environmental database information. The results of this study will contribute to the understanding of current and future recycling processes and will help guide future research towards innovative solutions of the global plastic waste problem.

5.06.P-We449 Life cycle assessment of advanced grade PLA product with novel end-of-life treatment through depolymerization

Spela Ferjan[1], *Anna Schwarz*[1] *and Josse Kunst*[2], *(1)TNO, Netherlands, (2)Arapaha B.V, Netherlands*

Using biobased plastics has the potential to avoid fossil resource depletion and fossil CO_2 emissions. Polylactic acid (PLA) is a fast-growing bio-based plastic made from fermented sugars. Nowadays, PLA is used to replace fossil-based polymers in healthcare and single-use applications, such as for packaging applications. However, PLA offers a much broader application range with the targeted use of a combination of its stereoisomers; PL(*L*)A and PL(*D*)A. A variety of these advanced grades of PLA can be used for multiple purposes in durable consumer products such as furniture. Recycling complex, mixed material and advanced grades of PLA is currently limited, as mechanical recycling has limitations in recycling mixed PLA grades. Using a depolymerization technology, products of such advanced grades of PLA can be recycled to form high-quality recycled PLA. A cradle-to-grave life cycle assessment study was executed to evaluate the sustainability of high-end durable product (a rug) with mixtures of PLA grade and the novel depolymerization technology. The findings of the study showed a 70 % reduction in CO_2-eq. emissions compared to a conventionally designed rug. However, an increase is indicated in the following environmental impact categories: land use, eutrophication, and environmental toxicity. Sensitivity analyses for collection rates showcased that design for collection and recycling are key to obtaining a more sustainable biobased products. Additionally, scenario analysis supported depolymerization for PLA as recycling technology with low CO_2-eq. emissions. Based on the results of the LCA and additional scenario analysis, the use of PLA is encouraged to be used in more durable and lasting products, such as furniture, from an environmental perspective, provided that the products are designed for collection and high-quality recycling to ensure material circularity.

5.06.P-We450 Updating Recycling and Substitution Ratios Throughout the Recycled Polyester Life Cycle

Heather Margaret Logan, PhD Candidate [1], *Valentina Rossi*[2], *Juliane Hermary*[3] *and Anders Damgaard Pr*[4], *(1)ENV, Technical University of Denmark (DTU), Kongens Lyngby, Denmark, (2)Sustain, Technical University of Denmark (DTU), Denmark, (3)Technical University of Denmark (DTU), Denmark, (4)DTU Sustain, Department of Environmental and Resource Engineering, Denmark*

As the EU transitions to a circular textile economy, it will be pivotal to use Life Cycle Assessment to assess which recycling routes provide the best trade-offs for recycling of post-consumer garments. As polyester makes up the majority of textiles in circulation today, it is imperative we explore the environmental impacts and benefits of polyester recycling throughout the value chain and consider how different blends, fibre qualities, and recovered quantities of post-consumer fibre play a role in viability of recycling routes, through the calculation of new recycling ratios. Moreover, due to the multiple products produced throughout the textile recycling and production process it is vital we consider how multi-functionality, and quality of recycling routes plays a role in calculating the substitution ratios for recycled fibres. Through combined Material Flow Analysis and Life Cycle Assessment scenario analysis of the post-consumer recycling value chain expected in Denmark in 2025 for polyester fibres we explore the role that the recycling ratios and substitution ratios play in creating robust and reliable assessments of polyester and polyester blended textile recycling futures.

5.06.P-We451 Application of Life Cycle Assessment as a decision-making tool for eco-design in the development of an automated and digitalized production chain for speed-bumpers (AD CORSSI)

Pablo Francisco de la Reta[1], *Charles Göbbels*[2] *and Angélique Léonard*[3], *(1)University of Liège, Belgium, (2)Reprocover, Belgium, (3)PEPs- Chemical Engineering Research Unit, University of Liège, Belgium*

Plastic recycling offers potential environmental advantages, such as reducing landfill and incineration rates and lowering greenhouse gas emissions and fossil resource depletion. However, a challenge is identifying applications where recycled plastic can effectively match the functional properties of the replaced virgin plastic, specifically the integration of recycled high-density polyethylene (HDPE) in the manufacturing of speed-bumpers for industrial vehicles.

The AD CORSSI project aims to develop an automatic manufacturing line to produce speed-bumpers made with recycled materials (recycled HDPE and recycled glass fibre). To achieve this, automation will focus on conveying recycled materials from the mixer to the mould, aiming to reduce variability in the current manufacturing process.

Currently, prioritizing environmentally conscious technological development is essential for a low environmental (including carbon) footprint and improved circularity. Eco-design at the early stage of research and development processes supported by Life Cycle Assessment (LCA), guides the development of zero-waste speed-bumpers and an automated manufacturing line. Additionally, it aids in comparing various end-of-life alternatives and contributes to developing optimization roadmaps for recyclability.

In this study, LCA quantitatively assesses the environmental impacts of producing a 25 kg speed-bumper with a 10-year lifespan and a resistance of 15 MPa. The LCA covers various HDPE waste feedstock, the production chain, usage and end-of-life considerations. Additionally, we conducted a comprehensive LCA comparison between the project-developed speed-bumper and conventional counterparts, examining three scenarios: polyurethane, concrete and the project-developed speed-bumper using recycled HDPE and recycled glass fibre.

Methodology Guidelines on LCA of recycled plastic products and Environmental Footprint 3.1 impact assessment method are used. The model is done in Simapro 9.5.0. A cradle-to-grave approach was followed, and the inventory was based on primary data collected from the plant and Ecoinvent 3.9 database was used as a secondary data source.

Eco-design strategies have led to a reduction in the environmental footprint of the speed-bumper developed in this project compared to current speed-bumpers. Recommendations for the most suitable materials and processes to facilitate the closed-loop recycling of speed-bumper will be provided.

5.06.P-We452 Development of an Approach for the Comprehensive Life Cycle Assessment of an Epoxy Resin System in Relation to Toxicity Categories

***Sabrina Sigourney Judie Diniz**, German Aerospace Center (DLR), Germany*

Due to the large number of chemicals used in polymer systems, creating a complete Life Cycle Assessment (LCA) including manufacturing, use-phase as well as end-of-life, is a major challenge. This Topic is examined in more detail using the example of an epoxy resin system. In addition to the use of a resin, a large number of reactive diluents and hardeners are used, for example, to optimally adapt these systems to their intended applications. Due to this complexity, simplified reference systems have often been used in previous studies in order to keep the effort for the Life Cycle Inventory within manageable limits. To identify potentially important gaps in the data situation and other problems in the context of an Life Cycle Assessment of polymer systems, a reference system is compared with a product system supplemented with the help of a literature study with regard to the Life Cycle Inventory and the Life Cycle Impact Assessment. In order to be able to make a consistent comparison, the modelling is based on the methodology proposed in the literature, which also forms the background for the Ecoinvent database. To supplement missing data, a literature study is first carried out to determine the chemical composition of the reactive diluents and hardeners analyzed in more detail. The product system under investigation is then modelled using a commercial LCA database and modelling software. During this modelling, the diversity of possible manufacturing processes for individual essential base chemicals and the use of a supplemental database containing additional chemicals also play an important role. In order to be able to determine differences in the subsequent impact indicator results more precisely, special attention is paid to the toxicity categories in the context of the Environmental Footprint assessment method in addition to the frequently used impact category of climate change. To check for any deviations, a sensitivity analysis is carried out within these categories to recognize important differences in the impact indicator results in accordance with DIN EN ISO 14044. In this way, differences potentially influencing the impact indicator results of the aforementioned categories have been identified so far. Among other factors, they can be attributed to the use of different additives and manufacturing processes and should be given greater consideration in the future.

5.06.P-We453 Lifecycle Challenges and Opportunities for Different Bio-Based Feedstocks

***Kealie Vogel**[1], Akshat Sudheshwar[2], Nadia Ilaria Malinverno[2] and Claudia Som[2], (1)Swiss Federal Laboratories for Materials Science and Technology (EMPA), St. Gallen, Switzerland, (2)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Climate-friendly and biodegradable alternatives to fossil polymers have long been sought as the world attempts to meet Net-Zero climate targets and curb plastic pollution. As such, biopolymers derived from biomass are often perceived as an ideal replacement for fossil polymers in various applications. However, the specific feedstock chosen to produce a bio-based material has a significant bearing on not just its physical properties but also its environmental impacts. Thus, it is crucial to distinguish between and consider the environmental benefits and drawbacks of biopolymers made of so-called first-generation feedstocks (i.e. edible crops), and second-generation feedstocks (i.e. inedible lignocellulosic biomass).

Here, we critically reviewed available studies containing production information on the biopolymers polylactic acid (PLA), lignin, cellulose, hemicellulose, cellulose nanocrystals (CNC), and cellulose nanofibrils/microfibrillated cellulose (CNF/MFC) and compiled a dataset on their consequent environmental impacts so as to visually map key environmental hotspots associated with the use of different feedstocks. We found that edible, first-generation feedstocks used to create biopolymers like PLA create production hotspots due to impacts from fertilizer and pesticide use. Additionally, issues with indirect land use change and biodiversity loss were identified as concerns for these feedstocks. For second-generation feedstocks of agricultural residues/wastes used for hemicellulose, CNC, and CNF, production hotspots arise from the inefficiencies of both waste-based extraction processes and sourcing, if residues are considered "co-products", i.e. sharing the impacts of agricultural production, rather than burden-free wastes. Conversely, lignin, cellulose, hemicellulose, CNC, and CNF biopolymers derived from second-generation woody feedstocks are promising candidates for replacing fossil polymers, with low sourcing impacts due to the minimal chemical inputs required in forestry. Nevertheless, non-climate impacts such as biodiversity loss, land use change, demand for wood in other sectors, and the availability and upscalability of bio-based resources to substitute fossil polymers must also be considered. Overall, we present within this work a comparative picture of the lifecycle benefits and challenges associated with bio-based feedstocks that must be addressed prior to substitution of fossil polymers with biopolymers.

5.06.P-We454 Life Cycle Assessment of single versus multiple use medical products: a case study for steam sterilization packaging

Tiffany Ramos[1]*, Ofir Eriksen*[2]*, Ciprian Cimpan*[2]*, Thomas Christensen*[3]*, Asta Hooge Poulsen*[1]*, Kristian Syberg*[3] *and Benyamin Khoshnevisan*[2]*, (1)Science and Environment, Roskilde University (RUC), Denmark, (2)University of Southern Denmark, Denmark, (3)Roskilde University (RUC), Denmark*

In 2019, the European Union produced 53 million metric tons of plastic waste, of which plastic packaging alone accounts for a substantial 14 million metric tons. Projections indicate that this figure could surpass 100 million tons annually by 2060. This pervasive use of plastic products and packaging spans across all sectors, with healthcare being a particularly significant contributor. This surge in plastic consumption can be attributed, at least in part, to the widespread adoption of single-use plastic items and packaging, which have surpassed reusable materials, primarily for reasons of infection control, cost reduction, and convenience. Polypropylene (PP) specifically, stands out as one of the most common and prevalent polymer types, constituting a significant portion of medical waste. Products such as PP blue sheets or sterilization wraps represent a significant portion of waste, that are unpacked and discarded before a patient enters the OT, representing a potentially sortable non-hazardous fraction of waste at the time of disposal. An existing alternative to single-use sterilization sheets are rigid sterilization cases (RSCs), typically crafted from metal and designed for reuse. Both products (blue sheets and RSCs) are used to enclose wire baskets containing surgical tools for steam sterilization and were chosen for comparison to reduce excessive PP fractions of waste by reducing the use of single use sterilization sheets. Methodological tools such as life cycle assessments (LCA) have been widely acknowledged for systematically and quantitatively comparing the environmental impacts of two products or systems with the same function, such as the blue sheets and RSCs. This methodology serves as a valuable tools for comparing the environmental impacts of products (and services) throughout their lifecycles, encompassing everything from the extraction of raw materials to production, transport, use, and disposal (end-of-life management). LCA results measure the impacts caused by the products and services on human health, ecosystem functions, and the depletion of natural resources, in this case the CO2 impact of both products were assessed. This study aims to compare the CO2 impact of both products throughout their lifecycles to assess which would be the most sustainable product choice for healthcare facilities. We also address the implications of switching from blue sheets to RSCs to provide insight to these implications in practice.

5.06.P-We455 Thermochemical decomposition and mechanical treatment of waste plastics as innovative and perspective technologies for production of recyclates

Tatiana Trecakova[1] *and Vladimír Kočí*[2]*, (1)University of Chemistry and Technology Prague (UTC), Czech Republic, (2)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic*

The situation of waste plastics is problematic not only in the Czech Republic but also in the whole European Union. Despite the measures taken to minimise the use of plastics, the amount of plastic waste has been increasing in recent years. Neither the Czech Republic nor the EU do not have sufficient capacity to process waste plastics. The problem of recycling of waste plastics is exacerbated in the Czech Republic and the EU by the problematic approach to the application of produced recyclates on the markets. The production of recyclates from waste also touches on a very topical issue of decarbonisation, where the aim is to reduce dependence on fossil fuels in the economy. This can be partly solved by the production of recyclates from waste which would otherwise be unused as raw materials and would put a strain on the waste management system, hence the environment. Technologies of thermochemical decomposition and mechanical treatment of waste plastics has the potential to enable further development of the circular economy and to help solve the situation of self-sufficiency and raw material security. The construction and operation of technologies for the production of secondary raw materials/recyclates nowadays has also important role in terms of increasing raw material security. The issue of availability of secondary raw material is nowadays not only one of the most important environmental but also social issues. The possibility of replacing important primary raw materials with secondary raw materials from waste can partly contribute to solving this issue, of course with an informed and responsible assessment of the environmental impacts associated with the production of these secondary raw materials or recyclates. A life cycle assessment method (LCA) was applied to compare the environmental benefits of these technologies. The study shows that the technologies of thermochemical decomposition and mechanical treatment can be tools of reducing the impacts of climate change in waste management and promoting the material recovery of waste, which are also objectives of European Union's waste management policy.

5.06.P-We456 Early-stage process design: Applying the Safe and Sustainable by Design framework to recycling of acrylonitrile butadiene styrene (ABS) plastic from electronics

Anna-Karin Hellström[1]*, Nina Melander*[2]*, Anna Strid*[3]*, Diego Penaloza*[3]*, Mattias Andersson*[3] *and Rolf Lindström*[3]*,*
(1)Environemntal Chemistry, RISE Research Institute of Sweden, Sweden, (2)RISE Research Institutes of Sweden, Sweden, (3)RISE Research Institute of Sweden, Sweden
In this study, we tackle the challenge of chemical contamination in the recycling process by focusing on the removal of brominated flame retardants from acrylonitrile butadiene styrene (ABS) plastic, a key obstacle in achieving a sustainable recycling within the circular economy.

Our approach, aligned with the Safe and Sustainable by Design (SSbD) framework, integrates circularity considerations from early design stage of recycled acrylonitrile butadiene styrene (ABS) plastic. We focus on the physical recycling process, where ABS is dissolved in a suitable solvent to separate and remove the flame retardants. This case study focused only on brominated flame retardants, although other additives with hazardous properties may also be present in the ABS.

Methodologically, we followed the SSbD framework's step 1, 2 and 4 beginning with a literature review and a non-target analysis to identify potential flame retardants in ABS. The RISE substitution tool, utilizing Hansen solubility parameters, guided our selection of appropriate solvents. These solvents underwent further process safety assessment, and in the final step, environmental performance was evaluated by incorporating input from lab-scale mass balance calculations using the WinGEMS process simulation tool.

A cradle-to-gate life cycle assessment was performed to identify hot-spots, which included a comparison with the production of virgin ABS from generic Ecoinvent data. Different scenarios featuring various mitigation measures were modelled, such as optimized filters, recirculation of solvents, treatment of direct emissions and substitution of solvents with alternatives from renewable sources.

The LCA results indicate that by implementing all of these measures, the chemical recycling of ABS process studied can achieve an environmental impact that is equivalent or lower than that of virgin production. However, while there is a significant reduction in climate impact, shifting to non-fossil-based solvents could create trade-off effects by increasing impacts in other categories such as water use, land use and eutrophication.

5.06.P-We457 Decarbonization roadmap of the plastic industry in China through life cycle degradable plastics substitution

Fan Wu*, Jinan University, China*
Plastics have become a crucial component of modern society, yet their enduring environmental impact poses significant challenges. In recent years, the spotlight has increasingly fallen on developing degradable alternatives to mitigate the long-term harmful effects of plastic waste accumulation. By integrating dynamic probabilistic material flow analysis (DPMFA) and life cycle assessment (LCA), we analyzed the dynamic changes in greenhouse gas (GHG) emissions during plastic life cycles, while clarifying the potential GHG reduction through degradable plastics substitution throughout the plastic value chain. Based on ARIMA, we estimated that from 2023 and 2030, China will produce 337 million metric tons (Mt) of PP, 263 Mt of PE, 239 Mt of PVC, 362 Mt of PS, and 554 Mt of PET. We constructed a DPMF network for these plastics, ranging from production to end-of-life management. The major applications for traditional plastics are packaging (38.68%) and medical textiles (31.91%), both of which have great potential for degradable plastic substitution. Through bottom-up analysis, we estimated that the cumulative substitution of degradable plastic in the next 8 years will reach 76.8 Mt of PLA, 0.995 Mt of PBS, 50.6 Mt of PBAT, 41.4 Mt of PHA, and 7.3 Mt of TPS. Furthermore, the GHG reduction potential and decarbonization roadmap for the plastic industry was estimated based on the substitution of each plastic during production and waste management considerations. The integrated DPMAF-LCA model can be utilized to forecast the future GHG reduction potential throughout the plastic value chain, while also providing reliable guidelines for decision-making in degradable plastic substitution scenarios.

5.06.P-We458 Understanding Stakeholder Perspectives to Overcome Barriers in Tackling Textile Fibre Pollution

Miranda Prendergast-Miller*, Abbie Rogers, Nkumbu Mutambo, Kelly J Sheridan and Alana James, Northumbria University, United Kingdom*
Microfibre pollution is ubiquitous across all environments (land, air and water) and is regarded as an emerging pollutant. While studies are underway to quantify fibres in different environments, we also need to understand the wider context of fibre pollution from the perspective of different stakeholders across the garment life cycle and stakeholder engagement with microfibre pollution as an environmental issue. A pilot study was conducted using semi-structured interviews with a range of stakeholders involved at various points in the fashion value chain, from sectors such as design, materials and manufacturing, and end-of-life (waste management). The interviews were conducted to identify the current understanding of microfibre pollution from different stakeholders and their perceived challenges in engaging in potential pollution mitigation strategies. Our findings revealed the breadth of agendas and actions across multiple actors and sectors and identified some of the drivers and barriers to change across the garment lifecycle. Our results converged around three key themes: awareness; governance; and stakeholder collaboration. The main findings are:

Awareness: microfibre pollution was recognised as an emerging pollutant, but there were significant gaps in knowledge, especially around impacts to soil environments; confusion in terminology; and a concern about the dominant focus on synthetic 'plastic' fibres, with little attention to 'natural' fibres.

Governance: there is a prevailing absence of data, baselines, thresholds and test methods, meaning that stakeholders currently have few or no legislative steers to act on.

Collaboration: there is a lack of industry response that engages stakeholders across the garment lifecycle.

Our findings highlight the need for multidisciplinary understanding of stakeholder perspectives to overcome the barriers to circularity in the fashion industry. This study reveals the need for data-driven environmental scientists to engage with stakeholders in garment design, materials and end-of-life to improve awareness of textile fibre pollution impacts, provide evidence to policy-makers, and to engage in cross-stakeholder collaborations. In this way, the environmental impact of fashion textiles can be fully considered within the garment lifecycle and help achieve sustainable circular practices for the industry.

5.06.P-We459 Comparative LCA of two chocolate-bars packaging alternatives: the contribution of raw materials and End-of-Life

*Francesco Arfelli[1], Daniele Cespi[2], Luca Ciacci Dr.[3], Marlena Roguszewska[4], Fabrizio Passarini Prof[2], **Eleonora Rossi**[2] and Gianluca Torta Dr.[5], (1)University of Bologna, Italy, (2)Industrial Chemistry, University of Bologna, Italy, (3)Department of Industrial Chemistry "Toso Montanari", University of Bologna, Italy, (4)KB Folie Polska Sp. z o.o., Poland, (5)Department of Industrial Chemistry "Toso Montanari", University of Bologna, Italy*

Urbanization and globalization have fueled a significant increase in food and packaging production and consumption. Packaging constitutes approximately 2% of the gross national product in developed nations and plastics comprises the 40% of applications, raising concerns related greenhouse gas emissions and other environemntal aspects. Therefore, there has been growing interest in exploring alternatives, with paper emerging as a prominent option. LCA has been widely applied to estimate the environmental impacts of both plastic and paper-based packaging, but comprehensive comparisons between the two alternatives are infrequent. This study aims to fill this gap by comparing the environmental performances of oriented polypropylene (OPPp) and paper-based (PBp) packaging of chocolate bars, encompassing industrial processing phase (IPP) and End-of-Life (EoL). The chosen functional unit is 1000 pieces of packed chocolate bars and the comparison is made on a cradle-to-grave basis. The OPPp and PBp product systems are modeled based on primary data from a Polish company and EoL scenarios are developed through laboratory tests. The study reveals that, excluding the EoL, PBp outperforms OPPp in 13/18 midpoint categories and the single score. Raw material contributions to Global Warming Potential (GWP) are approximately 34% for OPPp and 22% for PBp. Waste-to-energy (WtE) and recycling scenarios also favor PBp, with preferences in 10/18 and 16/18 midpoint categories, respectively. EoL contribution to direct GWP impacts is estimated at 43% for OPPp and 3% for PBp, with credits associated with avoided electricity production and avoided production of OPP and paper offsetting waste management burdens. In the recycling scenario, OPPp outperforms WtE for the single score and half of the examined categories, while for PBp, WtE performs better in only 3 categories. A sensitivity analysis suggests that increasing the renewable fraction in the energy mix could significantly reduce impacts. The study highlights the importance of accurate modeling of EoL using material-specific data to provide precise estimates. In conclusion, the study demonstrates that PBp packaging has lower environmental impacts compared to OPPp, but effective impact reduction requires addressing various life cycle phases, particularly the IPP. LCA proves to be a valuable tool for informing policymakers and increasing consumer awareness of the environmental impacts associated with packaging products and systems.

5.06.P-We460 A Comprehensive Life Cycle Assessment of Aircraft Cabin Interiors from Cradle to Grave

***Su Natasha Mohamad**[1], Rachael Rothman[1] and Anthony Ryan[2], (1)Chemical and Biological Engineering, University of Sheffield, United Kingdom, (2)Chemistry, University of Sheffield, United Kingdom*

A wide range of plastic materials used in aircraft cabin interiors complicates segregation, and the lack of research in this field has demotivated recycling when the aircraft reaches the end of its life. This results in a heterogeneous mixture of plastic waste, leading to prevalent waste management practices such as landfill disposal and energy recovery. The intricate composition of these plastic mixtures poses significant hurdles for achieving a sustainable exit for these polymers and realizing a circular economy. Therefore, to address this issue, the study analysed the environmental impact of different waste scenarios for assorted plastic parts from the cabin interior of an aircraft, including the passenger safety unit, window panes, passenger seat, cabin wall, and many more, using the life cycle assessment (LCA) approach. Samples were retrieved from the Aircraft Interior Recycling Association (AIRA, UK), and secondary data were supported by literature. All measurements on samples were carried out with IRAffinity-1S Shimadzu Fourier-Transform Infrared Spectroscopy (FTIR). Among the identified plastics are fiber-reinforced plastics, polyetherimide, polycarbonate, nylon, polyvinylchloride, polymethyl-methacrylate, and polysulfone. To assess the environmental burden and sustainability performance of these plastics, a systematic evaluation of the environmental impacts associated with the production, use, and disposal of these interiors was conducted using SimaPro 9.5 software. The LCA followed ISO 14040 and 14044 standards, where the goal, scope, system boundary, functional unit, impact categories, and assessment method were defined. Besides that, a few waste scenarios were modelled to understand the trade-offs between landfill, incineration, and potential recycling of several types of plastics. Result shows that the cabin wall is responsible for more than 60% of total CO_2 emissions during cabin interior production, i.e., 110 tons CO_2(eq.). Although the

weight percentage for polyetherimide (> 25%) is higher than fiber-reinforced plastics (~14%), the CO_2 emission for polyetherimide was only 24.4 tons CO2(eq.).

5.06.P-We461 Life Cycle Assessment of Aircraft Cabin Interiors from Cradle to Grave

Su Natasha Mohamad[1]*, Rachael Rothman*[1] *and Anthony Ryan*[2]*, (1)Chemical and Biological Engineering, University of Sheffield, United Kingdom, (2)Chemistry, University of Sheffield, United Kingdom*

A wide range of plastic materials used in aircraft cabin interiors complicates segregation, and the lack of research in this field has demotivated recycling when the aircraft reaches the end of its life. This results in a heterogeneous mixture of plastic waste, leading to prevalent waste management practices such as landfill disposal and energy recovery. The intricate composition of these plastic mixtures poses significant hurdles for achieving a sustainable exit for these polymers and realizing a circular economy. Therefore, to address this issue, the study analysed the environmental impact of different waste scenarios for assorted plastic parts from the cabin interior of an aircraft, including the passenger safety unit, window panes, passenger seat, cabin wall, and many more, using the life cycle assessment (LCA) approach. Samples were retrieved from the Aircraft Interior Recycling Association (AIRA, UK), and secondary data were supported by literature. All measurements on samples were carried out with IRAffinity-1S Shimadzu Fourier-Transform Infrared Spectroscopy (FTIR). Among the identified plastics are fiber-reinforced plastics, polyetherimide, polycarbonate, nylon, polyvinylchloride, polymethyl-methacrylate, and polysulfone. To assess the environmental burden and sustainability performance of these plastics, a systematic evaluation of the environmental impacts associated with the production, use, and disposal of these interiors was conducted using SimaPro 9.5 software. The LCA followed ISO 14040 and 14044 standards, where the goal, scope, system boundary, functional unit, impact categories, and assessment method were defined. Besides that, a few waste scenarios were modelled to understand the trade-offs between landfill, incineration, and potential recycling of several types of plastics. Result shows that the cabin wall is responsible for more than 60% of total CO_2 emissions during cabin interior production, i.e., 110 tons CO_2(eq.). Although the weight percentage for polyetherimide (> 25%) is higher than fiber-reinforced plastics (~14%), the CO_2 emission for polyetherimide was only 24.4 tons CO2(eq.).

5.07 Prospective Life Cycle Assessment for Sustainable Solutions in Times of Environmental Crises

5.07.T-01 Prospective Life Cycle Assessment to Support the Assessment of Early Stage Bioeconomic Technologies in RDI Projects

Vanessa Zeller[1]*, Almut Güldemund*[1] *and Foresto Priskila*[2]*, (1)Technical University Darmstadt, Germany, (2)Chair of Material Flow Management and Resource Economy, Technical University of Darmstadt, Germany*

Due to the climate and energy crisis the awareness for environmental assessments of products, technologies and sectors has increased and early stage assessments as well as future benchmark comparisons are required in many application fields. To support environmental assessments of early stage technologies, the life cycle assessment (LCA) community has developed prospective LCA frameworks. Ideally, pLCAs should accompany research, development and innovation (RDI) projects to support technology developer, but many barriers still occur to integrate pLCAs into RDI projects and accompanying RDI programs.

The purpose of this work is to make pLCA manageable in the context an accompanying RDI program. Therefore, we developed cooperation models and a stepwise procedure with an integrated upscaling step. For the upscaling step an existing pLCA framework was adapted to innovative bioeconomic technologies and the RDI program covering 10 RDI projects with approximately 50 project partners.

Based on the framework, the status quo and target scale were selected and the two upscaling mechanisms size scaling and technological learning were considered. Based on a classification scheme suitable upscaling modules for the pretreatment, conversion and downstream processes was selected in cooperation with the RDI projects and material and energy balances were compiled representing the current as well as the target scale of the investigated processes.These material and energy balances were used to construct LCI models. LCA results for the status quo and target scale assessment were calculated.

The LCA results show environmental impacts of selected RDI projects in different development stages and the contribution of scope 1, 2 and 3 impacts. RDI projects with low starting TRL show a high potential through upscaling, on average a reduction of 85%. For most of the technologies examined, the largest proportion of GHG emissions can be assigned to scope 2 emissions. This study demonstrates that further specifications of pLCA frameworks are necessary to make pLCA manageable in the context of RDI programs. This work suggest a stepwise procedure and cooperation models with data provider and adaptations of frameworks. Results indicate a significant reduction potential demonstrating the importance for pLCA for early stage technologies. The transparent implementation and interpretation help for non-LCA experts supports the consideration of LCA results in decision making processes.

5.07.T-02 Life Cycle Inventory Estimation of Energy Use in Pharmaceutical Production: Upscaling from Laboratory data

Muhammed Ayaj Ansar[1]*, Rosalie van Zelm*[1] *and Ad M. J. Ragas*[2]*, (1)Radboud University Nijmegen, Netherlands, (2)Environmental Science, Radboud University Nijmegen, Netherlands*

In the last decade, the surging global pharmaceutical production has prompted environmental concerns, addressable through Life Cycle Assessment (LCA). However, LCA implementation is hindered by restricted Life Cycle Inventory (LCI) data, mainly due to intellectual property protections. Among LCI categories, energy inputs typically contribute over half of the impacts in chemical manufacturing. Estimating these inputs by Process Design Calculations (PDC) based on laboratory data emerge as the most feasible method. Despite existing studies often overlooking crucial environmental factors and limiting accuracy, our study aims to develop an improved estimation method for pharmaceutical processes, covering API synthesis and product formulation. The method incorporates all relevant factors for impacts such as global warming, using upscaling procedures and derived PDCs from laboratory data.

The developed estimation method followed a stepwise framework. In Step 1, existing upscaling procedures were adapted, integrating engineering principles and chemistry from an extensive literature review. Scale-dependent process parameters were determined from process engineering references and equipment manufacturers' catalogues. Step 2 incorporated average designs and equipment sizes to form a generalized industrial plant. Step 3 focused on modelling Process Design Conditions (PDCs) for each unit operation (UO), emphasizing equipment-specific factors such as heat losses. Different methodological approaches were applied based on context such as considering the presence of existing PDCs. The final step involved future validation through cross-referencing with industrial data.

The developed estimation method included 16 unit operations, 20 equipment types/designs, and 35 sizes, representing an improved and extended version compared to previous studies. The method employed PDCs to estimate energy usage for all defined UOs in pharmaceutical production, including precursor production. Various methodological approaches, such as parameter scaling, empirical data integration, and heat loss modelling were used to derive these PDCs under various contexts. This study is the first to develop an estimation method for industrial-scale complete pharmaceutical production using actual equipment design and performance data. The generalized method facilitated its application, improving efficiency and feasibility within an LCA context to supported all levels of LCA practitioners.

5.07.T-03 Integrating Prospective Life Cycle Assessment in Energy System Optimization Modelling: Opportunities and Limitations

Anne van den Oever[1]*, Dominik Huber*[2]*, Daniele Costa*[3]*, Nicolas Ghuys*[4]*, Maarten Messagie*[1] *and Gauthier Limpens*[4]*, (1)ETEC department, Vrije University Brussels (VUB), Belgium, (2)ETEC department, Free University of Brussels (VUB), Belgium, (3)Energyville-VITO, Boeretang 200, Belgium, (4)iMMC, UCLouvain, Belgium*

Efficient decision-making in emerging technology development is crucial in addressing global climate goals. This work explores the integration of Prospective Life Cycle Assessment (LCA) with Energy System Optimization Models (ESOMs) to enhance the evaluation of the life cycle environmental impacts of energy system transitions. While LCA assesses environmental impacts from a life cycle perspective, ESOMs guide cost-optimal pathways for meeting reduction targets, considering sector interactions. Existing studies coupling LCA and ESOMs overlook future energy mixes and life cycle inventories. This research bridges this gap by coupling prospective LCA with the EnergyScope TD model, focusing on the cost-optimal transition of the Belgian energy system. Using premise, a prospective background database is created supplemented by additional life cycle inventories for specific technologies based on primary data, manual upscaling, and process simulation. Environmental impacts of 111 energy technologies and 24 resources relevant for Belgium are evaluated using EF 3.0 and Cumulative Energy Demand (CED) to construct impact databases for EnergyScope TD. Preliminary findings on the climate change impact of a combined cycle gas turbine power plant show that prospective LCA mainly influences the construction phase rather than the operation phase. The ongoing integration enables an analysis of how these findings shape investments and operations across the energy system. The integrated approach offers opportunities to assess competition between technologies for renewable resources and identify optimal resource and technology utilization. Despite these advantages, limitations include the extensive manual alignment of assumptions between the premise database and ESOM. Additional challenges involve integrating the optimization-dependent end-of-life stage, limited consideration of impact categories beyond climate change in the optimization process, and ensuring coherent projections for various impact categories. In conclusion, this work provides a robust framework for coupling prospective LCA with ESOM, yielding a consistent database for technologies in whole-energy system transitions. Recognized opportunities and limitations set the stage for further analysis, including automating the coupling process, assessing the impact on the optimal transition pathway, and incorporating additional impact categories, offering insights for future energy system planning and policy-making.

5.07.T-04 Dynamic-Prospective Life Cycle Assessment using Time-Explicit Life Cycle Inventory: Framework, Method and Case Study

Amelie Müller[1]*, Timo Diepers*[2]*, Giuseppe Cardellini*[3]*, Arthur Jakobs*[4,5]*, Niklas von der Assen*[6]*, Bernhard Steubing*[1] *and Jeroen Guinee*[1]*, (1)Leiden University, Netherlands, (2)RWTH Aachen University, Germany, (3)Flemish Institute for Technological Research (VITO), Belgium, (4)Paul Scherrer Institute (PSI), Switzerland, (5)Technology Assessment Group, Laboratory for Energy Analysis, Paul Scherrer Institute (PSI), Switzerland, (6)Institute of Technical Thermodynamics (LTT), RWTH Aachen University, Germany*

Life Cycle Assessment (LCA) has become a widely accepted method for assessing the environmental impacts of products. However, one of its shortcomings is that it neglects the time-dependency of processes by assuming a time-agnostic Life Cycle Inventory (LCI) phase, in which all processes occur simultaneously and don’t change over time. Such static LCA is ill-equipped to assess decarbonization pathways, for which both changes in production systems and the timing of emissions are important. Two up-to-now largely independent fields of LCA, dynamic and prospective LCA, reform this time-agnosticism from different angles. Dynamic LCA (dLCA) captures the timing of processes and emissions in the LCI phase, allowing a time-dependent Life Cycle Impact Assessment (LCIA) step. Prospective LCA (pLCA) projects future changes in production systems, with recent advances in sector-wide inventory modifications resulting in modified background LCI databases for specific future years.

This work proposes a novel framework to link prospective LCI databases with dynamic LCA calculations. By combining the two LCA methodologies, we obtain a time-explicit assessment of the actual production systems using representative data for each process at its actual time of production and tracking the timing of processes and emissions. The proposed approach aims at automatically using the LCI from corresponding time-specific prospective LCI databases for each process with temporal information. The approach is based on the open-source python LCA framework Brightway25 and builds on the existing dynamic LCA package bw_temporalis. Initial results are presented for a suitable test case and compared with the results of a static, dynamic and prospective LCA, each applied individually. The challenges and limitations of this novel methodology are highlighted and easy-to-follow guidance for when this joint prospective-dynamic methodology may be a preferred option over established LCA methods is provided. The proposed framework can help to provide greater accuracy about the environmental impacts of long-lived products in a changing economy, highlight time-dependent trade-offs and guide policy makers towards more time-sensitive LCA-based decision making.

The focus of this submission is the description of the overall concept, its advantages, and initial case study results. A detailed description of the practical implementation of the method is given in a separate, related abstract (#22593).

5.07.T-05 Strengths, Limitations, and Perspectives of coupling IAMs and LCA to study feasible and desirable societal pathways

*Alexis Chanel[1], **Anne de Bortoli**[2], Susie Ruqun Wu[3] and Estelle Louineau[3], (1)Magi, CIRAIG Polytechnique Montreal, Canada, (2)Génie chimique, Montreal Polytechnic, Canada, (3)ESG, CIRAIG, UQAM, Canada*

Environmental transition planning requires to quantify the impact of activities in uncertain futures. Prospective life cycle assessment (pLCA) answers this need, lately building on integrated assessment models (IAM). Such pLCA practices are growing and needed but also raise new questions.

This study first aims to discuss the practical implications of IAM-LCA coupling to conduct pLCAs through an advanced experience of *premise*. Secondly, it proposes a step back on IAMs by reviewing critical literature and interviewing economists and IAMs specialists. Third, it points out promising avenues for pLCA future practices.

The practical challenges related to conducting pLCAs based on IAMs encompass: (1) no guideline to help selecting an IAM while different IAMs may lead to vastly different results, (2) the complexification of LCA results interpretation without specific guidance, (3) a limited interoperability of existing prospective databases, and (4) the change of a restricted number of sectorial technologies considered.

The main theoretical limitations reported in IAMs' literature are that, first, mainstream IAMs assume a continued economic growth, and rely on *dramatic technological progress* to make it compatible with Paris agreement' net-zero targets. Secondly, most mainstream IAMS do not consider the *energy requirement of the energy supply systems*. Decreasing energy return on investment of fossil fuels combined with energy required for renewable energy production could lead to an "energy trap". More generally, IAMs ignore the *biophysical embeddedness* of economic activities, e.g., energy and materials requirement: their mitigation scenarios may be unfeasible under biophysical bottlenecks. Finally, all IPCC's last report mitigation scenarios come from IAMs based on *neoclassical economics*, that strongly simplifies the economy and may lead to unrealistic projections.

To conclude, we should handle prospective LCA with caution. Aligning parameter values in neoclassical IAMs with historical data is a basic precautionary principle. We should consider further IAMs based on alternative economic schools of thought – e.g., post-Keynesian IAMs (e.g., E3ME) based on empirical equations, or building upon them, ecological macroeconomic IAMs (.e.g., MEDEAS) considering biophysical embeddedness. Finally, we may want to untie from technocentrism and explore unusual socioeconomics, from simple down-scaling avenues (consumption decrease, low-techs) to a more radical degrowth.

5.07.P Prospective Life Cycle Assessment for Sustainable Solutions in Times of Environmental Crises

5.07.P-Tu506 Future greenhouse emissions of all-solid-state batteries

***Shan Zhang**, Department of Energy and Technology, Swedish University of Agricultural Sciences (SLU), Sweden*

All-solid-state batteries have emerged as an alternative to lithium-ion batteries (LIBs) in high performance electric vehicle application due to their promising performance in terms of energy density, safety and battery lifetime. This study evaluated the climate impacts of two all-solid-state battery pack, and compared to two lithium-ion battery packs under two scenarios with considering potential changes in background production processes between 2025-2050. To ensure a fair comparison, all battery packs were designed for the same energy capacity, with the same pouch cell size. A battery-dimensioning model was developed to calculate the required amount of components for each battery pack, as well as the corresponding energy density. In this study, two functional unit were applied: 1kWh battery capacity and 1kWh of energy delivered over battery lifetime. The changes in background system were captured using the python package Premise.

5.07.P-Tu507 Optimizing Energy Efficiency in Lab-Scale LFP Battery Cell: LCA Approach and Insights

***Debashri PAUL**[1], Viera Pechancova[2], Thaiskang Jamatia[2], Haojie Fei[3], Hueseyin Ersoy[4], Merve Erakca[5], Jens Buchgeister[4], Manuel Johann Baumann[6] and Petr Saha[3], (1)Tomas Bata University in Zlín, Zlín, Czech Republic, (2)Centre of Polymer Systems, Tomas Bata University, Czech Republic, (3)Tomas Bata University in Zlín, Czech Republic, (4)Institute for Technology Assessment and Systems Analysis (ITAS), Karlsruhe Institute of Technology (KIT), Germany, (5)Karlsruher Institut für Technologie (KIT) - Institut für Technikfolgenabschätzung und Systemanalyse, Germany, (6)Karlsruhe Institute of Technology (KIT), Germany*

The increasing demand on battery energy storage technologies that are sustainable and efficient makes it important to assess a product's entire life cycle, from the extraction of raw materials to end-of-life treatment. In the context of LFP batteries, which are increasingly employed for their safety, longevity, and better environmental performance, a lab-scale LCA of a battery serves as a crucial tool for identifying and mitigating potential environmental hotspots stemming from its cradle-to-gate impacts.

In this particular field, there is a research gap, given the distinctive differences between laboratory-scale manufacturing and larger-scale production. These variations encompass unique energy consumption patterns, challenges in resource utilization, and technological limitations. This study aims to investigate the amount of energy, which is utilized by equipment in dry room operations, and during battery cell manufacturing.

A cradle-to-gate life cycle assessment is carried out for the battery cell. The functional unit considered is battery storage capacity measured in kilowatt-hours (kWh). Battery has a mass of 26g, average voltage 3.2V, and has an energy density of 92Wh/kg. Primary data is from the pilot line and respective background database processes is from Ecoinvent 3.9.1. Two scenarios were considered, where in real time scenario with 5 cells per day equal capacity 11.6. If the lab unit had a continuous scale of production, it could produce 16 cells per day with total capacity of 38.3Wh which would be the ideal case scenario.

For the manufacture of 5 LFP battery cells, the highest unit process energy consumption comes from the dry and formation room counting up to 86% of total consumption. Lab-scale operations may require more thorough testing, experimentation, and prototyping, potentially resulting in higher demands on the dry and formation room's-controlled environment. The Life cycle impact assessment showed that there is a reduction of GWP by 69% per cell manufactured if the laboratory unit was running in full capacity (ReCiPe 2016 midpoint-H).

The study makes particular recommendations for future research, such as investigating lab-scale energy dynamics in more detail, identifying potential hotspots along with a mitigation strategy, and also taking renewable energy integration into account. These intended suggestions seek to close the noted research gap and advance the continuous advancement of environmentally friendly manufacturing methods.

5.07.P-Tu508 Potentials and hotspots of post-lithium-ion batteries: Environmental impacts and supply risks for sodium- and potassium-ion batteries

***Ryosuke Yokoi**[1], Riki Kataoka[1], Titus Masese[1], Vanessa Bach Dr.[2], Matthias Finkbeiner[3], Marcel Weil[4], Manuel Johann Baumann[5] and Masaharu Motoshita[1], (1)National Institute of Advanced Industrial Science and Technology (AIST), Japan, (2)Chair of Sustainable Engineering, Technical University Berlin, Germany, (3)Technical University of Berlin, Germany, (4)Helmholtz-Institute for Electrochemical Energy Storage HIU and Karlsruhe Institute of Technology KIT, Germany, (5)Karlsruhe Institute of Technology (KIT), Germany*

Rechargeable batteries are one of the key technologies to reduce greenhouse gas emissions in the transport and energy sector. Nowadays, lithium-ion batteries (LIBs) represent the dominant market share of rechargeable batteries. However, concerns regarding the environmental impacts of manufacturing and requirements for critical resources result in the need for developing alternative battery technologies as well as improving LIBs. This study assesses environmental impacts and supply risks associated with the production (cradle to gate) of 1 kWh of two post-LIBs, including sodium-ion batteries (SIBs) and potassium-ion batteries (PIBs), against LIBs by using LCA and criticality assessment. Six types of current and emerging batteries are explored in this study: $Na_{1.1}(Ni_{0.3}Mn_{0.5}Mg_{0.05}Ti_{0.05})O_2$-Hard carbon SIB (NMMT), $Na_2Fe_2(SO_4)_3$-$Na_3LiTi_5O_{12}$ SIB (NTO), and $KFeSO_4F$-Graphite PIB (PIB), $LiNi_{0.6}Mn_{0.2}Co_{0.2}O_2$-Graphite LIB (NMC), $LiFePO_4$-Graphite LIB (LFP), $LiFePO_4$-$Li_4Ti_5O_{12}$ LIB (LTO). The ecoinvent 3.7 and ReCiPe 2016 endpoint method (hierarchist) are used for background data and impact assessment method, respectively. The ESSENZ method is adopted to assess supply risks in terms of eleven categories. Post-LIBs showed comparable environmental performances and lower supply risks compared with LIBs. In particular, PIB showed the best performance for environmental impacts although being an immature technology compared to the others, which comprise a high degree of uncertainty. While LFP result was lower than SIBs (i.e., NMMT and NTO) in terms of environmental impacts, SIBs showed lower scores for supply risks. For the SIBs investigated, NMMT was better than NTO in both aspects. These results suggest that there is a trade-off among environmental, supply risk, and technological maturity aspects. The environmental hotspots were NiSO4 production for cathode for NMMT and NMC, and TiO2 production for anode for LTO and NTO. KFSF anode and cathode had no significant environmental impacts, achieving the best performance. The LIBs show larger supply risks than the SIBs and PIB, attributable mainly to Li and Co used as electrode constituents. The results show the potential to develop sustainable battery systems based on SIB and PIB and support battery developers in identifying hotspots towards developing new-generation batteries with lower environmental impacts and supply risks.

5.07.P-Tu509 Refining Life Cycle Assessments of Mobility Solutions: AI-Simulated Use Phase Calculations for Sustainable Transport

Albert Jan van Zuilichem, *IWAR Stoffstrommanagement und Ressourcenwirtschaft, Technical University Darmstadt, Germany*

There are around 26 million electric cars on the road worldwide. Trends show that the market share of electric cars will be 20% in 2025. The use phase of electric vehicles is their main selling point, distinctively surpassing internal combustion engine counterparts in mitigating GreenHouse Gas emissions. However, the use phase of vehicles bases its results on rough estimates and assumptions, resulting in uncertain and unspecific data. One example is multiplying the average energy consumption (kWh/km) by the average lifetime kilometres travelled, resulting in the lifetime kWh per electric vehicle. These calculations for the use phase are very general and unspecific, especially when analyzing emerging technologies and low TRL vehicles. Therefore, we are currently working on improving the specificity and certainty of the use phase calculations of mobility solutions, such as people and goods transports, by simulating them in software which AI models support. This software can recreate a road network model provided with GIS data. This model is then populated with a fleet of vehicles, and the AI generates a simulated traffic flow. A validated model can be constructed by iteratively fitting these simulations to actual traffic counting. The validated model can then calculate the vehicles' consumption on microscopic and macroscopic scales, amongst other data outputs. A Frankfurt model has been created and is in the process of validation. This model will simulate a novel mobility solution by replacing the business-as-usual fleet with autonomous vehicles. This software is hypothesized to decrease the uncertainty of use phase calculations for upscaling scenarios of pilot lab phase vehicles. Therefore, it enriches prospective Life Cycle Assessments of emerging mobility projects by improving on a crucial aspect, the use phase.

5.07.P-Tu510 Is it Really “Green”? Antisolvents for the Perovskite Solar Cell Production

Kamal A. Kamali, *Bertrand Laratte and Guido Sonnemann, University of Bordeaux, France*

The term “green” frequently appears in literature to describe materials with superior environmental footprint, driving researchers to prioritize these materials in technology development. The claim of “greenness” can be based on many factors, such as the material being biobased, biodegradable, or non-toxic, but unlikely to be supported by comprehensive life cycle data. In the case of chemicals, anisole, identified as a green solvent due to its low direct toxicity effects, has been explored for layer treatment in emerging perovskite solar cells technology. Solvent selection guides assess solvents based on criteria related to the environmental, health, and safety. For example, CHEM21 uses chemical properties such as boiling point and vapor pressure to determine the environmental and health risk of solvents during their use and end-of-life stages. Another guide, the GSK solvent guide, goes further to incorporate life cycle assessment (LCA) data in its scoring system. However, it should be noted that in some instances these inventory data are disclosed to be incomplete, yet the result of the assessment is presented as a single score, which does not fully convey the comprehensive environmental picture.

Conducting a full cradle-to-grave LCA on anisole and chlorobenzene used as an antisolvent in the production of perovskite solar cells revealed interesting results. Anisole demonstrated around 77-88% reduced ecotoxicity and carcinogenic human toxicity than chlorobenzene. Both had similar non-carcinogenic toxicity, with chlorobenzene edging out. In contrast, anisole’s impact on climate change was significantly higher than chlorobenzene, emitting 6.20 compared to 2.83 kg CO_2 equivalent. Other categories, indirectly affecting human health, followed this trend.

This challenges the claim of anisole being "green," mainly attributed to its high production stage impact compared to the one-step synthesis of chlorobenzene. These findings stress the importance of conducting prospective LCAs early in technology development to ensure environmental sustainability.

5.07.P-Tu511 Prospective LCA of Solid-State Fermentation Based Biostimulant Production: Unveiling Environmental Benefits

Enric Garcia-Muchart, ***Nancy Peña****, Daniel Egas, Laura Mejias and Oscar Martínez-Avila, University of Vic-Central University of Catalonia, BETA Technological Center, Spain*

Innovative and science-based solutions are needed, especially in addressing global issues and environmental challenges. In this context, the role of Prospective Life Cycle Assessment (LCA) emerges as a vital tool. Prospective LCA envisions and assesses the environmental implications of emerging technologies, products, and processes. This is particularly relevant in sectors like agriculture, where valorization of residues and secondary raw materials for biobased products are essential in transitioning from linear to circular systems.

Biostimulants are widely used in the agricultural sector, aiming to enhance nutrient uptake and promote plant growth. However, the environmental implications of their production methods remain largely unexplored beyond the benefits they offer. Generally, biostimulant production is energy and water-intensive and sometimes requires solvent extractions under stringent conditions. Thus, alternative biostimulant production approaches have been studied to reduce energy/water/chemical requirements by using low-cost and renewable sources, alternative processes, or green solvents. One of these novel approaches is the solid-state fermentation (SSF) of agro-industrial residues as raw materials, a promising method (batch scale - TRL 3) offering substrate versatility, low water and energy requirements, and limited waste generation.

The prospective LCA employed in this research covers SSF-based biostimulant production. Key parameters are systematically evaluated, including energy consumption, raw material extraction, transportation, and waste generation. The study aims to identify hotspots in the production process, providing insights into areas for improvement and sustainable practices.

The study further explores the feasibility of optimizing resource use, minimizing environmental impacts, and enhancing sustainability in low TRL bio-based technologies. This aligns with the overarching goal of prospective LCA—guiding ethical and sustainable innovation. This contributes to developing environmentally responsible practices in the agricultural sector and promotes the transition to circular systems.

5.07.P-Tu512 Prospective Life Cycle Assessment of Flow Chemistry Production for Active Pharmaceutical Ingredients
***Kristie Tjokro**, Valerio Barbarossa and Stefano Cucurachi, Leiden University, Netherlands*
To reach the objectives set within the European Green Deal, the pharmaceutical industry needs to decarbonize. Batch chemistry is the most common method for manufacturing active pharmaceutical ingredients (APIs). Continuous flow production has shown potential to be a greener, safer, and cheaper alternative to batch production, in line with the principles of the Safe and Sustainable by Design (SSbD) framework. Despite its advantages, flow chemistry for the pharmaceutical industry is still in its infancy. We conducted an ex-ante life cycle assessment (LCA) from cradle to grave to understand the differences between the two API manufacturing methods, thereby providing evidence of the environmental tradeoffs of transitioning from batch to flow chemistry. First-hand data is collected from pilot projects, thereby enabling the modelling of highly accurate production processes, while data gaps are bridged using stoichiometric approaches. Preliminary results based on a select number of material and energy flows show that implementing flow chemistry in place of batch production is associated with reductions in generated waste, greenhouse gas emissions, water use, primary energy use, and hazardous chemicals use. This work contributes to filling the existing knowledge gap on safer and more sustainable API production methods, therefore laying the groundwork for the operationalization of the SSbD framework in the pharmaceutical sector.

5.07.P-Tu513 Safe and Sustainable by Design: Development of an Integrated Approach for Scale-Up Drug Discovery Using P-LCA
***Jacopo Sorani**[1], Bernd Nowack[2] and Roland Hischier, PhD[3], (1)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (2)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*
The pharmaceutical industry is one of the most important industries in the world. It is responsible for the research, development, and production of drugs, which are essential for human health and well-being. However, the production and use of medicines can also lead to environmental problems, such as pollution and depletion of natural resources. Additionally, there are risks associated with drugs that can have side effects on human health, both during treatment and indirectly in some parts of their life cycle. Safe and Sustainable by Design (SSbD) is a holistic approach that should help to address the sustainability aspects together with environmental and health risks associated with the production and use of chemicals and materials during the early stages of its development. For this, the general SSbD framework needs to be adapted to specific groups of chemicals/materials. It is therefore necessary to develop and operationalize e.g. a specific SSbD framework for the design of drugs to identify and mitigate risks and sustainability issues associated with the production and use of them and to support the assessment of new pharmaceuticals.

As a first step towards a “Drug-SSbD” operationalization, a procedure will be developed for the scale-up of inventory data needed for the full LCA of drugs, in particular nanomedicines. It requires the adaptation of an existing framework, originally designed for enhancing the environmental impact assessment of chemical processes, to align with the scale-up of industrial pharmaceutical processes. The synthesis of high-purity substances demands specialized raw materials and involves intricate production steps, introducing unique environmental considerations. The use of Prospective LCA (P-LCA), will help not only to evaluate and anticipate the environmental impact associated with production during the scale-up but will also improve the possibility of comparing lab-scale processes with industrial ones.

Simultaneously, the second research direction delves into exploring risk assessment (RA) tools during the early stages of development, using available data or in silico methods to predict the toxicity and ecotoxicity of a new drug. Customized Quantitative Structure-Activity Relationship (QSAR) studies can support the P-LCA, through methods like USE-tox, connecting RA and LCA.

5.07.P-Tu514 Integrating Future Energy Scenarios into Prospective Life Cycle Assessment: A Case Study of Hydrogen Production Technologies

Juliana Steinbach[1], *Jenny Appaix*[2], *Raphaël Jolivet*[3], *Joanna Schlesinger*[2], *Paula Perez_Lopez*[4], *Romain Sacchi*[5] *and Thomas Beaussier*[6], *(1)Mechanical Engineering, MINES ParisTech, France, (2)OIE Mines Paris, (3)Mines Paris, PSL Research University, France, (4)MINES ParisTECH - OIE Research Center, France, (5)Paul Scherrer Institute (PSI), Switzerland, (6)ISIGE Mines paris*
This study focuses on assessing the environmental impacts of hydrogen production through water electrolysis. The research explores two methodologies for integrating future energy mix scenarios into Prospective Life Cycle Assessment (pLCA): the direct adaptation of electricity backgrounds from established LCA databases such as ecoinvent and the integration of projections derived from Integrated Assessment Models (IAM) using the open-source Python library *premise*. The latter approach allows for comprehensive modeling of transformations in electricity and energy-intensive activities.

A case study was conducted on hydrogen production using Alkaline Electrolysis Cells (AEC) and Proton Exchange Membrane (PEM) technologies. Parameters such as electricity mix, electrolyzer efficiency, and stack lifetime are varied to model future scenarios based on prospective energy mixes from RTE's "Energy Pathways 2050." Three scenarios for the future French energy mix in 2050 are considered, with different proportions of renewable and nuclear energy.

The assessment of hydrogen production technologies involves 1MW AEC and PEM electrolyzers. The study evaluates stack production, balance of plant, iridium production (PEM), and electricity consumption in a cradle-to-gate assessment. The assessment tool used is *lca_algebraic*, an open-source library based on the *Brightway2* framework.

The results of the hydrogen Prospective Life Cycle Assessment (pLCA) indicate low CO_2 emissions associated with current and future energy scenarios in France. A reduction in ionizing radiation is observed due to decreased nuclear power electricity. However, transitioning to renewable energy scenarios leads to shifts in eutrophication freshwater, materials resources, and land use impact categories.

An analysis of parameter contributions highlights that, even with a highly decarbonized electricity mix, electricity consumption remains a significant factor affecting results, while stack lifetime does not contribute significantly.

The study underscores the importance of pLCA in evaluating the environmental impact of future hydrogen production. Methodological comparisons reveal a trade-off between simplicity and accuracy. The case study emphasizes the environmental burden shifts associated with transitioning to renewable energy sources.

5.07.P-Tu515 Using Prospective LCA for the Assessment of Circular Economy Measures
Anne-Marie Isbert, *Sofia Haas and Anika Neitz-Regett, Forschungsstelle für Energiewirtschaft (FfE), Germany*
To reach the defined climate targets, it is essential to transform the sector with the highest share in greenhouse gas (GHG) emissions – the energy sector. This transformation comes with an expansion of newly built renewable energy plants, associated with increased material requirements and related GHG emissions. The circular economy (CE) approach, including measures for lifetime extension, resource recovery and circular design, is one way to mitigate these GHG emissions and to ensure a successful energy transition.

The study highlights the role of prospective Life Cycle Assessment (pLCA) as a method to assess the environmental impacts of CE measures. It shows, that the pLCA enables the assessment of CE approaches by integrating prospective aspects as changes in processes over time as well as time-shifting effects of CE measures into the traditional LCA model.

A pLCA is carried out for the CE measures lifetime extension and recycling for onshore wind turbines. Amongst others, the foreground model takes into account the electricity mix, production processes for materials, efficiency of the production processes, energy and material demand for reparation, refurbishment or remanufacture of the wind turbine as well as recycling processes. For all of these processes prospective data for material, energy and environmental flows are collected and the results of the pLCA are shown. An exemplary result for the required data, the pLCA of the future German electricity mix is shown, emphasizing the relevance of background adaptation, as the two calculations (with and without background adaptation) lead to significant differences in results for future years. By conducting a pLCA for the CE measures lifetime extension and recycling for onshore wind turbines, the study points out the necessary adaptation of foreground and background systems and the required data.

The presentation concludes by discussing how these results can be used for the identification of an optimal lifetime, the so-called ecological break-even. Furthermore, the question, how the presented pLCA methodology can be put into practice and to guide decision-makers toward implementing circular measures effectively for a sustainable energy transition, is critically discussed.

5.07.P-Tu516 Prospective LCA of Carbon Capture for Utilisation Technologies: Key challenges in low-TRL Biorefineries
Jorge Senan-Salinas Dr.[1], *Dianella Garro*[2], *Daniel Egas*[1] *and Sergio Ponsá*[1], *(1)University of Vic-Central University of Catalonia, BETA Technological Center, Spain, (2)BETA Technological Center, University of Vic-Central University of*

Catalonia (UVic-UCC), Spain
Carbon Capture for Utilisation (CCU) technologies could play an important role in climate change mitigation strategies. Nonetheless, most of the CCU technologies are not mature and, in most cases, they are emerging technologies at the lab or pilot scale. Despite the scale, there is a high interest in distinguishing which technologies have the most promising environmental outcome and discarding those whose potential environmental impact is higher than the benefits. For that purpose, prospective Life Cycle Assessment (p-LCA) has been pointed out as one of the most suitable tools. However, there are several limitations in the inventory quantification of Low Technology Readiness Level (TRL) technologies. Uncertainties about the processes scaling-up effect, process integration, and the up-scaling of lab protocols are a few numbers of examples of the issues that a p-LCA practitioner faces.

VIVALDI´s project exemplifies this case. VIVALDI covers the capture of biogenic carbon from bio-based industries to the production of high-valued Organic Acids (OAs) such as 3-hydroxypropionic (3-HPA) as well as nutrient recovery technologies with TRLs 3 to 5. Most of the technologies are electrochemical or bio-electrochemical technologies with a limited number of scale-up or without any scale-up references.

The poster aims to provide an overview of the main challenges identified and the battery of strategies found in the literature to overcome this issue and ensure the right support for different decision-makers: researchers, industry, and policymakers. Among the strategies found, it should be highlighted the bottom-up approach modelling or filtering technologies based on the best-case assumption method. Moreover, it should be highlighted the relevance of the substitution approach and normalisation with fossil-based OAs counterparts as a solution for benchmarking and comparison. As a conclusion, the authors present a miscellaneous group of techniques used to complete the whole overview of a complete CO2-biorefinery.

5.07.P-Tu517 Decarbonizing Transportation: Exploring Chlor-Alkali Hydrogen's Potential
Aleš Paulu[1] *and Vladimír Kočí*[2]*, (1)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic, (2)University of Chemistry and Technology Prague (UTC), Czech Republic*
The quest for decarbonization of transportation has intensified in recent years, prompting research into alternative fuels that can mitigate environmental impacts. Among others, hydrogen is frequently mentioned as a promising energy carrier with a potential to significantly reduce emissions, especially for heavy-duty vehicles and public transportation buses traversing long distances without frequent refueling.

Chlor-alkali hydrogen, a by-product of the chlor-alkali electrolysis process, could be particularly advantageous as a transportation fuel due to its availability as a by-product of an established industrial process, thus minimizing the need for additional dedicated hydrogen production infrastructure. However, the environmental performance of chlor-alkali hydrogen compared to the conventional fuels has seldom been quantified, neither has the overall potential of its production yet been explored.

This study delves into the prospective life cycle assessment (LCA) of chlor-alkali hydrogen as a potential future fuel source for transportation systems. Focusing on the European context, this study evaluates the environmental impacts in comparison to conventional fuels and projects the extent of chlor-alkali hydrogen production and its potential to decarbonize transportation. The total distance achievable by buses or heavy-duty vehicles powered by this hydrogen is quantified, while the associated challenges and limitations, such as infrastructure, technical advancements, or scalability, are addressed. The results are interpreted with respect to temporal aspects such as the composition of the electricity mix or the evolution of hydrogen demand and its production.

Overall, the research aims to provide insights into the viability and potential contributions of chlor-alkali hydrogen to a cleaner transportation landscape. The findings of the study could inform policy-making, guide strategic investments, and drive advancements in sustainable transport solutions.

5.07.P-Tu518 Life Cycle Assessment and Sensitivity Analysis of Radioactive Waste from Decommissioning the Fessenheim Nuclear Power Plant: Case of the very low-level radioactive waste treatment and disposal center
Zineb Guendouz[1]*, Michal Kozderka*[2] *and Vladimír Kočí*[3]*, (1)Department of Sustainability and Product Ecology+Faculté de Physique et Ingénierie, University of Chemistry and Technology Prague+ Strasbourg University, France, (2)Faculté de Physique et Ingénierie, Strasbourg University, France, (3)Department of Sustainability and Product Ecology, University of Chemistry and Technology Prague (UTC), Czech Republic*
The decommissioning of French nuclear power plants is expected to generate a large amounts of very low-level radioactive waste (VLLW). The current prohibition on reusing VLLW in France presents significant environmental challenges, as existing waste disposal centers face saturation by 2028, necessitating the urgent construction of new facilities.

While few life cycle assessments exist for nuclear power plant decommissioning, our study comprehensively focuses on managing VLLW. Centered on the 11,200 tons resulting from the Fessenheim Nuclear Power Plant decommissioning, our methodology emphasizes storage center construction, including packaging and transport processes. To enhance assessment reliability, we integrate a careful sensitivity analysis (±30% variation in each data element) and a Monte Carlo analysis within the SimaPro software. Developed with SimaPro software and ecoinvent databases, this method enables a precise VLLW life cycle analysis, revealing pivotal findings influencing effective waste management strategies.

Our analysis highlights packaging and transport as a pivotal factor significantly impacting respiratory inorganics, releasing harmful substances that affect human respiratory health. Moreover, the transportation process contributes 3290 tons of CO2 equivalent, significantly influencing global warming. The use of construction materials, particularly geomembrane HDPE and gravel, exerts notable impacts on various environmental categories, including human health, ecosystem quality, climate change, and resources. These materials significantly contribute to the overall environmental footprint during VLLW storage and management, emphasizing the urgent need to explore sustainable approaches to mitigate these impacts.

In addressing VLLW challenges, urgent innovative strategies are vital. Aligning VLLW treatment with international recycling norms, questioning its current radioactive waste classification in France, and exploring recycling possibilities are crucial for mitigating environmental impact. Additionally, reassessing VLLW as conventional waste and adopting post-demolition material recycling show potential in diminishing long-term environmental effects in nuclear settings. Our study highlights the importance of adopting inventive approaches to sustainably manage VLLW, providing substantial environmental enhancement and safer practices in nuclear decommissioning.

5.07.P-Tu519 Consequential Life Cycle Assessment of Mycoprotein as Meat Alternative in the EU Market
Adisa Ramadhan Wiloso[1,2]*, Elias Hurmekoski*[1,3]*, Lassi Ahlvik*[4] *and Hanna Tuomisto*[3,5,6]*, (1)Department of Forest Sciences, University of Helsinki, Finland, (2)University of Helsinki, Finland, (3)Helsinki Institute of Sustainability Science (HELSUS), University of Helsinki, Finland, (4)Department of Economics and Management, University of Helsinki, Finland, (5)Future Sustainable Food Systems Research Group, Department of Agricultural Sciences, Faculty of Agriculture and Forestry, P.O. Box 27, University of Helsinki, Finland, (6)Natural Resources Institute Finland (Luke), Finland*
This study investigates the environmental consequences of supplying more mycoprotein, a meat alternative produced from fungi, into European markets using a consequential life cycle assessment approach. We first defined a cradle-to-gate system based on secondary data taken from available literature and database, and applied marginal data for electricity to the foreground systems. The initial system was eventually expanded to include other systems that are not physically related, but are expected to be affected through market forces. We assumed that additional supplies of mycoprotein in the EU market will substitute animal meat, the degree of which can vary greatly depending on the type of the product and/or market, and indirectly leads to the by-products substitution as well. To illustrate this, we first applied perfect-substitution assumption as the baseline scenario for each point of substitution being identified, i.e., pork, beef, chicken, manure, leather, milk, and oil. We subsequently applied different substitution rates, which are estimated based on the own- and cross-price elasticities of these commodities sourced from the literature, as part of the sensitivity analysis. The environmental impact categories considered include global warming, cumulative energy demand, land use, and water use, which are calculated using software-integrated methods. We expect that the net environmental consequences of supplying an additional one kg of mycoprotein will vary to some extent under the two different scenarios: (1) perfect-substitution assumption (2) empirically-based substitution. Furthermore, we believe that the perfect-substitution scenario will give minimum environmental consequences due to the profound benefits of avoided emissions from livestock system. In addition, it is more likely that the energy use and enteric fermentation would be central to the environmental trade-off as they are the major sources of climate-related emissions in mycoprotein and cattle systems, respectively. To sum up, we expect that mycoprotein as a meat alternative can contribute to food security with minimum adverse consequences, particularly because it requires much less land than comparable livestock farming.

keywords: consequential life cycle assessment, food system, livestock farming, mycoprotein, substitution

5.07.P-Tu520 Life cycle assessment for farmed fish
Takuma Mori[1]*, Tomohiro Kuwae*[2]*, Satoru Yoshihara*[3]*, Takahiro Matsuura*[3]*, Itsubo Norihiro Dr*[4]*, Fujiyo Suehiro*[3]*, Hiromi Suzuki*[3] *and Hiroki Ookubo*[1]*, (1)Tokyo City University, Japan, (2)Port and Airport Research Institute (PARI), (3)Yachiyo Engineering, (4)Waseda University, Japan*
Life cycle assessment (LCA) of fish aquaculture is actively conducted in foreign countries such as Europe, the United States, and China, especially focusing on species such as salmon and sea bass. In Japan, however, there is a dearth of publicly available research in this area. One explanation for this situation may be the relatively low importance of fisheries certification in Japan.

Against this background, this study assessed the environmental impacts of farmed fish in Japan. Specifically, we focused on Japanese red sea bream (Todarodes pacificus) farmed in Ehime Prefecture in southwestern Japan. Japanese sea bream is an important cultured fish in Japan and is popular as an auspicious fish.

The aquaculture facility under study has a unique approach: an automated feeding system. This system uses AI to monitor fish feeding behavior and adjust feed amounts appropriately. The benefits of this system include economic gains for the fishermen through efficient feeding and environmental gains through reduced waste and marine pollution. In addition, the system eliminates the need to send a boat out for each feeding, making operations more efficient.

In addition to the automated feeding system, this study incorporated input data such as seedlings, bait, equipment, and vessel fuel, as well as output data such as dead fish. Data on seedlings has not been addressed much in previous studies due to a lack of data, but we were able to obtain key data for this study and incorporated it into the evaluation. We also incorporated into our evaluation the fact that the life span of an aquaculture net is approximately 5 years, which corresponds to two cycles of a sea bream.

For validation and comparison of the results of this study, we plan to clarify Japan-specific characteristics and issues, while taking into account overseas studies. Furthermore, while the calculations focus primarily on greenhouse gas (GHG) emissions, we plan to expand the study to different impact areas, such as eutrophication and acidification

5.07.P-Tu521 Life Cycle Assessment of LIFE Smart Agromobility project
María-Pilar Martínez-Hernando[1], *César Ruiz Palomar*[2], *Alfonso García Álvaro*[2], *Maria Carmen Suárez Rodríguez*[1], *David Bolonio*[1], *María Jesús García Martínez*[1], *Ignacio de Godos Crespo*[2] *and Marcelo Ortega*[1], *(1)Energy and Fuels, Universidad Politécnica de Madrid, Spain, (2)Chemical Engineering and Environmental Technology, Universidad de Valladolid, Spain*
The primary sector, particularly agriculture, plays a significant role in greenhouse gas emissions, with methane and ammonia being notable contributors. Acknowledging the pressing need to tackle these emissions, this study focuses on data from the LIFE Smart Agromobility project in Spain, funded by the European Commission under the LIFE 2019 program. The project aims to produce vehicular biomethane from pig manure, aligning with sustainability goals and reducing the environmental impact of the primary sector. In addition to reduce pollutant gas emissions, the initiative contributes to the reduction of fossil fuel usage and decreases energy dependence by locally producing renewable fuel. The dual objective of mitigating emissions and fostering energy independence underscores the project's broader environmental and strategic significance.

This research conducts a comprehensive examination of emissions, employing the Life Cycle Assessment (LCA) as its predominant analytical framework. The principal goal is to carry out an analysis of environmental impacts and determine the most sustainable approach within the unique context of LIFE Smart Agromobility. Furthermore, this work incorporates Monte Carlo Analysis allowing for the exploration of potential variations in emissions. By simulating diverse scenarios based on varying manure compositions, the analysis becomes more robust, accounting for uncertainties and providing a more realistic depiction of the potential environmental impact. This probabilistic modelling acknowledges the inherent variability in real-world conditions, enhancing the study's applicability and reliability.

The significance of this research extends beyond a quantitative evaluation; it contributes to a qualitative understanding of emissions management complexities. The results offer crucial insights into the dynamic nature of environmental impacts, emphasizing the need for adaptive strategies. In a world marked by changing climates and evolving agricultural practices, the adaptability of emission management strategies is a mandatory. The study's outcomes could be used to inform policy decisions, guide sustainable practices, and inspire further research of environmentally conscious approaches.

5.07.P-Tu522 Wood Buildings or Decarbonized Concrete ? A Prospective Life Cycle Assessment Perspective Coupling Forest Sector Modelling and Prospective Energy Scenarios
Thomas Beaussier[1] *and Juliana Steinbach*[2], *(1)ISIGE Mines paris, (2)Mechanical Engineering, MINES ParisTech, France*
Wood construction is an important levee towards the decarbonization of the construction sector, replacing traditional materials such as concrete and steel. Its development is part of transition pathways towards carbon neutrality at national and European level, as well as roadmaps fostering a circular and sustainable bioeconomy.

The intricate involvement of wood construction in diverse supply chains, with multiple co-products and circularity loops underscores the interest of using Life Cycle Assessment (LCA) as a systematic and all-encompassing approach spanning the entire life cycle.

To conduct a thorough assessment at both product and sectoral levels, it is imperative to integrate future decarbonization and material recycling strategies for carbon-intensive industries like concrete and steel. This integration is achieved through the coupling of LCA with specialized tools.

This study explores prospective LCA (pLCA) based on the coupling of forest and wood sector modelling with future energy mixes scenarios integrating projections derived from Integrated Assessment Models (IAM). Based on the open-source Python library *premise* [1], the approach facilitates the comprehensive modelling of transformations in energy-intensive activities within the inventory along the upstream value chains.

Key variables were parameterized, such as penetration of low-carbon industrial processes, material recycling level, and advancements in transportation technologies.

5.07.P-Tu523 Life Cycle Assessment of Magnetite Production Using Microfluidic Devices: Moving from the Laboratory to Industrial Scale
Olga Patricia Fuentes Daza[1], *Juan C. Cruz*[2], *Emmanuel Mignard*[1], *Guido Sonnemann*[1] *and Johann F. Osma*[2], *(1)University of*

Bordeaux, France, (2)University of Andes, Colombia
Magnetite nanoparticles (MNPs) have important applications in several industrial and scientific fields for the remediation of contaminated soil and water, for instance. Emerging technologies such as microfluidic techniques have been adapted to continuously synthesize MNPs showing appealing results, such as a
narrower size distribution. Therefore, this approach might become important for producing MNPs to meet industrial requirements.

This work proposes a possible scaling-up of the synthesis of MNPs using many microfluidic devices working in parallel. Such an increase is envisaged to go from a laboratory scale to an industrial scale. In this context, our work aims at investigating what would be the environmental impacts of such an increase in scale and understanding the possible shifting of burdens among environmental impact categories and from one part of the product life cycle to another. Therefore, we carried out a life cycle assessment (LCA) study considering all of the steps related to the microfabrication of the devices and to the production of MNPs at both the laboratory and industrial scales, including materials, electricity, and wastewater generated.

The LCA results showed that the rivets suitable for device inlets and outlets and the chemicals required for the synthesis process have the highest contribution to all impact categories, i.e., 80 and 90%, respectively. These results thus contribute to determining the overall environmental performance of each step during the synthesis of MNPs. The contribution analysis reveals that the manufacturing stage has a contribution of 97% at the lab scale, while the operation stage shows a contribution of 82% at the industrial scale. Finally, a sensitivity analysis is performed to identify the possible scenarios for replacing rivets required to manufacture microfluidic devices.

This work reports on the first LCA study of microfluidic devices, which we are aware of, that consider scaling-up calculations. Furthermore, the industrial production of the MNPs introduced here is an innovative process whose environmental impact, to our knowledge, had not been analyzed previously. Therefore, this study contributes to studying this process' overall feasibility by providing detailed information on the implementation of the LCA methodology to assess comprehensively emerging technologies such as microfluidics.

5.07.P-Tu524 Prospective life cycle assessment on carbon capture and utilization technology to decarbonise the steel and fertilizer industry

Anne Ottenbros[1]*, Mark Huijbregts*[2]*, Rosalie van Zelm*[1] *and Nicola Zecca*[3]*, (1)Radboud University Nijmegen, Netherlands, (2)Environmental Science, Radboud University Nijmegen, Netherlands, (3)Dipartimento di Energia, Politecnico di Milano, Italy*
Decarbonising the steel and fertilizer industries is essential to achieve the net-zero climate goals, as these industries account for 8% and 0.93% of the global greenhouse gas (GHG) emissions respectively. There are several strategies to decarbonise the steel industry, e.g. electrification or using carbon capture technologies. Similarly, the fertilizer industry can produce green ammonia and urea based on renewable green hydrogen from water electrolysis. Another approach is to combine waste streams from the steel industry as chemical feedstock for the fertilizer industry, and thus creating a more circular economy. This is investigated in the EU H2020 INITIATE project.

The INITIATE technology re-uses residual gasses rich in hydrogen, nitrogen and carbon as a resource for fertilizer production (i.e., ammonia and urea), by using sorption enhanced water-gas shift (SEWGS) technology. After fertilizer production, the remaining carbon dioxide is sequestered. In this way, the carbon footprint of both industries is expected to be lowered. This technology is still under development (i.e., pilot scale). For a fair comparison between the INITIATE symbiotic technology and conventional ammonia and urea production need to be compared at similar technology readiness levels (TRLs). Hence, a prospective life cycle assessment (pLCA) was performed to determine the environmental impact of applying this technology on industrial scale and identify improvement options. In the assessment, upscaling to industrial scale and potential scenarios future electricity supply were explored.

5.07.P-Tu525 Regionalized environmental burden-shifting from strategic metals supply for the energy transition: a prospective life cycle assessment

Marguerite Fauroux[1]*,* ***Anne de Bortoli***[2]*, Maxime Agez*[3] *and Elliot Muller*[4]*, (1)Magi, CIRAIG Polytechnique Montreal, Canada, (2)Génie chimique, Montreal Polytechnic, Canada, (3)CIRAIG - Ecole Polytechnique de Montreal, Canada, (4)Chemical engineering, CIRAIG Polytechnique Montreal, Canada*
The global shift towards renewable energies for achieving net-zero emissions relies heavily on strategic and critical metals (SCM). Essential components of solar panels, wind turbines, electric vehicles, and energy storage systems, SCMs raise concerns due to potential environmental risks throughout their life cycle. The objective of this study is to perform a prospective Life Cycle Assessment (pLCA) of the cumulative demand for SCM up to 2050, to identify the SCM and processes in the SCM value chains that have the greatest impact, as well as the impact categories that contribute most to the endpoint damages. Finally, by regionalizing the inventories, the study seeks to analyze North-South potential burden-shifting in the energy transition due to SCM supply.

First, the cumulative SCM demand until 2050 is estimated using an International Energy Agency (IEA) database for 3 IEA scenarios: Net Zero Emissions by 2050, Announced Pledges Scenario, and Stated Policies Scenario. An extensive literature review of existing pLCA studies is then conducted to benchmark calculation methods and areas for improvement. A preliminary static LCA of the cumulative demand for SCM is then performed using ecoinvent 3.8 and IMPACTWorld+. This preliminary study, together with the literature review, allows the selection of SCM to be refined in the model. Next, the python library *premise* is used to generate prospective ecoinvent databases for each scenario, and the following changing variables are modeled: primary production location, routes, ore grade declines, energy, water and chemical requirements, waste generation, and land use.

The metals with the highest cumulative demand were identified as aluminum and copper, followed by graphite and nickel. The preliminary static LCA revealed that copper and aluminum exhibit the most significant impacts on human health and ecosystem quality. Expected complementary results will include regionalization of mining and refining processes, as well as the impact of declining ore grades.

In conclusion, this study will provide insights into the environmental impacts of SCM supply, with aluminum and copper emerging as focal points. Recommendations will be provided to adequately support environmental SCM policies, to anticipate which countries could benefit from the energy transition and which countries would bear the costs, through the lens of North-South disparities already at stake in the consequences of climate change.

5.07.P-Tu526 A review of the application of Life Cycle Assessment in hydrogen and alternative carbon source integration in Electric Arc Furnace based steel manufacturing

Nethmi Sewwandi Kankanamge Dona[1], *Franco Donati*[1], *Stefano Cucurachi*[1] *and Rene Kleijn*[2], *(1)Leiden University, Netherlands, (2)Institute of Environmental Sciences, Leiden University, Netherlands*

The iron and steel industry accounts for an approximate of 4% of anthropogenic CO2 emissions in Europe, and 9% worldwide, due to the massive use of coal. According to the World Steel Association, 1.88 Billion tonnes (Bt) of crude steel were produced globally in 2020 emitting 2.21 Bt of CO_2. Electric Arc Furnace (EAF) approach can be identified as a less carbon intensive approach to steel production and an approach to realize the recycling of scrap resources. The proportion of crude steel in EAF worldwide remains at an average of 28%, and with the strict requirement for energy conservation and environmental protection, EAF steel production will continue to rise.

Hydrogen exhibits great potential applications in the steel and iron industry due to its high calorific value, good thermal conductivity and high reaction rate, though producing the hydrogen that is required for the full decarbonisation of the steel industry demands an increase in electricity production of 20%, and enhanced access to locally available cheap renewable electricity. Steel production also requires alternative carbon sources to replace the existing coal and coke use which contributes to an estimate of 40-70% of the direct emissions. There are alternative carbon sources for the EAF that can either be used as charged or injected carbon. Charcoal, biomasses, rubber tires and polymers are the current known alternatives.

This work will focus on the environmental impacts of integrating alternative carbon sources to the EAF with and without hydrogen integration. The analysis will discuss the environmental impacts of these sources with an emphasis on biomass alternatives. Biomass can be identified as a preferred alternative in steel industry due to its low sulphur content, high ratio of carbon to ash and high specific surface that will potentially improve metal quality and furnace productivity.

We will initially identify the currently available hydrogen based steel production technologies with their alternative carbon-sources. The results will be presented based on the application of ex-ante LCA in each integrated steel manufacturing technology. This work will contribute to the ex-ante LCA modelling of hydrogen and biomass based steel production systems by consolidating the methodological challenges associated with drafting the lab scale or industrial scale systems and identifying feasible alternative scenarios that can be applied in a wider and a commercial context.

5.07.P-Tu527 Beyond Lifecycle Assessment: cross-disciplinary methodologies to address challenges with environmental impact measures

Alana James[1], *Anne Peirson-Smith Prof*[1], *Kelly J Sheridan*[1], *Miranda Prendergast-Miller*[1], *Thomas Stanton*[2], *Anil Namdeo Prof*[1], *Matteo Gallidabino*[3], *Chimdia KeChi-Okafor*[1] *and Nkumbu Mutambo*[1], *(1)Northumbria University, United Kingdom, (2)Loughborough University, (3)King's College London, United Kingdom*

There is widespread global concern at the scale of the environmental, economic, and social impacts caused by the unrestrained growth in global fashion and textile production and consumption. Awareness of the extant environmental crisis facing the planet has necessitated a targeted call to action by the industry itself in addition to a range of associated stakeholders. Consequently, a wide inventory of Environmental Impact Assessment (EIA) metrics, methods and tools are increasingly being devised and utilised across the industry. However, complex, and globalised supply chains make EIA challenging from a traceability perspective, with practices of out-sourcing to second and third tier factories being commonplace. Furthermore, the understanding of the extent to which fashion impacts the natural world remains limited due to unreliable collation methodologies, segregation of the value chain, and utilisation of intangible indices. Unregulated self-reporting across the industry has resulted in unverified and unpredictable information being publicly communicated, with much industry and policy action being based on this untrustworthy data.

Assembling critical knowledge from the scientific community, juxtaposed with design capabilities, this project questions the *reliability, authenticity* and *useability* of current environmental and social assessment methodologies and critically analyses established indices and certifications. Through the development of a secondary systematic literature review, holistic mapping of existing metrics, and engagement with a range of relevant stakeholders (designers, brands, manufacturers, retailers, textile recyclers, consumers etc.) via focus group activities and one-to-one consultation, this research proposes a methdological toolkit to aid future research spanning creative and scientific fields of knowledge. Furthermore, participatory workshops with the science and design communities have provided validation and further development opportunities.

Collaboration between creative and science disciplines is paramount in the critical understanding, contextualisation and provision of evidenced based data when measuring EIA across the fashion sector. The development of the toolkit enables knowledge transfer across disciplinary boundaries and has extensive impact beyond academia, embedding research into the development of solutions regarding the way sustainability is measured and perceived from multiple stakeholder perspectives.

5.07.P-Tu528 Dynamic-Prospective Life Cycle Assessment using Time-Explicit Life Cycle Inventory: Methodology and Implementation

Timo Diepers[1]*, Amelie Müller*[2]*, Giuseppe Cardellini*[3]*, Arthur Jakobs*[4]*, Christian Zibunas*[1]*, Bernhard Steubing*[2]*, Jeroen Guinee*[2] *and Niklas von der Assen*[5]*, (1)RWTH Aachen University, Germany, (2)Leiden University, Netherlands, (3)Flemish Institute for Technological Research (VITO), Belgium, (4)Paul Scherrer Institute (PSI), Switzerland, (5)Institute of Technical Thermodynamics (LTT), RWTH Aachen University, Germany*

Life Cycle Assessment (LCA) is a key tool for evaluating environmental impacts of products and services, but typically overlooks the time-specific nature of processes. Traditional LCA assumes a static Life Cycle Inventory (LCI) where processes occur simultaneously and don't change over time. Neglecting such temporal variations is particularly insufficient in the assessment of decarbonization pathways, where understanding both the transition of production systems and the timing of emissions is essential. To incorporate a temporal dimension in LCA, two fields of research have emerged. First, dynamic LCA (dLCA) tracks the timing of processes and corresponding emissions, e.g., scheduling an end-of-life process a certain time after a construction process. Second, prospective LCA (pLCA) takes projections for future production systems into account, e.g., incorporating rising shares of renewable electricity. However, a comprehensive methodology combining both approaches is lacking.

We present a novel framework for joint dynamic-prospective LCA that is embedded in the open source python LCA software *Brightway25*. The novel framework allows users to define temporal distributions for processes and emissions and automatically match them to corresponding time-specific prospective LCI databases. The resulting dynamic-prospective LCI accounts for both the state of technologies in the production system at the actual time of each process (from the prospective databases), as well as the emission profiles of the biosphere exchanges. To achieve this, we build upon functionalities of the existing dLCA package *bw_temporalis*, using graph traversal and convolution to retrieve a timeline of processes with timestamps for each process of the production system. This timeline is used as a basis for modifications of the production system, introducing temporal copies of each time-distributed process. According to the timestamps, new links to corresponding processes in the prospective background databases are added, yielding an improved representation of the technosphere. In addition to these links within the production system, assigning temporal distributions to emissions allows for dynamic impact assessment.

The focus of this submission is the underlying methodology of the framework and its practical implementation. A detailed description of the overall concept and advantages of the framework as well as first case study results are submitted in a separate, related abstract (#23128).

5.07.P-Tu529 Handling Multifunctionality in Prospective Life Cycle Assessment – a Systematic Framework

Leon Zacharopoulos[1]*, Nils Thonemann*[2] *and Jutta Geldermann*[3]*, (1)University Duisburg-Essen (Uni DUE), Duisburg, Germany, (2)Leiden University, Netherlands, (3)University of Duisburg-Essen (Uni DUE), Germany*

Prospective life cycle assessment (LCA) supports environmentally guided decisions to be made in the early stages of the decision-making process. However, a key concern in prospective LCA research, such as in retrospective LCA, is the handling of multifunctional processes. In a retrospective LCA, the quality of by-products and their flow type (good or waste) is mostly determinable. Conversely, data of a prospective LCA is based on various explorative scenarios at different future points in time and fundamental assumptions about a future state. Likewise, the quality and flow type of the by-products may not be determined and might change over time, as the processing steps may differ between laboratory and commercial scale. Therefore, the characteristics of a process in terms of multifunctionality are variable in a prospective LCA in quality (e.g., price, substitution ratio) and flow type (good or waste). Hence, in a prospective LCA, handling multifunctionality entails additional pitfalls compared to retrospective LCAs. Despite existing frameworks focusing on handling multifunctional processes in LCA and frameworks for conducting prospective LCA, none adequately addresses the variability inherent to handling multifunctional processes in prospective assessments. From a systematic review of prospective LCA case studies and the existing frameworks, we derived five types of variability in a prospective LCA that influence the handling of multifunctionality. The five types of variability identified in this work are (i) changes in product quality, (ii) changes in the technology setup, (iii) changes in the legislation and regulations, (iv) price changes and (v) changes in mass balance. Based on these parameters, a framework that guides practitioners to handle multifunctional processes in prospective LCAs systematically is developed.

5.07.P-Tu530 Harnessing Machine Learning To Forecast Environmental Futures – Tomorrow's Waterscapes
Niklas Engberg[1] *and Carlos Felipe Blanco Rocha*[2]*, (1)Delft University of Technology, Netherlands, (2)Leiden University, Netherlands*
As the quest for sustainable and circular product and technology design intensifies, so does the need for early-stage informed decision-making. Ex-ante Life Cycle Assessment has been widely adopted to support such decision, but faces many challenges, for example the epistemic uncertainty of characterisation factors, used to study environmental and social impacts. One of the methods in literature to address this uncertainty is recalculating characterisation factors based on projected data from Integrated Assessment Models. However, the relatively complex and data-heavy Integrated Assessment Model calculations oftentimes do not match the scope of Life Cycle Assessment-studies.

In this study, we evaluate the potential of Machine Learning as viable alternative to Integrated Assessment Models for creating spatially explicit time-series of future characterisation factors. We demonstrate our approach based on the characterisation factors 'AWARE' and Water Scarcity Index, which assess the impact of human-induced water extractions in over 10,000 global watersheds. We developed multiple Machine Learning models trained on historical time-series from environmental datasets and corresponding characterisation factors and identified Deep Learning models like NBeats as well as gradient-boosting models like XGBoost, LightGBM to be best suited for the endeavour. Different temporal and spatial aggregations of the environmental variables were used to find the best suited input data for the machine learning models, taking computing time and accuracy into account.

Average surface temperature, precipitation, and consumption habits were identified as important covariates for predicting future water scarcity. Further feature engineering included clustering watersheds according to the scarcity behaviour over the course of the year. Cross-validation was used to control overfitting of the models. In certain regions, the Machine Learning models forecast decreasing water scarcity that diverges from the conclusions of other research in this area. This discrepancy underscores the need for additional validation and refinement of the models to ensure their accuracy and reliability in forecasting water scarcity trends.

Track 6. Environmental Policy, Risk Management, and Science Communication

6.01 Bird and Mammal Risk Assessment: Implementation of New Approaches for the Study of Higher-Level Effects in Wildlife Toxicology

6.01.T-01 Redefining the Terrestrial Vertebrates Risk Assessment: A Paradigm Shift Towards Next-Generation Approaches for Agrochemicals.

Ana Fernandez Agudo[1] *and Jose V. Tarazona*[2]*, (1)National Environmental Health Centre. Instituto de Salud Carlos III (ISCIII), Spain, (2)Institute of Health Carlos III (ISCIII), Spain*

The birds and mammals risk assessment (RA) approach has been mostly developed for pesticides, but in line with the One Substance One Assessment proposal should be extended to other areas. In addition, the reliance on animal-centric methods for pesticide safety assessment (SA) is facing growing resistance from society, pushing towards a paradigm shift in evaluating overall performance, sustainability, relevance to human health risk assessment, and ethical considerations. This emphasizes the need for a more flexible and purpose-driven approach in implementing New Approach Methodologies (NAMs) for SA.

With our work, we aim to generate a novel conceptual paradigm and the use of mechanistic information using NAMs and landscape frameworks for developing Next-Generation Environmental Risk Assessment (NGERA) to gather comprehensive risk information in a more holistic and efficient manner. This paradigm seeks to take a step forward for the assessment of Pesticides, Biocides and REACH substances focusing on integrated and more informative risk paradigms, based on simplified landscape models, population dynamics, and the variability of agroecosystems and agricultural management. This refined paradigm offers realistic outcomes and allows the integration of diverse regulatory initiatives, serving as a versatile and dynamic tool for comparing environmental effects, assessing aggregated exposure a combined impacts on target species, ultimately enhancing the reliability of risk assessments through optimized representation of real-world scenarios.

It aims to focus on the risk drivers triggering the impacts on biodiversity conservation and ecosystem services/functions. Integrating these models into the RA process for the different regulatory sectors, would provide a more comprehensive and realistic understanding of the environmental consequences, allowing for a more refined evaluation of potential harms and their consequences. This shift represents a holistic approach that considers not only the immediate risks posed by these substances but also their lasting effects on the environment.

To conclude, the proposed conceptual framework, integrating mechanistic information through NAMs and probabilistic NGERA, represents a purpose-driven effort to gather holistic risk information and reflects a commitment to advancing methodologies in response to evolving societal expectations through a paradigm shift.

6.01.T-02 Think Twice Before You Chose Your Study Site – Identification of Focal Species Study Areas Under the Revised Birds and Mammals Guidance Document

Ines Hotopp[1]*,* ***Anja Russ***[2]*, Benedikt Gießing*[1]*, Christian Wolf*[1]*, Thorsten Schad*[3] *and Markus Ebeling*[3]*, (1)Tier3 Solutions GmbH, Germany, (2)tier3 solutions GmbH, Leverkusen, Germany, (3)Bayer AG - Crop Science Division, Germany*

If the bird or mammal risk assessment of a plant protection product fails at the lower tier effect or exposure assessment approaches, refining the risk assessment by considering a specific focal species (FS) to replace the generic model species (GMS) is a crucial element. The FS is a real species that is present in the crop in focus or immediate off-field at the time of product application. Since the risk assessment for the FS needs to be sufficiently protective of all other species of the same feeding guild, the determination of the FS is crucial.

Therefore, the recently revised EFSA guidance document for the risk assessment for birds and mammals (2023) highlights the need to put more effort in the identification of the most vulnerable species per feeding guild as the most appropriate FS. It is now emphasised that not only prevalent and abundant species are to be considered, but also rare and/or more locally distributed species. Hence, already the selection of the study area to conduct a focal species study is crucial for not missing relevant species.

In order to consider all relevant species that might occur in the crop in focus or its immediate surroundings and at the respective time of year, we developed a stepwise approach to identify FS-candidates in winter cereals as an example.

In a first step, from a list of European bird species, all species that potentially use the crop are assigned to at least one feeding guild. For each of these species, their distribution during the relevant time of the year that is linked to the crop growth stage during product application is mapped. This step also takes into account seasonal distribution changes due to breeding, migration and overwintering. From this data set, regions in each regulatory zone are identified where preferably all relevant species (incl. rare and/or locally restricted species) occur and the crop is cultivated in a sufficient amount. We also give recommendations in case that no region can be found that covers all regionally distinct species.

A subsequent FS study following these theoretical considerations must ensure that all habitat types are covered and sufficiently replicated, in order to meet the requirements of all potentially relevant FS.

6.01.T-03 Seed treatment risk assessment scheme in the 2023 EFSA GD for birds and mammals: review and impact assessment

Dennis Sprenger[1]*, Manousos Foudoulakis*[2]*, Joerg Hahne, PhD*[3]*, Steven Kragten*[4]*, Kai Ristau*[5] *and Alan Lawrence*[6]*, (1)Corteva Agriscience, Moon Township, United States, (2)Corteva Agriscience™, Greece, (3)Bayer AG - Crop Science Division, Germany, (4)Syngenta Agro GmbH, Germany, (5)BASF, United States, (6)Alan Lawrence Ltd, United Kingdom*

An impact assessment for seed treatment uses according to EFSA 2023 is presented using industry owned active substance data, and underlying risk assessment assumptions as well implications for the availability of seed applied technologies for farmers in context with the EU green deal are discussed.

For tier 1, the EFSA 2023 online calculation tool was used and failure rate was compared to EFSA 2009.

For higher tier, two approaches were used to refine the reproductive risk for the exposure to treated seeds scenario according to refinement options outlined in EFSA 2023: i) quantitative refinement by introducing focal species, PT, fTWA value in case TWA can be used (all higher tier parameters were theoretical to allow for better comparison between compounds); ii) qualitative refinement by calculating the maximum searching area to reach the RAD.

Our preliminary analysis suggests that the EFSA 2023 risk assessment scheme for seed treatment uses is not fit for purpose. At tier 1, failure rate for the reproductive risk assessment for the treated seeds scenario is >90% of the tested cases. The tier 1 risk assessment does thus not allow to effectively separate high from low concern products as is the case for spray uses. At higher tiers, high conservatism (e.g. assumption of *ad libitum* access to treated seeds) and limited higher tier options not realistically reflecting relevant field conditions (e.g. PT and PD cannot be used in combination) make it difficult to meet the relevant trigger for the majority of compounds. The resulting need for complex WoE evaluations is predicted to result in a high workload for regulators and in inconsistent evaluations for the same data set.

In the light of activities to reduce pesticide exposure in Europe, seed treatments present an effective technology to limit exposure to non-target organisms. However, the EFSA 2023 risk assessment scheme renders the availability of seed applied technology to farmers as highly uncertain.

We therefore promote an open discussion with relevant stakeholders (e.g. a workshop with regulators, EFSA, industry) with the aim to develop a timely update of the seed treatment risk assessment scheme that is fit for purpose and more realistic for field conditions.

6.01.T-04 Modulatory Effects of Aquatic Resources on Neonicotinoid-Induced Developmental Toxicity in Tree Swallows (Tachycineta bicolor)

Biyao Han[1]*, Sonia Cabezas*[1]*, Margaret L Eng*[2]*, John V. Headley*[3] *and* ***Christy A. Morrissey***[2]*, (1)Biology, University of Saskatchewan, Canada, (2)University of Saskatchewan, Canada, (3)Watershed Hydrology and Ecology Research Division, Environment and Climate Change Canada, Canada*

Neonicotinoids are the largest group of insecticides sold around the world for decades. The widespread use of these insecticides in modern agriculture not only decreases non-target insect populations, which limits the availability of food for aerial insectivores, but also poses adverse effects on them due to acute and chronic toxicity. Agricultural intensification has also resulted in losses of wetland habitat and decreased availability of nutritious aquatic insect prey, which are enriched with polyunsaturated fatty acids (PUFAs), especially omega-3 fatty acids. Previous studies suggest wetland coverage and dietary PUFAs can improve growth of swallow nestlings. Thus, the use of neonicotinoid insecticides and loss of aquatic insect prey resources is suspected as major drivers for population declines in aerial insectivores worldwide. We hypothesized higher wetland density or oral supplementation of PUFAs may modulate the toxicity of neonicotinoid exposure in aerial insectivores. In 2022 and 2023, we conducted research on free-living tree swallow nestlings orally dosed with imidacloprid (0, 4, 6, 9, 13 µg/g bw) or clothianidin (0, 11, 23, 46, 75, 95 µg/g bw) in 2 experiments testing the additive effect of high or low wetland density or supplementation with high or low PUFAs (medaka fish oil or organic sunflower oil). Post-fledging survival and movement were also assessed by tracking the fate and natal site departure timing of nanotagged fledglings with the Motus network. Our results show that both insecticides significantly impaired the growth and condition of nestlings in a dose-depended manner. Chicks reared in the high wetland density sites had higher blood omega-3 PUFA levels. In 2023, higher wetland availability boosted nestling growth and reduced imidacloprid-induced toxicity. However, short-term beneficial effects of co-exposure to PUFA-rich oil appeared limited. 22% of nanotagged chicks exposed to imidacloprid successfully fledged and were detected outside of their natal sites compared to 50% in control group and 60% in clothianidin exposed group. No significant differences were noticed for the time of departure from their natal sites. Together, these findings provide first evidence of acute neonicotinoid insecticide toxicity in swallows, and data in support for management and conservation of aquatic resources in agricultural landscapes to reduce risks of insecticide exposure and enhance growth and survival of aerial insectivores.

6.01.P Bird and Mammal Risk Assessment: Implementation of New Approaches for the Study of Higher-Level Effects in Wildlife Toxicology

6.01.P-We462 Validation of Avian In Ovo Assay for Sex Steroid Hormone Disrupting Properties
Andrea Rivero Arze, PhD, *Elise Grignard, Pauline Lelandais and Philippe Hubert, Pepper, France*
Pepper (Public-private platform for the validation of endocrine disruptors characterization methods) is validating a method to determine the estrogenic and anti-estrogenic effects of pollutants in the embryos of White Leghorn chicken (*Gallus gallus domesticus*).

During the first phase of this validation (transferability phase), 3 laboratories tested 3 test items: 17α-ethinylestradiol (EE2), fadrozole hydrochloride and genistein; with strong estrogenic, weak estrogenic and anti-estrogenic effects respectively. The objective is to test the method's repeatability and reproducibility as well as identify the improvements needed in the Standard Operating Procedure.

At day 4 of the eggs incubation, 20µL of the test item diluted in DMSO are injected to the air chamber. The experimental set up consists of 5 groups: a negative control of non-injected eggs, solvent control and 3 doses with 10x dilutions starting at the highest soluble non-toxic concentration. At day 14 the embryos are sacrificed and morphological endpoints as the size of the gonads and the length of Mullerian Ducts are assessed. Moreover, qPCR analysis of the aromatase gene expression is done taking samples from the embryo's left gonad.

Male embryos exposed to EE2 presented a significant increase of their left/right gonads surface ratio which represents a feminization effect. Females exposed to fadrozole hydrochloride presented a significant decrease for this endpoint. The Mullerian Ducts length measures allowed to determine an anti-estrogenic effect. Finally, the aromatase gene expression showed an increase for the males exposed to estrogenic compounds and a decrease for the females exposed to the anti-estrogenic substance.

The method was successfully transferred from the developer laboratory to 2 other naïve laboratories. The results showed a good intra-laboratory repeatability and inter-laboratory reproducibility. Some minor difficulties that were experienced during the transferability phase allowed to propose changes to the Standard Operating Procedure (i.e. taking out some irrelevant endpoints, modify DMSO volume, etc.). A new clarified version will be implemented for the next phase of the validation where the 3 laboratories will test 12 blind-coded test items.

6.01.P-We463 Disentangling the Adverse Outcome Pathway of triazole fungicides on birds
Claudia Santamaria Cervantes[1], *Manuel Ortiz Santaliestra*[1], *Gudrun Wibbelt*[2] *and Rafael Mateo*[3], *(1)Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain, (2)Insitute for Zoo and Wildlefe Research (IZW), (3)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain*
Over the recent decades, a decline in farmland bird populations has been observed across Europe. This regression has been linked to agricultural intensification, a phenomenon characterized by different components, including the use of pesticides. Triazoles, a group of fungicides employed as seed coating treatment in crops, pose a potential threat to wildlife inhabiting agro-ecosystems, particularly granivorous birds that consume sown seeds. In Spain, these products are the most frequently detected in red-legged partridges (*Alectoris rufa*) hunted during the sowing season, with a prevalence of 29%. Triazoles can impact on the reproductive success of birds, reducing fertility rate and brood size. The aim of this study is to assess the reproductive effects on red-legged partridges exposed to seeds treated with tebuconazole and prothiconazole and begin to understand the mechanism by which triazoles may produce long-term effects on reproduction by carrying biometrical and histopathological analysis. Partridges were fed with wheat seeds treated at 0%, 20% or 100% of the labelled application rate. The exposure period lasted for 20 days in late autumn 2021, and reproductive parameters (including fertilization, hatching, and chick survival rates) were subsequently monitored in spring 2022 and spring 2023. In addition, gonadal size was assessed in 24 partridges euthanized at different experiment points, and tissue samples were collected for histopathological analysis. Significant reductions in fertilization, hatching, and chick survival rates were observed in couples in spring 2022, which fed triazole-treated seeds more than 4 months before. These findings agree with prior studies, that observed a 23% decrease in hatching rates and diminished brood size. No significant differences were found in the reproductive parameters checked in spring 2023. During histopathological analysis, different damages were identified, however no significant differences were found. The right testicle of birds that had consumed treated seeds was smaller than that of controls. The temporal delay in reproductive effects, occurring several months after triazole exposure in autumn, supports the hypothesis of disruption in steroid-regulated processes as the mechanism of toxicity. This study underscores the potential impact of use of triazole-treated seeds in agriculture on farmland bird populations and it is the first step to disentangling the adverse outcome pathway of triazole fungicides.

6.01.P-We464 Predictive framework for estimating exposure to and risks of Second Generation Anticoagulant Rodenticides (SGARs) for kestrels (Falco tinnunculus)
Ciara Marienne Sanchez Paredes[1], *Kathryn Arnold*[2], *Malcolm Burgess*[3], *M. Gloria Pereira*[4] *and Michael Fryer*[5], *(1)Environment and Geography, University of York, United Kingdom, (2)University of York, United Kingdom, (3)Centre for Conservation Science, Royal Society for the Protection of Birds, United Kingdom, (4)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (5)Ecotoxicology, UK Health Security Agency, United Kingdom*
Introduction**:** Transfer of an SGAR along the food chain is a relevant exposure pathway for secondary consumers, but the

European Chemicals Agency (ECHA) acknowledges that further research on non-target species, including raptors, as a basis for a quantitative assessment is required . In contrast, the European Food and Safety Authority (EFSA) revised guidance on risk assessment for birds and mammals outlines a tiered risk assessment scheme including exposure via secondary poisoning; however, it does not includes rodenticides. Therefore, our study aims to combine the current ECHA guidelines for rodenticides with the new, improved EFSA guidelines, 2023, in order to create a predictive framework for better estimating the exposure of SGARs and risk in kestrels.

Material and methods**:** ECHA, 2018 secondary approach and EFSA, 2023 tier 1 and 2 were integrated into our modelling framework. The daily kestrel exposure (E) (ug/g body weight/d) to SGARs was calculated using the EFSA, 2023. E is compared with the toxicological benchmark of "No Acute Effect Threshold (NAET)" derived from endpoint median lethal dose (LD_{50}). A value > 1 indicates that SGAR exposure represents a risk for the kestrel under the model assumptions.

Results and Discussion**:** Using field data of concentrations of four SGARs in rodents, we predicted that kestrels are daily exposed between 8.15 and 23.43 ng/g bw/d of brodifacoum, followed by bromadiolone (0.103-0.297 ng/g bw/d), difethialone (0.101- 0.292 ng/g bw/d) and difenacoum (0.046-0.135 ng/g bw/d). It is known that rodents have generated resistance to bromadiolone, so more toxic options such as brodifacoum are increasingly used. Moreover, brodifacoum has the highest log K_{ow}, the longest half-life and the lowest liver elimination rate, indicating that brodifacoum bioaccumulates in rodents more than other SGARs. The risk characterisation ratios indicate that the calculated daily exposure to brodifacoum represents a risk (R) > 1. Although in the present study, difethialone has the lowest NAET (0.88), compared with brodifacoum (1.87), Difenacoum (166.67) and Bromadiolone (1788.27). Brodifacoum has a longer acetonyl side-chain, which gives a high affinity to the active side contributing to its low LD_{50}, making brodifacoum a highly toxic compound.

Conclusions**:** This predictive framework provides the opportunity to investigate the relative exposure and risk of SGARs to kestrels and other raptors under a range of ecologically relevant scenarios.

6.01.P-We465 Higher tier refinement of the risk assessment for birds and mammals: Residue decline patterns in foliage food items

Kai Ristau, *Christian Imholt and Roland Kramm, BASF SE, Germany*

Under the new EFSA Guidance Document (2023) herbivorous generic model species, in particular the small herbivorous- and medium herbivorous mammal feeding guilds, will show a high failure rate at the screening step/ TIER 1 for foliar spray risk assessments of birds and mammals as part of the authorization process for plant protection products in EU. In higher tier risk assessment substance-specific foliage residue dissipation data will likely be often proposed as a refinement to replace the default DT_{50} of 10 d. In principle, when performing studies aimed at determining a substance-specific residue decline, the analysed food items should reflect the ones considered relevant for the risk assessment. For herbivorous mammals (or birds) the relevant food items are monocot and dicot weeds and/or crop plants for most crop systems (EFSA GD 2023, Annex A & B). There is, however, limited experience on how to execute field foliar residue studies with ‘real’ weed species as in the past it was a common approach to select crop species as surrogates for weeds assuming a similar dissipation pattern.

Compared to residue studies with crops field experiments with real weed species face several methodological challenges, e.g. the emergence behavior varies greatly among species and their composition is often strongly spatially - locally and across geographical regions - structured. In this project several field experiments in Germany and Spain were performed with a high variety of ‘real’ monocot and dicot weed but also crop- (wheat) plants. The field phase (foliar application + consecutive sampling of plant material) at all trial sites was completed in spring 2023 without perturbing influence by rainfall.

Different set-ups primarily aimed to realize a comparable temporal emergence of a sufficiently high number of typical arable monocot and dicot weed species (≥ 3, each), thereby reducing the temporal difference regarding timing of foliar application and consecutive sampling events for residue analytics.

Key lessons learned regarding the methodological challenges of field residue decline studies with real weeds will be shared in this presentation. Secondly, by assessing the obtained residue data the project aims to answer how the observed variation of residue dissipation can be attributed to the factors: 1) tested plant species (wheat, monocot and dicot weed species) and 2) geographical location – considering additionally the potential influence of dilution by growth.

6.01.P-We466 Mixture toxicity assessments in birds and mammals according to GD 2023 – is the calculated risk real?

***Sonja Wich*[1]**, *Christel Schopfer[1] and Tara Raftery Catron[2], (1)BASF SE, Germany, (2)BASF Corporation*

The new guidance document on “Risk assessment for Birds and Mammals” (BM GD 2023) provides an assessment scheme to address the risk from simultaneous exposure to multiple substances from plant protection products (PPP), referred to as “mixture toxicity”. Different substances are assumed to act additive (cumulative) or over-additive (synergistic).

Although true synergistic interaction in mammals is a rather rare phenomenon, occurring at high concentrations and involves in most cases chemical groups that can be well defined (Cedergreen 2014), the new guidance (EFSA 2023) proposes a low threshold to assume over-additivity rather than additivity of toxicity. In case the calculated endpoint assuming dose addition is by a factor of 3 higher than measured in the acute product toxicity study in mammals, EFSA concludes that a “mixture is proven more toxic than what is predicted the DA model” and consequently, “synergistic effects cannot be excluded”. To account for this uncertainty, an additional correction factor is calculated and applied to the risk assessment. Moreover, this correction factor is extrapolated to other exposure scenarios (from acute to long-term) and other taxa (from mammals to birds). In specific cases this approach might be justified. When applied in general it makes the risk assessment overly conservative, thereby resulting in a high and not justified risk for PPPs with several actives to dramatically fail the risk assessment.

We present a recent case of a mixture toxicity assessment, where the risk assessment in line with the new Guidance Document resulted in a complete failure of the acute risk assessment due to a calculated high product toxicity with presumed synergistic interactions of the involved active substances. The available dataset covers a range of acute studies on the active substances and a product study based on the Acute Toxic Class Method (OECD 423) with an LD_{50} in between 300 and 2000 mg/kg bw/d, which does not allow to calculate a precise endpoint. Although, it was clearly demonstrated that one active is driving mixture toxicity, a high acute risk using the most conservative estimate for acute toxicity from the product study was identified. Finally, as limited refinement options are foreseen in the new guidance, further experimental data were necessary to prove the applicability of dose addition and avoid an overconservative assessment.

6.01.P-We467 Refining Plant Residue Decline Data to Account For Decreasing Plant Water Content

Nils Kehrein[1]*, Klaus Hammel*[1] *and Markus Ebeling*[2]*, (1)Bayer AG - Crop Science Division, Germany, (2)Environmental Safety, Bayer AG - Crop Science Division, Germany*

For plant protection products, risk assessments for herbivorous mammals, such as voles and rabbits grazing in treated fields, are based on Residue Unit Dose (RUD) values which predict the concentration of an applied chemical on plant foliage in an animal’s diet, measured as mg a.s./kg plant per kg a.s./ha. Established RUD values are published in the EFSA Guidance Documents for the bird and mammal risk assessment, based on hundreds of residue trials where initial concentrations were determined after applications in the field and normalised to an application rate of 1 kg/ha.

RUDs for the category *monocot foliage* were established with residues from grass and, in large part, from cereal trials (share of 76%). Data from cereal trials was selected solely from early growth stages (BBCH 10-30), when plants are young, fresh, and tender, which represents the preferred diet of small and medium sized mammals.

Residue decline data in foliage can be used to refine long-term risk assessment, by calculating dissipation half-lifes (DT50) to be used in time-weighted average exposure factors (fTWA). However, often the only available residue decline data is from applications in late growth stages (BBCH 60+), since these will result in the highest residues at harvest in the commodity assessed for human consumer safety. The number of samplings in these trials are often lower than recommended for wild mammal risk assessments. Thus, such trials at late growth stages are often not well suited for exposure assessments on herbivorous mammals which prefer young plant material in their diet.

We found that the residues in foliage often appear to increase in these late growth stages which seems to be the result of plant material drying out, leading to increased concentration (mg a.s./kg plant) in the remaining drier plant material. We suggest correcting residue data from late cereal growth stage trials for this effect to better match trial results with the paradigm behind herbivorous wild mammal risk assessment.

As part of the approach, we estimated the change of fresh plant mass over time for cereals. The results were used to adjust residues based on the reported plant growth stage at time of sampling. The approach was able to explain apparent increases of residue concentrations during trials and allowed us to derive residue DT50 for affected trials, for which kinetic evaluations were impossible before.

6.01.P-We468 Time-to-Effect and Recovery of Effects in a Bird Reproduction Study Argues for Use of the Time-Weighted Average Factor (fTWA) for Eggshell Quality in the Regulatory Risk Assessment

Katherine K. Coady, PhD[1]*, Mark Christ*[2]*, Nina Hallmark*[3] *and Markus Ebeling*[3]*, (1)Environmental Safety, Bayer AG - Crop Science Division, (2)Environmental Safety, Bayer AG, (3)Environmental Safety, Bayer AG, Germany*

Eggshell thinning is an undesirable adverse effect that is observed for some pesticides in bird reproduction studies and may lead to eggshell cracking and ultimately failure of embryonic development. The EFSA Guidance Document (GD) 2023 for bird and mammal risk assessment states that no time-weighted average factor (fTWA) shall be used for effects on eggshell thickness that is not correlated with maternal bw/bw change or systemic toxicity. This approach assumes that single-day exposure would be sufficient to induce the measured effect on eggshell thickness. In an avian reproduction with an insecticide (code BCS-CW64991), severe eggshell cracking occurred with increasing severity over time and an observable recovery of the response with a cessation of exposure. Specifically, dietary exposure of BCS-CW64991 to bobwhite quail (18 pairs per treatment group) was conducted for 21-weeks (10 weeks of egg laying) with half of the replicates terminated at that time and half the replicates carried out for a 4-week recovery period on untreated diet. The treatment groups consisted of 0 (control), 100, 300, and 900 ppm a.i. in the diet. Significant eggshell cracking was observed ca. 2-3 weeks after the start of egg laying. Eggshell cracking effects continued to increase over the duration of the laying period. At the end of the exposure period, there were significant effects on adult feed consumption and the number of eggs cracked among all treatment groups (*i.e.*, LOAEC ≥ 100 ppm). Additionally, the total number of eggs laid, the live 3-week embryos of viable embryos, the hatchability of 3-week embryos, the number of 14-day old survivors of normal hatchlings, and the body weights of hatchlings and 14-day old survivors were all significantly reduced at 900 ppm (*i.e.*, LOAEC ≥ 300 ppm). Birds switched to untreated diet showed recovery with regard to eggshell cracking within 2-3 weeks. The presented case study demonstrates that the sensitive time window for exposure leading to effects on eggshell quality in bird reproduction studies may be much longer than the duration (approx. 1-day) of actual eggshell production. Thus, the current standard assumption in EFSA GD 2023 of short-term exposure leading to effects on eggshell thickness may well be overly conservative.

6.01.P-We469 Applying a DEB-TKTD model to analyse avian reproduction study data: a case study with three fungicides and northern bobwhite

Nika Galic[1]*, Jonathan D. Maul*[2] *and Steven Kragten*[3]*, (1)Syngenta AG, Switzerland, (2)Syngenta Crop Protection, (3)Syngenta Agro GmbH, Germany*

Sublethal effects to birds from exposure to plant protection products (PPP) are assessed through reproduction studies (OECD 206 and OCSPP 850.2300) in which several endpoints are measured (e.g., egg production, as well as mortality of adults and viability of offspring are monitored in addition to body weight and food intake of exposed adults). Through a specific experimental design, worst case exposure is assumed, and effect concentrations are derived. It is often observed that birds avoid feeding on treated feed, but this is typically not quantified or accounted for in the risk assessment. Assigning observed effects to food avoidance or direct PPP toxicity is possible with the application of mechanistic effect models. Here we applied the recently published avian DEB-TKTD model to analyse egg production data from studies with northern bobwhite. The model is based on a standard DEB model modified to account for the specific experimental design of reproduction studies and uses feeding observations as input. The new EFSA bird and mammal guidance recommends using TKTD models to provide a more realistic risk assessment, but this is challenged by the requirement for independent data for model validation which is at odds with efforts to reduce vertebrate testing. The model we applied here was partially validated with the reproduction study data and overall showed very good performance, therefore demonstrating its utility and ability to provide additional insights with the standard regulatory data. Based on observed feeding and concentrations in treatments, the model assigns changes in egg production to food avoidance, direct toxicity from PPPs in treated feed, or to a combination of the two. We present a case study with three fungicidal PPPs which show different combinations of effects from food avoidance vs direct toxicity. Fungicide A caused effects only in the highest treatment, of which 49% was due to direct toxicity and 51% was due to food avoidance. Exposure to fungicide B resulted in effects in the middle and highest treatment, where in the former 56% and in the latter 29% was due to food avoidance. Finally, exposure to fungicide C resulted in effects in all treatments and mostly related to direct toxicity: 76.5% in the lowest, 63% in the middle, and 96% in the highest treatment was due to direct toxic effects. We discuss these results in the context of the tiered approach and how it can inform risk refinement considering field relevance.

6.01.P-We470 Benchmark Dose Modelling: Expectation vs Reality

Sarah Priestly*, Amy C. Brooks, MBiolSci, PhD, IBERA Certified Environmental Risk Assessor, Emma Russell and Helena Crosland, Cambridge Environmental Assessments (CEA), United Kingdom*

In September 2022, EFSA (European Food Safety Authority) adopted a guidance document on the use of a benchmark dose (BMD) approach in risk assessment. The scientific committee (SC), who authored the guidance document, suggests that the BMD approach is more appropriate than a no-observed-adverse-effect-level (NOAEL), since in theory it makes more extended use of dose–response data and allows for quantification of the uncertainties in the data. In early 2023, EFSA released a revised bird and mammal guidance document (not yet noted) in which it states that a 10% effect level (EL10) should be used in the risk assessment rather than the NOAEL, and that this should be calculated using a Bayesian BMD tool created by EFSA.

A workshop was set up by EFSA to explain the background around the model and to provide clarity on use of the tool. The use of BMD was also covered during the 2023 bird and mammal guidance document workshop. Once the guidance document is noted, this analysis will need to be conducted on new and existing studies.

At CEA, we have run a substantial number of different datasets through the online tool and encountered numerous issues that we believe will become common due to the data generated in bird and mammal studies not being suitable for these types of analysis. The aim of this poster is to highlight the advantages of BMD, some of the challenges we have faced, and what we think needs to be improved for effective and meaningful use of the tool in the assessment of risk to wild birds and mammals.

6.01.P-We471 Bird-Brained? Migratory Bird Risk Assessment According to the New EFSA (2023) Bird and Mammal Guidance

Helena Crosland*, Amy C. Brooks, MBiolSci, PhD, IBERA Certified Environmental Risk Assessor and Emma Russell, Cambridge Environmental Assessments (CEA), United Kingdom*

The new guidance document on Risk assessment for Birds and Mammals (EFSA 2023) contains several chapters dedicated to the choice of acute and chronic endpoints for use in ecotoxicology risk assessment. Chapter 5.2.9. “Special consideration for migratory birds” is a small section of the guidance, amounting to less than a single page, but with the potential to have significant implications for the avian risk assessment for some substances.

According to the guidance, the mode of action (MoA) of the substance must be considered to determine whether this could potentially lead to effects that could impact migratory birds e.g. ability to gain weight, changes in behaviour. The potential increased sensitivity of migratory birds is assessed by using the existing dataset, which may include passerine data (for non-EU submissions). The mammalian dataset can also be used to assess the risks to migratory birds if there is sufficient similarity between the effects observed in birds and mammals.

As this section of the guidance is brief, there are several areas of uncertainty in terms of which data are important for the assessment e.g. acute vs chronic, passerine vs other bird species, bird vs mammal data. It is not clear to what extent MoA should influence the risk assessment. It is also not particularly clear what criteria need to be met in order to discount the risk to migratory birds, nor when higher conservativeness should be triggered if concerns regarding neurotoxicity are raised. Finally, the presence of this section seems to have been prompted by concerns that migratory birds are particularly sensitive to neurotoxic insecticides, but no explanation or citations are provided to support this assertion.

CEA has now performed several migratory bird scoping assessments in line with chapter 5.2.9. The aim of this poster will be to discuss our experiences so far, in terms of the concerns raised in specific assessments and general issues they have highlighted.

6.01.P-We473 Energy Content, Moisture Content and Energy Assimilation Efficiency by Birds and Mammals of Oil-containing Seeds and its Implications for Seed Treatment Risk Assessments

*Carlos Gutiérrez-Expósito[1], **Anja Russ**[1], Raquel Sainz Elipe[1], Christian Wolf[1] and Steven Kragten[2], (1)Tier3 Solutions GmbH, Germany, (2)Syngenta Agro GmbH, Germany*

Energy content, moisture content and energy assimilation efficiency values are essential parameters in the food intake rate and thus exposure calculations for bird and mammal risk assessments. The recently updated European Food and Safety Authority guidance document on birds and mammals risk assessment summarizes these parameters for different food items relevant for birds and mammals. For seed treatments values for cereal seeds are usually proposed to be used for other crop seeds as well. However, oil-containing seeds (e.g. sunflower, oilseed rape) are expected to have a significant higher energy content compared to cereal seeds. This would result in lower food intake rates and thus exposure from consuming such seeds.

In order to be able to calculate reliable exposure values for risk assessment purposes, we conducted a systematic literature review to collect information on the energy content, moisture content and energy assimilation efficiency for oil-containing seeds (sunflower, oilseed rape, soybean, peanut, sesame, safflower, linseed (flax), white mustard and castor bean). The search yielded 361 papers, of which 111 contained values for at least one of the parameters of the crops in focus. The review of the bibliographic sections of these papers resulted in 40 additional publications with relevant values.

Only values obtained from raw seeds or kernel (peanuts and sunflower) were taken into consideration for calculations. Values have been calculated as the average of the means for each crop. Energy content value of oil-containing seeds were 24.25 Kj/g (N = 124, sd = 3.00), while that for moisture content was 6.62 % (N = 296, sd = 1.06). Energy assimilation values were only available for peanut, oilseed rape, soy, linseed and sunflower for a very limited number of bird and mammal species. Mean energy assimilation efficiency for mammals was 82.37 % (N = 13, sd = 5.00), while those for birds were 54.81 % (N = 14, sd = 9.61) for Galliformes and 79.51 % (N = 10, sd = 5.04) for Passeriformes. The values presented here can be used for future birds and mammals risk assessment, especially for seed treatment products used in the respective crops.

6.01.P-We474 Outcome of a Virtual Workshop on Avian Higher Tier Studies Under the New EFSA Birds and Mammals Guidance Document

*Ines Hotopp[1], **Anja Russ**[2], Benedikt Gießing[1], Christian Wolf[1], Manousos Foudoulakis[3], Steven Kragten[4], Joachim Nopper[5], Dennis Sprenger[6] and Arnd Weyers[7], (1)Tier3 Solutions GmbH, Germany, (2)tier3 solutions GmbH, Leverkusen, Germany, (3)Corteva Agriscience™, Greece, (4)Syngenta Agro GmbH, Germany, (5)BASF, United States, (6)Corteva Agriscience, Moon Township, United States, (7)Bayer AG*

The new EFSA guidance document for the risk assessment for birds and mammals (2023) includes new requirements for higher tier studies but remains vague in the practical implementation of some aspects. In order to discuss practicable solutions to fill these gaps and find acceptable ways to conduct higher tier studies also in the future, a series of virtual workshops on higher tier refinement options for birds and mammals in the EU is planned for the following months.

The first workshop in this series will take place in March 2024 on avian focal species field studies. Stakeholders from industry, CROs, regulators and academia will be invited to join in an exchange at eye level. Practitioners in the field will present initial talks about the current status of higher tier refinement options and innovative approaches that would meet the new B&M guidance expectations. The talks will give an initiation for discussion of scientifically sound and yet practical ways of conducting and evaluating bird focal species field studies.

Participants have different backgrounds and opinions on the implementation of the guidance of higher tier studies as refinement options in the risk assessment of plant protection products. The workshop aims to find joint solutions to increase the trust in the study results for regulators on the one side and increase the security for industry that resource intensive field studies are accepted by authorities when conducted appropriately on the other side. The results of this first workshop will be presented on this poster.

6.01.P-We475 A Proposal on How to Consider 'Vulnerable Species' in Bird Focal Species Selection

*Ines Hotopp[1], **Anja Russ**[2], Benedikt Gießing[1], Christian Wolf[1], Steven Kragten[3], Arnd Weyers[4], Marie Fan, PhD[5] and Dennis Sprenger[6], (1)Tier3 Solutions GmbH, Germany, (2)tier3 solutions GmbH, Leverkusen, Germany, (3)Syngenta Agro GmbH, Germany, (4)Bayer AG, (5)BASF SE, Research Triangle Park, United States, (6)Corteva Agriscience, Moon Township, United States*

The revised EFSA 2023 Guidance Document for Birds and Mammals emphasises vulnerability as criterion rather than prevalence for focal species (FS) selection. Weyers et al. (2022) suggest to rank FS candidates according to their expected magnitude of exposure by calculating a species-specific daily dietary dose (DDD). With this, species experiencing a high exposure would be ranked as potentially more vulnerable and are identified as candidates for focal species. The DDD is calculated using – among others – the estimated 'proportion of diet an individual obtains from the (potentially) treated crop' (PT). A real PT is assessed through a radio-tracking field study, but not for all species such field data are available. Here, the frequency of occurrence in the surveys (FO_{survey}) conducted in each study field obtained from FS field studies is introduced as a proxy for PT in theoretical DDD calculations for the purpose of ranking FS according to their potential vulnerability. The presence of one or several individuals of a species during a high proportion of surveys – resulting in a high FO_{survey} - could be an indication of a high utilisation and, thus, a potential high proportion of foraging time in this crop. In order to evaluate the suitability of this approach, the empirical PT values from radio tracking studies for different bird species were compared with the respective FO_{survey} values for these species obtained in previously conducted FS studies in the same crop and BBCH stage. For this purpose, FS- and PT-field studies conducted for regulatory purposes were used as data source. Furthermore, the data was used to compare the ranking of FS candidates obtained using the new approach with the FS selection based on FO_{field} according to the former guidance document. Based on a pool of ten case examples a positive correlation was shown between PT and FO_{survey} as well as between FO_{field} and the newly derived DDD, suggesting that the proposed approach may be suitable. Only in very few cases were additional species identified as potentially requiring further consideration compared to the former FO_{field}-approach.

6.01.P-We476 Health Status of Animals Tagged in PT Studies: the Importance for Regulatory Acceptance

*Carmen Vives-Ferrándiz Sánchez, Benedikt Gießing and **Olaf Fuelling**, Tier3 Solutions GmbH, Germany*

In the EFSA Guidance Document on the risk assessment for birds and mammals, among the requirements and conditions for valid PT studies that should be considered, is mentioned that healthy individuals should be tagged. The Critical Appraisal Tool (CAT) for the evaluation of ecological field studies (Annex F of the Guidance Document) provides instructions for the reliability of a study in this regard, evaluating whether the general health and/or conditions of the animals studied are measured, described and reported. Thus, in order to fulfil this criterion, the field protocols and documentation of field studies must consider the well-being of the tagged individuals.

Several years ago, we started developing and using score sheets to describe the health status of the trapped individuals and further handling for animal welfare purposes. These score sheets have been constantly improved under consideration of comments from German animal welfare authorities. In our field studies, we use them to assess and document the general condition and the distress of captured individuals for both birds and mammals studies. The score sheets contain a list of possible situations and corresponding distress scores within three main sections: i) general condition of the trapped animal, ii) handling and measuring, iii) marking and tagging. It serves to evaluate the overall individual´s well-being that supports the selection of individuals suitable for tagging. Additionally, symptom-orientated aid measurements are given to support the recovery of the trapped individual if required. Clear criteria of symptoms are defined that prevents an individual from being tagged. Within our studies, the scores of each tagged individual are recorded during the trapping sessions. The animal welfare score sheets are filed as raw data and presented also in the reports. Moreover, in radio-tracking studies where the individual is continuously monitored for a complete activity period, its well-being is evaluated and recorded during each session in addition to the behaviour.

With such information on the health status available for the evaluator, this relevant criterion for the reliability of a study will be met. Therefore, we encourage using an animal welfare score sheets as a common methodology in the field studies and reflecting it in the reports.

6.01.P-We477 GPS Tracking to Estimate Exposure of Birds and Mammals to Plant Protection Products for Risk Assessments

***Olaf Fuelling**, Anja Cervencl and Benedikt Gießing, Tier3 Solutions GmbH, Germany*

In the European registration process for plant protection products, a risk assessment must be conducted for birds and mammals following the guidance published by the European Food Safety Authority (EFSA). A realistic estimation of the exposure of a certain species to these products is a refinement factor used for these risk assessments. The exposure is defined as the proportion of diet an animal obtains from a treated area (PT) with the assumption that this is equal to the time an animal is active within this area over the course of a day.

Until now, conventional VHF radio-tracking data have been used in order to provide an estimate of the PT values. We want to demonstrate the use of GPS tags as a new method to collect data for PT estimations in accordance with the recommendations by the EFSA using GPS data collected during an experimental set-up as well as during field studies with European rabbits *Oryctolagus cuniculus* and field studies with three different bird species.

It will be explained how data can be rated regarding their accuracy in order to select only 'high quality data' for the PT estimations. Example data will be presented to show how 'inactive' tracking records can be identified, e.g. by measuring the level of the movement of the tag by an in-built accelerometer in combination with behavioural observations of the animals. Furthermore, we present an approach for estimating PT values using buffer areas around each recorded GPS location in order to account for positional uncertainty.

Both, GPS and VHF tracking are suitable methods to study home range utilisation of animals, but both have their advantages and limitations. An advantage of GPS tracking is the complete avoidance of disturbance by an observer and the possibility to continuously track animals with very big home ranges, thus of animals that would not be possible to be followed by an observer during a VHF tracking session. However, due to the battery size needed to collect positional fixes at short intervals for at least one day, GPS tags suitable for PT studies are only available for larger animals so far.

GPS tracking provides a useful tool for collecting monitoring data for regulatory risk assessments. We therefore recommend a careful consideration of the tracking method to use when collecting monitoring data for PT estimates as the more suitable method depends on the species to be studied as well as on other factors such as home range size and landscape characteristics.

6.01.P-We478 Exclusion of Performance Outliers in Avian Reproduction Studies

***Gunther Ulric du Hoffmann*[1]*, Diana Temple*[1] *and Timothy Springer*[2]*, (1)Eurofins Agroscience Services, (2)Springer Ecotox Consulting, Canada*

Evaluating reproductive performance in avian studies using wild-type mallard *(Anas playrhynchos)* and northern bobwhite *(Colinus virginianus)* can be complicated when birds perform less than predictably. A common practice in advanced statistical analyses has evolved in which the data from outliers is removed from comparisons. When poor performance correlates to bird injuries or poor health, removal of the data from statistical computations can reasonably be justified. However, when no apparent underlying reason for anomalies exist, is exclusion of outliers justifiable? Natural variation in reproductive performance occur in all life forms. Here we examine the occurrence of outliers in two key reproductive parameters: egg production and embryo viability to examine the frequency of occurrence of outliers and their correlation to biological causes. We use historical control data (HCD) from 40 mallard and 40 northern bobwhite reproduction studies, conducted at Eurofins over the past ten years, to determine the prevalence of outliers and their relationships to biological causes and ultimately on their influence in determining a statistical NOAEC. Our research provides a basis for discussions on differentiating types of outliers, their biological relevance and weight in statistical inference for avian reproduction studies.

6.01.P-We479 Spatial Approaches to Field Study Characterisation and Representativeness to Address EFSA Guidance on the Risk Assessment for Birds and Mammals

Jillian LaRoe[1]*,* ***Christopher M Holmes***[1] *and Thorsten Schad*[2]*, (1)Applied Analysis Solutions, LLC, (2)Bayer AG - Crop Science Division, Germany*

New EFSA guidance on the Risk assessment for Birds and Mammals includes updates relating to the improvement of terrestrial vertebrate (TV) field studies for use in risk assessment of Plant Protection Products containing pesticide active substances. Within the guidance, two concepts are discussed: Field Study Characterisation and Field Study Representativeness. To address these concepts, a past terrestrial vertebrate field study was assessed and updated to address the new guidance needs for characterisation and representativeness. Field study characterisation involved collection and analysis of spatial data available for the study area and relevant to the species, including agricultural fields, grasslands, woody vegetation, forest, water/riparian areas. Percent area metrics were generated for several distances around the study fields, as well as examination of high-resolution imagery suitable for expert evaluation. Weather conditions during the field study were compared against 30-year monthly norms to verify the study year was not outside of expected variation from long-term averages. Field study representativeness was assessed at multiple scales, including EU, EFSA zone and Member State. The potential for species interaction between "habitat" (a proxy defined by spatial land cover data) with "use sites" (assumed treated fields by crop type derived from agricultural maps) was processed using gridded spatial data at a resolution of 10m. Shared border between habitat and use sites served as an interaction indicator summarized at the 1-km scale (i.e., how many of the 10mx10m use site grid cells were adjacent to habitat cells). The 1-km scale is suitable for further aggregation at various sizes based on species attributes. In this case, local landscape interactions were assessed by developing "scenarios" a 5kmx5km summation of the interaction indicator which was quantified across all EU member states. The scenario(s) encompassing the study fields were placed into the full distribution of all possible scenarios (EU, EFSA zone, Member State) to assess the study location relative to all possible use site / habitat interactions (i.e., possible field study locations). The quantitative approaches developed here can also be used to prepare upcoming generic terrestrial vertebrate field study designs and support optimized study site selection to meet the new EFSA guidance requirements.

6.01.P-We480 Long-term Toxicity to Birds and Mammals – Early Experience and Approaches to Benchmark Dose Calculation According to the Update to the EFSA Guidance Document

Apostolos Koutsaftis[1], *Christopher Taylor*[2], *Sarah Butler*[2] *and Mark Lafranconi*[3], *(1)ERM Regulatory Services Limited, Netherlands, (2)ERM Regulatory Services Limited, United Kingdom, (3)ERM Regulatory Services Limited*

Under mandate from the European Commission, a revision to the EFSA Guidance Document for the Risk Assessment for Birds and Mammals (EFSA Journal 2009; 7(12):1438) was published in 2023. It is anticipated that this Guidance Document will in the future become implemented for European regulatory assessment of Plant Protecton Products. Amongst the updated content in this revised Guidance Document is a much-expanded evaluation of the appropriate toxicity endpoint for long-term risk assessment for birds and mammals. Central to this revised evaluation is the use of Benchmark Dose (BMD) modelling to define a specific effect level dose for relevant sub-lethal toxic effects to birds and mammals.

The aim of the work presented here is to develop pragmatic and scientifically justified methods to evaluate bird and mammal long-term data sets, to isolate and further analyse using BMD modelling critical long-term toxicity studies and affected parameters. Ultimately, the objective was to avoid unnecessary analysis for studies and parameters that would not yield reliable predictions, or where such a prediction would not inform the critical long-term endpoint suitable for use in bird and mammal regulatory risk assessment.

Using hypothetical datasets alongside the recommendations of the revised EFSA Guidance Document (2023) and established principles of ecotoxicologically-relevant effect determination, analysis and sorting of study effect parameters was undertaken, leading to an isolation of individual toxic responses which would potentially influence an overall critical long-term toxicity endpoint. These parameters were then evaluated for prediction of a defined effect level dose using the Bayesian Benchmark dose online tool provided by EFSA. Finally, predictions of a defined effect level dose for the study parameters analysed were evaluated for reliability, comparability to a corresponding No Observed Adverse Effect Level (NOAEL) and to ultimately conclude on the long-term toxicity endpoint to be defined for regulatory use.

The work undertaken shows the importance and time-effectiveness of prior detailed analysis of underlying long-term toxicity data sets, allowing for a focus on only those studies and parameters showing a dose-response, and which would potentially influence an overall long-term bird or mammal toxicity endpoint for regulatory risk assessment use. Furthermore, this up-front analysis can help to avoid generation of BMD predictions of poor reliability.

6.01.P-We481 Storks and Pesticides in Rice Fields: A Feathered Perspective on Ecological Risk

Ricardo Petersen[1] *and Bruno Herlander Martins*[2,3,4,5], *(1)ERM International Group Limited, United Kingdom, (2)CIBIO, Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO Laboratório Associado, Instituto Superior de Agronomia, Universidade de Lisboa, Portugal, (3)CIBIO, Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO Laboratório Associado, Campus de Vairão, Universidade do Porto, Portugal, (4)BIOPOLIS Program in Genomics, Biodiversity and Land Planning, CIBIO, Campus de Vairão, Portugal, (5)School of Environmental Sciences, University of East Anglia, United Kingdom*

Flooded rice fields form dynamic ecosystems, hosting many species crucial for ecological balance. Among these inhabitants, the white stork (*Ciconia ciconia*) stands out as a keystone species, playing an important role in the intricate web of interactions. This study concentrates on the central position of storks in flooded rice fields and their significance in assessing pesticide-related risks.

GPS tracking data from 220 monitored white storks and the publicly available database of bird counts, E-bird, particularly at rice fields were used to investigate the unique ecological dynamics shaped by storks in flooded rice field ecosystems. Storks of different ages were tagged in Portugal and tracked between 2016 and 2022. The GPS devices recorded individual's location every 20 minutes from the moment individuals were marked until GPS battery died or animals were no longer alive, as well as the bird behaviour (resting, flying or foraging). To provide a broader comparison for bird species in rice fields during the same period, the E-bird database (https://ebird.org/portugal/home) was accessed to obtain the details on sightings by experienced ornithologists in rice fields over the same years, highlighting the most commonly found bird species.

Storks were the species most commonly found in flooded rice fields during the annual periods between August and November. While in dry rice fields, storks were only present in much lower densities. During the rice flood season in Portugal, storks spend most of their time foraging on the rice paddies, feeding mainly on crayfish and small vertebrates. Therefore, it is clearly demonstrated from both sources of information that storks can be considered as a focal bird species for the risk assessment of plant protection products in flooded rice fields due to their abundance, time spent feeding on the field itself and the possibility of secondary poisoning by eating contaminated organisms.

In summary, this presentation underscores the unique role of storks in flooded rice fields and their potential importance as focal species in risk evaluation of pesticides used in rice. By honing in on storks as the primary species of interest, we aim to provide targeted insights that contribute to the effective management of pesticide use in rice.

6.01.P-We482 Effects of Agrochemical Usage on Ecosystem Services Provided by Rice Fields

***Ana Lopez Antia**, Miguel Canedo-Arguelles and Silvia Lacorte, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Rice fields not only are key to sustain human societies, they also serve as vital habitats for waterbirds. Therefore, it is urgent to assess the potential consequences of agrochemical for birds. Here, we employed the ecosystem services concept, suggested as a tool to evaluate the impact of chemicals at an ecologically significant level, to assess the influence of pesticide usage on two crucial services offered by rice fields: rice production and habitat provision for birds. We conducted surveys among farmers to gather information on pesticide usage, sowing methods, soil characteristics, rice varieties, field headland management, and yield. For the chosen fields, we characterized the surrounding landscape and field headlands and we performed bird point counts of 5 minutes of duration in 3 sampling periods during the rice growing season.

We collected information on 79 fields cultivated following the agri-environmental system and 22 cultivated organically (from now on conventional and organic). We assessed the importance of each variable for bird abundance and diversity and found that the size of the rice was the most important factor, with smaller fields presenting higher bird densities. Landscape characteristics were also important to explain the use of rice fields by birds. We found that bird community composition significantly differed between organic and conventional rice fields ($p=0.009$). An indicator species analysis showed 6 species significantly associated with organic rice (all $p\leq0.04$), mostly related to headlands' vegetation. On the other hand, there were 5 species associated with conventional rice fields that breed or obtain their food from the in-field area of rice fields (all $p\leq0.04$). In this regard, it is important to mention that conventional fields are flooded approximately one month earlier than organic fields. In conventional fields, the abundance of most of these indicator species (5 out of 6) was negatively correlated with the usage of pesticides. Finally, we found that conventional fields were significantly more productive than organic ones ($p<0.001$) but within organic ones, we did not find an association between pesticide usage and crop yield.

Our results can serve to guide management solutions to optimize the balance between the two main ecosystem services provided by rice field: productivity and biodiversity conservation.

6.01.P-We483 Determining risks of triazole fungicides to birds and invertebrates under field conditions

*Claudia Santamaria Cervantes[1], **Paula Bolívar**[2], Manuel Ortiz Santaliestra[1] and Rafael Mateo[3], (1)Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain, (2)Castilla La Mancha University (UCLM), Spain, (3)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain*

The application of pesticides to crop fields supposes a release of deliberately toxic substances to the environment that is recognised as one of the main threatening factors to wildlife inhabiting agro-ecosystems. In this sense, triazoles are a group of fungicides widely used as foliar application and seed coating treatments to prevent from diverse fungal diseases. Triazoles act inhibiting the lanosterol-14α-demethylase, an enzyme that is essential to produce ergosterol, a basic component of the fungal cell membrane. In animals, this enzyme catalyses the initial reaction of endogenous synthesis of cholesterol. Our previous research has shown that triazole fungicides may reduce cholesterol synthesis, decrease sexual hormone levels, and affect reproduction in birds, reducing fecundation rate and brood size. Besides these direct effects, triazole fungicides might also be affecting avian communities indirectly through the reduction of arthropod biomass that constitutes the basis for chick diet. Experimental studies show that triazoles can affect reproductive and developmental parameters in arthropods by disrupting the synthesis of ecdysteroids.

We aim to determine the risk of azole fungicides on wildlife associated with agricultural areas under field conditions. For two years we have been monitoring the abundance and diversity of birds and invertebrates in 30 agricultural locations in central Spain dominated by rainfed cereal fields and with different pesticide use. We performed four annual samplings at each location during which we censused birds and invertebrates, and collected samples of cereal sown seeds, soils and leaves of herbaceous and arboreal crops to determine the presence of pesticides (especially triazoles). We also recorded other crop and habitat management measures (e.g. presence of margins and fallow lands, fertilizer application). We present preliminary results on the diversity and abundance of fauna associated to cereal crops depending on the use of seeds treated with triazoles to test the hypotheses that (i) increased intensification will reduce abundance and diversity of avian and invertebrate communities, (ii) the use of fungicides, and especially triazoles, will play a significant role in that reduction given the reproductive effect caused by those substances, and (iii) some habitat management measure can modulate the effects of pesticides on farmland birds.

6.01.P-We484 Impacts of triazole consumption on health and immunocompetence of passerine birds

***Jessica Jiménez Peñuela**[1], Manuel Ortiz Santaliestra[2] and Rafael Mateo[3], (1)Institute for Game and Wildlife Research (IREC), Spain, (2)Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain, (3)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain*

The scarcity of natural food sources during autumn and winter forces granivorous birds inhabiting farmlands to consume sown cereal seeds. These are usually coated with triazoles, the most used fungicides in current agricultural practices. Recent studies with red-legged partridges have shown that their consumption affects the synthesis of sterols, which results in the alteration of endogenous cholesterol levels and steroid hormone regulation. However, there is a lack of information about the effects on passerine birds, despite their small body size makes the ingestion of a few coated seeds to result in high exposure doses. Additionally, despite the well-known interactions between steroid levels and immunocompetence, little is known about the impact of triazoles on the avian immune system. We developed an experiment in which infected and non-infected house sparrows with avian malaria (a common avian blood parasite) will either consume triazole-coated or non-coated cereal seeds. We studied the effect of triazole treatment on body condition (calculated from length and weight), haematocrit (proportion of plasma and cellular fraction) and enzyme antioxidant activity in blood cells of birds. To estimate immunocompetence, we quantified white blood cells composition, avian malaria level of infection, and plasma levels of haptoglobin (a protein which increases with infection and/or inflammatory responses) and nitric oxide (an inflammatory and immune molecule produced to damage invading parasites). We hypothesized a decrease in the body condition, antioxidant enzyme activity and haematocrit, and an increase in the haptoglobin levels in infected and/or exposed birds. Moreover, we expected an increase in avian malaria parasitaemia and nitric oxide levels in triazole-exposed birds. These results could likely be used to provide a more integrated approach to the environmental risk assessment of these pesticides, in line with current efforts being taken at the EU level in this context, and to develop future conservation projects regarding farmland birds. Additionally, these results will contribute to the understanding of infectious disease dynamics and the evolution of host-parasite interactions under an anthropic-altered scenario.

6.01.P-We485 Behavioural Responses of Imidacloprid-dosed Farmland Birds to a Simulated Predation Risk

Laura Addy Orduna[1], Manuel Ortiz Santaliestra[2], Francois Mougeot[2], Paula Bolívar[3], Pablo R. Camarero[4] and ***Rafael Mateo****[5], (1)Instituto Nacional de Tecnología Agropecuaria, Argentina, (2)Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain, (3)Castilla La Mancha University (UCLM), Spain, (4)Instituto de Investigación en Recursos Cinegéticos, IREC (CSIC-UCLM-JCCM), Ciudad Real, Spain, (5)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain*

Birds can use passive or active strategies in situations of risk when a terrestrial predator approaches and these behaviors could be altered by the ingestion of neurotoxic pesticides. Since behaviour is a sensitive indicator of the impact of an exposure and an early warning tool, the objective of this study was to evaluate the effect of sublethal doses of imidacloprid on the behavioural responses of the red-legged partridge to simulated predation risk. We evaluated the effect of 0 (C), 1 (T1) and 6 (T2) mg/kg bw exposure doses of imidacloprid on the behavioural responses of the red-legged partridge *(Alectoris rufa*) to predatory threat simulations. For this, 66 partridges, males and females in equal proportion, were challenged in groups or individually to intra and interspecific alarm calls, to a predator silhouette as an aerial predation risk simulation, or to a fox model as a terrestrial predation risk simulation. The antipredator behaviours were divided into active responses (escape, active vigilance) and passive responses (passive vigilance, crouching, freezing). Latency, percentage of individuals who responded, duration of each response, speed of active responses, and vocalizations, were also measured. Blood imidacloprid concentrations (mean ± SE) were 20.3 ± 3.8, and 153.8 ± 22.0 ng/ml in birds of T1 and T2 groups, respectively, and below detection in controls. Partridges of the treated groups showed a shorter duration of the crouching behavior against the visual predatory stimuli than controls in the group challenge experiment and a longer duration of the passive vigilance against the intraspecific auditory stimulus in the individual challenge experiment. T1 birds in the group experiment showed a trend towards a higher speed of escape compared to C birds. Conversely, T1 birds in the individual challenge experiment showed a trend towards a lower speed during the active vigilance compared to birds C birds. No effects of imidacloprid exposure were observed on other antipredator responses. The exposure to imidacloprid can influence the antipredator behaviours of red-legged partridges, compromising their capacity to freeze, hide and be unnoticed by predators. Subtle neurobehavioural changes caused by sublethal exposures should be considered in the environmental risk assessment of all the neuroactive chemicals because of the consequences on survival under field conditions where predation is a main driver of population dynamics.

6.01.P-We486 Contamination of Second Generation Anticoagulant Rodenticides in the Eurasian Sparrowhawk and Assessment of Population Level Effects in the UK

Lee Walker*[1], Richard K Broughton Dr[1], David Noble Dr[2], M. Gloria Pereira[1], Elaine Potter[1], Kate R Searle[1] and Andrew C Johnson[1], (1)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (2)British Trust for Ornithlogy, United Kingdom*

We report levels of contamination of second generation anticoagulant rodenticides in the UK Eurasian sparrowhawk over a 30 year period. Using this data we predicted mortality rates induced by this exposure. Those mortality rates were applied to a population model to predict how sparrowhawk populations in four regions of Great Britain would have changed over the last three decades had the predicted SGAR-induced mortality not occurred. The population model combined British Trust for Ornithology on abundance of birds, mark-resighting of birds and nest records. The population model provides us with estimates for survival of different age classes of sparrowhawks (immatures, recruits and adults) and breeding success of birds of breeding age We included effects of rainfall on immature survival, and density dependence effects of the number of breeding birds on breeding success. We then used this fitted model to ask how different sparrowhawk population trends may have looked over the previous 3 decades assuming different levels of mortality from SGARs. Using this approach, the model estimated the actual trend in sparrowhawk population over time and observed counts of birds. We assumed that the observed data and trend includes a hypothetical effect of SGARs. Therefore, we used the model to ask what the sparrowhawk population could have looked like, is that hypothesized level of SGAR induced mortality were not present in the population. Results are consistent with SGAR related mortality potentially being influential at the population level in some regions of Britain

6.01.P-We487 Could the Use of Anticoagulant Rodenticides Against Plagues of Rabbits be the Cause of High Exposure in Predators and Scavengers?

Antonio Juan Garcia-Fernandez, DVM, PhD*[1], Isabel Navas DVM,[2], Pedro María-Mojica DVM,[3], Pedro Jiménez DVM,[4] and María Belén Nieto[3], (1)Toxicology Research Group, Faculty of Veterinary Medicine, Universidad de Murcia-IMIB, Spain,*

(2)Health Sciences-Faculty of Veterinary-IMIB, Universidad de Murcia-IMIB, Spain, (3)Health Sciences, Faculty of Veterinary, Universidad de Murcia, Spain, (4)Health Sciences, Universidad de Murcia, Spain
Nowadays anticoagulant rodenticides (AR) are widely used throughout the world for the effective control of rodent pests. However, it is suspected that these biocides could also be used against non-target species, such as rabbits, whose significant damage has been reported in some regions of Spain. It is well known that predator and scavenger species may suffer secondary poisoning by ARs when they ingest contaminated carcasses.

Liver from dead animals is generally the most commonly used sample for biomonitoring short- and long-term exposures to ARs. However, blood has hardly been used for these purposes. Despite this, at least from a theoretical point of view, the blood sample can be really interesting to evaluate scenarios of recent exposure to these biocides.

The hypothesis of this study is that predators and scavengers would be more exposed to ARs in areas affected by rabbit infestations because of the illegal use of these biocides to control this plague.

This study aims to evaluate, by analyzing 78 blood samples, the degree of recent exposure to 5 first-generation and 5 second-generation ARs (FGAR and SGAR, respectively) in two populations of griffon vultures (Gyps fulvus) from the southeast of Spain. Vultures were captured and sampled at two vulture feeding stations, 200 km apart, during 2018 and 2019, one of them located in a region affected by rabbits and the other in a region free of rabbit damage.

The results indicate that 95% of the vultures sampled had measurable levels of AR in their blood. Forty-percent of the samples were positive to the FGAR, while in the SGAR the prevalence was 93%. The relatively high frequency of detection of FGAR was due to the presence of diphacinone in the samples collected in the region affected by rabbit damage.

On the other hand, in general, the high incidence of SGAR, especially difenacoum (92.5%) and brodifacoum (80%) in both locations, indicates that these animals have been exposed to a quantity of rodenticides above that expected in a recent period.

Anyway, it is evident that the griffon vulture, as a scavenger species, is exposed to rodenticides (some of them unauthorized), so we must assume that other scavenger species, as well as predatory species, must be suffering a similar exposure to these biocides, and particularly in the affected areas by rabbit damages.

Acknowledgements: Thanks to all the collaborators who participated in the sampling. In loving memory of S. Espín.

6.01.P-We488 Evolution of Plumbism in Waterfowl From “El Hondo” Natural Park (Southeastern Spain) since 1998
Isabel Navas DVM,[1], María Belén Nieto[2], Bryan Andrés[3], José Peñalver DVM,[3], Pedro María-Mojica DVM,[2], José F. Calvo PhD[4] and ***Antonio Juan Garcia-Fernandez, DVM, PhD***[5]*, (1)Health Sciences-Faculty of Veterinary-IMIB, Universidad de Murcia-IMIB, Spain, (2)Health Sciences, Faculty of Veterinary, Universidad de Murcia, Spain, (3)Health Sciences-Toxicology, Universidad de Murcia, Spain, (4)Department of Ecology and Hydrology, Faculty of Biology, University of Murcia, Spain, (5)Toxicology Research Group, Faculty of Veterinary Medicine, Universidad de Murcia-IMIB, Spain*
El Hondo Natural Park is a wetland that was created in the 1920s to provide water for irrigation, but other relevant human activities as hunting and fishing have also been very relevant for decades. Millions of lead shots have been widespread in this wetland for more than 80 years. In 2001, a national regulation banning the use of Pb shots for hunting in Ramsar sites was approved in Spain.

In order to assess if this regulation was showing effectiveness on lead exposure in the waterfowl species inhabiting El Hondo, an appropriate biomonitoring scheme including specimens found death between 1998 and 2022 was carried out. The influence on tissue lead concentrations of many other variables were also assessed, like species, feeding behavior (divers, swimmers and flamingos), body weight, age, physical condition, cause of the death, clinical signs, and number and weight of the lead shot pellets found in the gizzard during the necropsy.

A total of 150 carcasses were necropsied and the lead concentration was quantified in samples of liver, brain and bone. Fifty-seven animals were classified as swimmers (17 mallard ducks - *Anas platyrhynchos*, 10 red-crested pochards - *Netta Rufina* and 30 marbled teals - *Marmaronetta angustirrostris*), 70 as divers (30 common pochards - *Aythya ferina* and 40 white-headed ducks - *Oxyura leucochephala*) and 23 were flamingos (*Phoenicopterus roseus*).

Lead concentrations before 2001 were higher than after the ban in all tissues and in all species, but these decreases were not significant. Linear regression model studies were carried out. The models showed that the type of feeding was the factor more relevant to explain the Pb concentrations in liver and bone. However, in brain the species was the factor more explanatory. After that, the interactions in each group were assessed. Number of lead shot pellets in the gizzards was the factor able to explain the lead concentrations in the three organs.

In conclusion, Pb concentrations have decreased since 2001; however, 22 years later, the impact of lead exposure on health in waterfowl remains high, mainly in divers species (white-headed duck and common pochard) and flamingo from El Hondo Natural Park. Moreover, the number of lead shot pellets in gizzards can be used together liver concentrations to estimate the risk associated to the ingestion of lead shot pellets. Other additional measures should be considered to reduce lead exposure in these species.

6.01.P-We489 Gene Loss events shaped the Chemical Defensome in Cetacea

*Raquel Ruivo[1], Bram Danneels[2], Diogo Oliveira[1], Raul Valente[1], Miguel M. Santos[3,4], Sofie Søderstrøm[5], Odd André Karlsen[5], Filipe Castro[1,6], Anders Goksøyr[5] and **Maria Fernández Míguez**[7], (1)University of Porto, Interdisciplinary Centre of Marine and Environmental Research (CIIMAR), Portugal, (2)Computational Biology Unit, Department of Informatics, University of Bergen, Norway, (3)CIIMAR - Interdisciplinary Centre of Marine and Environmental Research, University of Porto, Portugal, (4)Biology Department, Faculty of Sciences of the University of Porto, Portugal, (5)Department of Biological Sciences, University of Bergen, Norway, (6)Department of Biology, Faculty of Sciences, University of Porto, Portugal, (7)University of Bergen, Norway*

Whales and dolphins hold records of contaminant accumulation, due to their ecology and life history. Large loads of environmental chemicals (e.g. persistent organic pollutants and chemicals of emergent concern) were shown to bioaccumulate in many tissues, mirroring current trends in environmental chemical build-up: a trademark of the Anthropocene. How animals deal with environmental contaminants is largely influenced by the Chemical Defensome; that is, an integrated network of genes and gene pathways that participate in metabolic detoxification and excretion of xenobiotic chemicals. Yet, the repertoire of genes related to detoxification pathways seems to have undergone evolutionary adaptations across mammalian evolution, most notably in cetaceans. Interestingly, cetaceans were shown to lack two functional xenobiotic nuclear receptors: pregnane X receptor (PXR) and constitutive androstane receptor (CAR). PXR and CAR are ligand-modulated transcription factors, activated by xenobiotic and endobiotic substances, that orchestrate the expression of drug-metabolizing enzymes and transporters. Using comparative genomics approaches, including synteny analysis and gene inactivation inference, coupled to the transcriptomic analysis of liver RNA from a double knock-out PXR/CAR mouse model, we addressed the conservation status of PXR and CAR-driven genes coding for drug-metabolizing enzymes within cetacean lineages. Gene expression analysis highlighted differentially expressed xenobiotic metabolism genes in double knock-outs. Next, four cetacean species were analysed—blue whale (*Balaenoptera musculus*), narwhal (*Monodon monoceros*), vaquita (*Phocoena sinus*) and bottlenose dolphin (*Tursiops truncatus*)—and their genomic loci of interest were compared to human (*Homo sapiens*), cow (*Bos taurus*) and hippopotamus (*Hippopotamus amphibius*), the latter representing the closest species to Cetacea. A striking reduction in the number of genes from the prototypical oxidation and conjugation families regulated by PXR/CAR was found (Cytochromes P450s, UDP-glycosyltransferases, Sulfotransferases), in agreement with previous observations with Glutathione S-transferase clusters. Our results suggest a drastic reshaping of the Chemical Defensome in cetaceans.

This work is part of the project *Whales and polar bear in a petri dish: decoding marine mammal toxicology through in vitro and in silico approaches – Marma-detox* funded by the Research Council of Norway, project no. 334739, 2023-2027.

6.02.P Can Science Help to Respond to the Regulatory Challenge to Demonstrate the Safe Use of Chemicals for Combined Toxicity in the Environment?

6.02.P-We490 The Mixture Assessment (or Allocation) Factor as a tool for prospective mixture risk assessment: a discussion of the pros, cons and the way forward

***Thomas Backhaus**, Biological and Environmental Sciences, University of Gothenburg, Sweden*

Chemicals are subject to a prospective risk assessment before they enter the European market. Given that more than 20 000 chemicals are registered under REACH alone, and the increasing realisation that humans as well as the environment are constantly exposed to a complex melange of different chemicals, a major question in the context of substance-oriented regulatory frameworks such as REACH is: how can the risk of a mixture, which is typically higher than the risks of each of its individual components, be accounted for already during the registration and authorization of an individual substance? Specific, targeted mixture evaluations are usually not feasible, given that the specific evaluation of each relevant co-exposure scenario for all uses of a substance is well beyond the capacity of an individual registrant.

Therefore, the inclusion of an additional assessment factor (safety factor), termed the "Mixture Assessment Factor" (MAF), has been put forward in the European Chemicals Strategy for Sustainability (CSS), for industrial chemicals that are regulated under REACH. However, the term as used in the CSS lacks specification. As a consequence, several MAF types have been discussed in various meetings, workshops and also in the scientific literature.

This presentation will provide a brief overview of the different MAF types and then discusses their application in a regulatory context, using REACH as the prime example. Pros and cons will be analyzed with a view on the precautionary principle, the proportionality principle, cost-benefit considerations and risk acceptability.

6.02.P-We491 Substance-group specific Mixture Allocation Factors (MAFs) analysis using Dutch surface waters monitoring data

Emiel Rorije[1], *Lisa van Eck*[2], *Pim Wassenaar*[3], *Jaap Slootweg*[3] *and Leo Posthuma*[3], *(1)Centre for Safety of Products and Substances, National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Deltares, Netherlands, (3)National Institute for Public Health and the Environment (RIVM), Netherlands*
Current regulatory chemicals risk assessment does not consider exposure of aquatic environments to unintentional mixtures, leading to potentially insufficient protection of these environments. We have evaluated the (theoretical) effects of the introduction of a generic Mixture Allocation Factor (MAF) as a possible regulatory policy measure to improve protectiveness. This evaluation is based on scenario calculations using >5.000.000 measured environmental concentrations (MECs) of 878 unique chemicals in Dutch surface waters in the period of 2013-2018. The aim was to determine:

a) whether Dutch surface waters are sufficiently protected against mixture risks, and
b) whether, and in how far, implementation of a generic MAF, or of substance-group specific MAFs result in improved water quality.

To this end, the exposure data was used to calculate summed Risk Coefficient Ratios (RCRs) of all mixture components, followed by scenarios in which these RCRs were reduced by increasing MAF values to lower the overall risks (methodology Rorije et al. 2022 https://doi.org/10.1016/j.scitotenv.2022.153385). This process was repeated for MAFs that would only act on specific substance groups. Substance groups include SVHCs, metals, industrial-, pharmaceutical- and pesticide chemicals.

The monitoring data showed that the “toxic-free environment” (defined as ‘no mixture toxicity effects are expected to occur’) is currently not present in the Netherlands, warranting measures to improve water quality. Introduction of a generic and relatively low MAF leads to relatively large improvements in water quality – **“The first blow is half the battle”**. Implementing a MAF for only one specific substance group (e.g. SVHCs) or only in one legislative framework (e.g. industrial chemicals) is far less effective. However, both a generic as well as substance-group specific MAFs can potentially help to rapidly reduce the ‘Distance-to-Target’.

In conclusion: a) monitoring data from the Netherlands shows there is a need to consider mixture exposures in ecotoxicological risk assessment, and b) a relatively small MAF, even if introduced for only a subgroup of all chemicals present in the environment, can already lead to significant improvement in environmental quality.

The data suggest that implementation of MAF is key to the ‘toxic free environment’ goal, the ‘first blow’ matters most, and growing insights in water quality as well as MAF impact can be used to refine a MAF as needed.

6.02.P-We492 Comparison of mixture risk indicators in the aquatic environment

Fabian Gerhard Peter Balk[1], *Oliver Weisner*[2], *Peter von der Ohe*[3] *and Marion Junghans*[1], *(1)Swiss Centre for Applied Ecotoxicology, Switzerland, (2)Plant Protection Products, German Environment Agency (UBA), Germany, (3)German Environment Agency (UBA), Germany*
The environmental risk assessment of chemicals in the EU currently focuses largely on the exposure and effects of the substance or product of concern while neglecting the presence of other substances in the environment and related combined effects. In order to change that, the latest proposal by EU regulators suggests to use the mixture allocation factor (MAF) to consider the concurrent presence of other chemicals in the environment. The concept of concentration addition is applied, where the sum of the toxicity of each mixture component should not exceed the assumed safe risk quotient of 1. As a part of several PARC projects, we compare a range of MAF approaches for prospective risk assessment of mixture toxicity based on chemical monitoring datasets from European surface waters. Next to the MAF proposed by KEMI and REACH in 2021, we introduce two alternative MAF calculation methods and also plot the maximum cumulative ratio (MCR). The aim of the project is to compare the various approaches in their assumptions, the data requirements for their calculation, the calculated percentiles of the respective MAF distributions and calculated MAF values in order to evaluate their suitability and applicability to assess aquatic mixture risk.

6.02.P-We493 MEED: Progress with the Metals Environmental Exposure Data Collection program to Anticipate the Challenges of the EU Zero Pollution Ambition Policy and the Chemicals Strategy for Sustainability

Hugo Waeterschoot[1], *Marnix Vangheluwe*[2] *and Violaine Verougstraete*[3], *(1)Chemicals Management, (2)ARCHE Consulting, Belgium, (3)Eurometaux, Belgium*
The EU Chemicals Strategy for Sustainability (CSS) is one of the main pillars of the Zero Pollution Ambition and a key building block of the Green Deal. Although the REACH revision process is delayed, the potential introduction of a Mixture Allocation Factor (MAF), to demonstrate safe use and lack of impact on ecosystems from the cocktail of chemicals exposures encountered in environmental compartments, remains a key scientific challenge for the EU industry. The MAF contributes to the overall objective of reducing *exposures of chemicals to levels that are no longer expected to be harmful to health and the environment*.

The use of metals in technologies to achieve the Green Deal objectives, like electric vehicle batteries, solar cells, windmills and electronics results in unprecedented volume increases. It is therefore crucial to demonstrate that exposure levels of emitted metals will not increase proportionally to their uses and that the possible effects resulting from their combined exposure meet the challenge of the Zero Pollution Ambition, now and under future emission scenarios.

In anticipation, the EU metals sector designed a comprehensive “environmental exposure gathering program” (MEED), complemented by the development of scientific concepts and further test work, to measure and assess progress towards the Zero Pollution Ambition and the objectives of the EU biodiversity policy. The program runs for 3.5 years (2022- to mid-2025) and consists of 6 interlinked projects and is now halfway. Important milestones have been reached including: the identification of metals that contribute the most to the combined risks in soil and the aquatic environment, an update of today’s regional background levels for metals, a review and reappraisal of existing knowledge on metals mixtures & metals-organics mixtures interactions, the identification of testing needs to fill major gaps in the knowledge of mixture interactions, gap filling research on mixture toxicity and the design of a tiered assessment system for the local and regional biodiversity impact assessments. This poster presents the overall progress and intermediate conclusions of the MEED projects, while a detailed assessment of each of the individual milestones are presented in complementary posters.

MEED delivers a huge amount of data and relevant concepts to be used in REACH registration updates and that are key to assess progress with the Zero Pollution ambition policy of the EU in a scientific way.

6.02.P-We494 Metal Mixture Effects in the Aquatic Environment: Evaluating the Potential for Refinement of the Default Mixture Allocation Factor (MAF) Based on Experimental Data

***Charlotte Nys**[1], Maria Laura De Donno[2], Franz Marius Schmitt[3], Karel Viaene[1], Koen Oorts[1], Marnix Vangheluwe[1], Hugo Waeterschoot[4], Violaine Verougstraete[5] and Karel De Schamphelaere[3], (1)ARCHE Consulting, Belgium, (2)GhEnToxLab, Ghent University (UGent), Belgium, (3)Ghent University - GhEnToxLab, Belgium, (4)Chemicals Management, (5)Eurometaux, Belgium*

The European Commission calls for an investigation of the integration of combined exposure into REACH. To cover for such effects a default Mixture Allocation Factor (MAF) will be introduced, which probably will imply that the safety limit of single substances will be reduced. The implementation of a MAF will have a large impact on the environmental risk assessment of inorganics and may result in exceedances of safety limits at natural background concentrations. To anticipate the mixture correction under REACH, a dedicated research program on chronic metal mixture toxicity in the aquatic environment has been set up as part of the Metals Environment Exposure Data (MEED)-program. The current study discusses the progress made so far and gives an outlook on how the results may be potentially used to refine default MAF-setting for inorganic substances.

A comprehensive literature review of chronic metal mixture toxicity was conducted and amended with newly generated experimental data. The review showed that chronic metal mixture effects can be predicted with the standard mixture reference models, Concentration Addition (CA) and Independent Action (IA), whereby CA results in more conservative predictions compared to IA. The prediction performance of CA at low effect levels (i.e., 10% mixture effect) has been expressed as the Mixture Interaction Factor (MIF). The MIF quantifies the prediction performance of CA and is indicative of additive (≈1), antagonistic (>1) or synergistic (<1) interactions. For the comprehensive dataset, a median MIF of 1.3 has been derived, indicating that on average CA overestimates metal mixture toxicity at these regulatory relevant low effect levels.

MAF assessment strategies have traditionally been based on the application of CA at the regulatory threshold-level (e.g., predicted no-effect concentration or 5% hazardous concentration). As such, the MAF-derivations are associated with several implicit assumptions, which cover different levels of conservatism. The MIF directly quantifies part of this conservatism, i.e. at the species-level. As such, the MIF is proposed as a factor that may be used to increase the scientific relevancy of MAF-values for inorganic substances. Future research efforts within the MEED-project will further focus on quantifying the conservatism provided by a regulatory MAF setting and developing tools for scientific refinements of the proposed mixture risk assessment methodology for inorganic substances.

6.02.P-We495 The accuracy of the Concentration Addition and Independent action model to predict the toxicity of complex metal-metal mixtures to Daphnia magna – Is IA the better model?

***Franz Marius Schmitt**[1], Karel Viaene[2], Maria Laura De Donno[3], Charlotte Nys[2], Koen Oorts[2], Marnix Vangheluwe[2], Violaine Verougstraete[4], Hugo Waeterschoot[5] and Karel De Schamphelaere[1], (1)Ghent University - GhEnToxLab, Belgium, (2)ARCHE Consulting, Belgium, (3)GhEnToxLab, Ghent University (UGent), Belgium, (4)Eurometaux, Belgium, (5)Chemicals Management*

Chemical risk assessment is predominantly designed around the regulation of single substances. However, along their lifecycle, chemicals will end up in the environment, mix with other substances and form unintentional mixtures that are not regulated by legislations like REACH. To manage these unintentional mixtures, the European Union has proposed to introduce a generic MAF (Mixture Allocation Factor) into chemicals policy. However, the magnitude of the MAF value is currently being debated.

Chemical mixtures are mainly assessed according to the concentration addition (CA) model which generally assumes that the compounds present in the mixture follow the same Mode of Action. At low effect concentrations, CA seems to overestimate metal mixture toxicity at the species level.

For complex metal-metal mixtures, we tested the hypothesis that the independent action model (IA) is in general a more accurate predictor of metal mixture toxicity than CA. Deviations of the “observed toxicity” from the “predicted toxicity” by CA can be quantified with the MIF (mixture interaction factor), which indicates either additive (MIF ≈1), synergistic (MIF<1) or antagonistic (MIF>1) interactions, relative to CA.

Our second hypothesis was that the MIF increases with an increasing number of metals present in the mixture.

Both hypotheses were tested in three large mixture experiments using *Daphnia magna*, which assessed chronic mixture effects of different combinations of Ag, As, Ba, Cd, Cr, Cu, Mn, Ni, Pb and Zn. These metals and their mixture combinations were previously selected in another study, based on their environmental relevance in European freshwater. This study also revealed that 90% of the mixture toxicity pressure to *D. magna* (expressed as sum of toxic units, STU) is driven in most freshwaters by five metals or less.

Each experiment tested simultaneously each single metal and a binary, ternary, quaternary and quinary mixture combination. All mixtures followed an equitoxic ray design and an additional quinary combination was included based on environmentally relevant mixture ratios.

Preliminary results of the first metal mixture experiment support our hypothesis that the MIF increases with an increasing number of metals in the mixtures and that IA is a more accurate predictor of metal toxicity. Once completed, this study will add valuable experimental data to the ongoing discussion on how to assess and estimate the potential risks of combined metal exposure.

6.02.P-We496 A Tiered Toolbox to Assess the Impact of Metal Emissions on Biodiversity Integrating Mixture Risk Calculations, Biomonitoring and Metabarcoding – Pilot Study with a Belgian Brook

***Karel Viaene*[1]**, *Charlotte Nys[1], Nathalie Briels[2], Marnix Vangheluwe[1], Hugo Waeterschoot[3] and Karel De Schamphelaere[4], (1)ARCHE Consulting, Belgium, (2)ARCHE Consulting, Ghent (Wondelgem), Belgium, (3)Chemicals Management, (4)Ghent University - GhEnToxLab, Belgium*

A key part of the Green Deal as well as environmental permitting requirements is avoiding impact of chemicals on biodiversity. Current European risk assessment methodology does not assess the risk to biodiversity directly. Therefore, it is unclear how to demonstrate “absence of effects on biodiversity”. Within the Metals Environment Exposure Data (MEED) Ecorelevance project from Eurométaux, a tiered toolbox was developed to assess the local and regional additional impact of metal emissions (i.e., independent of other stressors) on biodiversity, by: mixture risk calculations (tier I), conventional biomonitoring (tier II) and metabarcoding (tier III).

In this study, the proposed toolbox was piloted to the Kleine Nete brook in Belgium as a test case. The study site contains two metal-processing plants and sampling sites were located up-, mid- and downstream from their emission points. Measured metal concentrations were corrected for bioavailability and translated to expected (mixture) risks using available mixture risk calculation tools. Additionally, the Kleine Nete is part of the biomonitoring network of the Flemish Environmental Agency (VMM), offering the opportunity to assess the impact of the metal emissions on long historical series of biodiversity indices of macrophytes, periphyton and macroinvertebrate communities. Finally, a sampling campaign of periphyton biofilms was initiated to determine the potential impact of metals using metabarcoding based on 18s rRNA markers. Species diversity in the periphyton biofilms was used as an indicator for biodiversity effects. This case study allows to evaluate the usefulness of individual techniques to assess the local impact of metal emissions on biodiversity and investigate how the different tiers can inform each other. In the future, this toolbox aims to provide stakeholders with a flexible, tiered methodology to answer regulatory concerns about local impacts on biodiversity.

6.02.P-We497 Comparison of Herbicide Mixtures at Two Catchments in Belgium

***Hanna Samantha Schuster*[1]**, *Nadine S Taylor[1], Arnd Weyers[2] and Robin Sur[3], (1)Cambridge Environmental Assessments (CEA), United Kingdom, (2)Bayer AG, (3)Bayer AG - Crop Science Division, Germany*

A large-scale monitoring study (2010 to 2013) was conducted at two Belgium catchments, Grote Kemmelbeek (GKB) and Kleine Aa (KAA), in an effort to better understand herbicide mixtures in agricultural landscapes. Both sites included a measuring point at the catchment outlet and a 2nd upstream. The concentrations of 12 herbicides and 1 metabolite were assessed on a sub-daily or daily frequency. A recent publication analyses the data from the upstream GKB site using a concentration addition approach to determine measurements that exceeded the Regulatory Accepted Concentration (RAC; exceedance events) resulting in potential effects of the mixture on algae and macrophytes. These exceedance events coincided with seasonal influences, and low rainfall during spring/summer 2011 correlated with a highly reduced number of these events. However, the most significant impact on the exceedance events was found to be a stewardship program that was implemented following an initial 8-month baseline measuring period. The stewardship directed farmers to use more advanced farming techniques, avoid spillages and other point sources. Exceedance events were reduced by more than half for algae and by approx. 10 times for macrophytes from the year the stewardship was established onwards. These findings show how local measures reducing point sources are highly effective and potentially more so than desk-based approaches focusing on diffuse sources.

Data were further analysed in comparison to the measuring point at the outlet of the GKB catchment, and to the data from both measuring points of the KAA catchment. These catchments differed in their size, land use, erosion likelihood and farms in the surrounding area. The KAA catchment is approx. 10 times larger than the GKB catchment (10K and 950 ha, respectively). Correspondingly, 950 farmers cultivate the land at KAA (120 farmers at GKB) and the KAA %farmland was found to be lower. Due to the comparably large size of the KAA catchment, no stewardship was conducted as part of the monitoring program.

Initial findings show that the quantity of exceedance events differs significantly between sites, with exceedance events being more prevalent at the GKB catchment compared to the KAA catchment. Although less prevalent, the events at the KAA site were found to be more often driven by true mixtures. The poster will investigate the drivers for mixtures beyond the RAC and discuss concepts and ideas to reduce these.

6.02.P-We498 Evaluating the Effects of Metal Mixtures on Freshwater Invertebrate Communities

*Adam Peters[1], Stijn Baken, PhD[2], Christopher Cooper[3], Mohammed Jasim Chowdhury[4], Emily Rogevich Garman[5], Adam C Ryan[6] and **Yamini Gopalapillai**[7], (1)wca environment Ltd., United Kingdom, (2)European Copper Institute, Belgium, (3)International Zinc Association, Belgium, (4)International Lead Association, (5)NiPERA Inc., (6)International Zinc Association, (7)International Copper Association, Ltd.*

Environmental Quality Standards (EQS) accounting for metal bioavailability, beyond hardness corrections, have now been developed and implemented throughout Europe for copper, lead, nickel and zinc for several years. Standards for lead and nickel were set on a Europe wide basis and those for copper and zinc have been set by individual member states. Available evidence suggests that ecological communities are not compromised to an identifiable extent at locations that comply with these EQS values, although the variability associated with ecological data means that there is some uncertainty associated with these findings. There is increasing regulatory concern at a European level about the possible effects of the mixtures of multiple contaminants in the environment. This is based on the concern that multiple contaminants, all of which are present at levels that are safe based on exposures to the individual substance alone, could result in adverse effects due to the additional stress resulting from multiple exposures. Copper, lead, nickel, and zinc are all commonly regulated metals for which robust EQS values are available that can be normalised for bioavailability. This study evaluates whether EQS derived for individual metals based on single substance exposures are sufficiently protective in the environment where a mixture of different metals may be present. Analyses of the response of the benthic macroinvertebrate community to exposures of both the individual metals and their overall mixtures were analysed based on both EQR N-Taxa, and EQR ASPT. A decline in ecological community quality, as EQR N-Taxa, is seen for some, but not all, of the individual metals considered and for the overall mixture. Single metal derived EQS values are protective of ecological quality, as expressed by EQR N-Taxa, although high metal exposures are associated with a reduced maximum achievable ecological quality based on EQR N-Taxa. Although high mixture exposures are also associated with reduced ecological quality this is only associated with very high total RCR values.

6.02.P-We499 Systemic Toxicity Screening of Mixture Chemicals in Consumer Products in Korea: Case Study on Cleaning Products

***Yongmin Jung**[1], Yeonjung Park[2], Dawun Lee[3], Jaekyeong Jung[3], Keon Kang[1], Hosik Choi[3] and Jinhee Choi[1], (1)School of Environmental Engineering, University of Seoul, Korea, Republic of (South), (2)Chemical Management Institute, TO21 Co. Ltd., Korea, Republic of (South), (3)Urban Big Data Convergence, University of Seoul, Korea, Republic of (South)*

In consumer products, diverse individual chemicals are mixed and co-exposed to consumers, underscoring the imperative for comprehending the mixture toxicity in the varied components employed across these products. Therefore, we conducted a case study with tiered approach to screen the systemic toxicity of binary combinations of chemicals used in Korean cleaning products. In step 1, we collected information on 5,171 cleaning products from the Korean consumer product database, Ecolife, and extracted 811 chemicals used as main ingredients. In step 2, we selected 52 chemicals, including the top 20 most frequently used chemicals and 32 chemicals under the government regulation. In Step 3, information on the hazards of individual chemicals was gathered from the reports published under K-REACH, EU REACH, US FIFRA, and EU-BPR. And the chemicals were grouped by their hazards such as respiratory, endocrine, and neurotoxicity. Subsequently, binary combinations of chemicals showing common hazard were prioritized based on their frequency of use in products. Additionally, we enhanced the evidence for binary combinations by comparing them with combinations obtained using association rules. In Step 4, we evaluated the mixture toxicity of the selected combinations through cytotoxicity screening. In this study, we identified binary combinations of chemicals that could cause mixture toxicity in cleaning products. This study highlights the blinding point and persistent challenges concerning the mixture toxicity of chemicals contained in products used in Korea. For further study, we plan to evaluate the mixture toxicity of these combinations in a mechanism-oriented approach by applying an integrated testing strategy based on adverse outcome pathway framework.

6.02.P-We500 Impact of exposure assumptions on the size of mixture assessment factors required to protect environmental receptors

*Paul Price[1], Ismael M Rodea-Palomares[2] and **Arnd Weyers**[3], (1)Risk Sciences, (2)Bayer Crop Science, (3)Bayer AG*

A Mixture Assessment Factor (MAF) is an additional safety factor proposed for use in the setting of ecological standards for individual chemicals. The MAF is intended to protect receptors from the cumulative effects of concurrent exposures to multiple chemicals. The Swedish Chemicals Agency (KEMI, 2021) recently proposed a numerical approach to derive the values of MAFs required for mixtures of chemicals measured in surface waters (the KEMI MAF). Although the KEMI MAF is an improvement over earlier approaches, it generates large estimates of MAF values because of assumptions made concerning certain inputs to the MAF calculations. The affected inputs include: the number of chemicals that reach an individual receptor; the allocation of the chemicals into mechanism-based assessment groups; the variation in combined exposures over time for an individual receptor; and the concentrations of chemicals that will occur under future controls of individual chemicals. In this work, we explore the impact of alternative assumptions for these inputs using methodologies developed in a recent publication (Price and Junghans 2023). A range of MAF values are generated for the mixtures reported by multiple large-scale surveys of EU surface waters. These values demonstrate how alternative assumptions for the inputs have significant impacts on the size of MAFs derived using the KEMI MAF approach.

6.02.P-We501 Addressing the Impact of the Mixture Allocation Factor (MAF) on Environmental Risk Assessment: Refining Regulatory Exposure Predictions Using Spatial Data and Modelling Approaches

***Christopher M Holmes**[1], Logan Insinga[1], Juliet Hodges[2], Jens Bietz[3], Liesa-Kristin Beuter Beuter, PhD[4], Geoffrey Hodges[5], Diederik Schowanek[6], James Dawick[7], Erin Maloney[8], Marc Geurts[9], Sabrina Wilhelm[10], Susan A Csiszar[11] and Henrique Anselmo, PhD[12], (1)Applied Analysis Solutions, LLC, (2)Safety & Environmental Assurance Centre, Unilever, United Kingdom, (3)Clariant Produkte (Deutschland) GmbH, Germany, (4)Nouryon AB, Sweden, (5)Unilever - Safety and Environmental Assurance Centre (SEAC), United Kingdom, (6)Brussels Innovation Centre, Procter & Gamble, Belgium, (7)Innospec Limited, United Kingdom, (8)Shell Global Solutions International BV, Netherlands, (9)Nouryon Chemicals B.V., Netherlands, (10)BASF Personal Care and Nutrition GmbH, Germany, (11)Procter & Gamble, Belgium, (12)Global Safety Assurance, Reckitt, Netherlands*

Under the Chemical Strategy for Sustainability (CSS), the European Commission has proposed the use of a mixture allocation factor (MAF) to address uncertainties and risks associated with unintentional chemical mixtures in the environment. Currently it is thought that a MAF may need to be applied to all single chemical registrations for the higher tonnage bands. It is expected that additional exposure and/or effect data generation will be needed for the risk assessment, and in some cases further risk management measures may be required to ensure environmental safety. The European Union System for the Evaluation of Substances (EUSES), also accessed via the CHESAR v1 tool is the standard model to determine exposure in support of chemical safety assessments (CSAs) under REACH. In the spirit of continuously refining safety assessments and models, we envisage an opportunity to update exposure model background data in EUSES/CHESAR in line with the evolution of wastewater treatment infrastructure in EU, and availability of better spatial datasets. This would ensure that regulatory modelling remains aligned with most updated data available and the situation in the field. In this work we explore field data and spatially explicit modelling approaches, some of which are probabilistic, in order to compare them with the current EUSES default parameters. We developed a spatially explicit model which applied the EUSES PEC calculation to estimate environmental concentrations at freshwater discharge locations of almost 22,000 European Urban Wastewater Treatment Plants (UWWTPs). Specifically, using publicly available data, we examined per capita water use, UWWTP connectivity and local UWWTP dilution factors to generate EU-wide distributions and to place these in context with default EUSES values. We demonstrate that spatially explicit exposure models are feasible for use in regulatory modelling and can give more realistic predicted environmental concentrations (PECs). Case studies have been performed comparing PEC_{local} values for freshwater using CHESAR v1 including both the current default data and the spatial approach. We expect that higher tier exposure data will be increasingly needed to ascertain that risk quotients remain acceptable even with a MAF applied.

6.02.P-We502 Monitoring risks of chemical mixtures in humans

*Antonio Franco, **Michael Olvedy** and Stephanie K Bopp, European Commission - Joint Research Centre (JRC), Italy*

Human beings are constantly exposed to chemical mixtures from various sources. While the safety of intentional mixtures is addressed in the chemical risk assessment under the EU legislation, the existence of unintentional mixtures has not yet been properly taken into account. The Chemical Strategy for Sustainability aims to strengthen the EU's policy in this area, including the development of indicators to analyse trends and progress towards policy objectives. Human biomonitoring (HBM) data offers an aggregated exposure insight that combines all exposure sources, independent of the pathway (exposure via consumer use/articles, diet, and environment) and policy specific domain. Here we propose a human health risk indicator based on HBM data to explore temporal trends in the risk from chemical mixtures. The indicator uses HBM data available in the Information Platform for Chemical Monitoring (IPCHEM), coming from studies such as Democophes and HBM4EU that investigated the presence of several chemicals in the general European population in the period spanning from 2007 to 2021. Chemicals were prioritised for HBM based on their health concern and EU policy relevance. The indicator is expressed as a ratio of internal exposure levels and the established health-based guidance values. The sum of ratios indicates a potential health risk associated with the monitored set of chemicals, whereas a sum greater than 1 indicates that further refinements are needed to confirm or exclude risks. The indicator only includes chemicals that were measured in both reference periods (P1:2007-2014 and P2:2014-2021) and for which internal reference values exist, yielding a total of 15 chemicals. Seven substances, in particular, are the main drivers of the risk: bisphenol A, the perfluorinated chemicals PFOS and PFOA, arsenic, cadmium and two phthalates (monobutyl phthalate and monoisobutyl phthalate). The comparison of risk ratios between the two time periods suggests a decreasing trend in risk. However, we are aware that differences in study set ups, including the age of participating subjects and the variation in the EU coverage, could have had a large influence on the overall trend. The future European HBM data that is being generated under the Partnership for the Assessment of Risks from Chemicals (PARC) and that will represent the next time point in our indicator will strengthen our ability to conclude on trends.

6.02.P-We503 Review of the human mixture risk assessment cases: Research needs for scientific evidences to select mixture allocation factors in human MRA

Sunmi Kim, *Kyounghee Kang, Haena Kim and Sangmoon Han, Chemical Analysis Center, Korea Research Institute of Chemical Technology (KRICT), Korea, Republic of (South)*

Humans can be exposed to numerous chemical mixtures that might impact health, and various mixture risk characterization methodologies have been used. But still, in regulatory silos, mixture risk assessment (MRA) is not included in detail and thus not be used for mixture risk management. To obtain real-world risks for humans, MRA should be applied as soon as possible, and providing scientific evidence is urgent. For this reason, this study aimed to gain future insights into MRA methodology development. In the first part, to determine the most frequently used MRA methods and data gaps, peer-reviewed literature was searched, and 39 studies were accepted for all eligibility criteria for study objectives. Currently, component-based and concentration-addition approaches were used in most studies, and risk characterization was conducted using Hazard Index (HI) methods most frequently. Still, no methodology considers interaction among chemicals. However, if the synergistic interaction exists among substances in the mixture, the mixture risk might be underestimated. Development of the MRA methods that consider chemical-by-chemical interaction is needed and considering the mixture reference dose (RfDmix) method is suggested here. In the second part, we tried to provide the weight of evidence for the mixture allocation factor (MAF). Recently, because of insufficient data for toxicity and exposure to mixtures, MAF is considered a rational alternative to treat mixture risk even though its pragmatism. Research needs and evidence might be provided by our case study using KoNEHS 3rd biomonitoring data, showing HI>1 in median and 95th percentile exposure scenarios for 11 kinds of non-persistent endocrine disrupting chemicals (EDCs). Our results demonstrated that health risks from unintentional mixtures are already at risk, and a 3- to 10-times lower limit for risk characterization can be suggested in the current exposure level. We expect our suggestions and case study to help make reasonable management options for total chemical exposures and apply options in chemical legislation.

6.02.P-We504 Offshore Chemical Regulatory System & Risk Assessment

Kirit Wadhia, *Environmental, NOV Inc, United Kingdom*

Protection of the marine environment from the discharge of chemicals used offshore is of global importance. Sustainable operations in the oil and gas sector requires a regulatory framework ensuring protection of the ecosystem and prevention of deleterious environmental impact.

Chemicals' use and discharge for petroleum exploration activities in the OSPAR region require chemicals to be registered via the OSPAR's Harmonised Mandatory Control System (HMCS). The objective of the HMCS is to protect the marine environment by identifying those chemicals used in offshore oil and gas operations with the potential for causing an adverse environmental impact and restricting their use and discharge to the sea. Thus, for the chemical supply industry there is pressure to develop products that comply and fulfil technical performance and environmental risk criteria, Operators' (oil companies) requirements are more linked to ensure optimum operational performance.

On the environmental regulatory front Recommendation 2012/5 requires Contracting Parties to implement a risk-based approach (RBA) for the management of produced water discharges from offshore installations. RBA utilises a stepwise screening tiered approach involving either whole effluent toxicity and/or substance -based approach with use of dispersion modelling to establish if chemical discharges are likely to result in adverse effects to the marine environment.

Does this approach regarding methodology and regulatory framework criteria address the evaluation of potential combined effects of chemicals? Does the regulatory implementation require field monitoring to assess the impact on the ecosystem?

6.02.P-We505 SAFETY ASSESSMENT OF FLOW BATTERY ELECTROLYTES IN NEW ALTERNATIVE MODELS SUCH AS ZEBRAFISH, CRUSTACEAN AND MICROALGAE

Andrea Weiner[1], Ander Arbelaiz[1], Christoph Rummel[1], Stefan Spirk[2] and ***Arantza Muriana***[1], *(1)BBD BioPhenix S.L. - Biobide, Spain, (2)Institute of Bioproducts and Paper Technology, Graz University, Austria*

Redox flow batteries are an emerging technology for medium and large-scale stationary energy storage. the safety and human toxicity aspects of the electrolytes in redox flow batteries as well as their corresponding environmental impacts are poorly documented. This proposal seeks to perform different bioassays to assess the toxicological and ecotoxicological screening of several quinone based electrolyte systems. The teratogenic potential and any goitrogenic properties of the items were assessed by the developmental defects and thyroid disruption in zebrafish embryos. The ecotoxicological profile was done by applying the *Daphnia magna* immobilization assay and the microalgae *Raphidocelis subcapitata* growth inhibition test. These last two assays are based on the OECD 202 and 201 guidelines and comprise a simplified and more efficient assay design, for further sustainability.

The results obtained for their teratogenic analysis reveal that some of the quinones were classified as toxic for zebrafish embryos and showed high percentages of affectations and mortality at the highest tested concentrations. However, one quinone redox active component was classified as not toxic since the teratogenic index value was not estimated and no more than 20% of affected embryos were observed under the tested conditions. No implication for any goitrogenic effect was assessed for the four tested electrolytes with the thyroid disruption assay. No changes in fluorescence intensity were detected after exposure to four compounds, all values being similar to the control. Two electrolytes were highly toxic to Daphnia magna since the differences in the percentage of immobilization between treated and control groups were higher than 20% at very low concentration ranges. Two other electrolytes were not toxic to daphnia in the tested concentration range since no or very low immobilization was detected after 48h of exposure. For the microalgae assays of the four electrolytes, a complete dose-response curve was calculated comprising 0 – 100% effect. All four test items induced toxicity with EC50 values in a similar range.

There are differences in the (eco-) toxicological profile between the test items. The newly designed quinones showed mostly less human toxicity and ecotoxicological potential across all assays. We can conclude the bioassays proposed in this work can properly assess the (eco) toxicological profile of different electrolytes more sustainably and in a dose-effective range.

6.02.PC Can Science Help to Respond to the Regulatory Challenge to Demonstrate the Safe Use of Chemicals for Combined Toxicity in the Environment?

6.03 Combining Prospective and Retrospective Soil Risk Assessment - From Predicted Risks Towards Holistic Approaches by Integrating Monitoring Results

6.03.T-01 Concepts to define a “normal operating range (NOR)” for soil biological systems
Michael Thomas Marx[1]*, Agnes Schimera*[2]*, Frank Staab*[3] *and Jörg Hanisch*[4]*, (1)Environmental Safety, Bayer AG - Crop Science Division, Germany, (2)ADAMA Deutschland GmbH, Germany, (3)BASF SE, Germany, (4)Rifcon GmbH, Germany*
The definition of a normal operating range (NOR) would be a very valuable tool to classify the statistical and biological results of species and population soil testing systems at different tiers. In the EFSA opinion on recovery an overarching definition for a NOR is described as “The acceptable range of values of a measurement endpoint that is normally observed during a predefined period for a reference population, community, ecosystem or process” (EFSA journal 2016:14(2):4313).

The definition of NORs in semi-field and field tests requires different scales of observation and a tailored application range of the NOR output. A proposal to basically define the NOR of a single observation timepoint in a field test for a specific taxon could be: “The NOR is defined as the percentage by which the abundances deviate from the mean control values for a given taxon at one observation point. The NOR includes all values of this taxon between a defined percentile range (NOR90 includes all values between the 5th and 95th percentile of all values for a given taxon)”. This NOR90 represents the statistical significance level of α=0.1 and can help to better classify the statistical output for this taxon in the subsequent observation timepoint.

The evaluation of Collembola field tests shows a potentially large impact resulting from a large variability in abundances for certain timepoints and the hierarchical level on the resulting NOR90 output. For e.g. *Lepidocyrtus cyaneus*/*L. violaceus* the NOR90 in autumn is calculated to be 95%, whereas for the family Entomobryidae (including the *Lepidocyrtus* species) a much lower NOR90 value of about 56% can be observed.

This basic NOR-definition can also be extended to other scales of observation. In a single 1-year soil field study such scales could be NORs defined by several observation timepoints in the same season (leading to a higher temporal resolution) or a time-dependent NOR through the whole study period. For soil monitoring purposes, NORs derived from a range of field tests and the inclusion of additional data derived from suitable publications and databases (e.g. Edaphobase, Collembola.org) could be relevant to define baseline scenarios for the investigated soil organism groups.

6.03.T-02 Applying the Pesticide Load Index to characterize ecotoxicological impact from pesticide use in the EU
Rui Catarino[1]*, Francesco Galimberti*[2]*, Stephanie K Bopp*[3]*, Thomas Fellmann*[4]*, Ana Klinnert*[4]*, Michael Olvedy*[3]*, Maria Luisa Paracchini*[1]*, Alberto Pistocchi*[3]*, Xavier Rotllan-Puig*[1]*, Jean-Michel Terres*[1]*, Marijn Van Der Velde*[3] *and Raphael D'Andrimont*[5]*, (1)European Commission - Joint Research Center (JRC), (2)European Commission - Joint Research Centre (JRC), Belgium, (3)European Commission - Joint Research Centre (JRC), Italy, (4)European Commission - Joint Research Center (JRC), D4 Economics of the Food System, (5)European Commission - Joint Research Center (JRC), Belgium*
Improving the sustainable of agriculture requires an advanced assessment of the ecological impacts of pesticides. Our study applies the Pesticide Load Index (PLI), already been used in Denmark and in England, to quantify pesticide risks to environmental health and biodiversity across the European Union. This could help to further integrate ecological considerations into assessments of plant protection products. The PLI is defined as the sum of the amount of applied pesticide active substances (AS) divided by the toxicity to non-target-organisms, including birds, mammals, and beneficial insects like bees and natural enemies of pests.

Our methodology bridges the gap between ecological health and pesticide risk assessment using three extensive data sets. The first data set includes EU-wide estimations of AS emissions at a 1km resolution. The second data set provides detailed AS use in France, including crop types. The third, from the Pesticide Properties DataBase, assesses ecological risks by comparing pesticide loads with ecotoxicological values. By integrating acute toxicity, chronic toxicity, and environmental fate, we gain a deeper understanding of possible pesticide impacts. Acute toxicity indicates short-term effects, while chronic toxicity addresses long-term consequences. Environmental Fate Load examines pesticides' behavior and transformation in the environment. The resulting granular PLI maps are essential for identifying areas with high ecotoxic levels, informing where additional risk mitigation measures are necessary.

In conclusion, the study's outcomes offers new insights into the ecotoxicological impacts of European Union pesticide risk distribution, equipping policy-makers and farmers with spatially explicit data to tailor strategies for biodiversity and ecosystem conservation. This can be used to inform and monitor the EU's Farm to Fork and Biodiversity strategies, particularly the goal of reducing pesticide use and risk by 50% by 2030. In addition, the comparison between crops, regions, and EU Member States could help in developing further protective and scientifically sound regulatory frameworks to bring potential economic benefits, increase agricultural resilience and reduce pesticide dependence by through nature–based (such as natural pest control and pollination) mechanisms.

6.03.T-03 Plant Protection Product Residues in Agricultural Soils Across Europe, and the Effect of the Farming System on the Soil Microbiome

Dennis Knuth[1]*, Vera Silva*[1]*, Paula Harkes*[1]*, Zuzana Bílková*[2]*, Jakub Hofman*[2]*, Jos Boekhorst*[3] *and Violette Geissen*[1]*, (1)Soil Physics & Land Management Group, Wageningen University & Research (WUR), Netherlands, (2)RECETOX, Masaryk University, Czech Republic, (3)Host-Microbe Interactomics, Wageningen University & Research (WUR), Netherlands*

As more and more studies show, the occurrence of mixtures of plant protection products (PPP) in soil is more often the rule than the exception. The effects of such mixtures on soil life are not completely understood yet. A "cocktail effect" of more than one PPP residue could lead to a higher chemical pressure on the soils and consequently soil life, which could reduce its capability to provide essential ecosystem services. In the SPRINT project, 101 organically (OF) and 100 conventionally (CF) managed fields were sampled across 10 European countries. The soil samples, collected at the middle of the 2021 growing season were analysed for 192 different PPP residues, and DNA was isolated for microbiome analysis. During the sampling campaign questionnaires about amongst others, the PPP applications were conducted. The application records were used to predict the environmental concentrations (PEC) of the PPPs in soil at sampling time. These PECs were compared to the measured environmental concentrations (MEC). DNA isolates were used for amplicon sequencing and to analyse differences in microbial composition (e.g., total, nutrient cycles) between fields under different farming systems. Additionally, PPPs with the same mode of action were clustered and the effects of these groups on the microbial composition were analysed. In total 101 different PPP residues were detected. At least one PPP residue was present in 99% of CF fields and 95% of OF fields, and mixtures of PPP residues have been detected in 96% of CF and 79% of OF fields. These high detection frequencies especially in OF fields are in part allegeable by organochlorine pesticides which have been long banned but persist since then. Without these there are still PPP residues found in 95% of CF fields but only in 64.4% of OF fields. Of the PPPs analysed and applied in the growing season before sampling, 51.5% have been detected 79% of PPP residues detected were not applied in the 2021 growing season. The PECs calculated did not fit well with the MEC, with both under and over-estimations of the environmental concentration. The first results of the analysis of the sequencing data show that the country is the main driver behind microbial composition. Indications are that the microbial (alpha-)diversity is not affected significantly by the farming system, but the composition is. Further analysis of the effect of different pesticide groups, and on different groups of microorganisms will be conducted.

6.03.T-04 Evaluation of the Ecological Risk of Pesticides Residues from the European LUCAS Soil Monitoring 2018 Survey

Antonio Franco[1]*, Diana Vieira*[1]*, Laure-Alix Clerbaux*[2]*, Alberto Orgiazzi*[3]*, Maeva Labouyrie*[4]*, Vera Silva*[5]*, Julia Köninger*[6]*, Ruud van Dam*[7]*, Edoardo Carnesecchi*[8]*, Jean Dorne, Bsc(Hons), Msc, PhD*[8]*, Jeanne Vuaille*[9] *and Arwyn Jones*[1]*, (1)European Commission - Joint Research Centre (JRC), Italy, (2)University of Louvain, (3)European Dynamics, (4)University of Zurich, Switzerland, (5)Soil Physics & Land Management Group, Wageningen University & Research (WUR), Netherlands, (6)Universidade de Vigo, Spain, (7)Wageningen University & Research (WUR), Netherlands, (8)European Food Safety Authority (EFSA), Italy, (9)European Environment Agency (EEA), Denmark*

The 2018 LUCAS pesticide survey provides a EU-scale assessment of 118 pesticide residues in 3,473 soil sites. This study responds to the policy need to develop risk-based indicators for pesticides in the environment. Two mixture risk indicators are presented for soil, based respectively on the lowest and the median of available no observed effect concentration ($NOEC_{soil,min}$ and $NOEC_{soil,median}$) from publicly available toxicity datasets. Two further indicators were developed based on the corresponding equilibrium concentration in the aqueous phase and the aquatic toxicity data, available as species sensitivity distributions.

The mixture risk indicator based on the $NOEC_{soil,min}$ exceeds 1 in 1.7 % of sites and 0.1 in 22% of sites. The insecticides imidacloprid and chlorpyrifos and the fungicides epoxiconazole and boscalid are the largest contributors to the overall risk. At each site, one or few substances drive the mixture risk. Modes of actions most likely associated to mixture effects include modulation of acetylcholine metabolism (neonicotinoids and organophosphate substances) and sterol biosynthesis inhibition (triazole fungicides). Several pesticides driving the risk have been phased-out since 2018. Following LUCAS surveys will determine the effectiveness of substance-specific risk management and the overall progress towards risk reduction targets established by EU and UN policies. Newly generated data and knowledge shall stimulate needed future research on pesticides, soil health and biodiversity protection.

6.03.P Combining Prospective and Retrospective Soil Risk Assessment - From Predicted Risks Towards Holistic Approaches by Integrating Monitoring Results

6.03.P-We506 Disentangling uncertainties in the Environmental Risk Assessment of pesticides for soil organisms – UNCERTAIN project
José Paulo Sousa[1]*, Daniela Alves*[2]*, Leticia Scopel*[2]*, Sara Leston*[3,4]*, Stephan Jänsch*[5]*, Peter Craig*[6]*, Jörg Römbke*[5]*, Bjoern Scholz-Starke, PhD*[7]*, Pia Kotschik*[8]*, Silvia Pieper*[8]*, Susanne Walter-Rohde*[8] *and Tiago Natal da Luz*[2]*, (1)University of Coimbra, Centre for Functional Ecology, Portugal, (2)CloverStrategy Lda, Portugal, (3)CFE - Centre for Functional Ecology, Portugal, (4)REQUIMTE/LAQV, Portugal, (5)ECT Oekotoxikologie GmbH, Germany, (6)Dept Of Mathematical Sciences, Durham University, United Kingdom, (7)darwin statistics, Germany, (8)German Environment Agency (UBA), Germany*
Several uncertainties associated with the Environmental Risk Assessment (ERA) process have not been taken into account, either due to unawareness or a lack of data and/or tools to handle them. European Food Safety Authority (EFSA) acknowledges these uncertainties and recently provided guidance on how to handle them in various scientific assessments, like in the ERA of pesticides. The UNCERTAIN project aimed to identify and quantify sources of uncertainties (SOU) that may occur in the ERA of pesticides, especially in the soil compartment. Moreover, new data was produced by carrying out a set of laboratory tests using a targeted combination of soils, test species and substances to close knowledge gaps on uncertainties that have not been adequately addressed by the data available in regulatory databases and the literature. These new data aimed to understand and describe how experimental results (subsequently used in risk and fate modelling) may differently affect the outcome of an ERA. Lastly, predominant and pre-defined SOUs were analysed using Bayesian network models combining results generated in the project and data from publicly available and protected databases. A total of 53 different SOU were identified but partly overlapped in different categories and only 14 were assumed to be quantifiable by adequate statistical methods, given the availability of suitable data. The new data produced showed that using artificial soils in ecotoxicity testing with soil invertebrates can be insufficiently protective in toxicity evaluation of chemicals. Data analyses of quantifiable single SOU did not suggest that including soil characteristics other than organic carbon (OC) content would significantly increase the variation explained. On the other hand, there was some evidence that models combining soil characteristics and chemical properties of test substances might be able to explain a substantial fraction of the variation in test outcomes not explained by OC percentage on its own. The current assessment factor (AF) of five for extrapolation of earthworm toxicity data from the laboratory to the field should be reconsidered to cover all the relevant uncertainties thus enabling an adequately protective ERA. For mesofauna, more data (pairs of laboratory and field study outcomes) are needed to reduce uncertainty about the extrapolation.

6.03.P-We507 Ecotoxicological tests for assessing single and mixture effects of antibiotics and copper
Alessandra Narciso[1,2]*, Livia Mariani*[1]*, Paola Grenni, PhD*[3]*, Jasmin Rauseo*[4]*, Francesca Spataro*[4]*, Luisa Patrolecco*[4] *and Anna Barra Caracciolo*[1]*, (1)National Research Council - Water Research Institute (IRSA-CNR), Italy, (2)Department of Ecological and Biological Sciences - Tuscia University, Italy, (3)Water Research Institute (IRSA), National Research Council (CNR), Italy, (4)National Research Council- Institute of Polar Science (ISP-CNR), Italy*
Antibiotics (ABs) are widely used to treat human and veterinary infections. Biosolids and manure, used as fertilizers in agriculture, can contain AB residues and can be a source of contamination for soil and water. Copper (Cu) can be found in co-presence with AB residues in agroecosystems due to its common addition in cattle feeds and in antifungal products to improve the agricultural productivity. Consequently, in real contamination scenarios, several types of pollutants can be present and can interact in different ways, including worsen or mask toxic effects of single substances. For this reason, it is crucial to evaluate mixture effects on different organisms and environmental matrices.

In this context, ecotoxicological tests with *Aliivibrio fischeri* were performed to assess single and mixture effects of Sulfamethoxazole (SMX), Ciprofloxacin (CIP), Chlortetracycline (CTC) and copper sulphate (Cu). Predicted toxicity values were calculated in accordance with the Concentration Addition model. Finally, water extracts from a soil co-contaminated by the same AB mixture and Cu, were tested for evaluating the overall effects in a real environmental matrix.

CTC resulted the most toxic AB for *A. fischeri* (EC_{50}=3.64 mg/L), followed by CIP (EC_{50}=96.93 mg/L) and SMX (EC_{50}=194.06 mg/L), while Cu was the most toxic compound (EC_{50}=0.78 mg/L). Comparing binary mixture measured and predicted toxicity values, SMX+Cu showed an additive effect, CIP+Cu a synergic effect and, interestingly, CTC+Cu an antagonistic effect. The other mixtures (ternary with the three ABs and quaternary with all the substances) showed additive effects, except for SMX+CIP+CTC that displayed an antagonistic effect.

Soil water extracts did not show toxicity, highlighting the possible buffering capacity of the soil used in these experiments. Further tests with *Lepidium sativum* and *Daphnia magna* were performed, and the results obtained were compared and discussed with those of *A. fischeri*.

Combined effect results can be due to different complexation processes between ABs and Cu that can mask or increase effects of the single chemical. The study of substance interactions in environmental matrices is a present and future challenge. This work represents a contribute to the research gap in the complex framework of mixture effect evaluations in a real environmental context.

6.03.P-We508 MICROSOIL - Investigation of Alternative Test Methods to Correctly Assess the Impact of Plant Protection Products, Biocides and Pharmaceuticals on Soil Microorganisms

***Vivian Reiermann**[1], Frank Zielinski[2], Jens Schönfeld[2], Pia Kotschik[2], Silvia Pieper[2] and Karsten Schlich[1], (1)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)German Environment Agency (UBA), Germany*

One aspect in the risk assessment of e.g. plant protection products (PPP) is the evaluation if one of the most important soil functions, the N-transformation (OECD 216) of soil microorganisms, is affected. However, focussing on one central function of the microbial community is not sufficient to determine the impact on soil microorganisms. The MICROSOIL project aims to identify sensitive alternative test methods to determine the effect of e.g. PPP on the microbial community. For this purpose, the MicroResp^{TM} test system (substrat induced respiration with various substrates), the ISO 20130 (exoenzymatic activities) and the ISO 15685 (ammonium oxidizing bacteria) were selected as alternative test systems. In addition, based on the recommendations of EFSA (2017), the fungal group was included, considering arbuscular mycorrhizal fungi (AMF) as a sensitive group.

The spore germination test (ISO 10832) will be used to evaluate the effect of PPPs, a biocide and a veterinary pharmaceutical on *Funneliformis mosseae*. This presentation aims to describe the process of i) establishing a culture of *F. mosseae*, ii) adapting the test setup outlined in the ISO 10832 for natural soils and iii) investigating the effect of six different test substances on the spore germination.

A culture of *F. mosseae* was successfully established using parsley as the symbiotic partner. Once sufficient spores were available, different natural soils (RefeSol 02A, RefeSol 04A, Lufa 2.1) were investigated as an alternative to artificial soil and sand suggested by ISO 10832. As the required germination rate was not reached with the natural soils, test conditions (e.g. the soil water content) were adapted. The reduction of the water holding capacity to 50 % was necessary to reach a sufficient germination rate. For Lufa 2.1, the required germination rate was not reached, which might be due to the low pH (< 5). RefeSol 02A (pH = 6.8; sand 79.7 %; silt 14.9 %; clay 5.4 %; soil texture: silt loam) showed a sufficient germination rate and sensitivity was validated using the reference substance benlate (1 mg/kg and 10 mg/kg). As a first fungicide tebuconazole (1 mg/kg and 10 mg/kg) was tested, but no significant inhibition was observed in the tested concentrations. Now, the effect of different other substances on the spore germination of *F. mosseae* will be tested using RefeSol 02A and likely another natural soil.

Acknowledgement - The study was funded by the German Environment Agency FKZ 3720 64 4110.

6.03.P-We509 Exploring the Biodiversity of Brazilian Soils: A Review on Earthworms, Enchytraeids, Collembolans, and Soil Mites

*Ricardo Petersen[1], **Francisca Ribeiro**[2] and Gregor Ernst[3], (1)ERM International Group Limited, United Kingdom, (2)ERM International Group Limited, Portugal, (3)Environmental Safety, Bayer AG - Crop Science Division, Germany*

Brazil, having approximately 846 million ha of land, faces challenges in managing its diverse environmental landscape, ranging from equatorial rainforests in the north to temperate coniferous forests in the south. Farming activities occupy around 60% of the total area. The soil ecosystems in Brazil are susceptible to changes in land use and environmental conditions. Key soil functions, including organic matter (OM) degradation, nutrient cycling, and water infiltration, are dependent on soil organisms. Their diversity, abundance, and seasonality are influenced by various abiotic factors, such as land use, rainfall, humidity, and temperature. The development of Specific Protection Goals (SPGs) within the framework of environmental risk assessment for pesticides becomes crucial, considering their 'Normal Operating Range' and functions in agricultural ecosystems. We conducted a literature review on the biodiversity of earthworms, enchytraeids, collembola, and soil mites in Brazil. Our aim was to evaluate their diversity and abundance across Brazil in relation to various abiotic factors. We synthetised soil biodiversity data from more than 120 field studies up to June 2023. From the retrieved publications, data related to study location, dates, sampling, soil characteristics, agricultural practices, organisms and density, were compiled in a database. We evaluated the average density of organisms vs the following factors: season of the year (rainy vs dry), OM %, soil pH and influence of tillage. Most of the ecological studies are on soil mites (> 40% of the studies), followed by earthworms, collembolans, and enchytraeids. Tillage has an impact on mesofauna density across the four groups of organisms, with a reduction in average density of collembolans and soil mites in the dry vs the rainy season. In relation to pH, Collembola and soil mite densities were higher at certain pH values, while earthworm densities were not strongly influenced by pH soil values. Other influencing factors will be presented.

Despite an increase of reported data on the abundance and diversity of soil invertebrates, our data underscores the deficiency in basic information regarding the occurrence and ecology of these organisms. This emphasizes the necessity for global collaboration to foster a comprehensive understanding of soil biodiversity in Brazil. A better understanding of the Normal Operating range is crucial to bring potential effects of pesticides into agro-ecological context.

6.03.P-We510 Case Study on Soil Organism Species Richness and Abundance on Agricultural Sites in Germany
Christoph Digel, *Olivia Roithmeier, Silvia Pieper and Pia Kotschik, German Environment Agency (UBA), Germany*
Risk assessment for in-soil organisms opens the possibility to conduct field studies as a refinement option if an unacceptable risk was indicated at the first step of the assessment. These higher tier field studies are conducted with field communities of soil organisms. Whereby a guideline is available for earthworms, no official specific test guideline for field studies with collembola or mites is available up to date. Information about expected values for abundance and diversity of natural communities of soil organisms has been gathered but evaluation of the data for environmental risk assessment questions are rare. Therefore, the variability of tested communities may be high and effects of pesticides on those communities might be dependent on the chosen site for the experiments. To gain a better understanding on the differences in natural communities across agricultural land and to further facilitate the development of a test guideline for higher field studies, we compiled a large dataset of species data and land use types across Germany.

Data on field studies with soil organisms submitted for the authorisation process of plant protection products in Germany was gathered from the internal UBA-database ICS. Moreover, the data base Edaphobase was used to gather and evaluate data on collembola, mites and earthworms on corresponding sampling sites. In a first step, sampling sites were grouped based on land use type. In a second step, grouped data was evaluated to identify preliminary expectations regarding species richness and abundance for soil organisms, acknowledging the land use type.

Based on the available data, we found significant differences in species richness between different land use types for earthworms and collembola. In soils on intense farmlands were significant less earthworm species present compared to extensive farmlands or grasslands.

Our analysis provides further insights in the differences of soil organism species diversity in agricultural fields. We aim at a better understanding of the prerequisites for field studies and provide data to support a harmonized assessment of expected soil communities in the field.

6.03.P-We511 The role of soil monitoring for the regulation of chemicals
Pia Kotschik[1], *Carsten Brühl*[2,3] *and Silvia Pieper*[1], *(1)German Environment Agency (UBA), Germany, (2)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (3)University of Kaiserslautern-Landau (RPTU), Germany*
Plant protection products (PPPs) are applied in large quantities [1], mostly through multiple applications [2] on agricultural land. Depending on the respective soil and acitve substance properties they may accumulate and remain in soils for years. In combination with other stressors, soil pollution can lead to a decline in soil biodiversity, which accounts for a large proportion of overall biodiversity and is a central building block and driver for soil fertility and other soil functions [3]. However, the overall soil contamination due to residues of PPPs in agricultural soils is largely unknown and cannot be compared with the state of knowledge on PPP residues in surface or groundwater.

The risk assessment of PPPs does not take into account possible pre-contamination of soils as well as an accumulation of substances [4], although it is known that soils can act as a sink for pollutant accumulations. The consequences of multiple and sequential PPP exposures from fresh and long lasting residues for non-target organisms, terrestrial biodiversity and the ecosystem are not sufficiently understood. So far, it has not been clarified to what extent this deficit leads to an underestimation of the risks in the authorisation procedures.

This study aims to define ‘soil monitoring’ with the focus on the risk assessment for plant protection products and gathers information on different kinds of monitorings within the regulatory approach. It compiles a subset of existing surveys in Germany and Europe and suggests further needs for the connection of monitoring programs with the risk assessment for PPP. Moreover, open questions regarding the conduction and design of monitoring programs are raised and the connection with strategies, regulations and directives within the green deal are made. The aim of this study is to draft the way to solve regulatory challenges and support the goals of the green deal as well as the soil monitoring and resilience law, aiming to reach 100 % healthy soils by 2030.

[3] FAO, 2020. State of knowledge of soil biodiversity -Status, challenges and potentialities’. [4] Frische et al. 2018. 5-Point programme for sustainable plant protection. Environ. Sci. Eur. 30, 8 (2018).

6.03.P-We512 Retrospective pesticide mixture risk assessment for agricultural soils
Fabian Gerhard Peter Balk, *Mathieu Renaud, Benoit J.D. Ferrari and Marion Junghans, Swiss Centre for Applied Ecotoxicology, Switzerland*
Plant protection products (PPP) are widely applied in agricultural fields for crop protection with potential accumulation in the

soil. As a result from the serial application or slow degradation of PPP, the soil and organisms therein may be exposed to a complex mixture of PPP residues. Research on the predictability of mixture toxicity as well as retrospective risk assessments have mainly focused on the aquatic compartment so far. In recent years the soil compartment comes more into focus as can be seen from the proposal for an EU directive on Soil Monitoring and Resilience. Also several monitoring studies have been done on PPP residues in agricultural soils. For an assessment of the risk of these residues on soil organisms mixture toxicity has to be considered. Based on a review on different mixture risk assessment concepts with the focus on soils we present an approach for retrospective mixture risk assessment for PPP residues on soil organisms. Main challenges and uncertainties are discussed.

6.03.P-We513 Chemical, Ecotoxicological And Ecological Indicators In Risk Assessment Of The Agricultural Area Long-Term Contaminated With Organic Pollutants

Agnieszka Klimkowicz-Pawlas*, Bożena Smreczak and Urszula Pasternak, Department of Soil Science Erosion and Land Protection, Institute of Soil Science and Plant Cultivation - State Research Institute, Poland*

Soils are multifunctional non-renewable resources providing goods and services essential for ecosystems and human life. Agricultural land is often located close to highly urbanised/industrialised areas and can be exposed to emissions of various organic and inorganic pollutants. As a consequence, soil quality can deteriorate and there is a risk of contaminants entering the food chain. Thus, risk assessment in areas particularly exposed to chemical degradation is still a big challenge. Most studies on environmental risk assessment have only analysed total pollutant concentrations and used chemical risk indexes, e.g. hazard quotient, toxic units or pollution load index, to assess the level of risk. Such approach does not provide information on the bioavailability and toxicity of chemicals and often leads to an overestimation of risk. Therefore, in our study we used an interdisciplinary approach whereby the final conclusions about the risk in a given area were based on the integration of detailed data from chemical, ecotoxicological and ecological analysis.

The study was conducted in the agricultural area exposed to the long-time contamination, located in the South-West part of Upper Silesia region in Poland. Chemical measurements comprised both total and bioavailable polycyclic aromatic hydrocarbons (PAHs) content. A battery of bio-assays describing effects on soil retention and habitat function was used for ecotoxicity testing, and ecological indicators included enzymatic activity, soil respiration, microbial biomass, carbon mineralisation and nitrification.

Environmental risk index ranged from 0.19 – 0.94 and was mainly due to high values of chemical risk index, while ecotoxicological and ecological results indicated no or low risk. The majority of the area (almost 90%) had acceptable risk levels, and very high unacceptable risk (EnvRI 0.77–0.94) was only at three sampling sites. Our study revealed that integration of data on the organism’s response and ecological indicators into evaluation provide realistic assessment and allows for delineating the area which needs additional action (further monitoring or remediation).

6.03.P-We514 ARAGORN: Achieving Remediation And Governing Restoration of contaminated soils Now

Hans Peter Arp*[1,2], Mari Engvig Løseth[1], Astrid Hasselbach[3], Katrine Vendelboe[3] and Xenia Trier[3], (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian University of Science & Technology (NTNU), Norway, (3)University of Copenhagen, Denmark*

Announcing the Horizon Europe project ARAGORN:

Soil contamination is a severe hazard to humans and the environment. We propose Achieving Remediation And GOverning Restoration of contaminated soils Now (ARAGORN) through development and implementation of a complete framework. The framework starts from the identification of contaminated sites and presents a decision-making tree to identify remediation and restoration strategies, and contribute to the aims of the EU Soil Strategy. The framework is grounded in scientific progress and adapted to fully support public and private land managers to take effective actions to protect, remediate and restore the environment on Europe’s polluted soils.

ARAGORN will provide better insights into contaminated sites and improve remediation and restoration decision-making by implementing robust mapping and monitoring tools that are fit-for-purpose and covers a wide range of contaminants. Neglected hotspot polluted sites will be identified by fit-for-purpose monitoring and decision strategies. This will enable public and private stakeholders of contaminated sites to move from regrettable remediation to restorative remediation.

ARAGORN will compile and test remediation strategies and sustainable soil decontamination solutions, and will develop and put in practice nature-based solutions, improve knowledge on biodiversity and deliver a framework for step-by-step decision making in terms of what is the best approach for resilient restoration in various European countries. The complete framework will be developed together with strategic engagement of land managers throughout Europe, and by rooting knowledge through co-creative processes and sustainable infrastructures.

The implementation will be done through a strong team of multidisciplinary scientists and practitioners with ongoing commitments with a diverse set of stakeholders across Europe at the local, national and EU level. We will interlink land managers and sectors across Europe to take effective action on soil health and provide longevity links and support to several EU policy and international commitments.

6.03.P-We515 Using vis-NIR spectroscopy for the evaluation of environmental quality in agricultural areas potentially contaminated

Valeria Ancona[1]*, Natalia Leone*[1]*, Annamaria Basile*[2]*, Gianluca Intini*[3]*, Mauro De Molfetta*[4] *and Vito Felice Uricchio*[1]*, (1)Italian National Research Council - Water Research Institute (CNR-IRSA), Italy, (2)Waste Cycle and Reclamation Section - Puglia Region, Italy, (3)Tecnologia e Ambiente srl, Italy, (4)Comune di Statte (TA), Italy*

The assessment of environmental quality of potentially contaminated areas intended for agri-food production pursuant to the Italian environmental law (DM 46/2019) provides for the adoption of specific criteria and investigation methodologies for the characterization of agricultural soils which, sometimes, require rather long and expensive acquisition and processing times.

As part of one of the first applications of DM 46/2019 to a large potentially contaminated area close to the city of Taranto (Southern Italy), the CNR-IRSA has experimented with an innovative investigation methodology, faster and cheaper than traditional analyses, which involves the use of visible-near infrared (vis-NIR) spectroscopy for the characterization of contaminated soils. This technology allows to quickly evaluate the nature and chemical, physical, and mineralogical properties of soils, and their state of contamination.

The spectral reflectance measurements, i.e. the ratio between the radiation reflected by a soil surface to that incident on it, were conducted in the laboratory on 108 composite soil samples deriving from the mixing of elementary samples taken in 73 homogeneous investigation areas, identified in the phase of characterization of the agricultural territories of Statte (TA) according to the methodology defined by the DM 46/2019. Particular attention was given to the analysis of PolyChlorinated Biphenyls (PCBs) which, in some composite samples, exceeded the regulatory limit (6 ng/kg), with maximum concentrations between 11.55 and 94.61 ng/kg. In fact, recent studies performed by the CNR-IRSA have demonstrated that high concentrations of PCBs can influence the color of the soil; therefore, in soils heavily contaminated by PCBs, it is possible to estimate with good accuracy the content of these contaminants through a simple determination of the color parameters by using a portable spectroradiometer; furthermore, by statistically relating spectral reflectance measurements to the results of laboratory chemical analyses, predictive models of some PCBs congeners can be calibrated by applying multivariate statistical methods.

Given its potential, vis-NIR spectroscopy can therefore represent a valid alternative to traditional analyzes for investigating potentially contaminated soils and be used both for pre-screening activities of the state of soil contamination and for the characterization and subsequent monitoring phases.

6.04 Environmental Toxicology and Chemistry in Africa: Exchanging Knowledge and Progress on Tackling Legacy and Emerging Pollutants

6.04.P-We516 Comprehensive Chemical Analysis to Unravel Exposure to Chemical Mixtures in Kenyan Rivers

Isaac Cheruiyot Tanui[1,2,3]*, Faith Kandie*[2]*, Martin Krauss*[4] *and Werner Brack*[3,4]*, (1)Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Moi University, Kenya, (3)Goethe University Frankfurt, Germany, (4)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany*

Chemicals in the environment pose unprecedented challenges to human and aquatic health. The ubiquitous presence of these contaminants raises concerns about their cumulative impacts. Several studies have focused primarily on single pollutants, often overlooking the complex interplay of multiple mixtures coexisting in the environment. Technological advancement, modern analytical techniques have enabled a more comprehensive understanding of environmental exposures, revealing an array of extensive mixed-toxicant situations. This study employed a comprehensive chemical analysis to unravel the exposure of aquatic ecosystems to chemical mixtures. By using liquid chromatography and mass spectrometry, we identified and quantified a diverse range of chemical compounds present in water samples. In total, 307 compounds with concentrations ranging from 0.3 ng/L to 6.6 µg/L were identified, with at least forty-six (46) of them detected in more than 50% of the samples. Tetrabutylammonium and the pharmaceutical amantadine was detected in all the samples (100% detection) with concentrations ranging from 3 ng/L to 59 ng/L and 4 ng/L to 49 ng/L respectively. The wet season of October and the dry season of February recorded the highest percentage of chemicals exceeding 5 ng/L with respect to the detected number of compounds. Exposure risk for crustaceans was the highest with values of up to 60 times beyond the acute threshold level. The top contributors of toxicity included the pesticides diazinon, pirimiphos- methyl, clothianidin and imidacloprid. Acute threshold level for algae was exceeded in the dry season of July while significant TU values for fish was recorded during the wet season of May. It's crucial to recognize that the risks observed in aquatic organisms are indicative of potential risks on humans. Understanding these risks is paramount for safeguarding the environment in the broader context of chemical exposure. These findings provide valuable insights into chemical pollution in Kenya

6.04.P-We517 Water Quality Challenges in South Africa: Gauging the Size of the Problem

Nick Rivers-Moore[1]*, James Dabrowski*[2]*, Leo Quayle*[3] *and Isabella Gosetto*[4]*, (1)Nick Rivers-Moore Aquatics, South Africa, (2)Confluent Environmental, South Africa, (3)Geonest, South Africa, (4)Joint Nature Conservation Committee (JNCC), United Kingdom*

Growing challenges of untreated wastewater effluent and runoff from agricultural landscapes are contributing to an approaching water quality tipping point in South Africa's rivers. However, not all rivers are equally vulnerable to this, or impacted equally over the course of a hydrological year. Identifying high risk areas of water quality vulnerability, and likelihood of impact at different times of the year, requires an understanding of pollution loads relative to hydrograph and rainfall patterns. A simple modelling method was implemented to characterize river flow patterns into flushing or buffering states. Periods of vulnerability to point (typically as constant inputs throughout the year) and non-point (variable inputs driven by rainfall patterns) pollutants relative to flow volume and flooding helps to identify critical seasons when aquatic biota are most likely to be negatively impacted by poor water quality. Mean daily flow rate time series > 55 years duration were downloaded from the South African national hydrological services database for six gauging weirs occurring in three rainfall regions. Each flow data file was analysed with non-parametric statistics, using the Indicators of Hydrologic Alteration approach. Flow time series were divided into two equal parts, representing historical versus current periods. Metrics were calculated for each site that describes a hydrograph in terms of frequency, duration, timing and magnitude of hydrological events. Differences between catchment hydrology were characterised using descriptive and multivariate methods. We anticipate that this will enable rivers to be classified in terms of their relative flushing and buffering capacities as a function of their baseflow and predictability (flashiness) metrics. Linking this to a national flow type classification provides a spatial key to identifying which rivers are more likely to be resilient to water quality problems. This has applicability in screening of water use licenses and catchment management.

6.04.P-We518 Let It Burn – Evaluation of Polycyclic Aromatic Hydrocarbon Emissions from Sugar Cane Pre-harvest Combustion

Patricia Forbes[1]*, Genna-Leigh Geldenhuys*[1]*, Elena Hartner*[2]*, Juergen Orasche*[2]*, Thomas Groeger*[2]*, Nadine Gawlitta*[2] *and Ralf Zimmermann*[2]*, (1)Department of Chemistry, University of Pretoria, South Africa, (2)Joint Mass Spectrometry Center (JMSC) at Comprehensive Molecular Analytics (CMA), Helmholtz Zentrum München, Germany*

The pre-harvest combustion of sugar cane to remove unwanted biomass is common practice in a number of developing countries, including South Africa. Although guidelines are in place to protect farm workers and local communities from the vast amount of pollutants which are released to the atmosphere during sugar cane burns, these are typically limited to the maximum permitted wind speed and direction. This study sought to identify additional parameters to inform best practice and thereby reduce environmental pollution and human exposure to potentially toxic emissions arising from sugar cane burning. Polycyclic aromatic hydrocarbons (PAHs) were thus one of the important classes of semi-volatile organic compounds (SVOCs) which were investigated, in both the gas and particle-associated phases.

Monitoring was conducted during five disparate sugar cane burns at different locations in the KwaZulu Natal Province of South Africa. Simultaneous sampling of gas and particle bound SVOCs at each site before and after the burn event was achieved by means of portable multichannel polydimethylsiloxane denuders placed 16 m from the edge of the respective field. The denuders and associated quartz fibre filters were thermally desorbed with analysis by comprehensive two-dimensional gas chromatography coupled to a time of flight mass spectrometer. Total PAH concentrations (gas + particle phase) ranged from 0.05 to 9.85 $\mu g\ m^{-3}$ per individual burn event. Over 85% of all PAHs were found to exist in the gas phase, dominated by two- and three-ring PAHs. These gas phase analytes also caused the majority of variance between the burn sites. The potential carcinogenicity of the emissions based on toxicity equivalent quotients (TEQs) reflected the large variance in total PAH concentration per burn event, with the highest TEQ being 5.97 $ng\ m^{-3}$.

Aside from the prevailing wind speed and direction, it was evident that the results in terms of PAH concentrations were also impacted by geographical location, as well as the sugar cane varietal which was being combusted. Additional laboratory based controlled burn studies conducted on the sugar cane waste material further illustrated the variable and complex mixture of the combustion derived SVOCs. The results of this study are important in informing best practice with respect to sugar cane burning for effective management and minimization of both environmental impacts, including climate change, and nuisance to the public.

6.04.T-01 Learnings From the Environmental Pollution Programme in South Africa: Building a Legacy To Manage and Mitigate the Impacts of Pollution

Isabella Gosetto[1]*, Jason Weeks*[1]*,* ***Nick Rivers-Moore***[2]*, Jon S McCosh*[3]*, Muthukrishnavellaisamy Kumarasamy*[4]*, Alexandra Cunha*[1]*, Sershen Naidoo*[3]*, Saskia Mori*[1]*, Natasha Hunt*[1] *and Emily Forbes*[1]*, (1)Joint Nature Conservation Committee (JNCC), United Kingdom, (2)Nick Rivers-Moore Aquatics, South Africa, (3)Institute of Natural Resources (INR), South Africa, (4)University of KwaZulu-Natal, South Africa*

Environmental pollution is one of the three interconnected planetary crises, along with climate change and biodiversity loss, which are placing global economic, environmental, and social well-being at risk. Pollution disproportionately affects the most vulnerable groups, with a higher proportion of annual pollution-related deaths occurring in low- to middle-income countries (LMICs). This motivated the UK's Department for Environment, Food and Rural Affairs (Defra) and the Joint Nature Conservation Committee (JNCC) to collaborate with partners across Africa and Asia on an Environmental Pollution Programme, funded by Official Development Assistance (ODA). The programme aims to build science-action partnerships for knowledge generation on managing and mitigating environmental pollution, through investments in human resources and action research. The presentation will share and reflect on the lessons learned in implementing ten research projects in South Africa through partnerships with local partners, from scoping phase to the development of a multi-year programme tackling environmental and regulatory challenges. Interventions in the form of pilot-scale solutions to mitigate pollution range from, the development of a water quality costing model, community-led management of solid waste and springs, to developing biological solutions to treating dairy wastewater. The learnings gained to date justify the replicability of the programme, particularly in other LMICs to share knowledge and ensure the legacy of the programme. This presentation will be used to reflect on these learnings in the hope of creating synergies with similar efforts globally.

6.04.T-02 Tackling Diaper Pollution: Enhancing Soil Moisture, Biomass Accumulation, and Growth Patterns of Napier Fodder through Entrenched Diapers and Biochar in a Degraded South African Landscape

Ayanda Lucky Shandu[1]*, Jon S McCosh*[2] *and Jason Weeks*[3]*, (1)University of KwaZulu-Natal (UKZN), Durban, South Africa, (2)Institute of Natural Resources (INR), South Africa, (3)IEH Consulting Ltd., United Kingdom*

Many South African communities lack waste collection services. While diapers are convenient and affordable for modern households, their utilization is negated by indiscriminate disposal, including landfilling, which threatens the environment. Additionally, areas in the Upper uMkhomazi Catchment, South Africa endure extensive land degradation and *Acacia mearnsii* encroachment which are global concerns. Communal farmers in the area also experience shortages in livestock fodder, particularly in winter. This study seeks to tackle this multifaceted challenge and explore the impact of entrenching diapers with biochar from invasive *A. mearnsii* on soil moisture, growth, and dry matter (DM) of Napier fodder.

A field experiment was conducted on degraded lands in South Africa. The treatments were control (CON), nappies only (NO), biochar only (BO), nappies + biochar (NB), nappies + fertilizer (NF), fertilizer + biochar (FB), and nappies + fertilizer + biochar (NFB) treatments. The nappies, biochar and fertilizer were entrenched, and Napier fodder was planted. Soil moisture was recorded by a H2S CS658 probe. Tiller numbers, plant heights and leaf chlorophyll content (SPAD-based) were also monitored, and the plants were harvested for DM yield 20 weeks after planting. Overtime towards winter, NFB, NF, NO, and NB showed a significant decline in soil moisture compared to CON, BO, and FB. The tiller numbers ranged from 3 (BO) to 14 (NF) tillers per plant. Plant heights increased with increasing growth period, with NF, NFB, and FB significantly taller followed by NB and NO, and lastly CON and BO. The NFB and NF treatments had significantly greater ($p<0.001$) leaf chlorophyll compared to the CON. DM yield ranged from 0.217 to 2.13 ton/ha, with NFB and NF having significantly the highest, while BO had the lowest. Monitoring for microplastics also occurred.

The findings of this study suggest that entrenching nappies and biochar addresses challenges of disposal of nappies, black wattle invasion, and fodder shortages through increased productivity of degraded lands.

6.04.T-03 Sustainable Waste Management in Ghana: An In-depth Analysis of the Dompoase Landfill Site and Its Implications for Community Development and Perceived Health risk

Frank Obed Tandoh*, Alhassan Sulemana and Kodwo Miezah, Kwame Nkrumah University of Science and Technology, Ghana*

In numerous African countries, inadequate solid waste management systems have led to heightened health risks for communities residing near landfill sites. This study aims to enhance our understanding of the health implications associated with living near the Dompoase landfill site in Kumasi, Ghana. Through an integrated approach involving GIS mapping, proximity analysis, and questionnaire surveys, the research investigates the existing landfill boundaries, assesses proximity-related health risks, and identifies key factors influencing public perception. A total of 400 questionnaires were randomly distributed among residents in Kuwait, Adagya, Aprabon, and Sokoban, areas surrounding the Dompoase landfill. Chi-square analysis was employed to scrutinize associations among variables. Utilizing the ring buffering analysis in ArcGIS, the study determined households and institutions in proximity to the landfill. Remarkably, 92.8% of respondents acknowledged a perceived health risk linked to living near the landfill. Categorizing the perceived health risk, 14.5% reported very high exposure, 34.8% high exposure, 21.8% moderate exposure, 20.8% slight exposure, and 8.3% deemed no risk. Significant influencers on perceived health risks included age, duration of residence, and the environmental and social impacts of the landfill.

6.04.T-04 The utility of environmental monitoring in understanding the recovery of estuarine habitats subjected to chronic and acute stressors: the case of the uMhlanga estuary in South Africa

Jon S McCosh[1]*, Matthew James Burnett*[2]*, Sershen Naidoo*[3]*, Syd Ramdhani*[2]*, Anusha Rajkaran*[4]*, Shaddai Daniel*[5] *and* ***Mzamo MN Mnikathi***[1]*, (1)Institute of Natural Resources (INR), South Africa, (2)University of KwaZulu-Natal, South Africa, (3)University of Western Cape, South Africa, (4)University of The Western Cape, South Africa, (5)University of the Western Cape, South Africa*

Environmental monitoring is critical in facilitating timely and prioritised decision-making for habitat restoration. This study focuses on the uMhlanga River and Estuary in South Africa, which has been subjected to long term chronic anthropogenic stressors and a catastrophic agrochemical spill in July 2021.

In response, remediation, rehabilitation, and monitoring programs have been initiated, and evidence of system recovery has been documented. We seek to answer the question: what are the most effective monitoring tools and approaches, for providing the necessary information to inform effective decision making for restoration and rehabilitation of polluted estuarine environments. This study assesses the utility a range of monitoring tools to track the recovery of the uMhlanga estuarine system, comparing it with reference sites (Mpenjati and uMdloti estuaries) to identify appropriate indicators for to understand recovery trajectories towards a reference condition.

The research employs a comprehensive approach, considering water quality indicators, remote sensing for vegetation mapping, blue carbon stocks, fish assemblages, bioindicators, and historical data. In this presentation, we focus on bioindicators and water quality indices, presenting findings for the uMhlanga and reference estuary sites.

Results indicate a significant impact on water quality parameters in the uMhlanga River and Estuary. Diatom data reveal elevated toxin concentrations in May 2022, evidenced by valve deformities exceeding threshold limits which were absent in a subsequent assessment in August 2023, suggesting system recovery. However, the prolific presence metal-tolerant diatoms indicate the potential presence of residual toxins.

Our initial results suggest that there is utility in the approach, yet more data is needed to confirm most effective indicators for tracking estuarine ecological recovery post-pollution events. This research contributes valuable insights into the recovery dynamics of estuarine ecosystems, essential for informed decision-making and effective interventions.

Acknowledgement - The authors thank the UK Joint Nature Conservation Committee (JNCC) and the UK Department for Environment, Food and Rural Affairs (DEFRA) for technical and funding support for this research.

6.04.P Environmental Toxicology and Chemistry in Africa: Exchanging Knowledge and Progress on Tackling Legacy and Emerging Pollutants

6.04.P-We516 Comprehensive Chemical Analysis to Unravel Exposure to Chemical Mixtures in Kenyan Rivers
Isaac Cheruiyot Tanui[1,2,3]*, Faith Kandie*[2]*, Martin Krauss*[4] *and Werner Brack*[3,4]*, (1)Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Moi University, Kenya, (3)Goethe University Frankfurt, Germany, (4)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany*

The results of this study are important in informing best practice with respect to sugar cane burning for effective management and minimization of both environmental impacts, including climate change, and nuisance to the public.

6.04.P-We519 Introduction to the Session on Understanding Pollution Issues Facing Low- And Middle-Income Countries, Sharing Knowledge with the Global South

Jason Weeks[1], *Jon S McCosh*[2] *and Emily Forbes*[3], *(1)IEH Consulting Ltd., United Kingdom, (2)Institute of Natural Resources (INR), South Africa, (3)JNCC, United Kingdom*

This series of presentation attempts to highlight the disparity between the global North and South in recognising and responding to the impacts of pollution on reducing biodiversity; often exacerbated by climate change and key threats to global human health. In terms of pollution reduction, international donor countries representing the global north have failed to respond to this growing public health crisis. Given the severity of pollution on the public health burden, there is a critical need for aid funding to be allocated specifically to pollution reduction. Data from 2016, have shown an average investment of $14/death for pollution, compared with for example, $1,250/ death for malaria and $190/ death for tuberculosis. People living in the world's poorest nations have many competing priorities, but such should not be used as an excuse to ignore environmental pollution within Official Development Assistance (ODA). What is required is recognition of these conjoined threats, a globally supported, formal science–policy interface to inform intervention, influence and share research and focus on policy developments. Viewed historically as a local issue to be addressed through local and national legislation, or through adopting policy from higher-income countries; it is now, however, increasingly obvious that with increasing industrialization and social-economic development, human activities have generated a series of global environmental issues, which in turn have brought health hazards and disease burdens to both the environment and to human society. Furthermore, solutions are linked to the complex relationship between environmental harm and economic development which sits within a broader pollution-economic nexus. As we consider a societal shift towards a circular economy, there is a need to consider a more shared and integrated frameworks for analysing the empirical evidence that connects pollution and development, and its implications for human well-being and the achievement of the sustainable development goals in the global south. The session is intended to share outcomes of pilot scale solutions to improve environmental quality and approaches to control or mitigate the consequences of pollution and build future opportunities for better regulatory controls. Presentations have focussed on solutions to address the perspective from the Global South and consider the barriers and regulatory restrictions that hinder knowledge sharing.

6.04.P-We520 Metal Element and Organochlorine Pesticide Levels in Elasmobranchs from the East and South Coast of South Africa.

Victor Wepener[1], *Nico Smit*[2], *Dawid Coetsee*[3], *Danielle Fourie*[3], *Ruan Gerber*[4], *Yoshinori Ikenaka*[5], *Mayumi Ishizuka*[5], *Yared Beyene Yohannes*[5] *and Bjoern Schaeffner*[6], *(1)Water Research Group, Unit for Environmental Sciences and Management, North-West University, South Africa, (2)Biological Sciences, North-West University, South Africa, (3)North West University (Potchefstroom Campus), South Africa, (4)School of Biological Sciences, North-West University, South Africa, (5)Hokkaido University, Japan, (6)North-West University, South Africa*

In 2011, a total of 81 elasmobranch species were classified as threatened within South African waters. The continuous increase of pollutants, caused by anthropogenic pressures, is a major contributor to the stress experienced placed on these species. As South Africa is mineral resource rich country, elements enter the marine environment through terrestrial run-off. In addition, many organochlorine pesticides that have been banned are still applied and therefore also end up in the marine environment. The aim of this study was to determine levels of selected elements and organochlorine pesticides (OCP) in 21 shark, ray and skate species along the South African coast. Muscle samples were prepared for element and OCP analyses using standard acid digestion and organic solvent extraction and clean-up procedures. Elements were analysed using ICP-MS and GF-AAS; and OCPs using GC-MS techniques. Clear spatial differences along the coastline as well as differences in element accumulation patterns between different types of elasmobranchs were observed. Benthic feeding species e.g., batoids, accumulated higher concentrations of Fe, Zn, and As and the shyshark species accumulated the highest levels of potentially toxic elements, i.e. Cd and Pb. The element accumulation fingerprint revealed regional specific exposure patterns. Of the 22 OCPs analysed only nine compounds were detected. The DDT and its isomers occurred in the highest concentrations, followed by HCBs and chlordanes. Accumulation patterns were related to intrinsic factors (e.g. sex and trophic position) as well as external factors such as migration and foraging behaviour. Shark species (e.g. White sharks, spinner and dusky sharks) that follow transoceanic migration patterns had high DDT levels which is the result of exposure from multiple sources and regions. However, high OCP concentrations were also recorded in philopatric species such as the scalloped hammerhead and bull shark, which have more restricted movements in and around nearshore and shallower regions. Thus, the exposure fingerprints were indicative of more regional OCP exposure patterns. There is currently no tissue residue-related measure of elasmobranch health. However, based on residue levels that are deemed safe for human consumption, most of the species could be regarded to be in a healthy condition.

6.04.P-We521 Integrated Knowledge Systems Towards Flood Resilience and Sustainable Solid Waste Management in South African Urban Informal Settlements

Admire Mutsa Nyamwanza Dr.[1]*, Katelyn Ann Johnson*[2]*, Anele Mthembu*[1] *and Zwivhuya Caroline Tshivhundo*[2]*, (1)Institute of Natural Resources NPC, South Africa, (2)Civil Engineering, University of KwaZulu-Natal, South Africa*

Climate change, an increasing urban population, and poor urban planning have increased flood-risk and the accompanying solid waste challenge in many coastal urban areas in developing countries. These challenges are more pronounced in informal settlements because: (a) they are often built on environmentally fragile locations such as river banks and coastal shores with high exposure to floods, (b) high poverty levels among residents resulting in low adaptive capacity, and (c) marginalisation of these localities emanating from their non-recognition in the larger city framework. Against this background, flood-risk assessments and response initiatives in these areas have primarily been informed by scientific approaches such as geographical information systems, without adequate incorporation of other forms of knowledge. Using the case of the coastal city of Durban, South Africa, our project explores the benefits of combining perspectives from different knowledge systems in understanding flood-risk and the accompanying solid waste challenge in urban informal settlements, towards developing solutions that are based on contextual and experiential aspects. Methodological techniques used include interviews and workshops with key experts and with informal settlement residents, and extensive reviews of literature. Emerging findings show that holders of scientific, practitioner, and local knowledge vis-à-vis flood risk and waste management are active in the selected case study informal settlement. They have, in isolated cases, collaborated particularly around a) generation and distribution of flood early warnings, b) river clean-up initiatives, and c) catchment rehabilitation projects, with clear benefits for flood resilience and solid waste management. We find that there is need for a clear framework for integrating knowledge systems towards flood resilience and solid waste management in these contexts and the project has developed a draft framework. Integrating knowledge systems will: i) ensure the participation of different actors in mapping flood risk thereby creating a sense of ownership and ensuring uptake of and support for solutions crafted to deal with flood risk and the solid waste challenge; and ii) open up opportunities for coordinated support from various actors for a range of decisions around flood risk response preparation, flood and waste infrastructural design and mitigation of waste-induced flood destruction of infrastructure.

6.04.P-We522 Achieving Community-Led Solid Waste Pollution Mitigation at the Catchment Scale: The Case of the Umkhomazi and Umngeni Catchments in Kwazulu-Natal, South Africa

Hlengiwe Nokuphiwa Zuma[1]*, Zinhle N Ntombela Miss*[2] *and Admire Mutsa Nyamwanza Dr.*[3]*, (1)Institute of Natural Resources (INR), South Africa, (2)Institute of Natural Resources, South Africa, (3)Institute of Natural Resources NPC, South Africa*

Solid waste management (SWM) is a pressing and complex global problem demanding continous efforts. SWM is not receiving the required attention compared with other sectors, and over half of solid waste is openly dumped, particularly in developing countries. In South Africa, pollution is closely linked with ineffective management of solid waste. Several municipalities in the country are battling to deliver effective SWM. Budget constrains are the main hindrances to proper management of solid waste, with the lack of awareness contributing to the escalation of pollution. This project aims to work with the communities to co-develop proper disposal and possible repurposing of solid waste. The project applied a mixed-method approach using desktop research, workshops and surveys. The project sites range from rural (Amangwane), peri-urban (Impendle) and urban (Sobantu) areas. Waste audit was conducted to identify waste types on illegal dumping hotspots within each area. Research findings will be used to inform awareness campaigns which will be implemented in each area. Consistent trends of certain waste types were observed across the three areas. All three study areas possessed similar waste disposal habits i.e. dumping waste on vacant fields within overgrown vegetation, nearby streams and rivers. Lack of waste collection services and inadequate knowledge of proper waste disposal seemed to be the main causes of illegal dumping. The need to conduct an awareness campaign on solid waste pollution came out strongly from all three communities. There is a significant difference in waste generated between each community, with Sobantu leading followed by Amangwane and lastly Impendle. Plastic waste was generally high across all three communities, with Sobantu having the highest accumulation followed by Amangwane and Impendle. Nappies were also recorded to be high in Amangwane during the waste audit as was indicated during the workshops but in Impendle and Sobantu, the nappies were relatively lower compared to what was indicated during workshops in these communities. The inconsistencies within the study with regard to waste quantities in urban, peri-urban, and rural compared to what is reported in the literature require further investigation. The waste audit provided insights into the most problematic waste types and this information will assist with determining the required interventions.

6.04.P-We523 Human Health Risk Assessments of Selected Metals in the Qwaqwa Region River Waters
***Ngitheni Winnie-kate Nyoka**[1], Dirk Jungmann[2], Beatrice Olutoyin Opeolu[3] and Patricks V. Otomo[4], (1)University of the Free State, South Africa, (2)University of The Free State, South Africa, (3)Cape Peninsula University of Technology, South Africa, (4)Zoology and Entomology, University of The Free State, South Africa*
Metal pollution is a global concern owing to its toxic and bioaccumulative properties and tendency to persist in the environment. Pollution of aquatic ecosystems has attracted considerable attention globally; however, not much attention has been given to waterheads, specifically in the QwaQwa region. We selected four major streams in the Qwaqwa region (Namahadi, Metsi-Matsho, Mphukojwane and Elands Rivers) that are important to the upper Vall River basin. We aimed to assess the water quality across the selected rivers, compare it with the national guidelines, and use indices to estimate health risks. We mainly focused on the variations between the upper, middle, and densely populated lower reaches. The selected sites were sampled over two years during dry and wet seasons. The physicochemical parameters and concentrations of 10 elements (As, Al, Ca, Cu, Fe, Mg, Mn, Sr, V) were determined in water samples. Our findings revealed that concentrations ranged from below the detection limit to an average of 15. 23 mg/L in water samples, where Ca, Mg and Mn were the main contributors to the total concentrations. Compared with Target Water Quality Ranges for Aquatic Ecosystems, Al, Cu, Mn, and Zn concentrations were above permissible limits in all sample sites. On the other hand, Al, Fe, and Mn concentrations revealed a general exceedance of Target Water Quality Ranges for Domestic Use standards. Regarding the total concentration, the Mphukojwane River's upper and middle sites were the most polluted, followed by the Elands River, the lowermost site. Average Daily Dose (ADD) estimates for Mn in the MPU site and Sr in the MPM & EL sites water were higher than the acceptable reference dose for the ingestion route. A significantly higher ADD value for Cu was observed in most sites except for EL and MM. Moreover, Mn at Mphukojwane upper, Sr at Elands and Mphukojwane middle had a Hazard Quotient value higher than the threshold value of one for dermal exposure routes. Most rivers displayed an increase in the rate of pollution from the upper to the lower reaches, which highlights the pressure of industrialization and other factors. These findings are of specific significance for the utilisation and protection of water resources in the basin and the protection of public health risks emanating from poor water quality.

6.04.P-We524 Microplastics across the drinking water supply chain of Addis Ababa, Ethiopia.
***Selamawit Gebremedhin Tekle**[1], Maaike Vercauteren, PhD[2], Esayas Alemayehu[3] and Jana Asselman[4], (1)Blue Growth Research Lab, Ghent University, Flanders, Belgium, (2)Ghent University (UGent), Belgium, (3)Faculty of Civil and Environmental Engineering, Jimma University, Ethiopia, (4)Blue Growth Research Lab, Ghent University (UGent), Belgium*
Owing to their excellent versatility, durability, relatively low production costs and inherent advantages that promote diverse applications, plastics provide enormous societal benefits ever since its mass production started in the 1950s. Nonetheless, due to aging and fragmentation processes of the residue of plastic wastes, microplastics are formed and become a pressing global concern as they are closely tied to human health.

Different studies have proven that microplastics are almost everywhere including the air we breathe, the food we eat, and the water we drink, with a diverse range of polymer types, shapes, and sizes. However, there is little information about the extent of microplastics in drinking water systems of middle and low income countries, like Ethiopia, where pervasive plastic wastes are serious threats. The situation gets even worse in highly populated areas, where efficient, economical and technologically sound drinking water treatment plants, that provide a barrier for microplastics accessing the drinking water, are lacking.

Addis Ababa, the capital of Ethiopia, is the primary city with more than 5 million inhabitants and in which more than 70% of them are living in slum areas. Despite this large number of people, very little attention is given for drinking water supply infrastructures including advanced drinking water treatment plants.

In this research, the relative distribution of microplastics across the drinking water production line in Addis Ababa was determined. Accordingly, water samples were collected from raw water and treated water outlet of the largest conventional drinking water treatment plant in Addis Ababa, from storage tank and from municipal drinking water taps both in standard and slum areas of the city both during dry and wet seasons. Microplastics were extracted and identified using Fourier transform infrared spectroscopy.

This study is conducted because of the need in bridging the knowledge gap concerning microplastics distribution in drinking water from low and middle income countries. In addition, the efficiency of the available conventional drinking water treatment plant in removing microplastics and the contribution of the piping system across the drinking water distribution network for microplastics in the tap water will be determined. This research can support the development of appropriate mitigating measures and standards for better plastic management.

Keywords: Microplastics, drinking water, Ethiopia

6.04.P-We525 Spring Protection For Sustainable Water Supply: A Case Study Of Water Use And Quality Within Two Selected Sub-Catchments In Kwazulu-Natal Province, South Africa

Thabo Makhubedu[1], *Zanele Makhaya*[2], *Mfundo Myende*[2], *Brigid Letty*[2] *and Natasha Hunt*[3], *(1)Institute of Natural Resources (INR), (2)Institute of Natural Resources, South Africa, (3)Joint Nature Conservation Committee (JNCC), United Kingdom*

In South Africa many rural areas lack access to formal water services and about 80% of rural villages rely on springs to satisfy their water needs. Unfortunately, the physical, chemical and biological quality of the spring water consumed by communities is often compromised by a combination of factors such as livestock trampling, contaminated surface runoff, pollution, and poor management of the broader area. Consumption of microbial-contaminated water has severe implications for human health. Globally, over 50 kinds of diseases are caused by poor quality drinking water quality, and 80% of diseases and 50% of child deaths are related to poor drinking water quality. The project aimed to provide a comprehensive analysis of water quality of natural springs and co-develop interventions that protect the springs and enhance ecological infrastructure through local landscape restoration and rehabilitation. Surveys were conducted in 77 households in four rural communities (i.e. Mbhava, eMambedwini, Ndonyela and Sambane) of KwaZulu-Natal province to determine their water-use practices, perceptions of water quality, and household water-treatment methods. Drinking water samples from abstraction and collection points were tested for physicochemical and microbiological quality in the dry and wet seasons. All participants used spring water for drinking, cooking, washing and cleaning. Except for eMambedweni spring users, over 96% of participants perceived that springs were facing pollution challenges from contaminated surface runoff, human and livestock interference. Over 73% of participants did not treat spring water before use. Water from three springs tested positive for *Escherichia coli* and total coliforms and in some cases high levels of nitrate. The general trend was that densities of *Escherichia coli* and total coliforms were lower in the dry season due to lower discharge of contaminated surface runoff into the spring sources. The findings of this study highlighted that rural communities in KwaZulu-Natal rely on poor quality spring water to meet their household water needs. Furthermore, the presence of high levels of *E. coli* and total coliforms found in spring water has severe implications for human health, and authorities should strengthen spring protection interventions to minimise pollution and improve water quality. There is also a need to create awareness about potential hazards associated with drinking water from natural sources.

6.04.P-We526 Application of bioassays for the evaluation of aquatic toxicity of a WWTP effluent in Western Cape, South Africa

Sihle Mlonyeni, Omoniyi Kolawole Pereao and ***Beatrice Olutoyin Opeolu****, Cape Peninsula University of Technology, South Africa*

Management of wastewater from diverse sources is important because effluents are discharged into the aquatic environment after treatment. In this study, the water quality of the Veldwachters River and associated ecotoxicity risks of the wastewater treatment plant's (WWTP) effluent were evaluated. Physicochemical characterisation over four seasons and ecological risk assessment of WWTP's effluent using aquatic organisms comprising the producer *Raphidocelis subcapitata*, consumer *Daphnia magna* and decomposer *Tetrahymena thermophila* as experimental models were investigated. The crustaceans were subjected to 48 h exposure for mortality while algae and the protozoan were exposed for growth inhibitions at 72 h and 24 h, respectively. Physicochemical characteristics were within regulatory limits. Growth inhibition was observed in autumn and winter for *R. subcapitata* and in summer and spring for *T. thermophila.* Crustaceans *D. magna* (consumer) was classified as Class III (acute toxicity) for the effluent in all seasons. Meanwhile, the most sensitive organism in the applied battery of biotests was the protozoan *T. thermophila* (decomposer), demonstrating a toxic unit (TU) > 100, while *R. subcapitata* and *D. magna* demonstrated 1 TU < 10. These results showed that the effluent has potential toxicological effects on aquatic organisms and provided insights into the required intervention strategies for pollution reduction.

6.04.P-We527 Examining Polycyclic Aromatic Hydrocarbons in the Orange-Senqu River Catchment: Impact on Ecosystems and Health

Bianca Michelle Vogt[1], *Hindrik Bouwman*[2] *and* ***Rialet Pieters***[3], *(1)North West University (Potchefstroom Campus), South Africa, (2)Zoology, North-West University, South Africa, (3)North-West University, South Africa*

The transnational expanse of the Orange-Senqu River Catchment (OSRC), spanning Botswana, Namibia, Lesotho, and South Africa (SA), faces a significant ecological challenge marked by the pervasive presence of polycyclic aromatic hydrocarbons (PAHs). This study scrutinises the specific concern of PAHs, identified by the United States Environmental Protection Agency (USEPA) as sixteen priority congeners necessitating monitoring and regulation due to their deleterious effects on wildlife and human health. This study delves into the specific concern of PAHs, employing a comprehensive analysis of sediment samples collected from 75 sites. Multiple toxicity assessment approaches were employed: (1) toxicity, quality, and ecological risk were evaluated by comparing PAH concentrations to an international sediment quality guideline (SQG); (2) the sediment quality guideline index (SQG-I) was calculated; (3) risk quotients were determined; and (4) carcinogenic and mutagenic potentials were explored in terms of benzo(*a*)pyrene-equivalent assessments, quantifying total benzo(*a*)pyrene (B[*a*]P) equivalent concentrations ($\sum_{16}$B[*a*]P_{TEQ}) and mutagenic equivalents ($\sum$B[*a*]P_{MEQ}). Individual PAH concentrations exhibited a range of

0.5–1001 ng/g dry mass (dm), with cumulative PAH levels in sediment (2.4–4969 ng/g dm). The eastern region of the OSRC displayed moderate to high PAH contamination. The SQG and SQG-I pinpointed specific sites in SA with anticipated toxicity. The highest $\sum_{16}$B[*a*]P_{TEQ} value was 530 ng/g dm, with substantial contributions from B[*a*]P, benzo[*b+k*]fluoranthene, and dibenzo[*ah*]anthracene. Despite localised hotspots, low carcinogenicity was suggested for the majority of the OSRC. However, three sites exhibited high carcinogenicity and mutagenicity ($\sum$B[*a*]P_{MEQ} 555–634 ng/g dm). Projections suggest a risk of moderate to high toxicity and suboptimal sediment quality for benthic organisms, highlighting concerns about potential adverse ecological impacts and health risks. Elevated contamination at specific sites in SA was attributed to industrialisation, emphasising the urgent need for targeted interventions to mitigate PAH-related risks in the OSRC. This study provides crucial insights into the complex interplay between PAHs and the aquatic environment. It informs future regulatory frameworks, underscoring the significance of proactive measures to protect the well-being of ecosystems and human populations.

6.04.P-We528 Abidjan Convention and the Chemical Management Strategy

Kirit Wadhia, *Environmental, NOV Inc, United Kingdom*

Protection of the marine environment from the discharge of chemicals used offshore is of global importance. Sustainable operations in the oil and gas sector requires a regulatory framework ensuring protection of the ecosystem and prevention of deleterious environmental impact.

The Convention on Cooperation for the Protection, Management and Development of the Marine Environment and Coastal Areas of the West, Central and South Africa Region (Abidjan Convention) has been instigated with the rationale of integrating a concerted management of regional ecosystems. Pertaining to the Convention, the Malabo Protocol provides Contracting Parties of the region with a common framework to better supervise the development of these activities and ensure their compatibility with the protection of the marine environment. This development came in response to the accelerated development of offshore oil and gas activities in the region. The implementation plan fundamentally requires a clear understanding of a viable strategy, taking into account the elements and aspects that currently exist.

The objective of this conveyance is to examine the pertinent considerations of adaptation of chemical management strategy from a global perspective. The goals and plan to align with existing international standards will be assessed. Implications of capacity and infrastructure to achieve defined standards and the need for scientific and technical co-operation to facilitate progress will be analysed. Challenges and concerns focused on categorisation of chemicals and ecotoxicological testing will be addressed, as well as monitoring programmes and implementation procedures and overall objectives.

In essence the existing challenges of the Malabo Protocol will be highlighted, and potential scope for prudent course of action to advance the mission of the Abidjan Convention will be portrayed. This fufils the aim to "Protect, Conserve and Develop the Abidjan Convention Area and its Resources for the Benefit and Well-being of its People."

6.04.P-We529 Investigating the feasibility of phycoremediation for dairy milking parlour wastewater in South Africa.

Jon S McCosh[1], *Saskia Mori*[2], *Ashutosh Pandey*[3], *Ncumisa Mpongwana*[3], *Ismail Rawat*[3] *and Sheena Kumari*[3], *(1)Institute of Natural Resources (INR), South Africa, (2)Joint Nature Conservation Committee (JNCC), United Kingdom, (3)Durban University of Technology, IWWT, South Africa*

The dairy industry in South Africa is important for the local economy and yet, is a significant contributor to the countries wastewater pollution burden. We share the results of phycoremediation experiments involving the use of microalgal consortia to treat dairy wastewater (DWW). This is relevant given that South Africa is a lower-middle income country, with limited information available to help farmers to efficiently treat their wastewater while recovering essential nutrients, particularly in light of diminishing freshwater reserves and rising fertiliser costs.

Four dairy farms in KwaZulu-Natal Province, participated in the research where detailed wastewater audits were conducted and the physico-chemical constituents of the wastewater determined. Monthly samples were used for characterisation of the wastewater. Subsamples were treated with algal consortia inoculum and incubated to enrich the microalgae consortia. The enriched consortia were used for further phycoremediation experiments. Comparative growth profiles were analysed employing different concentrations of wastewater and the biodegradation kinetics were assessed to evaluate nutrient removal potential.

The observation of algal consortium growth in the dilutions indicates a positive response to certain concentrations of DWW. However, a notable growth limitation was noted as DWW concentrations increased. This limitation is attributed to the elevated turbidity, which impedes light penetration, hindering the essential photosynthetic activity of algae. The findings from the biodegradation kinetics revealed promising potential for nutrient removal in the treatment of dairy wastewater. However, the observed efficacy suggests the necessity for further adaptation experiments to augment removal efficiency. Future research aims to formulate strategies that enhance the removal of chemical oxygen demand. Additionally, the results spark curiosity about the possible involvement of native microorganisms present in dairy wastewater slurry ponds. These microorganisms may have adapted to the unique constituents of the wastewater, prompting the need for in-depth exploration. Investigating the role of these indigenous microorganisms holds promise for refining wastewater treatment processes and underscores the importance of ongoing research in this domain.

6.04.P-We530 Odonata as indicators of heavy metals and environmental impact on an operational gold mine in South Africa.

Velesia Lesch*, Hindrik Bouwman and Dorman Ian Luyt, Zoology, North-West University, South Africa*

Odonata occupy a dual niche perspective of both prey and predator in terrestrial and aquatic environments. Adult Odonata can be located near most freshwaters during summer, even those on an operational gold mine.

The mining industry in South Africa contributed over 12 billion US dollars to the South African GDP for 2021. The number of illegal miners is also increasing. Mining regulations require regular investigation into the impact of operations on the environment. These investigations will ultimately aid in decision-making in rehabilitation and mine closure efforts. Biotic and abiotic samples were collected.

Adult and nymph Odonata and sediment were collected over two years from seven aquatic locations in an operational gold mine in South Africa. Sampling locations included mine catchment dams, drainage ditches, return water dams, tailings storage facilities, and natural watercourses. Three additional locations served as reference locations. Additionally, species surveys were conducted for adult dragonflies to award each location with a dragonfly biotic index score (DBI) using the Dragonfly Biotic Index Manual of Freshwater Assessment for South Africa.

All samples were analysed for 28 metallic elements using ICP-MS at an accredited laboratory. Adult Odonata were located and sampled at all sample locations. However, nymphs were not found at three sites, while two additional locations had very few. Sediment samples collected from these sites had arsenic, cadmium, chromium, copper, lead, mercury, and zinc concentrations exceeding the probable effect levels of the Canadian Sediment Quality Guidelines for the Protection of Aquatic Life. Heavy metal concentrations in adult dragonflies were generally lower than concentrations quantified in nymphs from the same locations. The analytical results and DBI scores aided in identifying heavy metal hotspots and would aid in future rehabilitation efforts.

6.04.P-We531 Occurrence, Elimination and Risk Assessment of Organic Micropollutants: A Case Study of Selected Wastewater Treatment Plants in Western Kenya

Faith Kandie[1]*, Rashid Mwalimu*[2]*, Ruth Chepchirchir*[2]*, Isaac Cheruiyot Tanui*[3]*, Isaac K'Owino*[4]*, Martin Krauss*[5] *and Werner Brack*[5]*, (1)Moi University, Kenya, (2)Chemistry and Biochemistry, Moi University, Kenya, (3)Helmholtz Centre for Environmental Research (UFZ), Germany, (4)Pure and Applied Chemistry, Masinde Muliro University of Science & Technology, Kenya, (5)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany*

Inefficient wastewater treatment plants (WWTPs) in addition to poor waste disposal strategies and sanitation facilities has resulted to pollution of surface and ground water systems. Occurrence of these compounds in the aquatic environment pose adverse effects to exposed organisms. Despite continuous consumption of these chemicals, monitoring has been inadequate especially in developing countries. This study aimed at identifying OMPs and their transformation products (TPs) in selected WWTPs as a route to human exposure, evaluating the removal efficiency, and performing risk assessment of OMPs present in the effluent on standard test organisms. Four WWTPs were selected and 400 mL of water sampled from the influent and effluent. Solid phase extraction was performed and analysis done using Liquid Chromatography coupled to a High-Performance Mass Spectrometer. Toxic unit (TU) approach was applied for risk assessment. A total of 310 compounds were detected across the WWTPs comprising of pharmaceuticals, pesticides, TPs and industrial compounds. Pharmaceuticals had the highest compounds detected (90). Compound concentrations were up to 841 µg/L (caffeine), 43 µg/L (2-oxindole), 24 µg/L (ibuprofen) in the influent and 830 µg/L (caffeine), and 95 µg/L (lauramidopropylbetaine) in the effluent. TPs were detected at high concentrations including deoxycholic acid (719 µg/L). Compounds such as cholic acid, 2,4-Dichlorophenol, and propylparaben were removed efficiently (100%) whereas others such as carbamazepine (-93%) and acetamiprid (-74%). From the risk assessment, crustaceans showed the greatest potential risk of toxicity with diazinon, bendocarb and carbendazim driving this risk. Low but substantial risk was observed for fish and algae with TU up to 0.5. Based on frequency and extent of exceedance of acute and chronic thresholds, 16 compounds including diazinon, and carbendazim by were prioritized for monitoring and abatement in western Kenya. This study shows the presence of OMPs in WWTPs and the potential risk to aquatic organisms. Invertebrates were shown to have greatest potential risk for toxicity compared to algae and fish with selected compounds driving the toxicity. These risk driving compounds have been prioritized as candidate compounds for monitoring and abatement in Kenya.

6.05.P Flame Retardants and Regulation, Connecting Substance Grouping and Circular Economy

6.05.P-Mo501 Implications of lowering Low POP Content Limit values for the Circular Economy

Stuart Harrad Prof[1]*, Martin Sharkey*[2]*, William A. Stubbings Dr*[1]*, Harald Berresheim*[2]*, Marie Coggins*[2]*, André Henrique Rosa*[3] *and Daniel Drage Dr*[1]*, (1)University of Birmingham, United Kingdom, (2)University of Galway, Ireland, (3)São Paulo State University (UNESP), Institute of Science and Technology, Brazil*

To minimise unintentional contamination of articles with restricted brominated flame retardants (BFRs) because of recycling plastic items treated with BFRs, the European Union has introduced Low POP Content Limit (LPCL) values for waste, that if exceeded mean that the articles in question cannot be recycled. LPCLs were initially set at 1,000 mg/kg, but are set to be lowered progressively to 500, 200, and 100 mg/kg in the next few years. Examination of data generated by a comprehensive survey of BFRs in waste articles in Ireland in 2019–20 identified that approximately 2,800 t/yr exceeded the LPCL value in force at that time. Enforcement of this 1,000 mg/kg limit for polybrominated diphenyl ethers (PBDEs), hexabromcyclododecane (HBCDD), and tetrabromobisphenol-A (TBBP-A) would remove 78% of these BFRs from the Irish recycling stream. This demonstrates the effectiveness of the LPCL approach to minimising recycling of BFRs. Reducing LPCL concentrations would increase the proportion prevented from being recycled to 82, 84, and 85% depending on whether the limit was 500, 200, or 100 mg/kg respectively. Set against this, while enforcement of a 1,000 mg/kg LPCL would render 3.1% of the mass of the waste categories examined unrecyclable; this increases to 4.0, 4.9, and 5.6% when the LPCL is 500, 200, and 100 mg/kg respectively. Further research into the implications of such changes to limit values is recommended.

6.05.P-Mo502 Illegal Recycling is not Circularization: Extremely High Levels of Legacy Brominated Flame Retardants in Children's Toys from European Markets

Chijioke Olisah[1]*, Lisa Melymuk*[2]*, Petr Kukučka*[2]*, Petra Pribylova*[2] *and Martin Boudot*[3]*, (1)Recetox, Masaryk University, Brno, Czech Republic, (2)Recetox, Masaryk University, Czech Republic, (3)Premières Lignes Television, France*

Given that 90% of toys on the market contain plastics, there are concerns about the presence of hazardous chemicals like polybrominated diphenyl ethers (PBDEs) due to the use of recycled plastics in new toy manufacturing. In this study, eighty-four toys purchased from large Europe shops were screened for bromine using XRF, and 11 of those with bromine content higher than 500 µg/g were further analyzed for ten PBDEs using GC-MS/MS. All samples had some PBDE content, and BDE-183 and -209 were detected in 10 of 11 samples. The summed PBDEs concentration in all toys ranged from 0.0002 to 106820 µg/g (median ± standard error: 27631 ± 11185 µg/g). The most abundant PBDE was BDE-209, detected at concentration ranging from <LOD to 105000 µg/g (24600 ± 10489 µg/g), accounting for an average of 91% of PBDEs in all samples. BDE-183 ranged from <LOD to 14100 µg/g (2290 ± 1302 µg/g); while other detected PBDEs were at trace levels. Nine of 11 toys had extremely high levels of BDE-209; concentration in these toys were in the mg/g range, up to 105 mg/g, or 10% BDE-209 in one toy radar. Nine samples exceeded the EU's Low POP Content Limit (LPCL) for the summed PBDEs concentration by 5 to 100 times and the Unintentional Trace Contaminant (UTC) limits for Deca-BDE by 500 to 10,000 times. The PBDEs concentration reported in this study are among the highest reported for children's plastic toys around the world, and this is a call for concern. The extremely high PBDE levels suggest direct recycling of e-waste plastics into toy components. According to the EU Toy Safety Directive, nine of the children's plastic toys analysed in this study should not be used or sold to the public. These findings highlight the gaps in enforcement of chemical safety regulations, and also jeopardize the investments in circular economy.

6.05.P-Mo503 Comprehensive Risk Assessment of E-waste Dismantlers Occupational Exposure to Organophosphate and Halogenated Flame Retardants Using Monte Carlo Simulation

Lara Cioni*, Aleix Balasch Garcia and Ethel Eljarrat, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

Flame retardants (FRs) are frequently added to electrical and electronic equipment to retard the development of fire. As the use of this kind of equipment significantly increases and a lot of equipment becomes quickly obsolescent, there has been a dramatic increase in the production of electronic waste (e-waste). While e-waste recycling is a necessity, the release of FRs, such as organophosphate esters (OPEs) and halogenated FRs (HFRs), during this activity can pose risks to the environment and human health. In particular, e-waste dismantling workers can suffer high FRs exposures and assessing this occupational exposure becomes a priority. The goal of this study was to provide a comprehensive risk assessment of occupational exposure to OPEs and HFRs for the largest e-waste dismantling facility in Catalonia (Spain). Risks from exposure to FRs through inhalation and dermal uptake were assessed in terms of non-carcinogenic (non-CR risk) and carcinogenic risk (CR risk) using Monte Carlo simulation. Monte Carlo simulation allowed the calculation of a probability distribution of the risks associated with FRs exposure, taking into account several exposure uncertainties. The probability distributions of the non-CR risk from FRs exposure through inhalation were below the threshold for adverse effects for all compounds except for BDE-153 and BDE-209, for which there was only a 1% probability of the risk being above the threshold. The evaluation of the non-CR risks for mixtures of FRs through inhalation also showed limited risks. The probability distribution of the cumulative exposure to all FRs suggests only a 1% probability of non-CR risks. This limited risk was driven by HFRs exposure since the probability distribution for OPEs was completely below the threshold for non-CR effects. However, since not all FRs result in the same health effects, the risks associated with exposure to FRs mixtures were also evaluated in terms of specific health end-points. For FRs with liver effects, no risks from inhalation were observed, while for FRs with neurobehavioural effects, there was only a 1% probability of health risks. Using Monte Carlo simulation it was possible to provide a comprehensive description of the occupational risks of e-waste dismantlers coming from exposure to FRs. Additionally, the risk assessment was enhanced by the evaluation of the risks from exposure to mixtures of FRs in terms of chemical groups and specific health effects.

6.05.P-Mo504 Safe, Sustainable and Circular by Design Organophosphate Flame Retardants

Hannah Flerlage[1]*, Steven Beijer*[1]*, Bianca Stadelmann*[2]*, Tiago J Martins*[1]*, Emeline Delcros*[1]*, Ge Xie*[3]*, Michiel Kraak*[4]*, Ingrida Bagdonaite*[5]*, Antonia Praetorius*[5] *and Chris Slootweg*[1]*, (1)Van 't Hoff Institute for Molecular Sciences, University of Amsterdam, Netherlands, (2)University of Amsterdam (UVA), Netherlands, (3)Amsterdam Institute for Life and Environment (A-LIFE), Vrije Universiteit Amsterdam, Netherlands, (4)University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Freshwater and Marine Ecology (FAME), Netherlands, (5)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands*

Organophosphates can serve as versatile flame retardants in a variety of materials and uses. However, many organophosphate flame retardants have become notorious environmental pollutants. Tris(2-chloroethyl) phosphate (TCEP) and its analogue tris(3-chloropropyl) phosphate (TCPP) are examples thereof. While TCEP is listed as substance of very high concern under REACH since 2010, TCPP has only recently been suggested to be added to the candidate list and a new study by the US National Toxicology Program found evidence of carcinogenicity. Both chemicals are frequently found in environmental monitoring studies.

In this work we present a case study of redesigning the molecular structure of these organophosphate flame retardants for increased safety and sustainability. The design aims to increase biodegradability as a handle to prevent environmental pollution from leakage, e.g. when applied as additive flame retardant on textiles. The structure moreover contains functional groups that could allow permanent linking to matrices to be recycled with the material.

We compare this new OPFR to TCEP and TCPP, as well as the structurally intermediate alkyl phosphates triethyl phosphate (TEP) and tripropyl phosphate (TPP), which are used as polymer additives. Properties related to Persistency, Mobility, Bioaccumulation and Toxicity were predicted for these compounds using available, established, and applicable QSAR models. The poster will present the designed alternative and compare modelled properties with results of experimental testing.

For experimental testing of properties relating to function and safety, we successfully synthesized the designed alternative OPFR. Biodegradability screening experiments show an increased mineralization of the alternative compound compared to the chlorinated OPFRs and the alkyl phosphates. Acute and chronic ecotoxicity studies were performed with the algae *Raphidocelis subcapitata* and the crustacean *Daphnia magna*. Preliminary results show notably lower toxicity of the alternative compound than TCEP and TCPP. Furthermore, testing of the flame retardant function and material compatibility of the designed alternative is ongoing. To sustainably produce the alternative OPFR research is underway in our labs to synthesize organophosphates from phosphates recovered from wastewater, working towards circular, safe and sustainable OPFR.

6.05.P-Mo505 Flame retardant-contaminated food contact items and toys sold on the U.S. market
Sicco Brandsma[1], *Erika Schreder*[2] *and Megan Liu*[2], *(1)Vrije University Amsterdam, Netherlands, (2)Toxic-free Future*
Plastics often consist of a complex mixture of unreacted intermediates, monomers, and additives such as dyes, fillers, antioxidants, flame retardants (FRs), UV stabilizers, surfactants, and plasticizers, all to improve or modify the performance of the product. Many of these additives migrate during use and/or pose threats to human and environmental health during production and disposal. Although the EU has banned organohalogen FRs in electronics displays, few policies in the US regulate the use of FRs. Brominated compounds used to flame retard electronics have been found in consumer products purchased in Africa, Europe, and Asia due to lack of regulation and poor recycling practices. To investigate if U.S. consumer products that do not require flame retardancy are contaminated with regulated/unregulated FRs, a selection of food contact items, hair accessories, kitchen utensils, and toys was analyzed for the presence of 21 FRs. The Br content in the plastic consumer products measured with XRF ranged from 51 to 18600 ppm. BFRs and PFRs were detected in 17 of the 20 consumer products, and the BFR levels correlated well with the Br content in all but 3 cases. TBBPA was the most common FR, detected in 75% of the consumer products followed by BDE-209 (70%), 2,4,6-TBP (70%), DBDPE (60%), BDP (60%), RDP (60%), TPHP (55%) and TTBP-TAZ (50%). The highest BFR levels were found for BDE-209 with concentrations up to 11900 mg/kg detected in a sushi container. In 70% of the plastic products the levels exceed the unintentional trace contaminant limit of 10 mg/kg for decaBDE (BDE-209) as introduced by the EU. The decaBDE replacements, DBDPE and TTBP-TAZ, were also frequently detected, indicating that these compounds have also made their way into the waste electrical and electronic equipment (WEEE) stream. The finding of multiple hazardous FRs in plastic consumer products is worrying and points to the need for elimination of hazardous additives to support the move to a circular economy. Besides various BFRs previously detected in electronics displays, the finding of other FRs can be seen as a confirmation of WEEE-specific contamination as none of the consumer products analyzed needed to contain FRs. The appearance of WEEE fractions in plastic consumer products is a result of poor recycling practices and lack of FR regulation.Ongoing research is further investigating the presence of other plastic additives in these consumer products using the non-target screening approach.

6.05.P-Mo506 Release hotspot identification during manufacturing of a halogen free fire-retardant additivated composite for railway applications
Virginia Cazzagon[1], *David Burrueco-Subirà*[1], *Camilla Delpivo*[1], *Sébastien Artous*[2], *Bastien Pellegrin*[2], *Delphine Tissier*[3], *Arrate Huegun Mutiloa*[4], *Patrizia Pfohl*[5], *Valeria Berner*[6], *Socorro Vázquez-Campos*[1] *and Simon Clavaguera*[2], *(1)Leitat Technological Center, Spain, (2)Atomic Energy Commission (CEA), France, (3)Technical Center IPC, France, (4)CIDETEC, Parque Científico y Tecnológico de Gipuzkoa, Spain, (5)BASF SE, Germany, (6)Fraunhofer Institute for Chemical Technology ICT, Germany*
The ability of manufacturing new chemicals that are “inherently safe and more sustainable from production to end-of-life” including circularity is currently a pressing task in the context of the green transition, especially for persistent and toxic substances such as flame retardants. For this reason, in the context of the Horizon Europe project SURPASS (Safe-, sUstainable- and Recyclable-by design Polymeric systems - A guidance towardS next generation of plasticS), a new epoxy-vitrimer based composite integrating non releasable fire-retardancy moieties was developed with the aim to obtain more durable and /or recyclable material for railway applications. The SSbD framework developed by the Joint Research Center

(JRC) has been implemented in the integrated SURPASS approach and further applied in the railway sector developing lightweight composite materials. Indeed, the new composite is improving sustainability (replacing a metal-based material with a polymeric one, thus decreasing the energy consumption), increasing safety (using a halogen free flame retardant) while maintaining the desired functionality. In this work, the release hotspot identification has been conducted to determine potential release of materials (e.g., additives such as flame retardant, non-intentionally added substances and microplastics) along the life cycle of the product (from the manufacturing to its end-of-life) as Step 2 of the SSbD framework implementation. The hotspot identification has been performed by combining in a template key information on materials, products and processes involved in the case study, considering the specific data needed for workers, consumers, and environmental exposure assessment according to current regulations. The template has been filled to identify potential needs for re-design considering occupational, consumer and environmental safety in the innovation phase.

6.05.P-Mo507 Where are the Chemicals? (WatCh)

James Delaney, *Chief Scientist's Group, Environment Agency United Kingdom, United Kingdom*

Polybrominated diphenyl ethers (PBDEs) are a group of 209 man-made organobromine compounds. They have been used as flame retardants in a wide range of products including textiles, electrical and electronic equipment, and foams. The persistent and bioaccumulative properties of PBDEs, along with their potential negative impacts on humans health and aquatic life have led to commercially supplied 'penta-, octa- and decaBDE' being classified as persistent organic pollutants (POPs) under the Stockholm Convention. Furthermore, owing to the strict fire safety requirements for furniture and fittings in the UK and Ireland introduced in the 1980s, PBDEs are a particular problem in the UK environment.

The Natural Capital and Evidence Synthesis (NCES) team in the Environment Agency (EA) are looking at the material flow of POPs such as PBDEs and their impacts on the environment. To do so, project 'Where are the Chemicals?' (WatCh) is combining a series of conceptual models, including Source-Pathway-Receptor (SPR) and Life Cycle Assessment (LCA), to understand more about the material flow of PBDEs from their manufacture to disposal to their exposure to environmental receptors. Evidence outcomes of 'Project WatCh' will be used to identify regulatory interventions opportunities to explore, evidence gaps, insights to where & when pollutant risks may occur; opportunities for early stakeholder engagements, and potentially influence future policy discussions on POPs. The evidence and modelling work for 'Project WatCh' is being led by the NCES team. However, data inputs, advice, and guidance is also being provided by experts across the Chemicals Directorate in the EA.

To date, a systematic literature review has taken place, so that all research relevant to material flow analysis of PBDEs has been selected and critically appraised. Also detailed analysis of current and historical PBDE databases has been carried out, including building a data inventory. Some early results from the 'WatCh model prototype' show the levels of commercially supplied PBDE congeners 'penta-, octa- and decaBDE' that were historically manufactured in the UK between the early 1970s and the late 1990s, which allowed predictions on the levels of each congener that are currently found in different waste streams to be made.

6.05.PC Flame Retardants and Regulation, Connecting Substance Grouping and Circular Economy

6.06.P How to Effectively Communicate Results From Environmental Assessment Frameworks to Support the Decision-Making Process

6.06.P-We532 Holistic multiple stressor impact assessment methodology for application to vulnerable and disadvantaged communities

Charlie Menzie[1], *Ann Morrison*[2], *Melissa Kleven*[2], *Andrew Deines*[2], *Qiuyan Yu*[2], *Brianne Duncan*[3] *and Sean Ryan*[4], *(1)Ecological Sciences, Exponent Inc., (2)Exponent Inc., (3)Exponent, (4)Exponent, Inc.*

There has been growing attention to addressing vulnerabilities of populations living under marginal conditions. These conditions may stem from socioeconomics, access to health care, physical changes in environments due to climate and other factors, and pollution. United States environmental policies are currently emphasizing the need for cumulative impact analyses to support programmatic, regulatory, and project decisions that pose additional burdens on already overburdened communities. These policies fall under the Environmental Justice initiative. Similar policy attention is emerging around the globe especially with respect to impacts of climate change, chemicals, and migrations of people. We have developed a holistic multiple stressor assessment methodology that involves participation from the impacted communities, government agencies, and business community. The methodology is organized around the concept of Human Well Being (aka One Health) and integrates human health risks with impacts upon ecosystem services. Human health risks and ecological impacts are normalized to a common metric scale so that baseline conditions and subsequent changes can be viewed collectively for individual health risks and environmental impacts; these individual risks and impacts are not added together as that can obscure important directional changes in health or environmental conditions. The integration of multiple stressors is accomplished through the presentation of results as part of discussions within and among the different groups. Thus, dialogue is essential to the process as different groups will likely perceive the results from varied cultural and personal perspectives. The proposed methodology focuses on defined populations that share common attributes, and the analytical framework allows for the designation of multiple populations so that cumulative impacts and associated gains and losses can be understood at various societal and spatial scales.

The strength of this approach is that it integrates the technical aspects of cumulative impact assessment with stakeholder engagement. Achieving the right level of detail and using various communication tools are important for reaching a shared understanding among diverse groups.

6.06.P-We533 How can we explain to the public what Sick Building Syndrome is and how to defend against it?
Pavla Fojtíková*, University of South Bohemia in České Budějovice, Czech Republic*

Seventeen Sustainable Development Goals were adopted at the UN Summit in September 2015. UN Secretary-General Ban Ki-moon opened the summit by saying that the new agenda is a promise from political leaders to the people of the world. The goals should be understandable to everybody. If we are to meet the goals, we must understand them. Our daily behavior, our approach to other people and resources, should be influenced by these goals. An important part of this process is to be able to convey scientific issues to the general public. The issue of Sick Building Syndrome was approached from this perspective.

A project by university students with the driving question, "How can we explain to the public what Sick Building Syndrome is and how to defend against it?" was carried out in the interdisciplinary course Introduction to Toxicology. In the first part of the semester, students gained basic knowledge through lectures, interactive videos, work with professional texts and sources of information, and a practical laboratory assignment. The second part of the semester was devoted to the project itself. They worked on the Sick Building Syndrome topic in 4-member teams made up of students from different stages of their studies. The audience was specified but forms of outcomes for the real audience were based on principle "Students' voice and choice".

Project-based learning leads students to gain skills, accept responsibility and strengthen civic sense. The output of the project (video, blog, guidelines, speeches etc.) enables the scientific information to be communicated to the general public, allowing its implementation in everyday life.

6.06.P-We534 Combining LCA and eLCC with a Foresight Exercise: Sustainability Assessment of Water Reuse Chains in the Mediterranean
Valentina Guerrieri[1]*, Remi Declercq*[2]*, Simone Amadori*[3]*, Matteo Vittuari*[3]*, Stevo Lavrnic*[3] *and Attilio Toscano*[3]*,*
(1)Department of Agricultural and Food Sciences, University of Bologna, Italy, (2)R&D Department, ECOFILAE, France, (3)Department of Agricultural and Food Sciences, Alma Mater Studiorum University of Bologna
Water reuse represents a valuable opportunity to tackle water scarcity in the Mediterranean area. Nonetheless, the efforts in integrating water reuse in mainstream water management practices face several challenges such as low public acceptance, high costs of reclamation and difficulties to comply with safety standards. While innovative treatment technologies emerge to achieve a safe wastewater management, comprehensive assessments to identify environmental hotspots and external costs associated with their application are still insufficient to ensure long-term viability of those initiatives and to inform decision making processes.

To identify environmental impacts and unveil the internal and external costs of reusing water, this paper develops a methodological framework to assess the sustainability of innovative wastewater treatment technologies by performing a Life Cycle Assessment (LCA) and an environmental Life Cycle Costing (eLCC).

By applying the framework on a pilot case study in Italy and upscaling the analysis to a real scenario, results shows that innovative technologies could decrease environmental impacts compared to a Business-as-Usual scenario with conventional wastewater treatment processes. Even though costs performances of innovative technologies were lower in the case of primary treatment and innovative treatment for emerging pollutants proved limited when upscaling to bigger volumes of treated wastewater.

Building from the hotspot identified in the analysis, the results from the foresight exercise identify rules enforcement on freshwater and wastewater pricing and the promotion of awareness campaigns as the key strategy to increase financial incentives and investment, to promote the reliability of solution and to increase public awareness for contributing to water reuse diffusion in the future.

Thus, the paper provides a methodological framework able to unveil the environmental impacts and costs of water reuse chains, to inform science-based policies by testing a tool to communicate results and to translate them in a set of actions to increase public acceptance and to promote the diffusion of non-conventional water resources in the Mediterranean.

6.06.P-We535 Avoiding errors of the third kind: Prescriptive decision analysis to bridge the gap between public knowledge needs and scientific knowledge generation
Timothy J Canfield *and Brian E. Dyson, U.S. Environmental Protection Agency (US EPA)*
Science translation methods hold promise for turning scientific observations into usable knowledge for the public and actionable interventions that can improve human health and environmental quality. Accordingly, the obverse holds equivalent merit. Often the knowledge needs of decision-makers and the public are subsumed by scientists into more expediently measured proxies. This runs the risk of committing a Type III error or getting the right answer to the wrong question. When

addressing the pressing decision information needs of society, a clear rendering of the problem context and concerns of the public is needed to bridge the gap between scientific knowledge needs and scientific knowledge generation. Prescriptive decision analysis provides a pragmatic approach to characterizing decision problems and communicating the knowledge needs of stakeholders and decision-makers to technical experts for improved data-driven environmental decision-making. Precepts of decision analysis are exemplified through the desktop application DASEES. DASEES (Decision Analysis for a Sustainable Environment, Economy, and Society) is a general decision consequence analysis application that integrates socio-economic and environmental impacts from proposed actions within a preference structure for the evaluation of alternative options and decision scenarios. DASEES facilitates an analytic-deliberative process for group decision making providing tools for risk assessment, valuation, trade-offs, and uncertainty analysis. The deliberative aspects of DASEES support issue framing, developing objectives (stakeholder values), and evaluation measures through stakeholder engagement. The analytic aspects support the integration of data, information, models, and tools identified as necessary to assess the consequences of proposed solutions. DASEES provides a framework for scientists, decision makers, and stakeholders to use relevant data and information effectively and identify additional research needed to fill knowledge gaps. DASEES allows broad inclusion of stakeholders, transparency of the decision process, and an archive of the decision information for future stakeholders who might want to review or revise the decisions in the future.

6.07.A Improving Chemical Regulation Through Robust Science, Data Accessibility, and Interdisciplinary Collaboration

6.07.A.T-01 The implementation of the substitution principle in European chemical legislation: a comparative analysis

*Daniel Slunge[1] and **Thomas Backhaus**[2,3], (1)Environment for Development/FRAM, University of Gothenburg, Sweden, (2)Biological and Environmental Sciences, University of Gothenburg, Sweden, (3)Institute for Environmental Research, RWTH-Aachen University, Germany*

Background: The substitution of hazardous chemicals with safer alternatives is an important objective in European chemical policy, but implementation has been slower than expected. We conduct a comprehensive analysis and comparison of the implementation of the substitution principle in European regulations for pesticides, biocides, and industrial chemicals. Specifically, we examine and compare the criteria and processes associated with the identification of candidates for substitution and the assessment of alternatives.

Results: We find only minor differences in the criteria applied to identify candidates for substitution amongst pesticides, biocides, and industrial chemicals, but larger differences concerning the processes used. While all substances that are to be approved as a pesticide and biocide are systematically evaluated against the established criteria for substitution, the substitution process for industrial chemicals only focuses on those substances identified as substances of very high concern. The main reason candidates for substitution remain on the market is the lack of identified safer chemical alternatives and the insufficient consideration of non-chemical alternatives, caused, at least to a large extent, by the comparatively weak incentives provided by current regulations.

Conclusions: The systematic approach for the identification of industrial substances of very high concern (SVHC) under ECHAs “Integrated Regulatory Strategy” is much welcome. However, no final conclusion on SVHC properties or the need for regulatory action has been drawn for approximately 90% of the REACH-registered substances, as often even basic hazard and exposure data are missing. Hence, at least a screening-level evaluation of SVHC properties should become a mandatory part of the substance registration under REACH. To reduce the risk of strategic behaviour in the search for alternatives to industrial chemicals identified as SVHC, a setup in which regulatory authorities play a larger role as information and knowledge brokers should be considered. Investments in innovation as well as improved sharing of information and a better distribution of the workloads amongst European authorities might also improve the identification of safer alternatives. However, without stronger incentives, making it more costly for companies to continue using hazardous substances relative to safer alternatives, initiatives to promote substitution are likely to have limited success.

6.07.A.T-02 Understanding Policy Incoherence as a Driving Force for the Lock-in of Hazardous Chemicals in Automotive Plastics

***Anna Shalin**[1,2], Miriam L. Diamond[3], Bernd Nowack[4] and Zhanyun Wang[5], (1)ETH Zurich, Switzerland, (2)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)University of Toronto, Department of Earth Sciences, Canada, (4)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (5)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Why does society continue to use highly hazardous substances despite knowledge of their potential for harm? Blumenthal et al. (2022) recently revealed, through a series of case studies, the “lock-in” of continued use of hazardous chemicals due to complex interactions between economic, social, technological, and political factors that reinforce the status-quo. The authors further recommended to use the “lock-in” framework to systematically understand and address the continued use of hazardous chemicals.

The current study aims to extend the understanding of lock-in by conducting a case study on the contribution of various current and prospective legal frameworks to the lock-in of hazardous additives in automotive plastics. Specifically, this study seeks to understand how different regulations jointly influence the selection and phase-out of chemical additives in automotive plastics.

It starts with identifying the key legal frameworks for a comprehensive EU-level examination, encompassing chemical safety, waste management, vehicle safety, and related policies. A comparative analysis of relevant policies, in consultation with policy-makers, researchers, and industry representatives, is conducted with an evaluation of policy synergies or potential conflicts.

The analysis highlights that strong policy incoherence exists with respect to safe management of chemicals used in automotive plastics, and that this misalignment in regulation plays a key role in re-enforcing the lock-in of hazardous chemicals. With substantial changes proposed in 2023 to management of end-of-life vehicles, this study highlights the urgency for policy makers to address existing regulatory gaps to avoid contributing to the continued lock-in of hazardous chemicals in the automotive sector.

6.07.A.T-03 Mapping Substances Subject to Overlapping Regulations within the EU's Chemicals Regulatory Framework

Mathilda Andreassen *and Marlene Ågerstrand, Stockholm University, Sweden*

The EU's chemicals regulatory framework includes regulations for everyday products such as cosmetics, food packaging and medicines as well as regulations for pesticides, biocides and industrial chemicals. Most substances entering the EU market have to be registered and assessed for potential hazard and risk, but test requirements, risk assessment processes and management options vary depending on how the substance is used. i.e. which regulations apply. Substances with several uses may therefore be assessed and regulated under more than one regulation resulting in potentially diverging assessment and management outcomes. In the EU Chemical Strategy for Sustainability, the European Commission launched the approach 'one substance, one assessment' to tackle the inconsistencies of assessing the same substance under various pieces of legislation. A more defined strategy to this approach is yet to be announced. More knowledge is needed on how the current regulatory system falls short in assessing these substances and what is needed across regulations to reach a more harmonised hazard and risk assessment approach. In this study, we have mapped out the current state by identifying substances with overlapping regulations to understand the scope of the problem and its potential downstream effect. In addition, we have performed in-depth analyses of a number of substances regulated under more than one regulation to identify inconsistencies and gaps in the risk assessment processes. Lastly, we propose steps towards a 'one substance, one assessment' approach in the assessment and management of chemicals in the EU.

6.07.A.T-04 Prioritization and Identification of Emerging Pollutants for National Environmental Screening and Monitoring Programs in Norway

Aina Charlotte Charlotte Wennberg, MSc[1]*, Malcolm Reid*[1] *and Pawel Rostkowski*[2]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)Norwegian Institute for Air Research (NILU), Norway*

Every day new chemicals are put on the market which might potentially be of environmental concern. It is estimated that more than 350 000 chemicals are in trade today, and approximately 100 000 are in use in the EU market. However, only 22 529 substances are submitted to REACH registration. Thus, there is huge gap in information regarding chemicals that might be of emerging concern in the environment.

The Norwegian national monitoring programs for pollutants are used for assessing the impact of chemical stressors to the environment and screening programs are used for identifying emerging pollutants. However, establishing analytical methods for new chemicals is resource intensive, and only a limited number of chemicals are prioritized to be included each year. Thus, it is important to do a thorough evaluation of possible candidates with regards to both risk assessment and possilble presence in the environment prior to selecting chemicals for monitoring. The lack of complete databases for chemical risk data makes the prioritization and evaluation of possible emerging contaminants challenging. Data is spread across the internet, and it is not easily compared. Conflicting or duplicate identifiers for chemicals, differences in data formats, tests, and methods for data generation are major challenges. There is also a lack of awareness among end-users of the uncertainty in data that is generated from predictions or models. Many of the tools and databases do not include information on applicability domain (AD) score or other quality indicators of predicted data.

In this project, multiple lines of evidence from different data sources, data types, and test systems are combined in a transparent assessment to give a score on persistence (P), bioaccumulation (B), mobility (M), and toxicity (T) for each chemical and the reliability of each of these assessments. This is implemented in a prioritization tool (PIKME) for filtering or ranking chemicals according to risk of being P, B, M or T and in addition according to the reliability of the assessment. This was coupled with the probability of detection in environmental samples based on possible use, previous detection, type of sample matrix, and analytical method. This allows versatility of the tool depending on the scenario to be explored: i.e., prioritization of a list of substances, screening of the most toxic in the database, selecting substances with low reliability and high predicted risk.

6.07.A.T-05 Data Harmonization of Contaminants in Fishery Products for Improvement in National Monitoring Programmes: the Spanish Case Study

Maria Vittoria Barbieri[1], *Valentina Araya Piqué*[1], *María del Pilar Gonzalez Muñoz*[2], *Julian Blasco*[2] *and Ethel Eljarrat*[1], *(1)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Institute of Marine Sciences of Andalusia, Spanish National Research Council (ICMAN-CSIC), Spain*

One of the objectives of the Marine Strategy Framework Directive is to ensure that the levels of contaminants in seafood for human consumption remain low and within safe limits. In Spain, the legislation includes a very small number of pollutants, like some heavy metals (Cd, Hg and Pb) and persistent organic pollutants (dioxins, PCBs and PAHs). Although the EU countries have the obligation to provide data about the levels of regulated pollutants in seafood, lack of data harmonization has been observed in the past report periods, due to the fact that there is no standardized protocol for sampling and data reporting of contaminants, and part of the information is lost in this step. Thus, this work aims at identifying gaps in the monitoring programmes, in order to evaluate which points should be addressed for their improvement and to achieve a good ecological status of the marine environment.

Firstly, we obtained data from the previous Spanish monitoring campaigns and we performed a detailed literature search to compile a list of prioritized compounds. After that, a sampling campaign for the new period 2023-2025 has been designed, including selected fish, crustaceous and mollusks species from different Spanish demarcations. Methodologies based on liquid chromatography (LC) or gas chromatography (GC) coupled to mass spectrometry (MS/MS) and inductively coupled plasma mass spectrometry (ICP-MS) have been implemented for organic and inorganic pollutants, respectively.

The results helped to identify some gaps in the monitoring programmes. We found a high level of missing information and data incompleteness. In particular, data on the exact origin of the analyzed species were not always reported, although is essential to better address the needs of the different Spanish Autonomous Communities for what concerns fishery contamination. In most cases, the analyzed species did not reflect the real population consumption of seafood, and with these data we cannot provide a proper risk to human population. Another problem is the small number of contaminants currently included in national monitoring programmes. As observed, the current selection of investigated contaminants is insufficient to cover the real contamination scenario of marine environments. The evaluation of new contaminants and the associated risk assessment would be a major contribution to improve the current legislation gaps at both national and EU level and establish safe levels and good ecological status.

6.07.B Improving Chemical Regulation Through Robust Science, Data Accessibility, and Interdisciplinary Collaboration

6.07.B.T-01 FAIR data to support Chemical Risk Assessment and Regulation – The PARC ambition and approach

Iseult Lynch[1,2], *Luke Slater Dr.*[2,3,4], *Georgios V. Gkoutos*[2,3,4], *Anastasios Papadiamantis*[1], *Katarína Řiháčková*[5], *Richard Hůlek*[5], *Vikas Kumar*[6], *Rob Stierum*[7], *Dirk Devriendt*[8] *and Jan Theunis*[8], *(1)School of Geography, Earth and Environmental Sciences, University of Birmingham, (2)Centre for Environmental Research & Justice (CERJ), University of Birmingham, United Kingdom, (3)College of Medical and Dental Sciences, Institute of Cancer and Genomic Sciences, University of Birmingham, United Kingdom, (4)Centre for Health Data Science, University of Birmingham, United Kingdom, (5)RECETOX, Masaryk University, Czech Republic, (6)Institut d'Investigació Sanitària Pere Virgili (IISPV), Hospital Universitari Sant Joan de Reus, Universitat Rovira I Virgili, Reus (Tarragona), Spain, (7)Risk Analysis for Products In Development (RAPID), Netherlands Organisation for applied scientific research TNO, Netherlands, (8)VITO-Health, VITO NV, Belgium*

Risk Assessment, whether for humans or the environment, requires access to high quality data regarding both exposure and hazard of chemicals, which presents a significant challenge currently as each domain has its own methodological approaches and conventions in how to capture, store and share data, and these are not necessarily compatible (interoperable in technical terms). Thus, a major effort within PARC is being devoted to developing the working practices, and technical solutions, to enable the integration of human and environmental exposure and hazard datasets, and their use/re-use for enhanced chemical risk assessment and responsive regulation. Core to this effort is making PARC data FAIR – Findable, Accessible, Interoperable and Reusable – and machine actionable, which means that information is structured in a consistent way so that machines (computers) can be programmed against the structure. Implementation of FAIR requires intensive collaboration between domain experts who generate datasets and accompanying metadata and the technical experts who develop the support structures to enable FAIR data, such as structured and harmonized vocabularies, workflows for generation of FAIR data packages / FAIR data capture templates, tools for visualisation of PARC datasets and reporting on progress towards FAIR data. Our vision is an ecosystem of data repositories of specific data types (e.g., omics, chemical information) with an overlayed data harmonization layer to enable integration and visualization - the PARC FAIR Data Hub. To facilitate this, landscape mapping of existing FAIR enabling resources has been performed, via FAIR Implemtation Profiles, extension and harmonization of ontologies for PARC domains and development of a roadmap of how to optimally implement FAIR for each domain was initiated. PARC's FAIR ambition acknowledges that we cannot foresee all potential re-uses of PARC data, but recognizes that if we link datasets and their metadata well, they will be amenable to any possible future uses. The PARC FAIR Data Hub provides workflows for PARC-produced data / metadata to enable functional linking & machine actionablity to support long term findability and re-use, adding value by addressing regulatory concerns, contributing to the Digital Single Market, and ensuring positive Socioeconomic Impact from publicly funded research.

Funded via PARC (Grant Agreement No. 101057014) with co-funding for UK contribition via Innovate UK (project ID 1752317).

6.07.B.T-02 A database on pharmaceuticals in the environment: what do stakeholders need?

Cristiana Cannata[1], *Rodrigo Vidaurre*[2], *Ad M. J. Ragas*[1] *and Caroline Moermond*[3], *(1)Environmental Science, Radboud University Nijmegen, Netherlands, (2)Ecologic Institute, Germany, (3)Centre for Safety of Substances and Products (VSP), National Institute for Public Health and the Environment (RIVM), Netherlands*

In order to characterize pharmaceutical pollution, the potential impact of human medicinal products on the environment may be assessed by performing an environmental risk assessment (ERA). A significant amount of data has been generated but is currently dispersed across multiple data sources that are often hard to track down and find, such as regulatory ERA reports for products authorised after 2006 and databases with peer-reviewed data. Because of this, obtaining a complete overview of all available ERA data for a certain pharmaceutical is nearly impossible. To address this issue, an up-to-date and comprehensive database serving as a centralised repository for data related to pharmaceuticals in the environment (PiE) is required. Regulators, academic and industry partners within the PREMIER project are working together to provide a transparent source of ERA data that could be used for various purposes, including scientific research and regulatory risk assessments. Besides the database, PREMIER will develop a digital assessment system (DAS), which will support performing ERAs using the available data in an appropriate and transparent way. The aim of this study is to complete the first step in the database development process, which is the identification of user requirements. To this purpose, we reached out to over 100 professionals that work on PiE. We asked them what kind of data and tools should be incorporated in the database and what features of the database they wish to use. The results showed that the work of most respondents is affected by data gaps regarding ecotoxicity, monitoring and metabolism. A lack of information on the mechanism of action of APIs mainly affects stakeholders working with authorisation, production and use of medicines. Gaps in mass spectrum data, modelled environmental concentrations and metabolism data have a greater impact on academic researchers and stakeholders dealing with environmental and water quality. Respondents also showed a clear preference for a transparent and comprehensive database, with detailed study reports preferred over brief summaries. Overall, we demonstrated that the key actors working on PiE strongly endorse the development of a database and assessment tools to support the ERA of pharmaceuticals. By providing an overview on the target users' requirements, we completed the first crucial step in the development of an accessible system to assess the environmental risk of pharmaceuticals.

6.07.B.T-03 Towards FAIR Sharing of Chemical Monitoring Data

Stephanie K Bopp[1], *Alberto Cusinato*[2], *Alessandro Carletti*[1], *Michael Olvedy*[1], *Marta Baccaro*[2] *and Antonio Franco*[1], *(1)European Commission - Joint Research Centre (JRC), Italy, (2)European Commission - Joint Research Center (JRC), Italy*

The European Commission's Chemicals Strategy for Sustainability proposed to establish a common open data platform on chemicals (CDPC) to facilitate the sharing, access and re-use of information on chemicals coming from various sources. The existing Information Platform for Chemical Monitoring (IPCHEM) will be one element in the future CDPC, hosting chemical occurrence data.

IPCHEM, is an already established single access point where EU, national and regional authorities, and researchers can find and share information about chemical concentrations in different media. IPCHEM contains currently nearly 600 Million concentration measurements in environmental media (air, water, soil, biota), indoor air, food and animal feed, and in humans. Our challenge is to accommodate data of different domains, originating from different regulatory or research monitoring programmes. Our aim is to make the data not only findable and accessible, but to enhance interoperability and ultimately facilitate the re-use of the data.

We achieve this by harmonising the most relevant fields which are common to all domains, while we keep information that is dataset specific and integrate it "as-is". This is important to provide some level of comparability while ensuring no information is lost and enable a transparent documentation. For transparency and reusability of the data, we also provide publicly available rich metadata describing each dataset.

In the presentation, we will explain the different steps taken in IPCHEM for improving the sustainability of the platform, our interactions with data providers and users, approaches for open and restricted data access, and quality control. We will show examples of use illustrating practical ways how the data can support answering policy and research questions in the area of chemical, environmental and health policies. Such examples include the use of pesticide residues in soil or human biomonitoring data to build indicators to evaluate the progress in reducing exposure related risks over time.

6.07.B.T-04 So FAIR, So Clean: How the cleanventory Approach Provides Reliable Data for Chemical Structures Regulated in Global Trade Markets

Raoul Wolf[1], *Sivani Baskaran*[2], *Hans Peter Arp*[3], *Emma Schymanski*[4], *Zhanyun Wang*[5] *and Sarah Hale*[6], *(1)Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian Geotechnical Institute (NGI), Oslo, Norway, (3)Norwegian University of Science & Technology (NTNU), Norway, (4)Luxembourg Centre for Systems Biomedicine (LCSB), University of Luxembourg, Luxembourg, (5)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (6)DVGW: TZW*

With the number of regulated chemicals ever rising, there is need for a harmonized information system on regulated chemicals, especially under the newly established concept of "one substance – one assessment". As part of the H2020 project ZeroPM (https://zeropm.eu), a fully reproducible and open-source global chemical inventory – the "cleanventory" – is being developed. A modern database infrastructure will facilitate wide-spread use of the database, strictly following FAIR principles (Findable, Accessible, Interoperable, Reproducible). The database will be publicly available and include features for programmatic access. The public, legislators, and industry stakeholders will also have the possibility to review all the code and build their own "cleanventory" from scratch.

So far, over 990,000 inventory entries with over 225,000 unique CAS Registry Numbers and over 410,000 unique chemical names have been integrated. This amount of information could be considered "big data", but we put considerable efforts towards the quality of the data, *i.e.*, also ensuring "good data". To identify chemical structures from inventory entries, CAS Registry Numbers and chemical names are used. To convert inventory identifiers to InChI strings (*i.e.*, structural information), four freely available API services are used: PubChem (compound and substance domain), CAS Common Chemistry, CCTE CompTox, and NCI/CADD Chemical Identifier Resolver. To identify the "most probable" chemical structure for every inventory entry (*i.e.*, the combination of CAS Registry Number and chemical name), a weighted consensus ranking approach was developed to assign each InChI strings an identification score.

Over 344,000 unique InChI strings were retrieved by the API services. After a weighted consensus ranking approach, over 126,000 unique InChI strings are identified as being the "most probable" chemical structure for the given inventory entries. This high-quality database of chemical structures on global trade markets will support the EU Chemical Strategy for Sustainability initiative by effectively enabling the concept of "one substance – one assessment" by providing robust, curated, and transparent data and workflows.

Acknowledgement - This work is part of the project "ZeroPM: Zero pollution of persistent, mobile substances" which has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 101036756.

6.07.B.T-05 From Parcel to People: development of an indicator to monitor risk to residents from pesticide use in agricultural areas

Francesco Galimberti[1], *Alessandro Carletti*[1], *Rui Catarino*[1], *Alessio Ippolito*[2], *Arwyn Jones*[1], *Pietro Florio*[1], *Michael Olvedy*[1], *Alberto Pistocchi*[1], *Flavio Marchetto*[3], *Marijn Van Der Velde*[1], *Diana Vieira*[1], *Astrid Verheggen*[1] *and Raphael D'Andrimont*[4], *(1)European Commission - Joint Research Centre (JRC), Italy, (2)European Food Safety Authority (EFSA), Italy, (3)European Chemicals Agency (ECHA), Finland, (4)European Commission - Joint Research Center (JRC), Belgium*
The increase in global pesticide use has mirrored the rising demand for food over the last decades. Despite the resultant boost in crop yields, there are increasing concerns about the impact of pesticides on biodiversity and ecosystems, as well as the undeniable adverse effects on human health, especially among populations residing close to agricultural zones. This work investigates the complexities of pesticide exposure in such residential areas within France.

By integrating a range of novel spatial datasets and exposure assessment methodologies, we have developed an indicator to highlight the levels of pesticide risk faced by residents. By spatializing pesticide sales data and juxtaposing it with pesticide authorization for specific crops, we developed a detailed map depicting potential pesticide loads at the parcel level across France. This spatial distribution served as the basis for an exposure assessment, carefully modelled based on the European Food Safety Authority’s guidelines, measuring the risk quotient of pesticide exposure.

The indicator, which combines the exposure map with population distribution data, provides a more nuanced understanding of pesticide risk not related to dietary exposure. Our analysis, even if centered on France, lays down an approach that could be extrapolated across the EU, supporting a data-driven approach aimed at measuring and reducing exposure to pesticides.

The comparative assessment with existing datasets, such as the LUCAS soil survey and the Treatment Frequency Index from the ADONIS map, although not entirely consistent, shows the potential and areas in need of refinement for our methodology. As Europe progresses towards its goal of halving pesticide use by 2030, our study emphasizes the need for more detailed attention to pesticide-related issues. Additionally, it highlights the critical importance of harmonized and high-resolution data in steering the region towards more sustainable farming systems. Our indicator assists policymakers and stakeholders in navigating the complex dynamics of pesticide use and its implications.

6.07.P Improving Chemical Regulation Through Robust Science, Data Accessibility, and Interdisciplinary Collaboration

6.07.P-Th491 The European Network of Human Biomonitoring Laboratories: Advancing the European HBM Platform in PARC

Marta Esteban López[1], *Susana Pedraza-Díaz*[1], *Noelia Domínguez-Morueco*[1], *Sara Esteban García-Navas*[1], *Ana Virgolino*[2], *Sergio González*[1], *Elena Varea-Jiménez*[1], *Juan José Ramos*[1], *Hans Mol*[3], *Amrit Kaur Sakhi*[4], *Cathrine Thomsen*[4], *Carla*

Trindade Costa[5,6,7], Tamás Szigeti[8], Darina Dvorakova[9], Vlasta Masanova[10] and Ana Isabel Cañas Portilla[1], (1)National Centre for Environmental Health, Instituto de Salud Carlos III, Spain, (2)Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Portugal, (3)Wageningen Food Safety Research, Wageningen University & Research, Netherlands, (4)Norwegian Institute of Public Health, Norway, (5)Environmental Health Department, National Institute of Health Doutor Ricardo Jorge, Portugal, (6)EPIUnit, Institute of Public Health, University of Porto, Portugal, (7)Laboratory for Integrative and Translational Research in Population Health (ITR), Portugal, (8)National Center for Public Health and Pharmacy, Hungary, (9)Department of Food Analysis and Nutrition, University of Chemistry and Technology Prague (UTC), Czech Republic, (10)Faculty of Medicine, Slovak Medical University, Slovakia
Human Biomonitoring (HBM) provides information on real-life human exposures and is a useful tool for assessing the effectiveness of regulatory actions. In the last years, efforts have been dedicated towards building a European HBM platform that can support risk assessment by enhancing HBM capacities across Europe, provide relevant data to contribute to exposure evaluation and to inform the development of public and environmental health policies. As part of it, the European Network of HBM Laboratories was set up within the HBM4EU project to connect experts in analytical chemistry and HBM and support the less experienced laboratories to improve their skills.

To extend the network and better understand the real HBM analytical capacities in Europe, a questionnaire was sent to the laboratories previously included in the network, as well as to new laboratories nominated by the PARC National Hub Contact Points. The survey collected information on the laboratories' capacity to quantify different chemical groups (> 20) in various human matrices, data on instrumental techniques used and limits of quantification, among others.

Information was obtained from 108 laboratories from 27 countries. Metals is the group of substances more widely analysed (60%), followed by bisphenols (32%), phthalates (31%), organochlorine pesticides (31%) and PFAS (28%). The substances less analysed are dioxins and furans, and musks (5.6% and 0.9%, respectively). Blood, urine and hair are routinely analysed but the analysis of chemicals in less common matrices (e.g. amniotic fluid, saliva), as well as in of innovative samples (e.g. dried blood spot samples and volumetric absorptive microsampling) is also reported. The results of the first analysis of the collected data have been conveyed to the final selection of exposure biomarkers to be analysed in the PARC General Survey.

A further analysis will allow to identify the real capacities and skills of the European laboratories performing HBM analyses. This will be the basis for building the future activities of the network in terms of training and interactions, as well as to identify urgent needs to be addressed, such as the development of new analytical methods. The European Network of HBM Laboratories is an important step to achieve a common approach to HBM in Europe, can improve HBM capacities at country level and is a perfect scenario for opportunities and collaboration among European HBM laboratories.

6.07.P-Th492 Strengthening Collaboration for Next-Generation Environmental Risk Assessment (NG-ERA): A Horizon Europe PARC Platform and Process for Governance of Scientific Coordination

***Romana Hornek-Gausterer**[1], Maria Uhl[1], Matthias Herzler[2], Nicole Bandow[3], Peter von der Ohe[3], Lina Wendt-Rasch[4], Pascal Sanders[5], Magnus Lofstedt[6] and Johan Axelman[4], (1)Environment Agency Austria (EAA), Austria, (2)German Federal Institute for Risk Assessment (BfR), Germany, (3)German Environment Agency (UBA), Germany, (4)Swedish Chemicals Agency, Sweden, (5)Fougères Laboratory, French Agency for Food, Environmental and Occupational Health and Safety, France, (6)European Environment Agency (EEA), Denmark*
The Partnership for the Assessment of Risks from Chemicals (PARC) provides a European-level partnership for regulatory actors and researchers in the EU to address the challenges faced in human health and environmental risk assessments (ERAs).These challenges include assessments of low-dose effects of chemicals; indirect and combined effects of multiple chemicals. Climate change and habitat loss on biodiversity decline are currently not explicitly addressed in PARC but could be included if a platform is developed. Further, fragmented regulatory assessments under the current substance-by-substance approach strongly suggest that innovative and integrative approaches across regulatory sectors are needed. To this end, a cross-disciplinary project is under development to strengthen the collaboration within PARC and with external projects, aiming to develop and facilitate the implementation of Next-Generation ERA (NG-ERA). A strong engagement of European regulatory agencies in PARC should facilitate regulatory relevance and uptake. As a partnership at the EU level, PARC has the potential to provide a platform to facilitate collaborations for a more efficient use of research resources and to enhance the scientific foundation of new approaches and tools developed for regulatory adoption.

The objective of this project is to establish a collaborative platform and processes for the governance of scientific coordination in NG-ERA. This involves mapping existing efforts, identifying gaps, and to develop a framework and processes for cross-project collaborations. The project aims to be linked to an ongoing activity in PARC, that explores collaborative approaches for NG-ERA of pesticides: *Risk assessment to support and promote efficient overall protection of biodiversity*. Please contact us to become a partner in the development of this platform to strengthen the effort to integrate data, knowledge and areas of expertise and to better protect our environment.

6.07.P-Th493 OECD QSAR Assessment Framework: Advantages and disadvantages of a tool designed to assess and ultimately strengthen predictive NAMs

***Paul Thomas**, Floriane Larras, Franklin Bauer, PhD, Gaspard Levet and Maxime Edelblout, KREATiS SAS, France*

NAMs are an essential piece of the upcoming Green Deal if Europe is to move to a "toxic free environment" and safe and sustainable by design products. *In silico* NAMs up to now have obtained less recognition than their *in vitro* cousins in this sprint towards faster and more animal free methodologies. And yet, *in silico* NAMs are ultimately the fastest, cheapest alternative to laboratory methods and potentially the most elucidating, particularly so, when they are based on mechanistic interpretation.

The ambition of the fairly recent QSAR Assessment Framework (QAF) is to help regulators across the OECD member states to better assess the likely prediction capacity of QSARs by using a reflective step-by-step check list to arrive at a consensus result. There is no doubt that as we are submerged by QSARs of all types and levels of quality, the QAF will both increase overall acceptance and use of these methods by the regulatory community as only the most robust QSARs will survive assessment.

On the other hand, the QAF further limits the wider applicability and potential of QSARs, restricting their capacity to reduce animal testing and their use as tools that can further the science in a way that empirical studies alone cannot.

In this poster we will provide demonstrations of the advantages of QAF. We will also prepare case studies where mechanistic QSARs have the necessary functionality to assess certain situations already well recognized within the science of ecotoxicology but QAF does not contain sufficient flexibility to allow recognition of this fact. An example is where toxicity is greater than the water solubility limit for certain (hydrophobic) substances for certain endpoints and where "unambiguous algorithms" cannot be obtained. Other examples will be elucidated and remedies proposed.

6.07.P-Th494 Shifting Towards NAMs Based Risk Assessment: A Korean Case Study

***Dawoon Jung**, Yunsun Jeong, Sung Yong Jung and Ranhee Kang, Korea Environment Institute (KEI), Korea, Republic of (South)*

Under the Act on Registration and Evaluation of Chemicals in Korea, all chemical substances manufactured in or imported into Korea must be registered. It is estimated that over 1.402,000 tests are required for about 17.096 substances by 2030. Although the Ministry of Environment has set the goal of conducting 60% of all chemical risk assessment using alternative testing methods, the use of alternative methods in chemical hazard assessment remains less than 10%. Therefore, a careful examination of the current state of the technological development, legal base, and regulatory application of new approaches methods (NAMs) is necessary in order to enhance the institutional advancement of animal alternative testing in chemical risk assessment. In this study, we analyzed the current legal, systematic, and research status of NAMs in Korea. At the same time, we conducted detailed interviews with stakeholders to identify major issues in the current regulatory application process. As a result, we proposed a strategy to promote NAMs in chemical risk assessment in Korea. First, the technical and regulatory expertise of alternative test methods must be enhanced through organizational separation of development and validation, and regulatory application. Second, we need to reprioritize the methodologies that warrant funding by gathering input from experts as well as government and industrial stakeholders. At the same time, administrative support during process of development-validation-international acceptance (e.g., OECD test guideline) has to be strengthened. Finally, the regulatory application of alternative test methods should be enhanced by strengthening technical and administrative training for the practitioners. The results of this study will contribute to the advancing and institutional implementation of alternative methodologies for animal testing in the chemical safety assessment in Korea, fostering a paradigm shift toward safety assessment centered on next generation risk assessment. This study was conducted with the generous support of KEITI (RS2023-002-15309) and KEI (RE2023-018).

6.07.P-Th495 Differences and similarities between levels of protection of the aquatic ecosystem under different EU chemical regulations - Part I: surface waters

***Annette Aldrich**[1], Sandrine Andres[2], M. Carmen Casado-Martinez[3], Sabine Duquesne[4], Alexandra Kroll[5], Peter von der Ohe[4] and Marion Junghans[5], (1)Federal Office for the Environment (FOEN), Switzerland, (2)INERIS, France, (3)Swiss Centre for Applied Ecotoxicology Eawag (EPFL), Lausanne, Switzerland, (4)German Environment Agency (UBA), Germany, (5)Swiss Centre for Applied Ecotoxicology, Switzerland*

Environmental regulation of chemicals in the EU was implemented to protect the environment against potential adverse effects. As a chemical may be suitable for different uses, different regulations may apply to the same chemical. While all uses may impact the same environmental compartment, one substance may have several different regulatory threshold values for the protection of surface water ecosystems. For many years this had no consequence because there were no points of contact between the different regulations that could have flagged inconsistencies. During the last decade though, the comparison of concentrations measured in surface water from monitoring campaigns for pesticides to thresholds values showed that, depending on the selection of the threshold value, the resulting risk may be acceptable or not. This created confusion among scientists and in the public domain, where the expectation prevails that there could only be one threshold concentration that can be labelled "safe" based on current scientific knowledge. This discrepancy has led the European Commission to set the objective of the Chemicals Strategy for Sustainability to move towards the 'one substance, on assessment' approach, the aim being to improve efficiency, effectiveness, coherence and transparency of hazard assessments across all relevant legislation. To support this EU strategy and to consolidate and strengthen the chemical risk assessment, the EU funds a partnership under Horizon Europe (PARC). Here we report from a project aimed to elucidate whether the risk assessments of a chemical under different regulations indeed differ in their level of protection. For this purpose, we compared the scopes and protection goals of the various legal frameworks as well as the underlying data and methodologies. We compiled and compared regulatory requirements for active substances for authorization for plant protection products (EC 1107/2009), biocidal products (EC 528/2012), veterinary medicines (EU 2019/6) and REACH as well as effects assessment for retrospective risk assessment under the EU WFD (EC 2000/60). The investigation focused on differences in the procedure, the protection goal, the conceptual approach and resulting management measures. We used imidacloprid as a case study to pinpoint congruence and differences between the assessments for the aquatic compartment. This presentation complements the results for the sediment compartment, which are presented in a separate contribution.

6.07.P-Th496 Differences and Similarities Between Levels of Protection of the Aquatic Ecosystem under Different EU Chemical Regulations - Part II: Sediments.

*Annette Aldrich[1], Sandrine Andres[2], **M. Carmen Casado-Martinez**[3], Sabine Duquesne[4], Alexandra Kroll[5], Peter von der Ohe[4] and Marion Junghans[5], (1)Federal Office for the Environment (FOEN), Switzerland, (2)INERIS, France, (3)Swiss Centre for Applied Ecotoxicology Eawag (EPFL), Lausanne, Switzerland, (4)German Environment Agency (UBA), Germany, (5)Swiss Centre for Applied Ecotoxicology, Switzerland*

Environmental regulation of chemicals in the EU was implemented to protect the environment against potential adverse effects in water, sediment, soil and air caused by their use. While all uses may impact the same environmental compartment, the environmental assessment requirements differ between environmental compartments and, for a same environmental compartment, it may differ from one regulatory framework to another. As chemicals may be suitable for different purposes, different regulations may apply for the same chemical. For many years, this had no consequence because there were no points of contact between the different regulations that could have flagged inconsistencies. During the last decade though, the comparison of concentrations measured in surface water from monitoring campaigns for pesticides to threshold values showed that, depending on the choice of the threshold value, the resulting risk may be acceptable or not. This discrepancy has led the European Commission to set the objective of the Chemicals Strategy for Sustainability to move towards the 'one substance, on assessment' approach, the aim being to improve efficiency, effectiveness, coherence and transparency of safety assessments across all relevant legislation. To support this EU strategy and to consolidate and strengthen the chemical risk assessment the EU funds a partnership under Horizon Europe (PARC). Under PARC, a project is implemented aiming to elucidate whether the risk assessments of a chemical under different regulations indeed differ in their level of protection for the aquatic ecosystem. We compared the scopes and protection goals of the various legal frameworks for the sediment compartment as well as the underlying data and methodologies. Specifically, we compiled and compared regulatory requirements for active substances for authorization for plant protection products (EC 1107/2009), biocidal products (EC 528/2012), veterinary medicines (EU 2019/6), and REACH as well as effects assessment for retrospective risk assessment under the EU WFD (EC 2000/60). The investigation focused on differences in the procedure, the protection goals, the conceptual approach and resulting management measures. This presentation complements the results for imidacloprid regarding the surface water compartment, which are presented in a separate contribution.

6.07.P-Th497 Phenanthrene: A Regulatory Journey in the European Union

***David MV Saunders**[1] and Louise Camenzuli[2], (1)Shell Global Solutions, Netherlands, (2)ExxonMobil, Belgium*

Phenanthrene is a ubiquitous polycyclic aromatic hydrocarbon (PAH) which has been subjected to rigorous regulatory scrutiny within the European Union's Registration, Evaluation Authorization and Restriction of Chemicals (REACH) framework. Here we provide a concise summary of the regulatory assessment of Phenanthrene under REACH and highlight key aspects of the multi-year process.

Phenanthrene is a constituent of Coal tar pitch high temperature (CTPHT) which was classified as a substance of very high concern (SVHC) in 2009, due to the properties of its main constituents. In this assessment Phenanthrene was identified as a constituent in CTPHT with very persistent & very bioaccumulative (vPvB) properties. Subsequently, in 2018 an SVHC dossier for Phenanthrene was submitted by the French Member State Competent Authority. The SVHC submission was agreed by the Member State Committee in 2018 and Phenanthrene was included on the Candidate List of substance of very high concern for authorization.

In 2021, a judgement by the European Court of Justice (ECJ) concluded the lack of manifest error in the assessment of Phenanthrene. It also highlighted that substances on the candidate list could, upon review of new information, be de-listed. The court indicated that the European Chemicals Agency (ECHA), where necessary, must carry out a re-examination of the SVHC conclusion when new & relevant information is provided. This decision effectively identified a novel regulatory mechanism under Article 58 (8) of REACH.

In early 2022, a data package with new lab-based information was provided to the European Commission's Directorate General for Internal Market (DG GROW) under the novel mechanism identified by the ECJ. This communique requested the reassessment of the Phenanthrene SVHC conclusion. DG GROW, in defining this novel process, formally requested that ECHA assess the information for its novelty and relevance. In late 2022, ECHA concluded that the new information did not impact the conclusion of Phenanthrene as a SVHC and therefore no further steps were necessary.

There are several important aspects of the Phenanthrene regulatory journey which are worth highlighting, including that the chemical is not registered under REACH which limits the potential regulatory mechanisms of action, the ECJ's identification and formalization of a mechanism to submit new, relevant information, and the novel process developed by DG GROW and ECHA for the submission of said new information.

6.07.P-Th498 High level screening strategy to determine impact of new CLP hazard classes on chemical portfolios
Valentina Ricottone[1]*, Willemien Wieland*[2] *and Chris Sinclair*[3]*, (1)Sustainable Products & Supply Chain Operations, ERM International Group Limited, United Kingdom, (2)Sustainable Products & Supply Chain Operations, ERM NEDERLAND B.V., Netherlands, (3)Consumer Health, Bayer Public Limited Company, United Kingdom*
A central ambition of the EU Green Deal is the transition towards a toxic-free environment. New hazard categories under the Classification, Labelling and Packaging (CLP) Regulation (EC) No 1272/2008 came into force in April 2023 related to Endocrine Disruption, Persistent/Mobile/Toxic (PMT), very Persistent/very Mobile (vPvM) and the existing PBT/vPvB (B stands for Bioaccumulative) classifications. For all substances placed on the market in the European Union these categories will need to be implemented as per 1st November 2026. It can be foreseen that substances classified for one or more of these categories will be restricted or banned from the EU market in the future. This can have a major impact on the marketed products portfolio and supply chain security of companies.

ERM has developed a strategy to identify chemicals within a chemical company's portfolio that potentially fall under the new hazard categories. The portfolio is evaluated following a high level, stepwise approach taking into consideration all data available for a substance in the public domain, starting from data published by authorities worldwide. These data are evaluated and if no conclusion can be drawn on the possible hazard classification, *in-silico* and read-across data from similar substances are also used to aid the evaluation. Finally, all data are evaluated in a weight of evidence approach and, if possible, a conclusion on the classification is drawn. The classification is ranked based on the reliability of the collected data.

Substances used in the Bayer Consumer Health European product portfolio were identified for screening that either had the potential for classification and/or were present in important products for the business. The overarching aim was to develop an understanding of the associated business risks of potential classification for Bayer Consumer Health and the associated supply chain, determine the potential impact and feasibility of product reformulation and ultimately develop more sustainable products that continue to allow consumer self-care.

This screening approach represents a first step to identify chemicals affected by the new hazard classes under CLP. It is an essential step to mitigate business risks but, more importantly, it is a tool to increase the sustainability of the chemical portfolio of a business. An overview of the strategy employed and major learnings in its implementation to a consumer health ingredient portfolio are presented.

6.07.P-Th499 REACHing for solution: case of chemical regulation and regrettable substitution
Ola Dosunmu[1]*, Andrew Sweetman*[2]*, Nigel Watson Prof*[3]*, Rob Whiting*[4] *and Avtar Matharu Prof*[5]*, (1)Lancaster University, Lancaster, United Kingdom, (2)Lancaster University, United Kingdom, (3)Lancaster Environment Centre, Lancaster University, United Kingdom, (4)Wood Group, United Kingdom, (5)University of York, United Kingdom*
Chemical regulation is generally regarded as a major driver in the substitution of hazardous chemicals. As a substance of concern is subject to regulatory scrutiny and/or going through regulatory process of being identified as a substance of very high concern (SVHC), industry can respond through the use of alternatives.

The REACH Regulation aims to ensure control of the risks from hazardous chemicals to human health and the environment and encourage innovation and use of alternative chemicals or technologies where available. Processes such as authorization and restriction are key drivers in this. For example, authorization aims to encourage the substitution of hazardous chemicals with safer alternatives or technologies where available and possible.

Despite best efforts by both the industry and policymakers, instances of substitution with unintended consequences have been reported. But very little is known about the role that chemical regulation plays in this. This study therefore aims to stimulate discussion on this perspective by addressing the following questions (i) does chemical regulation unintentionally drive regrettable substitution? (ii) in what ways does regulation exacerbate regrettable substitution?

These questions have been answered through engagement with stakeholders using online questionnaire and interviews. Stakeholders including policymakers, industry, NGOs, academics and consultants were engaged. Feedback was gathered and analysed.

Preliminary finding(s) and opinions from the stakeholders are "banning a group or class of substances may lead to unintended consequences e.g. losing important chemicals from the supply chain", "the need for policymakers to provide clear and workable guidance" and "lack of regulatory certainty is anti-innovation and investment".

The findings will help contribute to policy development, ensuring the aim of regulation to protect human health and the environment from risks of harm from hazardous chemicals is achieved.

6.07.P-Th500 German Court Judgement: The Right to Environmental Information Grants Access to Environmental Risk Assessment Data and Studies from the Human Medicinal Product Authorisation Procedure
Carolin Floeter[1]*, Susanne Schwonbeck*[2] *and Kim Teppe*[3]*, (1)Environmental Engineering, Hamburg University of Applied Sciences (HAW), Germany, (2)Fraunhofer Institute for Toxicology and Experimental Medicine (ITEM), Germany, (3)Umweltbundesamt (UBA), Germany*
The pollution of pharmaceuticals in the environment is of concern and risk mitigation measures should further be developed. Environmental risk assessment (ERA) is part of the European authorisation procedure of veterinary/human medicinal products since 2005/06, but the availability of these data for the field of environmental protection is limited (Schwonbeck et al. 2021).

In a legal dispute, the plaintiff applied for access to data and studies on environmental risk assessment for selected medicinal products for human use from the national competent authority, relied on §4 I German Environmental Information Act. As the regulatory authority did not grant access after hearing the marketing authorisation holder (MAH) and invoked intellectual property rights, among other things, the Administrative Court of Cologne, Germany, made a final decision in this case (ECLI:DE:VGK:2023:0713.13K5068.18.00):

The competent authority is required to grant the plaintiff access to the complete environmental risk assessments, i.e., all documents of the submitted dossier required under Annex 1 part I. module 1. point 1.6. "environmental risk assessment" of Directive 2001/83/EC and information for each of the selected substances (medicinal products).

By clarifying the accessibility of ERA data and ERA studies, the German court has made a groundbreaking decision with European implications. The decisive legal bases for this are anchored in European law, and a detailed legal analysis has already been provided in the "Oelkers papers" (Oelkers & Floeter 2019; Oelkers 2020; Oelkers 2021a; Oelkers 2021b) and the "Feasibility Study of an Active-substance-based Review System ('Monographs') and Other Potential Alternatives for the Environmental Risk Assessment of Veterinary Medicinal Products Final Report" for the European Commission (Schwonbeck et al. 2021).

The scientific and environmental law implications of this judgement are presented.

Schwonbeck, S., Breuer, F., Hahn, S., Brinkmann, C., Vosen, A., Radic, M., Vidaurre, R, Alt, J., Oelkers, K., Mezler, A., Floeter, C. (2021): DOI: 10.2875/94477.

6.07.P-Th501 Environmental Fate Data of Chemicals from Regulatory Dossiers – Harmonisation of Public Assessment Reports across different Regulation?
Susanne Schwonbeck[1]*, Prasit Shrestha*[2] *and Boris Meisterjahn*[3]*, (1)Fraunhofer ITEM - Institute for Toxicology and Experimental Medicine, Germany, (2)Ecological Chemistry, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (3)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*
In the EU, chemicals are regulated differently depending on their use (chemicals, biocidal products, medicinal products for human or veterinary use, plant protection products). However, for all substances the environmental fate and effect data provided by industry is usually considered confidential. Consequently, across different regulatory frameworks either limited or quite detailed information and summaries on adverse effects or behaviour in the environment are published as endpoints in (European) Public Assessment Reports (PAR or (E)PAR). When it comes to metadata associated with environmental fate endpoints (e.g., amount of non-extractable residues (NER), minimum and maximum DT50, DT90, transformation products, use of radioisotopes, used kinetic model, goodness of fit, etc.) such data are in most cases not publicly available.

The legal situation for veterinary medicinal products (VMP) has recently changed (Regulation (EU) 2019/6), while the regulation for medicinal products for human use is currently being revised (https://health.ec.europa.eu/medicinal-products/pharmaceutical-strategy-europe/reform-eu-pharmaceutical-legislation_en). In both cases, a monograph system for ecotoxicological and environmental fate data is to be introduced. It is particularly important for the scientific community that the information in the monographs is much more detailed than in the EPAR or PAR. Read-across studies and data comparability studies require a high amount of detail that exceeds the one that is stated in these assessment reports.

To illustrate this need for harmonisation and comparability of data, we will present results from a comparison of data from publicly available batch simulation studies in soil, water/sediment and water (OECD 307, 308 and 309) and address important details that are crucial for answering scientific questions. Data was taken from public sources such as the REACH database (ECHA registration dossiers), from the peer-reviewed scientific literature and grey literature.

6.07.P-Th502 Perspectives on Increasing Complexity in the Environmental Fate and Ecotoxicology Regulatory Space
*Kari Moshenberg[1], **Aleksandra Zakryś Zalewska**[1], Andreas Häusler[1], Martina Dunker[1] and Marise Borja[2], (1)GAB Consulting GmbH, Germany, (2)Syntech Research Group, France*
Current environmental fate and ecotoxicology challenges relevant to PPP registration include lack of agreement on risk assessment (RA) approaches for complex active substances (AS) (UVCB, inorganic, naturally-derived), difficulty interpreting higher-tier approaches, implausible study designs, and uncertainty in guideline implementation timelines. These obstacles often result in EFSA data gaps which multiply issues to be resolved by MS during product registrations. In contrast, recently published guidance present elaborate RA frameworks for birds, mammals, bees, residues in drinking water treatment, and soil exposure modelling without addressing the existing challenges. Thus, there is a twofold problem of increased scientific complexity coupled with unresolved regulatory uncertainty.

While reasoned, science-based approaches for evaluating AS are urgently needed, we see a growing misalignment between guidance and obstacles faced when conducting RA. Increasing regulatory complexity without first resolving existing challenges and evaluating unanticipated consequences does not serve the common goal of sustainable agriculture in the EU. Particularly for biopesticides, inorganic, and UVCB substances, fit for purpose guidance is a priority. Reasoned guidance is integral to ensuring plausible study designs; e.g. the new bee guidance proposes an unreasonable number of treatment fields for a honeybee study (up to several hundred). This highlights the necessity of feasibility checks and tailored calculation tools to reliably conclude on further testing.

Case studies applying new and proposed approaches to existing AS would be an excellent first step to better understand the impact of new guidance. Further, increased opportunities for transparent exchanges for evaluations of non-standard compounds would both lessen the regulatory burden and increase opportunities to find timely, collaborative solutions. Lastly, there is an urgent need for guidance that facilitates reasoned RA of complex compounds while leaving flexibility for substance-specific approaches.

In conclusion, increasingly complex assessment frameworks could magnify uncertainty in EFSA evaluations which could then significantly increase workload for MS already at capacity and limit their ability to evaluate novel approaches. It is imperative that notifiers and evaluators are equipped with appropriate tools to support evaluation of AS and products and achieve the goal of sustainable crop protection in the EU.

6.07.P-Th503 Improving Implementation of the Stockholm Convention and other Global Governance Frameworks for Chemical Management in the Republic of Korea
***Yunsun Jeong**, Dawoon Jung and Yang-won Suh, Korea Environment Institute (KEI), Korea, Republic of (South)*
The Republic of Korea ratified the Stockholm Convention in 2007, and as a subsequent action, ‘Persistent Pollutants Control Act’ was enacted. According to this law, every five years, the Ministry of Environment develops a master plan for the implementation of the Convention. While this national plan encompasses most of the necessary fields for implementing the Convention, achieving some goals, such as preemptive response to the decisions of the Convention, are challenging within the current national policy timeframe. For instance, although there have been updates to the list of persistent organic pollutants (POPs) and POPs candidates, the preparation in Korea for responses (e.g., ratification, national chemical production status and risk evaluation) is progressing slowly. Recent global initiatives on chemicals, including the Science-Policy Panel on chemicals and wastes and a New Plastic Treaty (plastic-associated chemicals), will require national responses and actions in Korea such as undertaking a gap analysis of relevant policies and authorities. However, to the best of our knowledge, there has not been sufficient national-scale progress on those initiatives. To address the aforementioned issues, we propose establishing a national scientific-policy panel in Korea. This panel would be a format of governance consisting of national POPs experts (scientists), the relevant chemical industries, regulators, and policymakers. The role of panel would involve conducting relevant and valuable assessments, offering policy-relevant advice, cooperating with the international scientific communities, participating as the scientific advisory to the national representatives in COPs, and effectively disseminating the results of its work to audiences across various sectors who can take meaningful action. By establishing a national science-policy panel, Korea can actively contribute to the decision-making processes of global governance frameworks on chemicals with the accumulated knowledge, opinions, and experiences. A more proactive role of panel should be explored in the long-term, for instance, proposing chemicals relevant to the Korean population to be monitored in the national biomonitoring scheme, which would be a notable example of science-based decision making. Given the growing emphasis on science-based decision-making in the chemical management, Korea should take this opportunity to lead and proactively contribute to global initiatives.

6.07.P-Th504 HEALTH-BASED LIMIT VALUE REPOSITORY – CURRENT STATUS AND FUTURE CHALLENGES
***Bianca Pieczyk**, Franziska Breuer, Susanne Schwonbeck, Oliver Licht and Ariane Zwintscher, Fraunhofer Institute for Toxicology and Experimental Medicine (ITEM), Germany*
Health-based limit values (HBLV) are used in scientific and regulatory contexts to protect human health and the environment from adverse effects after exposure to different chemical substances and mixtures. They are usually defined as the highest dose or concentration at which no adverse effects are expected or at which the risks are considered acceptable in the light of the benefits of its use. Scientific HBLV are derived by using experimental data and further uncertainty factors, while regulatory HBLVs may consider further modification due to socio-economic, technical feasibility or political aspects in the derivation

process. Currently, limit values are accessible on separate online platforms in different structures and formats. These limit values are often showing limited detail of metadata, validity, reliability and a low level of transparency on their derivation process and thus complicating their reuse.

Within the project “Designing EU repository of health-based limit values and collating information for the first version of the repository” (ENV/2021/OP/0019), commissioned by the European Commission’s Directorate General for Environment (DG ENV), Novamechanis Ltd. and Fraunhofer ITEM were awarded to develop the first outline for an EU-uniform repository of human, animal and environmental HBLVs in a centralized and structured platform. As part of this project, 128 HBLVs were systematically identified and mapped, including background information and associated metadata, from the databases EUCLEF, Open Food Tox, the EU Pesticide database and a questionnaire conducted and provided by DG ENV. Furthermore, the user patterns, needs and requirements of the prospective users of the planned repository were requested and analysed in an online survey. The collected HBLVs from the mapping process and assessed knowledge from the survey lead to a first list of limit values and metadata to be included in the future repository.

The project showed that the current system for reuse of HBLV needs further improvements and a new repository is very welcomed by all user groups. In conclusion, the planned centralized and structured HBLV repository would contribute to the reuse and harmonisation of HBLVs and thus to the EU objectives of the ‘One substance, one assessment’ approach in the Chemicals Strategy for Sustainability of the European Commission.

6.07.P-Th505 The Mixture Allocation Factor & Options to Address Unintentional Environmental Mixtures Across Substance Regulations

*Daniel Frein[1], Wiebke Galert[2], **Enken Hassold**[2], Anja Kehrer-Berger[1], Ute Kühnen[3], Jan Pridöhl[3], Susanne Schmidt[1], Jona Schulze[4], Gabriele Treu[2], Peter von der Ohe[4] and Oliver Weisner[5], (1)Biocides, German Environment Agency (UBA), Germany, (2)Chemicals, German Environment Agency (UBA), Germany, (3)Pharmaceuticals, German Environment Agency (UBA), Germany, (4)German Environment Agency (UBA), Germany, (5)Plant Protection Products, German Environment Agency (UBA), Germany*

Across Europe, the prospective environmental risk assessment (ERA) focuses on single chemicals and is conducted under separate regulatory frameworks, i.e. for plant protection products, biocides, REACH chemicals, as well as for human and veterinary pharmaceuticals.However, a variety of chemicals enter the environment together from different sources, irrespective of their legal framework, leading to co-exposures that may cause joint effects. While requirements to address intentional mixtures (e.g. product formulations) and aggregated exposures (i.e. emission of one substance from different uses) exist in some substance-oriented legislations, obligations to assess and regulate unintentional mixtures are missing. In the European Commissions’s Chemicals Strategy for Sustainability, a so-called MAF (Mixture Allocation Factor) was proposed as a generic regulatory management tool for REACH to address risks due to the co-exposures and subsequent combined effects of chemicals. However, this approach might not work for all substance-oriented legislations and is far from being the “one and only” solution to effectively address mixture risks. Its applicability, challenges and benefits have to be evaluated for each relevant legislation. We discuss the challenges for the assessment and regulation of mixture risks via generic and specific approaches and outline different options for the different substance-oriented legislations. Options are for example: the MAF as a generic approach, specific mixture assessments for defined scenarios via component-based approaches, or the prioritization of mixture drivers and substance exceedances followed by regulatory measures. Moreover, the development of an accessible data basis and communication tools for users as well as discussions on societal needs and benefits are needed. Overall, overarching approaches across prospective and retrospective legislations are warranted to approach the Zero Pollution Ambition to finally benefit from a reduction of chemicals.

6.07.P-Th506 A Gap Between Risk Assessors and Risk Managers in the Case of Pharmaceuticals in the Environment

***Boris Kolar** and Mojca Durjava, National Laboratory of Health, Environment and Food, Slovenia*

The emission of pharmaceuticals into the environment can have a serious impact on the exposed ecosystems. Therefore, it is difficult to comprehend the existing gap between pharmaceutical and environmental legislation. Currently, there is no direct legal link between the conclusions from environmental risk assessment (ERA) (as a part of pharmaceutical authorization) and the management of the environmental impacts when the product reaches the market.

When the outcome of the ERA indicates a risk for the aquatic compartment and risk mitigation measures are set in the summary of the product characteristics (SPC), no legal obligations are in place to communicate this information to authorities responsible for environmental management.

In Europe, various chemical regulatory regimes (covering industrial chemicals, pesticides, feed additives, biocides, and pharmaceuticals) are in place (EU COM, 2018). The transparency of protected data related to use, fate and behaviour and the environmental effects substantially differs within different regulations. While comprehensive and detailed ecotoxicological information is provided within legislative frameworks covered by REACH and BPR (industrial chemicals, biocides), pesticides and feed additives, the same data for pharmaceuticals are scarce, not easily accessible and often limited just to outcomes of the procedure (Oelkers, 2020).

Environmental data from the pharmaceutical authorisation procedure are relevant for policy under the Water Framework Directive (WFD)(Directive 2000/60/EC), the Urban Wastewater Treatment Directive (WWTD) (Directive 91/271/EEC, as amended by Directive 98/15/EC) and the Industrial Emissions Directive (IED) (Directive 2010/75/EU), where this piece of information is used for the derivation of environmental quality standards (EQS) or emission limit values.

The gap between regulatory frameworks should be bridged through enforceable legal provisions. The monograph system or/and the chemicals strategy objective to move towards "one substance, one assessment" could serve as mechanisms for transparently reporting the relevant data (The European Commission, 2020). These legal provisions should also foresee that national authorities responsible for environmental management may provide feedback on environmental issues due to the use of pharmaceutical products, e.g., monitoring data, to the National Competent Authority for medicinal products and/or European Medicines Agency.

6.07.P-Th507 Enabling circular non-toxic supply-chains.

*Natasja Börjeson and **Marlene Ågerstrand**, Stockholm University, Sweden*

Today's production and consumption systems are putting a strain on natural resources at a pace that surpasses society's ability to manage the challenges that follow. In attempts to organize its response to anthropogenic pressure actors globally are developing circular economy strategies as means of sustainable use of resources. An important but often disregarded part of the circular economy is hazardous chemicals. Such chemicals are part of everyday products and when recycled they will inevitably be part of the circular loop of resources. The realization of a non-toxic circularity has several challenges, such as global supply chains and fragmented chemical regulation. This paper discusses how to enable circular non-toxic supply chains with a focus on goal conflicts and synergies connected to circular chemicals management, issues of transparency and traceability in supply chains, and managing difficult trade-offs and knowledge gaps concerning circularity and end-of-life. The study is exploratory and builds on semi-structured interviews and reference group discussions with respondents working with chemicals management and circular economy. The results show that a transition to a circular non-toxic economy is impeded by insufficient legislation and policy incoherence. Moreover, there is low transparency and traceability of chemical content in global supply chains, which in turn leads to a low control of chemical content in materials and products and difficulties for actors to make informed decisions. This may lead to a circulation of legacy and hazardous chemicals, thereby significantly increasing consumer and environmental exposure. However, designing products and materials non-toxic from the start enables several circularity synergies and opportunities for a sustainable use of resources. The results also illustrate how a hazard-based approach to risk management further enhances circular supply chains and safer consumer products. This study enhances the discussion on the circular economy by discussing the barriers, challenges and synergies concerning hazardous chemicals in the circular loop of resources. Further, it demonstrates relevant steps towards the realization of circular non-toxic economy use is necessary in a transformation to a society that meets the current environmental and resource challenges.

Keywords: Circular economy, non-toxic, supply chains, resource use, chemicals management

6.07.P-Th508 Impurity assessment in the EU from an (eco)toxicological perspective. How do we know if an impurity is relevant and if it enhances the (eco)toxicity of an active substance?

***Esteban García-Ruiz, PhD**[1], Inga Taraschewski[2], Hanna Skarpos[2], Mauricio López-Jordà[1], Veronika Blatz[2] and Lisa Bertomeu[3], (1)knoell Iberia S.L., Spain, (2)knoell Germany GmbH, Germany, (3)ISK Biosciences Europe N.V.*

In light of the most recent EU strategy for the sustainable use of chemicals, it is evident that in order to comply with its more complex objectives, there is a need for implementation of chemical regulation from a broader perspective. Thus, interdisciplinary work is needed for an increasing number of assessment procedures. The assessment of impurities is a clear example in which the joint efforts of experts from different fields like Chemistry, Toxicology and Ecotoxicology are required for addressing the issue in a holistic approach.

The assessment of impurities has been a regulatory requirement for many years. However, low attention seems to have been given to the relevance and impact of the impurities, present in the technical material together with the active substances, on their ability to alter the (eco)toxicity. Under the sustainability framework the attention is now increasing, but for now, there is still little feedback from authorities available on the process, possibly because the assessment relates to the confidential information of the dossiers. This lack of feedback is hindering the adoption of a clear and concise evaluation procedure.

Based on our experience with several submissions and first reactions from authorities, we come to present an approach, in which we detail the assessment steps for each impurity of potential (eco)toxicological concern identified in the 5-batch analysis study. For the individual steps, we will describe the inputs required from the (eco)toxicological experts as well as the interactions with the other expert fields involved in the process by using a workflow scheme, in which the gaps and uncertainties of the evaluation are highlighted. Further, we discuss the relevance and usability of each source of information supporting the (eco)toxicological assessment (studies, databases, in silico predictions) in the context of this stepwise approach. With this work, we aim to provide answers to the questions of whether a given impurity is relevant or not and if the impurity is increasing the (eco)toxicity of the active substance considering the proposed specifications of the technical material.

6.07.P-Th509 The CATs are out of the bag: Experiences to date with Critical Appraisal Tools

***Helena Crosland**, Sarah Priestly and Amy C. Brooks, MBiolSci, PhD, IBERA Certified Environmental Risk Assessor, Cambridge Environmental Assessments (CEA), United Kingdom*

In October 2022, EFSA (European Food Safety Authority) published a proposal document for the use of Critical Appraisal Tools (CATs) for non-standard ecotoxicology studies. The document outlines the theory behind the development of the CATs, why they are considered relevant, and the seven types of studies they have been created for. CATs for two additional study types are also provided as part of the revised EFSA 2023 bird and mammal guidance document.

The premise of these tools is that they provide a framework for the evaluation of non-standard studies (i.e. where guidelines are not available), in theory making the evaluation of such studies easier, and making outcomes more consistent across studies and regulators. Although application of these CATs is currently not mandatory, the inclusion of two of these in the (yet to be noted) EFSA 2023 bird and mammal guidance implies that EFSA are keen on their implementation. However, it is not yet clear when mandatory application of these tools will be required, nor if regulators will begin to use them in the meantime on newly performed, or existing, studies.

Since the release of the CATs, CEA has had experience in evaluating studies and updating study reports using the requirements in these tools. The aim of this poster is to provide examples of the use of CATs for certain study types; to summarise changes to reporting and/or study plans which may be needed in response to the CATs; and to highlight potential implications for the ecotoxicology risk assessment from their use.

6.07.P-Th510 Are Current Regulatory log Kow cut-off Values fit-for-purpose as a Screening Tool for Bioaccumulation Potential in Aquatic Organisms?

***Sylvia Gimeno**[1], Kai Benjamin Paul, PhD BSc MRSB CBiol[2], Pauline Remuzat[3] and Marie Collard[1], (1)DSM-Firmenich, Belgium, (2)Blue Frog Scientific, United Kingdom, (3)Blue Frog Scientific, France*

Persistent, Bioaccumulative and Toxic (PBT) and very Persistent and very Bioaccumulative (vPvB) are regulatory hazard categories that have been set to manage the possible risks to humans and the environment from these chemicals. In industrial chemicals regulations, their aquatic Bioaccumulation potential is usually assessed first with a screening based on the octanol/water partition coefficient (K_{ow}). However, current log K_{ow} cut-off values triggering classification, categorisation and/or further fish bioconcentration testing are not harmonised worldwide, and they have never been assessed for their regulatory relevance. In this study, the experimentally determined log K_{ow} and fish bioconcentration factors (BCF) of 532 chemicals were compared. While the analysis underlined the robustness of using log K_{ow} as a screening tool (5/532 were false negatives; log Kow: non-bioaccumulative, but BCF: bioaccumulative), it also demonstrated the conservatism of the cut-offs used worldwide. Indeed, many chemicals were deemed potentially Bioaccumulative based on log K_{ow} when a fish bioaccumulation test showed no concern (false positives), therefore, leading to unnecessary use of vertebrate animals. Our analysis shows that the log Kow cut-off could be increased to 4.5 in all regions for all purposes without leading to a reduced protection of humans and the environment.

6.07.P-Th511 Taking into account data quality and uncertainty to guide informed chemical substitution of PMT/vPvM substances

***Joanke van Dijk**[1], Romain Figuière[2], Marlene Ågerstrand[3] and Bernd Nowack[4], (1)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Department of Environmental science, Stockholm University, Sweden, (3)Stockholm University, Sweden, (4)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Measures are needed to protect water sources from substances that are mobile, persistent and toxic (PMT) or very persistent and very mobile (vPvM). PMT/vPvM substances are used in a diverse range of applications, including cosmetic products. Our previous research showed that the combined application of the essential-use and functional substitution concepts can be used to phase out these substances in cosmetic products, due to e.g. the availability of safer alternatives identified through an alternatives assessment. Existing experimental data was used in this assessment, which was primarily obtained from REACH registration dossiers. However, aspects with regards to the limitations of the experimental data were not considered. Furthermore, it will be important to include results from non-standardised tests as well as considerations of data quality and uncertainty to help the decision-making process when evaluating chemical alternatives. In addition, the use of in silico predictions is key to fill in data gaps as experimental data is often not available. The reliability of these in silico models and their outcomes also necessitates careful evaluation as, for example, the models need to be scientifically valid, relevant for regulatory purposes and applicable to the chemical structure of interest. Our objective was to develop and implement an uncertainty evaluation for the hazard assessment of chemical alternatives, consequently increasing the transparency of alternatives assessments. Our proposed evaluation system draws inspiration from established frameworks like the Criteria for Reporting and Evaluating Ecotoxicity Data (CRED) and Transparency, Reliability, Accessibility, Applicability and Completeness (TRAAC). Finally, we aimed to explore how both experimental and in silico data can be effectively combined in the pursuit of moving towards safer chemical alternatives and contribute to the better management of chemicals.

6.07.P-Th512 Revisiting Data Quality – Illustration with Fish BCF Data

***Dave T. F. Kuo**, National Taiwan University, Taiwan*

Data quality is an important but often overlooked aspect of ecotoxicological data. Current practice on data quality assessment typically involves the implementation of domain / phenomenon-specific screening protocol based on presupposed data quality criteria that could be traced back to various analytical or theoretical aspects of the experiment in question. The general principles of classifying data quality have been developed and applied for over two decades. Despite the widespread implementation of data quality screening, the validity and effectiveness of such approach – which can lead to exclusion of certain measurements from subsequent meta-analysis or modeling applications – has not been carefully examined. This study aims at providing a first look at the effectiveness of data quality screening based on presupposed data quality criteria using the well-established fish bioconcentration factors (BCF) database as an example. The original data quality tags associated with the fish BCF measurements were adopted without modification and/or re-evaluation though these were used as pivots to differentiate and compute compound-specific log BCFs. A suite of analyses were used to examine how log BCF values changed as a function of their data quality tags or criteria status. No statistical differences in log BCF between overall low-quality and high-quality measurements were observed for close to 90% of the examined chemicals. Among the 6 presupposed data quality criteria for BCF, at least 3 were found to exhibit minor influence / bias on log BCF values. Tree models of deviation in log BCF also revealed the lack of common hierarchical elements in the error structure of the deviation. This result was also consistent when tracking the difference from high-quality log BCF as a function of number of data quality criteria violated. Finally, it can be demonstrated that simple averaging without data quality differentiation produces statistically identical log BCF as those obtained with high-quality measurements without any noticeable dependence on BCF or log K_{OW}. These unexpected results suggested that the applied data quality assessment was, overall, not as effective as supposed. A number of plausible explanations were highlighted and discussed. Implications of data quality assessment on benchmarking and modeling environmental chemistry and ecotoxicology are discussed.

6.07.P-Th513 Reporting Chemical Data in the Environmental Sciences
Sivani Baskaran[1], *Parviel Chirsir*[2], *Shira Joudan*[3], *Raoul Wolf*[4], *Emma Schymanski*[2] *and Evan Bolton*[5], *(1)Norwegian Geotechnical Institute (NGI), Oslo, Norway, (2)Luxembourg Centre for Systems Biomedicine (LCSB), University of Luxembourg, Luxembourg, (3)Chemistry, University of Alberta, Canada, (4)Norwegian Geotechnical Institute (NGI), Norway, (5)National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health*
Environmental science, including chemistry and toxicology, is a highly interdisciplinary field incorporating researchers with various backgrounds and expertise such as: environmental chemistry, toxicology, atmospheric sciences, biology, data sciences, health science, plus physical, organic, analytical, and biological chemistry. One key aim of this scientific intersection is to understand the behaviour of chemicals in the environment and the interactions of chemicals with humans and other organisms. This interdisciplinary aspect is critical to addressing issues of chemical pollution, environmental sustainability, and health. However, to be effective in tackling these issues, standardized methods for reporting chemical data must be used. This is becoming increasingly important as reliance on and use of computational analysis methods, and particularly cheminformatic tools, grows. At the same time, the number of chemical structures in databases is growing exponentially. Although there are methods for clearly identifying chemicals, from database specific identifiers to names and structural information, most environmental chemistry and toxicology journals have few or no requirements and expectations for reporting chemical data. Thus, correctly identifying chemicals in literature can pose a significant challenge. This poster will review the different methods available for chemical identification and provide minimum reporting requirements for identification of chemical species using structural information and provide resources on how to access and use this information. The purpose is thus to provide recommendations on how to report chemical data in a Findable, Accessible, Interoperable and Reusable (FAIR) manner within environmental science, chemistry, and toxicology. This will broaden the scope and applicability of environmental research to empower community efforts to tackle issues of chemical pollution and sustainability in a comprehensive manner.

6.07.P-Th514 Curated Mode-of-Action Data and Effect Concentrations for Chemicals Relevant for the Aquatic Environment
Wibke Busch[1], *Tobias Schulze*[2], **Bente Nissen**[1] *and Lena Kramer*[1], *(1)Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Department of Effect-Directed Analysis, Helmholtz Centre for Environmental Research (UFZ), Germany*
Chemicals in the aquatic environment can be harmful to organisms and ecosystems. Knowledge on effect concentrations as well as on mechanisms and modes of interaction with biological molecules and signaling pathways is necessary to perform chemical risk assessment and identify toxic compounds. To this end, we developed criteria and a pipeline for harvesting and summarizing effect concentrations from the US ECOTOX database for the three aquatic species groups algae, crustaceans, and fish and researched the modes of action of more than 3,300 environmentally relevant chemicals in literature and databases. We provide a curated dataset ready to be used for risk assessment based on monitoring data and the first comprehensive collection and categorization of modes of action of environmental chemicals. Authorities, regulators, and scientists can use this data for the grouping of chemicals, the establishment of meaningful assessment groups, and the development of *in vitro* and *in silico* approaches for chemical testing and assessment. This work is published and available via Scientific Data (Schulze et al. 2023) and ZENODO (10.5281/zenodo.7983816).

6.07.P-Th515 Towards Safer Insect-Based Feed and Food: Evaluating Metal Uptake and Elimination in the Larvae of Black Soldier Fly
Marija Prodana[1], *Ana Rita R. Silva*[1], *Amid Mostafaie*[1], *José Nereu Pinto*[1], *Patricia V. Silva*[2], *Inês Coelho*[3], *Paula Alvito*[3], *Andreia Rego*[4], *Bryan W. Brooks*[5], *Susana Loureiro*[6] *and Diogo N. Cardoso*[1], *(1)CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)CICECO & Department of Materials and*

Ceramic Engineering, University of Aveiro, Portugal, (3)Food and Nutrition Department, National Institute of Health Dr. Ricardo Jorge, Portugal, (4)Food and Nutrition Department, Food and Nutrition Department, National Institute of Health Dr. Ricardo Jorge, Portugal, (5)Environmental Science, Environmental Science & Public Health, Baylor University, (6)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal
The advantages of the use of insects for food and feed are manifold. Insects are rich in protein, lipids and other nutrients and characterized by a highly efficient bioconversion capacity. Another added value in the view of circular bioeconomy is their potential to utilize a broad spectrum of food sources in the rearing facilities, including residual biomass, rather than to compete with highly relevant food commodities (wheat, soybean, etc.). Before using alternative feedstocks (bio-waste), ensuring the safety of these insects as food and feed is essential. This study aimed to evaluate the uptake and elimination of the common contaminants: cadmium (Cd), arsenic (As), and lead (Pb) by the larvae of *Hermetia illucens* (black soldier fly, BSF). Two-phase bioaccumulation studies were employed: a 5-day uptake phase (larvae were fed on contaminated substrate), followed by a 5-day elimination phase (larvae were fed on clean substrate). The substrate used was the Gainesville diet spiked with $CdCl_2$, $NaAsO_2$, and $Pb(NO_3)_2$ at the concentrations corresponding to 2 mg/kg of Cd and As, and 10 mg/kg dry substrate of Pb, based on the EU regulatory benchmarks for maximum allowed concentrations in feed. The control consisted of organisms exposed to clean substrates in both phases. The photoperiod of 16h/8h (light/dark), and temperature of 25±2°C were used during the exposure. The animals were sampled daily, followed by the 12-hour depuration, lyophilization and quantification of the metals by inductively coupled plasma mass spectrometry. The obtained data sets from the two phases were used in toxicokinetic modelling. The kinetic bioaccumulation factors were 1.21, 1.45 and 6.13 for As, Pb, and Cd, respectively. Our results showed that BSF larvae accumulated the three metals in concentrations above the levels permitted by existing legislation (2 and/or 10 mg/kg dry substrate). The highest uptake rate was that of Cd, followed by As and Pb. However, larvae reached internal concentrations recommended for safe use as food for other animals after 2 (As), 4 (Pb) and 5 (Cd) days in clean substrate. We propose the implementation of this depuration period after exposure to bio-waste, which may vary depending on the classes of contaminants involved. Toxicokinetic studies are adequate tools for the safety assessment of insects as feed and food, and they also define the conditions that assure their sustainable use in bio-waste management.

6.07.P-Th516 Towards Safer Insect-Based Foods: Evaluating Benzo(a)pyrene Uptake and Elimination in Yellow Mealworms
***José Nereu Pinto**[1], Regina M. B. O. Duarte[2], Ana Rita R. Silva[1], Marija Prodana[1], Ana Góis[1], Patricia V. Silva[3], Amid Mostafaie[1], Pedro F. Brandão[2], Ivã G. Lopes[4], Amadeu M.V.M. Soares[1], Bryan W. Brooks[5], Susana Loureiro[1] and Diogo N. Cardoso[1], (1)CESAM & Department of Biology, University of Aveiro, Portugal, (2)CESAM & Department of Chemistry, University of Aveiro, Portugal, (3)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal, (4)Department of Biosystems and Technology, Swedish University of Agricultural Sciences (SLU), Sweden, (5)Environmental Science, Environmental Science & Public Health, Baylor University*
Currently, feeding the world’s population sustainably and safely is crucial. Edible insects are at the forefront of sustainable food production, with some species showing the capacity to become vital tools for circular economic strategies. Given insects' ability to convert organic material into valuable products, it is imperative to understand the hazards associated to potential contaminants in their feed. While metals and mycotoxins have received major attention in research, the study of Polycyclic Aromatic Hydrocarbons (PAHs) remains scarce. PAHs are relevant due to their widespread sources, toxic nature and unexplored bioaccumulative potential in edible insects. Moreover, current EU legislation concerning PAHs is limited as there are no current legal thresholds for PAH concentrations in feed.

This study aims to evaluate the uptake and elimination kinetics of Benzo(a)pyrene (BaP) in the Yellow mealworm (*Tenebrio molitor*) as a representative compound of PAH contamination. Organisms were exposed to substrates spiked with different BaP concentrations (0.03, 0.3, and 3 μg BaP/g substrate) for 21 days (uptake phase), followed by 21 days in a clean substrate (elimination phase). Organisms were sampled at 0, 1, 3, 7, 14, 21, 22, 24, 28, 35 and 42 days, and at each sampling time, organisms followed a 24-hour depuration period previous to BaP measurements in sampled organisms. This work showed that insects can eliminate BaP from their bodies and verified a dose-dependent accumulation of BaP. After 21 days of exposure, larvae accumulated BaP, with Kinetic Bioaccumulation Factors of 1.93, 3.27, and 2.09 for 0.03, 0.3, and 3 μg BaP/g, respectively, exceeding the lowest threshold in food regulation (0.001 $\mu g/g$ in infant formulae). However, following a 13-day period in a clean substrate, organisms pre-exposed to a concentration of 0.03 μg BaP/g eliminated BaP and fell under the regulatory values (half-life (DT50) of 4.19 days). Differing, organisms exposed to 0.3 and 3 (DT50s of 4.3 and 10.2, respectively) still retained BaP levels over the legal limit after the 21 days of the elimination phase.

In summary, the edible insect food industry requires the establishment of clear PAH guidelines for insect feed while aligning with existing human consumption regulations. This research highlighted the necessity for scientifically regulating PAHs in edible insects.

6.07.P-Th517 Clarifying Regulatory Needs to Advance the Environmental Risk Assessment of Chemical Pesticides
***Johan Axelman**[1], Annette Aldrich[2], Yann Devos[3], Sabine Duquesne[4] and Vanessa Mazerolles[5], (1)Swedish Chemicals Agency, Sweden, (2)Federal Office for the Environment (FOEN), Switzerland, (3)European Food Safety Authority (EFSA), Italy, (4)German Environment Agency (UBA), Germany, (5)French Agency for Food, Environmental and Occupational Health & Safety (ANSES), France*
The EU Partnership for the Assessment of Risks from Chemicals (PARC) aims to develop next-generation chemical risk

assessment to protect human health and the environment. Within PARC, the Task 6.4.4 "*Risk assessment to support and promote efficient overall protection of biodiversity*" is dedicated to advance the regulatory prospective environmental risk assessment (ERA) of chemicals, with an initial focus on chemical pesticides. This will be undertaken within the current regulatory framework of pesticides as well as beyond, with the ambition of striving towards a systems-based approach for ERA.

Currently, five main projects are carried out under Task 6.4.4, of which the "clarifying regulatory needs" project plays an overarching role for the four research-based projects (i.e. exposure, effects, benchmarked ERA and landscape-based ERA), as it aims to ensure the regulatory and policy relevance of the research conducted under Task 6.4.4. This will be achieved by: (1) tailoring the research questions addressed in Task 6.4.4 to relevant policy targets and strategies under the European Green Deal; (2) identifying actionable scientific knowledge; and (3) delivering knowledge, data and scientific tools for ERA that can be taken up smoothly in a regulatory context. As such, the "clarifying regulatory needs" project will guide the research, and foster the development and implementation of scientific tools proposed under the current Task 6.4.4 projects.

To achieve this goal, an iterative and collaborative knowledge-building process will be followed. Thereby, the views and perspectives of relevant stakeholders will be collected and discussed at the European, national and regional levels through a series of online surveys and workshops throughout the duration of PARC The feedback gathered will enable to further assess the strengths and weaknesses of the current ERA framework for pesticides, and explore avenues to advance it. This poster will report on the main outcomes of the initial round of stakeholder engagement, which will focus on risk assessors and is scheduled to take place in Q1-Q2 of 2024

6.07.P-Th518 Three Pesticide Indicators Based on Sales Data, Exposure, Ecotoxicity and Risk Mitigation Measures to Show Trends in the Risk Potential of Pesticides
Laurent Boualit[1]*, Johannes Ranke*[1]*, Marcel Mathis*[1]*, Thomas Poiger*[2]*, Judith F. Blom*[3] *and Marianne Balmer*[1]*, (1)Agroscope, Switzerland, (2)Plant Protection Products – Impact and Assessment, Agroscope, Switzerland, (3)Plant Protection Products - Impact and Assessment, Agroscope, Switzerland*
In recent years, a number of indicators with different levels of complexity have been proposed to evaluate trends in plant protection product (PPP) risks, each with advantages and disadvantages. Very simple approaches like the Harmonised Risk Indicator (HRI) have been criticised for largely neglecting crucial factors such as exposure and ecotoxicity.

The environmental risk indicators presented here (Korkaric et al. 2022, Korkaric et al. 2023) aim to provide a more holistic perspective on a national level, specifically designed for Switzerland. Based on national sales data of PPP, the approach integrates exposure, ecotoxicity, and the estimated impacts of risk reduction measures. In this way, an indicative trend analysis of the risks for organisms in surface waters and terrestrial habitats, as well as of the risk of groundwater contamination is obtained.

The basic idea is to weight the outcome of a regulatory risk assessment with an estimate of the treated area, obtained from the amount sold annually and a mean application rate. Risk mitigation measures are considered in terms of their effectiveness, the relevance of the affected exposure pathway concerned, and the degree of implementation. For the surface water compartment, all parts of this scheme were implemented, taking into account product specific mitigation measures as well as general point source mitigation measures. For semi-natural habitats (terrestrial ecosystems outside the treated fields) a simplified scheme is currently used. A simplified approach is also used for the groundwater indicator, based on the treated area and the estimated concentration of transformation products from regulatory groundwater exposure assessments.

In this poster, we present the implementation of the approach as well as well as the evolution of these indicators for the period 2012-2022.

Korkaric M., Lehto M., Poiger T., de Baan L., Mathis M., Ammann L., Hanke I., Balmer M., Blom J.F. (2023) Nationale Risikoindikatoren für Pflanzenschutzmittel: Weiterführende Analysen. Agroscope Science, 154, 1-48.
Korkaric M., Ammann L., Hanke I., Schneuwly J., Lehto Hürlimann M., Poiger T., de Baan L., Daniel O., Blom J.F. (2022) Nationale Risikoindikatoren basierend auf dem Verkauf von Pflanzenschutzmitteln. Agrarforschung Schweiz, 13, 1-10.

6.07.P-Th519 Synthetic pyrethroids and water quality
Joost Lahr[1]*, Els Smit*[1]*, Corine Komen*[1]*, Simon Buijs*[1] *and Kees Westendorp*[2]*, (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Deltares, Netherlands*
Synthetic pyrethroids are a group of chemically related compounds used as pesticides and pharmaceuticals. The synthetic pyrethroids share similar properties such as a tendency to adsorb to particles, sediments and animal tissues. They are also extremely toxic to aquatic invertebrates and fish.

A recent model study showed that three synthetic pyrethroids, deltamethrin, esfenvalerate and lambda-cyhalothrin, are responsible for 90% of the total environmental impact by plant protection products from open cultivation in Dutch surface waters.

Also, most synthetic pyrethroids are difficult to measure in water at the level of their environmental quality standards such as from the Water Framework Directive (WFD-EQS). They are therefore 'non-evaluable'. Because of their high potential impact in waters and their non-evaluability, synthetic pyrethroids are considered as problematic substances in water quality management.

The authorisation criteria for most synthetic pyrethroids used in Plant Protection Products (PPP) are orders of magnitude higher than the environmental quality standards for surface water. This may lead to water quality standards being exceeded. Authorisation criteria for synthetic pyrethroids used in biocides are also higher than the EQS, but differences are smaller than for PPPs. In the case of synthetic pyrethroids that are both used in PPP and biocides, authorisation criteria for biocides are significantly lower than for PPP.

These differences between regulatory thresholds are the consequence of regulatory frameworks having different protection goals and methods, and different ways of collecting and using scientific data. The imbalance between authorisation criteria and WFD-EQS for synthetic pyrethroids leads to different insights into their effects on surface water quality and hampers a consistent approach towards minimising the impact of these substances. A more uniform assessment of these substances at the European and national level could be a solution to this.

Existing measures to reduce the environmental impact of synthetic pyrethroids in the Netherlands include Emission Reduction Plans (ERPs) by manufacturers and measures in the framework of Integrated Pest Management, such as using alternative methods of pest control or more environmentally friendly insecticides. Fewer environmental emissions of synthetic pyrethroids to surface waters would potentially result in a significant improvement of chemical and probably the ecological .

6.07.P-Th520 PCBs an Emerging Pollutant of Concern...?
David Megson[1]*, Ifeoluwa Grace Idowu*[2] *and Courtney Sandau*[3]*, (1)Manchester Metropolitan University, United Kingdom, (2)University of Manitoba, Canada, (3)Chemistry Matters Inc., Canada*
Polychlorinated biphenyls (PCBs) are man-made chemicals that were once extensively manufactured in various industrial applications as commercial mixtures. PCBs were subsequently acknowledged as environmental contaminants. Health risks associated with PCB exposure prompted a worldwide discontinuation and the implementation of stringent regulations governing their production, utilization, and disposal. Most research related to PCBs concentrates on assessing the congener components found in commercial mixtures, or marker substances representing those mixtures (e.g. i7 PCBs 28, 52, 101, 118, 138, 153 and 180). Biomonitoring studies are reporting declines in environmental PCB concentrations because they only focus on a few PCBs linked to historic commercial PCB mixtures. However, studies that have looked for all 209 PCBs are detecting elevated concentrations of by-product PCBs that are not linked to commercial mixtures.

By-product PCBs are PCBs that are inadvertently generated during a variety of different chemical processes. The have been referred to previously as inadvertent PCBs, incidental PCBs (i-PCBs) and non-Aroclor PCBs. These PCBs have been identified as the dominant source of exposure in some residential properties in the U.S. They have been estimated to contribute between 4-50% of the total PCBs found in marine mammals in the North Atlantic Ocean. They are also dominating PCB profiles in Chinese soils and sediments.

There is currently a discrepancy in current legislation that means the importance of these PCBs is only set to continue. Current legislation in the U.S. permits the release of higher concentrations of PCBs produced as by-products, than PCBs that were produced intentionally. There are limits on the concentrations of inadvertently produced PCBs in commercial products, however these may not be stringent enough. We estimate that more PCBs may be currently produced as by-products than were produced in the 1970s during peak aroclor production. Is it therefore possible that we need to designate PCBs as an emerging pollutant of concern?

6.07.P-Th521 Exploring Practice, Challenges, and Priorities for Human Health and Ecological Risk Assessments in Indigenous Communities in Canada: A Multi-sector Survey
Katie Chong*, Gordon Hickey and Niladri Basu, McGill University, Canada*
Environmental pollution poses unique and complex risks to many Indigenous communities in Canada, often because of unique exposure pathways and impacts on culture, spirituality, language, and traditional food systems. However, to date institutionalized human health and ecological risk assessment (RA) approaches have not been developed or implemented with these unique contexts in mind. Through amendments to Canada's Environmental Protection Act, there is regulatory interest in developing new approaches to RA, and thus an opportunity to increase their relevance for the Indigenous communities in which they will be ultimately applied. Therefore, we conducted an anonymous online survey of those who are involved with RA in Indigenous communities in Canada, including community members and the variety of sectors they collaborate with, to: first, understand RA practice in Indigenous communities; second, explore challenges with conventional RA methods and compare these across sectors; and third, gather perspectives on the development of new approaches. A total of 38 completed survey responses were received (14.1% response rate). For our first objective, RA practice professionals spanned Indigenous community environment and health offices (21%), Indigenous governments (8%), federal and provincial governments (21%), and academia (45%), and had a wide range of experience levels with risk assessment work, ranging from less than a year to

over 20 years. For our second objective, risk communication was seen as the most challenging step of the risk assessment process (71% of responses “difficult”), with key differences between respondents working within and outside of communities. There was agreement amongst nearly all respondents that time (86%), cost (76%), and resource availability (86%) were moderate to severe problems. In response to our third objective, relatively few respondents (16%) had heard of New Approach Methodologies for RA, while 76% of respondents (and 100% of community-based respondents) agreed there was a need to develop new and improved RA approaches. Participants emphasized cumulative risk assessment; risk communication; and Indigenous leadership and autonomy as priorities for new RA methods. Overall, there were notable differences in perspectives amongst sectors; improved communication and multi-sector collaboration may advance RA practice. Future research will focus on the design and development of RA approaches lead by collaborating communities.

6.07.P-Th522 Phase out of lead in hunting ammunition – a perspective from an EU Member State: Denmark

*Niels Kanstrup[1] and **Rafael Mateo**[2], (1)Ecoscience, Aarhus University, Denmark, (2)Wildlife Toxicology, Instituto de Investigación en Recursos Cinegéticos (IREC) CSIC-UCLM-JCCM, Spain*

Session 6.09

Lead is a widespread metal that society has used for millennia, and its toxicity has been recognised for almost as long. Yet, it is only within the last half century that society has actively sought to phase out the use of lead, for example in petrol and paint, for human health reasons. Hunting ammunition spreads lead in the environment where it serves as a major source of poisoning and constitutes a health risk to people consuming game meat. Hunting remains today the largest single source of dispersed lead in ecosystems. Mass-produced types, where lead is replaced with non-toxic, safe and effective alternative metals are available.

Denmark was one of the first countries to enact regulation of lead ammunition. After increasing awareness of the risks of lead shot to waterbirds in the 1970s, the first regulation of lead shot for sport shooting was introduced in 1981. In 1986 lead shot for hunting in wetlands was banned, followed by a ban on lead shot in upland hunting in 1993 and a total ban on lead shot in hunting and on trade and possession in 1996. From April 2024 the regulation has included also lead in hunting rifle ammunition.

Here we highlight the perspectives for the Danish regulation of lead ammunition to materialize in a *de facto* stop of dispersal of lead from ammunition to nature and ecosystems and to what degree this will benefit nature conservation, human health, and the sustainability of hunting. Studies show large compliance with the present regulations of lead gunshot and, consequently, low lead concentrations in key species of predators and scavengers. Furthermore, game meat lead concentrations have decreased to a safe level in Denmark compared to countries with no restrictions. Over the last five years, Danish hunters have increasingly and voluntarily switched from lead to non-lead in rifle ammunition and the perspectives for solid compliance with the 2024 regulation are very promising.

In Denmark there is around 170.000 hunters comprising app. 3 % of the total population thus one of the highest densities in Europe. Hunting is inspired by both Scandinavian, German, French, and British traditions. So even if Denmark is small in terms of land it represents traditional hunting forms and wildlife management in most of Europe. Denmark’s lead-free hunting journey can therefore be an inspiring example of how Europe and other continents can build a non-toxic future.

6.07.P-Th523 REACH registered Per- and Polyfluoroalkyl Substances (PFAS) in firefighting foams: Is ecotoxicological data sufficient to assess environmental risk?

***Anais Espinosa**, Constantin Dallot, Levy Patrick and Valérie Sapin, Health & Chemical Safety Office, SOCOTEC ENVIRONNEMENT, France*

PFAS, or Per- and Polyfluoroalkyl Substances, are synthetic chemicals employed in various industries for their specific properties such as resistance under extreme conditions or water and grease resistance. These substances have become a growing source of concern due to their persistent and bioaccumulative nature leading to widespread contamination of soil, water, and ecosystems. They are also associated with potential health risks including developmental issues, immune system dysfunction, and an elevated risk of certain cancers.

The apprehension surrounding PFAS has led to the introduction of various regulations, navigating from individual cases to a broader, group-oriented approach based on structural definition.

ECHA recently proposed a restriction of their use in firefighting foams with an objective of a 13 000 tonnes emission reduction within 30 years addressing consequences of their potential to bioaccumulate, their persistence and their toxicity for human health.

Because environmental exposure and its effects on wildlife are out of scope of this ongoing restriction, the question of ecotoxicological risk arises.

In an attempt to make this evaluation for firefighting foams PFAS currently on the market, we identified active registrations under REACH (EC1907/2006). For each of these substances, the ecotoxicology data set was analysed for both aquatic and air breathing organisms. Data availability in disseminated registration dossiers was compared to literature.

Among the list of 78 PFAS used in firefighting foams proposed by ECHA in its restriction proposal, only 10 are registered under REACH at tonnages up to >1000 T.

Although acute aquatic toxicity data is available in every analysed dossier, data relevant for risks assessment is incomplete. Literature survey revealed a rich data set for historical PFAS whereas data for firefighting foams PFAS currently in use is scarce.

6.07.P-Th524 Assessing Awareness and Compliance With Fish Consumption Advisories on the Upper Hudson River: Implications for Risk Management of the Hudson River Superfund Site

***Jeffrey Bolnick*[1]**, *Sam Byrne[1,2], Sam Roubin[1] and Makenna Burr[2], (1)Middlebury College, (2)St. Lawrence University*

Polychlorinated biphenyls (PCBs) are a known environmental pollutant. From 1947 to 1977, General Electric (GE) dumped approximately 1.3 million pounds of PCBs into the upper Hudson River from their factories in Hudson Falls, NY and Fort Edward, NY. In order to prevent exposure to PCBs via fish consumption, the New York State Department of Health (NYSDOH) issues fish consumption advisories throughout the Hudson River. The NYSDOH also instates a “Do Not Eat” order for fish caught in the upper Hudson River - from Glens Falls, NY to Troy, NY. There is limited research regarding the effectiveness of such advisories in preventing the consumption of contaminated fish in a Superfund site. We surveyed 150 anglers who were actively fishing in the Hudson River from Hudson Falls, NY to Troy, NY. Participants were surveyed regarding their knowledge of the fish consumption advisories and consumption of fish from the upper Hudson River. Anglers were found to have an incomplete awareness of the advisories, and a number of individuals chose to consume fish that they caught. Awareness of advisories was inversely correlated with fish consumption, although a number of individuals who were aware of the advisories still chose to consume. Age, race, and possession of a fishing license were associated with awareness of fish consumption advisories. Institutional controls appear to have somewhat of a positive impact in preventing exposure to PCBs. However, given that a subset of individuals chose to consume fish caught in the upper Hudson River, these controls are not fully effective in their goal of preventing dietary exposure to PCBs. Remediation strategies for contaminated waterways should consider incomplete adherence to fish consumption advisories. This research provides unique insight into the efficacy of fish consumption advisories as a regulatory policy aimed at limiting human exposure to chemicals in fisheries.

6.07.P-Th525 Developing UK-specific chemical emission futures within the global context

***Stephen Lofts*[1]**, *Hongyan Chen[1], Sam Tomlinson[1], Sam Harrison[1], Robert Dunford[1], Simona Pedde[2], Zuzana Harmáčková[3] and Paula Harrison[1], (1)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (2)Wageningen University & Research (WUR), Netherlands, (3)Stockholm Resilience Centre, Stockholm University*

Chemical emissions result from numerous environmental and climatic, technological, socioeconomic and political drivers. The use of exploratory scenarios is one approach to develop understanding of how drivers may evolve, interact and affect emissions.. By linking the broader context of socioeconomic and political context to future emissions, policies and practices can adapt to and/or mitigate impacts. The challenge is to identify a framework that covers all relevant drivers at the appropriate scale, matching higher level drivers with context-specific facts. The UK Shared Socioeconomic Pathways (UK-SSPs) describe five contrasting socioeconomic pathways for the United Kingdom that coherently provide a range of challenges. They provide resources including narratives, systems diagrams and 50 semiquantitative socioeconomic variables, and have already been used to develop quantitative spatial projections including land use and population.

For chemical emission estimation, further scenario enrichment to quantify the variables directly driving emission quantities and patterns (proximal drivers). Some quantitative drivers are already available as UK-SSP outputs, but others, such as from the supply of raw materials for production, chemical import and export trends, demand for specific chemicals, and societal attitudes to chemical use, need to be developed. Using an internal participatory approach, we have derived approaches to estimate trends in the future inputs of metals to UK soils, and ongoing work is expanding this to involve external policy-related stakeholders in the estimation of emission trends for a range of substances, for the projection of future trends in water quality across the UK. The process that we have developed for deriving trends in proximal drivers for a chemical or group of chemicals involves (i) identification of the proximal drivers, accounting for all sources of the chemical or chemical type, and (ii) elucidation of historic trends in the proximal drivers, using a multi-actor participatory approach.

We will describe the approach to proximal driver trend estimation, and show examples of derived trends and discuss the key points, advantages, potential disadvantages and possible developments and improvements to this emission trend derivation approach.

6.07.P-Th527 Health Risk Evaluation on Recycled Plastics: the Case Study of Dermal Exposure of Plasticizer from the Actual Recycled Plastic Products

Naoya Kojima[1], ***Naohide Shinohara*[1]**, *Tomoko Oguri[2], Isamu Ogura[1], Hideo Kajihara[1], Keisuke Nakamura[2], Eriko Yamazaki[2], Nobuyasu Hanari[2] and Masashi Gamo[1], (1)National Institute of Advanced Industrial Science and Technology (AIST), Japan,*

(2)The National Institute of Advanced Industrial Science and Technology, Japan
n the context of the Circular Economy, plastic recycling has been drawing attention. One of the problems is that there have been few risk assessments for contained substances that can be found in recycled plastics, include both intentionally and unintentionally added. In the absence of quantitative risk assessment, recycled plastics might be required excess safety and/or recycled plastics with ensuring sufficient safety might be supplied in market. As the results, the circular amount of recycled plastic would not be increase.

Focusing on the specific issues of recycled plastics, we need to develop and suggest the appropriate methods of chemical analysis and risk assessment. Then we launch the first case study consisting of the following steps.

1. Collecting the samples of pellet for recycled plastic and interview their recycling manufacture.
2. Sample analysis to identify and quantify the chemicals which is regulated and/or restricted to control chemical risk. From these results, we aim to suggest analytical methods appropriate for risk assessment on recycled plastics.
3. Exposure assessment by material flow analysis and model simulation under the various use/application cases.
4. Risk assessment: *f*(Toxicity, Exposure, Scenario).

We have asked several recycling manufactures to provide sample pellets and interview. From 10 manufactures, we received about 50 sample pellets and 1 sample product (plastic holder for nail clipper).

For some of these samples, we analyzed and measured contained substances by mass spectrometry and X-ray fluorescence analysis. Prioritizing the detected chemicals and metals, we selected phthalates as our first case study and examined their acceptable/tolerable daily intakes for risk evaluation. Then we assumed exposure scenario that plastic holder for nail clippers caused their dermal exposure and set parameters such as contact time (minute) and transfer coefficient (cm/s), and we evaluated their human health risk.

Exercising and summarizing these case studies based on the actual recycled plastics we aim to publish Safety Assessment Guidance for various stakeholders in the recycled plastics supply chain who are responsible for quality control, risk management and product liability.

Acknowledgement: The part of this study is based on results obtained from a project, “Circular Economy System”, in Cross-ministerial Strategic Innovation Promotion Program, Cabinet Office, Japan commissioned by Environmental Restoration and Conservation Agency.

6.07.P-Th528 Unveiling Hidden Threats: Non-Conventional Endpoints In Environmental Risk Assessment For Enhanced Contaminant Impact Understanding.

***Jacqueline Hilgendorf*[1]**, *Wing Sze Chan[2], Oihane Del Puerto[3], Jian Ge[4], Harmony Lautrette-Quinveros[5], Kevin Noort[6], Shivani Ronanki[7], Susana Loureiro[1] and Henriette Selck[2], (1)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal, (2)Roskilde University (RUC), Denmark, (3)Syngent Crop Protection AG, Switzerland, (4)Department of Ecoscience, Aarhus University, Denmark, (5)Lund University, Sweden, (6)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (7)Department of Toxicology, Wageningen University & Research (WUR), Netherlands*
Environmental risk assessment (ERA) is an essential tool for evaluating the potential ecological effects of chemicals. However, current ERA practices rely heavily on conventional endpoints such as mortality, growth, and reproduction. Although these endpoints provide valuable information, they may not be sufficient to protect wildlife populations when considering chemicals with specific modes of action (MoAs), such as neurotoxic compounds, or when present in concentrations below threshold values but over a long time. With an increasing number of new chemical compounds and new MoAs, there is an urgent need to modernise current ERA practices to adequately protect the environment and its inhabitants. Incorporating non-conventional endpoints (e.g., biochemical, physiological and behavioural endpoints) can aid in identifying potential adverse effects of contaminants that cannot be detected with conventional ones. The current paper aims to review and discuss the importance of non-conventional endpoints and if and when it is necessary to include them in ERA in addition to conventional endpoints.

Literature research was performed to assess under which, if any, circumstances non-conventional endpoints may prevail over conventional ones. For this purpose, the term conventional endpoint was defined by summarising all endpoints used in OECD and ISO guidelines. In a subsequent step, the term non-conventional endpoint was determined using the standartox and SCOPUS database and the VOSviewer software to construct a bibliographic map and sort out the emerging endpoint groups scientifically validated for ERA. Connections between these endpoints and temporal trends for their use were also analysed. After identifying the essential non-conventional endpoints, a more in-depth literature search was conducted, selecting several case studies comparing conventional and non-conventional endpoints to examine their importance based on the chemicals' MoA, exposure conditions and ecological protection goals. We recommend using non-conventional endpoints, such as behavioural endpoints (e.g. activity, phototaxis), to detect chemicals with specific MoAs that can lead, for instance, to neurotoxicity, olfactory impairment or endocrine disruption or can harm the environment at low, environmentally relevant concentrations due to undetected effects with non-monotonic dose-response curves. Finally, we will present our constructed framework, summarising our suggestions to improve modern ERA.

6.07.P-Th529 Common Approach for Setting Environmental Self-Classifications for Metals and Metal Compounds
Dagobert Heijerick[1]*, Hugo Waeterschoot*[2]*, Stijn Baken, PhD*[3] *and Jelle Mertens*[4]*, (1)ARCHE Consulting, Belgium, (2)Chemicals Management, (3)European Copper Institute, Belgium, (4)EPMF, Belgium*
The methodology and data treatment approaches that are applicable for the determination of the environmental classification of metal and metal compounds have been outlined in various international and European regulations and official guidance documents. The classification approaches presented in these documents, however, have been interpreted in different ways by industry and regulators. Different classification strategies, for example, were followed in the recent regulatory harmonized environmental classifications for Copper and Lead.

To promote a common interpretation of these provisions for self-classification, Eurometaux organized an Environmental Classification Workshop that was held in Brussels in December 2023, aiming for the development of a common self-classification strategy among metal associations and metal industry. The proposed classification strategy applies the concept of "the best science available" in relation to the regulatory frameworks and promotes that inorganic substances that have been assigned to the same environmental hazard category for a specific environmental endpoint indeed have comparable hazard profiles.

A correct categorizing of substances requires that they are assessed against the same benchmarks. For environmental classification purposes these benchmarks should be acute and chronic adverse effects under standardized test conditions for a number of standard surrogate species that represent three key trophic levels (algae, crustaceans, fish). Deviating from these principles by considering additional information for data-rich substances, such as other taxonomic groups or non-standard test conditions, may lead to substances with similar hazard profiles receiving different classifications. A similar logic can be followed when considering the appropriate effect-parameters.

The environmental classification scheme includes a tiered methodology to derive acute and chronic Ecotoxicity Reference Values for the metal toxicophore based on relevant and reliable ecotoxicological information. The final tier applied depends on the data-richness of the metal (use of geometric mean values, bioavailability normalization, SSD-application, pH-banding).

The application of the Environmental Classification scheme for metals and their compounds, alloys and related complex materials developed at the workshop will ultimately lead to a harmonized application of the environmental classification rules for these substances.

6.07.P-Th530 Beyond 'Surface Activity': Addressing Challenges of Standard Chronic Aquatic Toxicity Testing with Surfactants
Erin Maloney[1]*, James Dawick*[2]*, Lauren McAnally*[3]*, Ricky Stackhouse*[4]*, Susan A Csiszar*[5]*, Jens Bietz*[6]*, Marc Geurts*[7]*, Liesa-Kristin Beuter Beuter, PhD*[8]*, Sabrina Wilhelm*[9] *and Philipp Hopp*[9]*, (1)Shell International, Netherlands, (2)Innospec Limited, United Kingdom, (3)Innospec Limited, (4)Sasol, (5)Procter & Gamble, Belgium, (6)Clariant Produkte (Deutschland) GmbH, Germany, (7)Nouryon Chemicals B.V., Netherlands, (8)Nouryon AB, Sweden, (9)BASF Personal Care and Nutrition GmbH, Germany*
Surfactants are high production volume chemicals, often registered under the highest tonnage band (> 1000 tonnes per year) under Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH). Thus, chronic aquatic toxicity testing is a standard information requirement for the production, import, and sale of these substances in the EU. In the OECD Guidance Document on Aquatic Toxicity Testing of Difficult Substances and Mixtures (OECD 23) 'surface activity' is identified as a property of a difficult test substance, and surfactants are identified as being associated with a range of testing difficulties due to this property. However, surfactants (e.g., alcohol ethoxylates, alkyl amines, alpha olefin sulfonates, etc.) are often associated with other properties which make them 'difficult to test'. For example, surfactants can be surface active and poorly soluble/hydrophobic, toxic at low concentrations, photodegradable, biodegradable, adsorbing, ionized, multi-constituent, and/or UVCB substances. This can make it difficult to carry out successful chronic aquatic tests using standard methodologies, even with due consideration of recommendations in OECD TG 23. All of these factors can result in test failure (leading to animal welfare issues like excessive use of vertebrate fish) and/or generation of effect values that may not be useful for quantitative risk assessment or classification and labeling. As such, there is a need to identify pragmatic and tangible strategies through which chronic aquatic test requirements for these surfactants can be addressed. This will become critical as REACH registrations extend to polymers, and the scope of registration increases.

To address this issue, a project was developed through ERASM (https://www.erasm.org) to leverage existing data and the (eco)toxicological expertise of industrial scientists and research organizations to address the issue of conducting chronic aquatic toxicity testing on surfactants. This project aims to: 1) generate robust definitions of 'difficult to test surfactants' based on substance properties; 2) provide robust evidence of challenges encountered during chronic testing using standard methodologies; and 3) critically review the applicability of available alternative chronic test methods for these substances.

Overall, this will yield guidance that can be employed during chronic surfactant testing, improving the likelihood of test success and utility of derived effect data.

6.07.P-Th531 Evidence on the effects of Flame Retardant substances at ecologically relevant endpoints: A Systematic Map Protocol

***Lowenna Jones*[1]** *and Kathryn Arnold[2], (1)Politics and International Relations, University of Sheffield, United Kingdom, (2)University of York, United Kingdom*

Background: Flame retardants are a diverse group of chemical substances that are widely used in products, such as furniture, textiles, electronics and building materials, to prevent or slow the development of fire. Flame retardant (FR) substances are known to pose a risk to human and environmental health, with complex pathways of exposure and contamination. Once released into the environment, some FR substances are known, or predicted to have direct and indirect effects on long term survival, development, physiology and behaviour across a range of species, including humans and wildlife. Over time, FR substances have become the focus of many environmental and (human) health risk assessments. Systematic Evidence Maps (SEMs) have been identified as an underutilised tool for chemical risk assessment, providing a core and reliable approach to evidence-based toxicology. A list of potential FR substances has been developed (i.e. Bevington et al., 2022) however, detailed information on the risk, or hazard of such substances to human and environmental health has not yet been collated. As such, the goal of this systematic evidence map is to identify, organise and map the available evidence on the (eco)toxicological effects of FR substances across ecologically relevant endpoints.

Methods: The methodology set out in this protocol serves to document decisions made *a priori* regarding the conduct of the systematic evidence mapping. We will search several electronic academic (PubMed, Web of Science, Google Scholar) databases, and grey literature sites (OpenGrey) for existing evidence on the (eco)toxicological effect of FR substances to the environment. Eligible studies must contain primary research investigating the risk (or hazard) of one or more FR substances and study an ecologically relevant adverse effect. Ecologically relevant effects include impacts on growth, development, survival, reproduction and behaviour. Taxonomic groups considered for inclusion are those classified as animal, plant, bacteria and/or fungi. Human data will not be included. Articles will be screened in two phases – firstly, Title and Abstract, before a full-text review. A single reviewer will screen all articles with an independent reviewer confirming articles for exclusion. Assessment of each article's quality will not be assessed for this evidence map. Results of the evidence map will be published in a narrative summary and visualised in a publicly available interactive map.

6.07.P-Th532 Implications for Implementing the "Essential-use" Concept in Chemical Regulations

***Romain Figuière*[1]**, *Zhanyun Wang[2], Armin Siegrist[3] and Ian Cousins[4], (1)Department of Environmental science, Stockholm University, Sweden, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)ETH Zurich, Switzerland, (4)Department of Environmental Science, Stockholm University, Sweden*

The essential-use concept was first introduced in 1987 in the Montreal Protocol to phase out the use of ozone-depleting substances, except for certain essential uses. More recently, the European Commission proposed to use the concept in the decision-making processes of restriction and authorisation under REACH, with the aim to render the processes more efficient and aligned with societal needs. This study aims to inform the ongoing EU work on the criteria for the essential-use concept. It analyses how existing regulatory outcomes from the REACH restriction and the Stockholm Convention differ from the essential-use concept, and the reasons for eventual discrepancies, by determining the main reason justifying granting a derogation from existing restrictions. To do so, it analyses the opinions of the socio-economic analysis committee and POP review committee following the READ approach. The REACH restriction dossier on intentionally added microplastics, and the listing of PFOA under the Stockholm Convention serves as case studies to check whether, by using the same information, an outsider would reach the same conclusion when applying the essential-use concept. An overall evaluation of previous decisions on application for authorisation is also performed to determine number of cases for which the essential-use concept could have been applied to. The results suggest that 100% of the previous exemptions under the Stockholm Convention and 32% of the derogations to restrictions under REACH were recommended for reasons related to the essential-use concept. Furthermore, it has been estimated that the essential-use concept could have influenced the conclusions in 28% of those cases. Regarding the REACH Authorisation, the essential-use concept could have been applied in 95% of the cases. The case study on microplastics demonstrates that enough information is provided in the restriction dossier to perform an essentiality assessment overall, but more information on concrete applications of the microplastics is needed in some cases. Similar observations can be made in the case of PFOA. Overall, this study suggests that it is not needed to drastically change the chemical regulations to implement the essential-use concept in the decision-making, but it would implicate that the industry would need to provide more technical information on the actual functions provided by a substance of concern if they wish to get a derogation for their use.

6.08.A Nano and Advanced Materials Safety: Research Progress, Industrial Applications and Regulation

6.08.A.T-01 Nano-Adsorbents for sustainable remediation: efficiency evaluation and fate after utilization

Nitin Kumar Khandelwal, *Indian Institute of Technology Roorkee, India*

Nano-adsorbents have emerged as efficient agents for mitigating environmental contamination, particularly in the removal of heavy metal cations and oxy-anions. While their efficacy in pollutant removal is well-established, questions surrounding their disposal and long-term environmental impact require careful consideration. This study delves into the intricate dynamics of diverse nanocomposites, examining their contaminant removal capacities, redox-transformation capabilities, and fate in simulated landfill conditions. Through a sequential leaching approach, the research sheds light on the nuanced interplay between nano-adsorbents and environmental matrices, emphasizing the importance of post-contaminant removal fate. The findings contribute valuable insights to the development of sustainable cleanup technologies by delineating disposal strategies that prioritize environmental resilience.

Notably, redox-active nanoparticles, characterized by strong contaminant binding, advocate for possible safe disposal practices. Conversely, weak binders like layered double hydroxides offer the potential for contaminant recovery and reuse. This comprehensive understanding of nano-adsorbent behaviors informs the development of environmentally conscious cleanup technologies, striking a balance between efficiency and the mitigation of long-term environmental risks. As we navigate the complexities of nano-adsorbent applications, these insights pave the way for resilient environmental management strategies in the face of escalating pollution challenges.

6.08.A.T-02 Nanofertiliser Use Can Reduce Volatilized N Emissions from Soil – Reducing the Pollution from Crop Production

Jessica Chadwick[1]*, Sami Ullah*[2] *and Iseult Lynch*[3]*, (1)GEES, University of Birmingham, United Kingdom, (2)University of Birmingham, United Kingdom, (3)School of Geography, Earth and Environmental Sciences, University of Birmingham, United Kingdom*

Nanomaterial usage in agriculture offers several possibilities for enhancing a crop's yield, quality, and resilience to stress. A key challenge in current agricultural practice is that excess Nitrogen (fertiliser) application causes water pollution through runoff and leaching and contributes to air pollution through production of the (greenhouse) gas N_2O and volatile NH_3. Using nanomaterials in conjunction with synthetic nitrogen fertiliser, may enable more targeted delivery of nutrients to plants. This increase in nutrient uptake efficiency would minimise reactive nitrogen (Nr) losses leading to more sustainable agriculture. This body of work screened a wide variety of engineered nanomaterials for their efficacy in seed priming before taking promising candidates forward for study in soil-based application as nanofertilisers. From the initial screening list of 40 nanomaterials of various composition, a small selection of zeolites and metal-oxide nanomaterials were delivered to lettuce via soil with leachate and volatilized N gases sampled over the 8-week growing period. In addition, after destructive sampling of the lettuces, nanomaterial endpoints of agglomeration, dissolution, and chemical changes to the constituent elements (speciation) were monitored. Initial results indicate that the metal-oxide $Ce_{0.75}Zr_{0.25}O_2$ co-application with a half-dose of NPK (nitrogen, phosphorus and potassium) fertiliser was able to decrease volatilisation of N_2O and NH_3 gases compared to conventional NPK fertilisation, with similar decreases also seen for ammonium, phosphate and nitrate concentrations in the leachate. This work posits that nanomaterial co-application with reduced amounts of synthetic nitrogen fertiliser could be a viable technique in the future of agriculture to maintain yields of lettuce while actively reducing Nr emissions from agricultural soil. Different nanomaterials however have widely differing impacts on different crops (e.g., wheat responded differently), with differences in nutrient use efficiency and agricultural pollution impacted by a range of nanomaterial and soil parameters, indicating that careful nanomaterial design and testing is necessary.

6.08.A.T-03 Integrated Approaches for Environmental Safety Assessment of Nanoforms Embedded in Paint Fragments – SAbyNA Project

Patricia Solorzano[1]*, Melissa Diogo Faria*[2]*, Rubén Francisco Martínez López*[3]*, Jerome Rose*[4]*, Mélanie Auffan*[5] *and Socorro Vázquez-Campos*[6]*, (1)Hehs, Leitat, Spain, (2)Environmental Toxicology, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (3)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (4)CNRS, France, (5)CEREGE, France, (6)Leitat Technological Center, Spain*

Implementing nanotechnology in new products is occurring rapidly, contributing to new and improved products in many sectors including energy, health, safety, etc. Ensuring that these innovative nano-enabled products (NEPs) are safe and sustainable for human and environmental health has become a priority for the European Commission and a challenge for industries to comply with the recommended frameworks. In this sense, the aim of SAbyNA project (H2020-NMBP-15-2020) is to generate a digital Guidance Platform to facilitate the development of Safe and Sustainable-by-Design (SSbD) nano-enabled products, encouraging industrial companies to implement the SSbD Framework proposed by the EC. This project has evaluated several case studies from different industrial sectors, including the paint industry, which has included different nanoforms (NFs) in their formulations in recent years. The specific structural characteristics of the NFs such as their size, shape, and greater surface area allow modifying the properties of the newest generation of paints enhancing their quality, durability, performance, etc.

A paint case study in SAbyNA has been the focus of environmental persistence and toxicity evaluation in this study: mixed metal oxide nanoparticles (MMO NP) embedded in polymeric paint matrixes characterized and shipped by CEREGE and ALLIOS collaborators.

This study has addressed the persistence (biodegradation evaluation) and the (eco)toxicological hazard profile of the NEP in the aquatic environment, via the integration of different standardised methods, such as: i) Microbial respiration inhibition: based on the OECD 209 merged with the OECD 301F and the ISO 14851:2019 and ii) algae acute aquatic toxicity assay, OECD 201, studies performed before and after biodegradation. These studies showed that the addition of NFs (MMOs) into paints leads to an improvement of the (eco)toxicological profile of the paints studied, while also slightly reducing their persistence.

Acknowledgements – This work was developed under the "Simple, robust and cost-effective approaches to guide industry in the development of safer nanomaterials and nano-enabled products (SAbyNA)" project, financed by the Horizon 2020 EU's research and innovation funding program.

6.08.A.T-04 Safe and sustainable by design approach for the safety assessment of advanced bio-based nanomaterials used for the production of polyurethane foams

Rossella Daniela Bengalli[1], *Maurizio Gualtieri*[1], *Andrea Doldi*[1], *Cinzia Bragato*[1], *Luca Ferrero*[1] *and Paride Mantecca*[2], *(1)Earth and Environmental Sciences, POLARIS Research Center, University of Milano-Bicocca, Italy, (2)Department of Earth and Environmental Sciences, POLARIS Research Center, University of Milano-Bicocca, Italy*

Bio-based nanomaterials (B-NMs), derived from biomass and renewable resources, may be applied in the production of polyurethane (PUR) foams used in construction, automotive, and other industries to confer them special properties (e.g. antibacterial, flame retardant). However, the human and environmental safety associated to the exposure to these new advanced materials (AdMa) and resulting nano-enabled products (NEPs), is poorly investigated. Here we report a safe and sustainable by design (SSbD) approach that has been adopted for the safety evaluation of AdMA and NEPs throughout their life cycle. The framework is based on consecutive steps. First, field monitoring campaigns are performed at different pilot lines (PLs) for the production of PUR foams. Aerosol emissions are characterized by using different particle counters and smart sensors. The particle number concentration (PNC) and lung deposited surface area (LDSA) values are measured along the different steps of the production processes. Secondly, the NPs hazard assessment are performed, with *in vitro* models representative of the lung and immune system (co-culture of A549 cells + THP-1-derived macrophages), also cultivated at the air-liquid interface (ALI). Then, key events related to cytotoxicity, oxidative stress and inflammatory responses, according to an adverse outcome pathways (AOPs) oriented strategy, are measured. In parallel, the safety of B-NMs on the environment are evaluated through the fish acute toxicity test (FET) using zebrafish. Finally, leaching test on fresh and artificially aged PUR foams will be performed, characterized and tested by FET to retrieve safety data on the use phase and end-of-life of the new materials. Data from monitoring campaigns showed that the PNC values vary depending on the production processes (e.g. mixing, foaming, cutting) and PL technical characteristics. Results from *in vitro* models, showed that B-NMs are safe considering the endpoints analysed. Also, the B-NMs did not affect the development of the embryos, in terms of mortality and malformation rates. The proposed SSbD framework, through exposure and hazard assessment at the different stages of NPs and NEPs life cycle, contributes to obtain a more realistic interpretation of the risk of innovative AdMa and provides new awareness for defining better decision criteria that will support a more rapid intake of novel safe(r) NEPs in the market. The work was supported by EU-H2020 project BIOMAT, GA n. 953270.

6.08.B Nano and Advanced Materials Safety: Research Progress, Industrial Applications and Regulation

6.08.B.T-01 Inhalation hazard of multicomponent Advanced Materials: a case of successful confirmation of New Approach Methodologies (NAMs) by in vivo data

Veronica Di Battista[1,2], *Agnieszka Gajewicz-Skretna*[3], *Svenja Seiffert*[1], *Lan Ma-Hock*[1], *Lars Skjolding*[2], *Anders Baun*[2] *and Wendel Wohlleben, Dr.*[1], *(1)BASF SE, Germany, (2)DTU Sustain, Technical University of Denmark (DTU), Denmark, (3)Faculty of Chemistry, University of Gdansk, Poland*

Oxide-based perovskites designed for automotive catalysts contain multiple metal elements whose presence is crucial to achieve the targeted performance. Due to their multicomponent character and their enhanced functionality, they are regarded as Advanced Materials.

They are highly stable in the exhaust operating conditions; however, little is known about their stability in physiological conditions. As some of the metallic components are hazardous to humans and the environment, perovskite's benefits in cleaner air must be balanced with their safety.

Within HARMLESS (GA no. 953183), for the risk screening at earlier design stages, we rely predominantly on Novel Approach Methodologies (NAMs) due to ethical reasons, speed, and parallel testing of several versions. Here we selected i*n chemico* Novel Approach Methodologies (NAMs) from the Integrated Approaches toward Testing and Assessment (IATAs) for inhalation: bio dissolution in lung simulant fluids and surface reactivity assay.

We found that the composition and surface properties of six different Lanthanum-based perovskites compromise their stability in the physiological conditions of the lung, influencing the oxidative damage of the particles and the bioaccessibility of leaching metals. At pH 7.5 and 4.5 simulant fluids, both relevant for pulmonary clearance, dissolution depended minimally on the Palladium or Platinum doping but rather on the content of Nickel and Cobalt. We observe consistent biotransformation of the perovskite materials in acidic pH, where the leached Lanthanum ions, but not other metals, re-speciated into lanthanum phosphate nanoparticles, increasing the observed oxidative damage in a non-synergistic way.

The *in chemico* results were confirmed by the measured multi-component clearance from lungs into urine after *in vivo* inhalation by male Wistar rats, and were benchmarked against well characterized spinels materials for ranking purposes. Our case study showcases how *in chemico* NAMs are suitable for grouping and read across of multicomponent Advanced Materials, being valuable tools for early stages hazard screening, in a Safe and Sustainable by Design (SSbD) context.

6.08.B.T-02 Acute and Subacute Toxicity of Micro- and Nanoplastics from 3D printing: a Repeated 28-day In Vitro Approach Using an Advanced Human Bronchial Epithelial Model

Itziar Polanco[1], Juliana Carrillo[1], Adrián García-Salvador[1], Mari Venäläinen[2], Jussi Lyyränen[2], Satu Suhonen[2], Nienke Ruijter[3], Ana Candalija[4], Apostolos Salmatonidis[4], Marie Carriere[5], Morgan Lofty[6], Matthew Boyles[7], Davide Lotti[8], Jesús Guzmán-Mínguez[9], José F. Fernández[10], Flemming R Cassee[3], Julia Catalán[2], Isabel Rodríguez-Llopis[1], Socorro Vázquez-Campos[4], Felipe Goñi de Cerio[11] and ***Alberto Katsumiti[12]****, (1)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (2)Finnish Institute of Occupational Health, Finland, (3)National Institute for Public Health and the Environment (RIVM), Netherlands, (4)Leitat Technological Center, Spain, (5)Univ. Grenoble Grenoble Alpes, CEA, CNRS, IRIG-SyMMES, CIBEST, France, (6)Institute of Occupational Medicine (IOM), United Kingdom, (7)Edinburgh Napier University, United Kingdom, (8)LATI Industria Termoplastici S.p.A., Italy, (9)Instituto de Cerámica y Vidrio, ICV-CSIC, Spain, (10)Icv, Spanish National Research Council (CSIC), Spain, (11)Biotechnology, GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (12)GAIKER Technology Centre, Spain*

It has been shown that the 3D printing process may release volatile organic compounds (VOCs) and micro- and nanoplastics (MNPs). Once inhaled, its deposition in the respiratory system may induce acute, subacute and chronic adverse effects. As animal models not always provide relevant human toxicity data, New Approach Methodologies (NAMs) based on advanced in vitro models are highly reccomended. Among these advanced in vitro models, primary human bronchial epithelial models (PBEC, i.e. MucilAirÔ) are promising models. The objective was to evaluate the potential acute and subacute effects of MNPs release from 3D printing on the respiratory system. We tested the acute and subacute toxicity of polycarbonate (PC) MNPs (< 5 µm) with and without single wall carbon nanotubes (SWCNT) and polypropylene (PP) MNPs (< 5 µm) with and without silver nanoparticles (Ag) on the in vitro PBEC model. PBEC inserts were exposed to 0.1, 10 and 1000 µg/mL of all MNPs for 4h per day up to 28 days. Cytotoxicty, cell barrier integrity and inflammatory response were monitored at time 0 and 4h, and at days 7, 14, 21 and 28. Cell internalisation, genotoxicity, and oxidative damage were measured at day 28. According to the particle size distribution analysis based on number size distribution performed at the TEM, all samples contained few particles > 1 µm (1-13%), and the majority varying from 0.25 to 0.30 µm. EDX analysis showed that in PP+Ag sample, a low percentage of Ag nanoparticles (0.425 wt.%) was detected, whereas PC+SWCNTs sample contained 0.052 wt.% SWCNT. Based on the in vitro results, acute exposures to MNPs (4h) decresed the barrier integrity, being the effects more evident 7 days after of exposure. In the same line, 4h of exposure increased the cytotoxicity, but higher effects were seen 7 days after. Similar toxic potency was observed comparing PC and PP, and no differences were found between PC and PC+SWCNT, whereas PP+Ag was more toxic than PP alone. Preliminary results indicate that repeated short-term exposures (4h) to MNPs with and without nanomaterials induce acute but mainly subacute effects (up to 7 days). Therefore, PBEC is a sensitive in vitro tool able to discern differences in particle toxicity in the presence and absence of nanomaterials, thus being useful for inhalation risk assessment of particulate materials. This work was supported by the EU H2020 Project SAbyNA (GA no. 862419).

6.08.B.T-03 Case studies assessing suitability of in silico modelling tools and read-across approaches for nanomaterial hazard assessment

Laurence Deydier Stephan[1]*, Marianne Matzke[2], Andrea Richarz[1], Dimitra-Danai Varsou[3], Antreas Afantitis[4] and Maria Antoniou[5], (1)European Chemicals Agency (ECHA), Finland, (2)European Chemicals Agency (ECHA), Helsinki, Finland, (3)NovaMechanics MIKE, Greece, (4)Department of ChemoInformatics, NovaMechanics Ltd., Cyprus, (5)Department of ChemoInformatics, NovaMechanics MIKE, Greece*

The study presented here gives insight on available frameworks and state-of-the-art developments for read-across and other *in silico* approaches, which can be alternatives to conventional nanomaterials (NMs) hazard and risk assessments. During this study a systematic literature review was carried out to identify the available models and tools for the computational hazard and risk assessment of NMs.

This review was followed by an analysis to map the aspects of models that are fully implemented (model development, validation, and documentation), as well as identifying potential data gaps and flaws which could be improved. Next, expert opinions were collected and incorporated in the findings to present a complete and integrated view of the nanoinformatics field. Finally, the applicability, the strengths and limitations of the models were demonstrated through the development of three case studies using as many of the identified tools as possible.

Based on the collected results, we conclude that the nanoinformatics field is moving forward, as there are already available reliable models and the infrastructure needed to implement them as user-friendly tools (e.g., supported by different EU-funded projects). Nonetheless, there is room for improvement regarding the inclusion of information on the applicability domain of the models within the tools and the availability of training material for each tool as illustrated by the case studies. Confidence of the relevant stakeholders in the developed models is still low, mainly due to the limited modelling information from the developers, the lack of sufficient data to provide the correct applicability domain, and the lack of validation with conventional experimental methods. Building trust in the use of appropriately reported and validated computational methods that are also scientifically supported, is therefore the next step towards *in silico* approaches gaining widespread public and regulatory acceptance as alternatives to conventional hazard and risk assessments.

6.08.B.T-04 Implementation of Grouping Strategies for Nanoecotoxicology

Andrew Barrick[1], *Judit Kalman*[2], *Nicolas Manier*[3], *Amelie Chatel*[4], *Maria Luisa Fernandez-Cruz*[5] *and José M. Navas*[6], *(1)Auburn University, (2)Rey Juan Carlos University, Spain, (3)Institut National de l'Environnement Industriel et des Risques (INERIS), France, (4)Université Catholique de l'Ouest, France, (5)INIA - National Institute for Agricultural and Food Research and Technology, Spain, (6)Department of Environment and Agronomy, Institute for Agricultural and Food Research and Technology, Spanish National Research Council (INIA-CSIC), Spain*

Nanoecotoxicology focuses on the hypothesis that alterations to the nanoform can influence ecotoxicological potential. It has also been hypothesized the pristine chemical properties can be used to predict ecotoxicity. Grouping and read-across approaches have been proposed to streamline regulatory compliance, as assessing novel products on a case-by-case basis is not effective governance. Predicting risks for novel materials, however, requires access to historical data.

The aim of this work is to highlight lessons learned from the NanoReg2 project and to emphasize the need for FAIRification of nanomaterial research to successfully implement grouping approaches. The research focuses on representative industrial nanomaterials available at the European Commission's Joint Research Centre's Nano Repository and nanomaterials from industrial partners associated with the NanoReg2 project. Fish cell lines, mussel hemocytes, algae, and *Daphnia magna* were all exposed to the same nanomaterials, whose suspensions were prepared using the same protocol, to establish a comprehensive dataset with comparability among nanomaterials.

Modelling through multiple correspondence analysis (MCA) assessed the relationship between pristine physicochemical properties, system dependent physicochemical properties and ecotoxicological responses. The presented work establishes one of the most robust data sets for analyzing the relationship between physicochemical properties and ecotoxicological endpoints. The model focused on two key questions: 1) the relationship between biological endpoints and the description of ecotoxicity and, 2) how key physicochemical properties describe ecotoxicity. Results are preliminary; however, the MCA model demonstrated that there are clear separations of data based on the ecotoxicological test conducted.

This research is a representative first step in exploring the hypothesis that pristine physicochemical properties can be used in read-across approaches to predict ecotoxicity of untested nanomaterials with similar physicochemical properties. Access to high quality data with well characterized properities is crucial for the development of predictive modelling. One of the major limitations in the analysis is that system dependent properties of nanomaterials play a major role in the discrimination between nanomaterials. This challenges regulatory paradigms as testing environment will lead to a different behavioral profiles.

6.08.P Nano and Advanced Materials Safety: Research Progress, Industrial Applications and Regulation

6.08.P-Th533 Assessment of the Advanced Material Molybdenum Disulfide (MoS2) and Layered Double Hydroxides (LDHs) Nanosheets Effects in vitro Using Zebrafish Liver Cells

Anastasia Georgantzopoulou[1], *Sebastian Kuehr*[1], *Patricia Carvalho*[2], *Tania Gomes*[1], *Samantha Eslava Martins, PhD*[3], *Sukdeb Pal*[4], *Pravin Naoghare*[4] *and Ailbhe Macken*[1], *(1)Norwegian Institute for Water Research (NIVA), Norway, (2)SINTEF, Norway, (3)Norwegian Institute for Water Research (NIVA), Oslo, Norway, (4)National Environmental Engineering Research Institute (CSIR), India*

Among the emerging advanced materials, layered nanostructures such as molybdenum disulfide (MoS_2) and layered double hydroxide (LDHs) nanosheets are increasingly being applied in several fields including environmental remediation. During the production, use and disposal, these material will reach the environment. However, their potential hazard is poorly understood. Due to the continuous development of novel nanomaterials (NM), their diversity in composition and structure and subsequent needs for hazard assessment, effective strategies to assess their environmental impacts are needed. The use of in *vitro* models can contribute to increased understanding of molecular and cellular mechanisms in a high-throughput and cost-effective manner and can address the challenge of the plethora of NM continuously being produced. Fish cell lines can be versatile tools as non animal methods (NAMs) to assess the effects of NM, among other contaminants, in the aquatic environment. The aim of the study was to elucidate the behaviour, potential biocompatibility and effects of the novel layered nanostructures MoS_2 and Mg-Al-LDH *in vitro* using the zebrafish liver cell line ZFL and evaluate its suitability in nanotoxicology studies.

In the first set of experiments, the cells were exposed to increasing concentrations of MoS_2 and LDH for 24-48h. The effects on metabolic activity, membrane integrity, lysosomal integrity and reactive oxygen species (ROS) formation were assessed. NM interference controls were included to assess the potential NM interference with the respective assays. The NM in the stock dispersions and exposure media were characterised with transmission electron microscopy (TEM) and dynamic light scattering (DLS). The first results show no adverse effects of the LDH NM *in vitro* despite the high exposure concentrations used which presents their potential as a novel material for environmental applications. A decrease in metabolic activity and membrane integrity was observed upon exposure to MoS_2 nanosheets, albeit at high concentrations. The formation of ROS appeared to be the most sensitive endpoint in the ZFL cell line. Ongoing work focuses on gene expression and NM uptake studies *in vitro* as well as comparing *in vitro* with *in vivo* responses using the zebrafish embryo test.

Financial support was received from the Research Council of Norway and the Ministry of Science and Technology, Government of India (project SCANNER, 299261).

6.08.P-Th534 Development of a Human Hazard Strategy for Assessment of Nanoforms and Nano-Enabled Products in the SAbyNA Guidance Platform

Ana Candalija[1]*, Nienke Ruijter*[2]*, Flemming R Cassee*[2]*, Itziar Polanco*[3]*, Alberto Katsumiti*[4]*, Isabel Rodríguez-Llopis*[3]*, Julia Catalán*[5]*, Polly McLean*[6]*, Matthew Boyles*[6,7]*, Morgan Lofty*[6]*, Jessica Marshall*[6]*, Marie Carriere*[8]*, Ralph Vanhauten*[9]*, Lion Traas*[9]*, Hedwig Braakhuis*[2,10]*, Cristina Fabregas-Ordoñez*[1]*, Virginia Cazzagon*[1] *and Socorro Vázquez-Campos*[1]*, (1)Leitat Technological Center, Spain, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (4)GAIKER Technology Centre, Spain, (5)Finnish Institute of Occupational Health, Finland, (6)Institute of Occupational Medicine (IOM), United Kingdom, (7)Edinburgh Napier University, United Kingdom, (8)Univ. Grenoble Grenoble Alpes, CEA, CNRS, IRIG-SyMMES, CIBEST, France, (9)ThinkWorks B.V., Netherlands, (10)TNO, Netherlands*

The SAbyNA Guidance platform is an integrative and interactive web-based service that gives the industry support towards the development of safer nanoforms (NFs) and nano-enabled products (NEPs) over their whole life cycle, considering hazard, exposure, functionality, Life Cycle Assessment, and costs. The hazard assessment is a critical part of the platform which aim is to identify potential hazards of a NF or NEP at an early stage of product development, preventing the user from large investments in money or time and guiding them towards Safe(r) by Design interventions.

The human hazard strategy developed within the platform starts with a screening phase requiring information on chemical composition, physicochemical properties, and likely exposure routes. CLP classification of the NFs is considered, and preventive flags are raised if Substances of Very High Concern or harmful substances are detected. For a more thorough assessment, the user is guided towards a hazard strategy tailored for inhalation and dermal exposure, considering several toxicity endpoints in a hierarchical manner: dissolution rate in physiological fluids, cytotoxicity, genotoxicity, reactive oxygen species generation, and inflammation. Additional endpoints as skin irritation and absorption, and barrier integrity are considered for dermal exposure. Specific guidelines on data retrieval from databases and on data generation using an in vitro testing strategy are provided. Toxicity tests were selected and optimised for their efficiency in use and applicability to NFs considering relevant use conditions and end-of-life. Meaningful thresholds of effects were set up and the results for the different endpoints were combined for final outputs on the NFs potential hazard. The applicability of the strategy was verified in two case studies for two different industrial sectors, paints and 3D printing. To validate its predictive capacity, the outputs of the hazard strategy were compared to existing in vivo hazard data or data obtained using higher tier toxicity testing.

The resulting hazard assessment strategy provides the industry with useful guidelines and tools on data gathering and a set of easy-to-use, robust and cost-effective testing approaches for the prediction of potential NFs hazards. This early warning system supports the implementation of safe-and-sustainable-by-design on NFs and NEPs and is compatible with early stages of product development and along the whole material's life cycle.

6.08.P-Th535 20 years of European nanomaterial legislation – closing the final gaps

Maria Bille Nielsen[1]*, Lars Skjolding*[2]*, Anders Baun*[2] *and Steffen Foss Hansen*[1]*, (1)Technical University of Denmark (DTU), Denmark, (2)DTU Sustain, Technical University of Denmark (DTU), Denmark*

Developments within nanotechnology have increased rapidly the past decades. In 2004 two highly influental reports shed, as some of the first, light on the potential negative societal implications of nanotechnology. The reports were published by the Royal Society & the Royal Academy of Engineering and the European Commission, respectively. Both reports provided a list of recommendations on how to address the risks of nanomaterials and the European Commission introdcued the so-callled "incremental approach" – establishing that existing legislations should be revised, where needed, to cover nanomaterials. In this study we sat out to investigate how the recommendations from the two reports from 2004 have been addressed, now almost 20 years after they were presented, and how legislations have been amended to account for nanomaterials. Furthermore, we map out remaining challenges related to nanomaterial legislation and future steps to overcome these. In order to do this, we analyzed essential European legislations relevant to nanomaterials in accordance to e.g. definitions, information requirements, decision support tools, risk management and strengths and weaknesses. Status on each recommendation in the two reports from 2004 was assessed as met to either a high, medium or low degree. Status on the recommendations were evaluated via targeted literature searches at Web of Science, screening of legislations/test guidelines/guidance documents and expert judgement. We found that 13 out of 29 recommendations have been met to a high degree, 14 out of 29 have been met to a medium degree and 2 out of 29 have been met to a low degree. These findings indicate great achievements within nanosafety and nanomaterial legislation. Nevertheless, as some concerns are still left partly or fully unsolved, further efforts are needed. In particular, future efforts should be prioritised to ensure use of a uniform nanomaterial definition, further development of standardised risk assessment and characterization methods for nanomaterials and further attempts to eliminate/minimise unintentional nanomaterial emissions. In adidition, we recommend to strengthen enforcement and implementation of existing nano-specific requirements, as well as revising legislations that do not consider nanomaterials, where needed.

6.08.P-Th536 Ecotoxicity assessment of "smart" coatings for marine corrosion protection

Patricia V. Silva[1]*,* ***Roberto Martins***[2]*, Fernando Perina*[2]*, Mariana Bruni Marques do Prado e Silva*[3]*, Joana Figueiredo*[4]*, Rodrigo Montes*[1]*, João Tedim*[1] *and Susana Loureiro*[5]*, (1)CICECO - Aveiro Institute of Materials & Department of Materials*

and Ceramic Engineering, University of Aveiro, Portugal, (2)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (3)São Paulo State University (UNESP), Brazil, (4)Department of Biology, University of Aveiro, Portugal, (5)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal
Corrosion is one of the greatest challenges facing modern society. It affects a wide range of sectors, from construction to energy production, resulting in substantial financial burdens, safety risks, and environmental impacts. Protective coatings are the most used solution for preventing corrosion; however, most effective anti-corrosion methods lack environmental friendliness. Industry is channeling efforts to find efficient, effective, and eco-friendly solutions to meet the UN Sustainable Development Goals. Nanotechnology plays a pivotal role in finding sustainable approaches to combat corrosion. The immobilization of active ingredients in engineered nanomaterials (ENMs) such as layered double hydroxides (LDHs) or silica mesoporous nanocapsules (SiNC) are promising solutions as they prevent the direct interaction of active compounds with other coating components and allow their controlled release under specific conditions (*e.g.*, presence of chlorides), reducing application rates and environmental releases. Despite LDHs/SiNC being deemed eco-friendly ENMs, their ecotoxicity must be evaluated to ensure environmental safety. The aim of this study was to evaluate the ecotoxicity of "smart" anti-corrosion marine coatings to infer their eco-friendly potential. Coatings with different additives incorporated were tested: zinc aluminium (ZnAl) LDHs stabilised with nitrite, ZnAl LDHs with hexacyanoferrate, ZnAl LDHs with vanadate, and SiNC with phenolphthalein. The experimental design consisted of microscope slides with applied coatings and placed in vials containing artificial seawater. One set of vials had slides with induced damage, another set had intact slides. The test lasted 28 days, and water was collected at different times for chemical analysis and ecotoxicity testing with three marine species: *Phaeodactylum tricornutum* (diatom), *Tetraselmis chuii* (green microalgae) and *Brachionus plicatilis* (rotifer), according to standard test guidelines. Results revealed very low to no toxicity of all coatings to the species, with *T. chuii* being the most sensitive one, while no toxicity was observed in *P. tricornutum*. These results demonstrate the eco-friendly potential of these "smart" coatings and support the environmentally safe application of tested functional nanomaterials in marine anti-corrosion paints. This work highlights the advantages of collaboration between academia and industry for effective implementations of Safe and Sustainable by Design strategies.

6.08.P-Th537 Safe and Sustainable by Design (SSbD) strategies for advanced manufactured materials: a case study on perovskites for catalysis

Veronica Di Battista[1,2]*, Susan Dekkers*[3]*, Eugene Van Someren*[3]*, Veronique Adam DR*[4]*, Blanca Suarez Merino*[4]*, Anders Baun*[2] *and Wendel Wohlleben, Dr.*[1]*, (1)BASF SE, Germany, (2)DTU Sustain, Technical University of Denmark (DTU), Denmark, (3)TNO, Netherlands, (4)TEMAS Solutions GmbH, Switzerland*
In the EU funded project HARMLESS (GA no. 953183), we develop Safe and Sustainable by Design (SSbD) strategies with focus on nano-enabled Advanced manufactured Materials (AdMa); we aim to guide companies in making decisions during AdMa design stages, when options are many and budget is low.

Previous experience and stakeholder analysis is used to integrate existing and newly generated data & models into a user-friendly Decision Support System (DSS). In this platform, we use predictive tools, non-animal testing (i.e., Novel Approach Methodologies(NAMs)) guided by Integrated Approaches toward Testing and Assessment (IATAs) and established OECD guideline protocols, for assessing safety and sustainability aspects at each innovation stage, named ideation, lab phase and pilot phase.

We tested the DSS infrastructure for six SSbD versions of perovskite materials, component in three-way catalysts, located at the lab phase of the innovation stages. These materials incorporate different amounts of Lanthanum, Cobalt, and Nickel with doping amount of Platinum and Palladium to enhance their performance as exhaust cleaning catalyst, providing cleaner air.

The DSS interface provides specific advice at each innovation stage, addressing human safety aspects (occupational and for consumers), environmental safety, sustainability during the life cycle and AdMa performance. Safety comprises both hazard and exposure aspects. The proposed interface aligns with the latest SSbD draft framework from the Joint Research Centre (JRC) of the European Commission. However, our assessment is not stepwise but remains flexible in order to be more generally applicable to nano-enabled materials that do not consist or contain of particles. The DSS provides advice and recommendations to the user, to find the best balance of performance, safety, and sustainability.

Our study shows that among the six SSbD versions of the perovskites in analysis, the one with the best compromise between all aspects, is the one consisting of 8% in weight of Nickel and Palladium doping (LaCoNi_Pd).

6.08.P-Th538 Multispecies ecotoxicity assessment for "safe-by-design" of metal nanoforms for paints – a case study of SAbyNA project

Melissa Diogo Faria[1]*, Ruben Martinez*[2]*,* ***Patricia Solorzano***[2]*, Mélanie Auffan*[3]*, Maria Rivero*[2]*, Armand Masion*[3] *and Socorro Vázquez-Campos*[4]*, (1)Environmental Chemistry, Leitat Technological Center, Spain, (2)Hehs, Leitat, Spain, (3)CEREGE, France, (4)Leitat Technological Center, Spain*
The "safe by design" (SbD) approach is a proactive strategy used in various fields, including the paint industry, to integrate safety considerations into the design and development of products from the outset. In the context of paints, adopting an SbD

approach involves considering the potential hazards associated with the components and manufacturing processes, and taking steps to minimize or eliminate these hazards at the earliest stages of product development.

The SAbyNA project (H2020-NMBP-15-2020; https://www.sabyna.eu/) was developed with the main aim to produce a Guidance Platform for the industries to eventually implement safe-by-design more efficiently and cost-effectively. Within this project, several case studies from different industrial sectors have been evaluated, including the paint industry, which has included different nanoforms (NFs) in their formulations in recent years. The specific structural characteristics of the NFs such as their size, shape, and greater surface area allow modifying the properties of the newest generation of paints (NEPs: nano-enabled products) enhancing their quality, durability, functionalization, etc. However, SbD must also consider safety aspects related to the environmental compartment at the innovation stage to support decision-making. Zinc-based mixed metal oxide (MMO) nanoparticles (size 1.85 – 7.06 nm) were found to have more efficient functionality for the formulation of outdoor paintings. Three Zn/Al-based nano-MMO were synthesized at different annealing temperatures (1000, 800, and 600°C) and coated with an organic ligand (_C). Previously performed functionality assessments, selected coated nano-MMO synthesized at 1000°C (nano-MMO 1000_C) as most efficient for solar reflectance. To test which NF could be the safest alternative for the environment, an ecotoxicity screening was performed using *Daphnia magna* and microalgae *Raphidocelis subcapitata* toxicity assays. Results showed the micro algae to be more sensitive than daphnia. Nano-MMO 1000 with and without coating presented similar toxicity, therefore, the organic coating did not affect the toxicity of nano-MMO 1000. The remaining NFs were not found toxic. In addition, algae growth inhibitoin was found correlated to presistant prevalence of large aggregates of nano particles (~300 to 460 nm) in the exposure medium.

6.08.P-Th539 Ecotoxicological Assessment of Graphene Containing Commercial Product in Aquatic Ecosystems: From Single Species Approaches to Aquatic Microcosms.
Florian Chapeau[1]*, Xuan Van Nguyen*[2]*, Julie De Oliveira*[3]*, Boris Eyheraguibel*[4]*, Maïalen Barret*[2]*, Eric Pinelli*[2]*, Emmanuel Flahaut*[5]*, Laury Gauthier*[3]*, Florence Mouchet*[2] *and Lauris Evariste*[3]*, (1)University of Toulouse III - Paul Sabatier, France, (2)UMR5245 CNRS-UT3-INPT Laboratoire Ecologie Fonctionnelle et Environnement, France, (3)UMR5245 CNRS-UT3-INPT laboratoire Ecologie Fonctionnelle et Environnement, France, (4)Puy de dome, Institut de Chimie de Clermont-Ferrand - UMR 6296, France, (5)CIRIMAT UMR CNRS 5085 UPS INPT, France*
Graphene-based nanomaterials (GBMs) are garnering increasing global attention due to their unique properties. However, this rapid expansion raises concerns about potential environmental risks associated with their environmental dissemination occuring throughout their life cycle. Although ecotoxicological studies have been conducted on raw materials, commercial products are overlook yet. The objective of this research is to assess the toxicity towards aquatic ecosystems of a commercial ink composed of few-layer graphene (FLG), dispersed with sodium deoxycholate (SDC) as dispersant. Standardized single-species tests were conducted on organisms such as algae (*R. subcapitata*), crustaceans (*D. magna*) and amphibians (*X. laevis*). Additionally, experiments were carried out using microcosms. The systems were composed of natural biofilms and chironomids (*C. riparius*) as primary consumers. The metabolic state and diversity of biofilms were monitored, along with the growth and emergence dynamics of chironomids. At environmentally relevant concentrations (0.1 mg/L), both the commercial formulation and SDC alone induced disturbances in microbial communities, suggesting a potential imbalance in the ecological functions performed by these taxa. Furthermore, a decrase in chironomid growth was observed at the larval stage for the commercial product and dispersant, while the effects were maintained in adults only exposed to SDC alone. Disturbances were also noted in sex ratios at emergence, thereby possibly threatening the species' life history traits and survival under natural conditions. Overall, the results from both single-species tests and microcosms underscore a strong effect of the dispersant on the toxicity of the evaluated product, with a mitigation of SDC toxic potential through its interaction with FLG. This study provides a realistic assessment of FLG toxicity through a commercial formulation under environmental conditions.
Keywords: Nanomaterials, Aquatic ecotoxicology, Microcosm

6.08.P-Th540 Regulatory testing of fate (OECD 29, 318) and aquatic toxicity (OECD 201, 211) on selected ZnO nanoforms
Karsten Schlich[1]*, Maria Vogt*[2]*, Kirsten Germing*[2]*, Boris Meisterjahn*[2]*, Nicola Schroeder*[2]*, Thorsten Klawonn*[2]*, Burkhard Knopf*[2]*, Christopher Cooper*[3]*, Frank Van Assche*[3]*, Christine Spirlet*[4] *and Howard Winbow*[3]*, (1)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (2)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (3)International Zinc Association, Belgium, (4)International Zinc Association*
In 2019, the REACH-registration dossier of ZnO underwent an evaluation by the European Chemicals Agency (ECHA) who decided on the need for data on fate and effect for all nanoforms present on the EU market. Until then, the registration dossier listed a large number of ecotoxicity studies, including fish, aquatic invertebrates, algae and aquatic plants. Based on these literature data it was determined that nanoforms of zinc oxide are less or equally toxic than the dissolved Zn^{2+} cations (i.e., the hypothesis being that zinc ions represent worst-case toxicity). However, all of the tested ZnO nanoforms covered by the literature featured no coating and most targeted primary particles sizes around 30 nm, meaning not all of the Zn nanoforms available in the EU market were covered. Furthermore, there were also a few studies in the dossier that contradicted the ion-worst-case-toxicity hypothesis. Therefore, the relative toxicity and fate of all available nanoforms remained unclear from ECHa's perspective.

A testing scheme was then specified in the evaluation decision to determine the specific effect and fate of the zinc oxide nanoforms. This testing scheme was divided into two steps. In the first step fate data regarding the particle transformation/dissolution (TD; OECD TG 29) and dispersion stability (OECD TG 318) was requested for 28 zinc oxide nanoforms, which represented the nanoforms available in the EU market at this time. The fate of the 28 nanoforms was screened to classify the particles in terms of their solubility and stability. The testing scheme stated that nanoforms should be grouped according: to the highest, lowest and a mean dissolved Zn^{2+} concentration (based on the results from the TD test, OECD TG 29); and to low dispersion stability, high dispersion stability and condition-depending dispersion stability (based on the results from the dispersion stability testing, OECD TG 318). In the second step, representative nanoforms from the aforementioned groups were chosen to investigate their chronic toxicity to aquatic organisms using the freshwater algal growth inhibition test (OECD TG 201) and *Daphnia magna* reproduction test (OECD TG 211) considering nano-specific test adaptations as available at the time, when the OECD GD 317 was not available yet.

The poster will present the outcomes of the fate and aquatic toxicity studies, the lessons learned from this process and recommendations for improvement of testing nanomaterials.

6.08.P-Th541 Ecotoxicity assessment of ENMs: harmonization of Daphnia standardized protocols.
Fábio Yu Chen[1], *Patricia V. Silva*[2], *Ana Lopes*[3] *and Susana Loureiro*[4], *(1)CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)CICECO & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal, (3)Department of Biology, CICECO and Department of Biology, University of Aveiro, Portugal, (4)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal*
Proper characterization and safety assessment of engineered nanomaterials (ENMs) face major challenges due to their unique traits (*e.g.*, small size, high surface area, potential for reactivity), making it difficult to assess and foresee the ecotoxicity of ENMs in biological systems.

Appropriate Test Guidelines (TGs) and Guidance Documents (GDs) are necessary to ensure that requirements are met for evaluating and approving ENMs, for example, in European regulations like REACH. TGs and GDs are crucial in establishing standardised dispersion procedures and ensuring compliance with conditions for assessing ENMs toxicity. Standardised dispersion methods address issues unique to unstable ENMs, such as preventing/reducing agglomeration/aggregation to improve material dispersion throughout testing. These standard approaches will also produce more consistent and reliable data across investigations. This work is within the scope of the NanoHarmony project, which supports the development of TGs and GDs for test methods tailored to ENMs deemed a regulatory priority. Challenges include accounting for water column ENMs' behaviour (*e.g.*, sedimentation and agglomeration) and various exposure methods, such as test vials of different materials or dimensions, which may result in different behaviours, exposures, and toxicity.

Taking this into consideration, the aim of this study was to 1) evaluate the efficiency of the dispersion of ZnO NM110, MWCNT NM400, Bentonite NM600, and TiO_2 NM104 ENMs according to the Enhanced Dispersion Method of The NanoReg protocol, 2) evaluate the ecotoxicity of these ENMs to *Daphnia magna*, following the Acute Immobilisation Test (OECD No. 202). For this, various exposure systems were used to compare the effects of using plastic vs. glass setups and test vials with different depths (petri dish vs. flask).

Overall, results demonstrated higher toxicity of *D. magna* exposed to ZnO NMs (LC50 from 1.63 mg/L to 2.36 mg/L), while no toxicity was found for Bentonite NMs (LC50 > 500 mg/L). Lower LC50 values were obtained in the plastic experimental setups compared to the glass one and with a reduced water column. This study provides valuable information and recommendations to aid in adapting standardising techniques and methodologies, such as the Acute Immobilisation Test of OECD No. 202, for assessing the hazard of ENMs in *D. magna.*

6.08.P-Th542 Developmental Effects of Cadmium Telluride Quantum Dot Nanoparticles in Zebrafish Embryo and Larva
Raveesha KP[1], *Gangadhar RS Mr*[1], *Mahesh As Mr*[1], *Kumar V Arun*[1], *S Nijil*[2], *Patil Prakash*[3], *Kini Sudarshan*[2] *and Pardhasaradhi Vasireddy Dr*[4], *(1)Ecotoxicology, Eurofins Advinus Agrosciences Services India Private Limited, India, (2)Nitte University Centre for Science Education & Research, Nitte (Deemed to be University), India, (3)Central Research Laboratory, K S Hegde Medical Academy, Nitte (Deemed to be University), India, (4)Environmental Fate, Metabolism and Residue, Eurofins Advinus Agrosciences Services India Private Limited, India*
Manufactured nanomaterials (MN) which have applications in biomedical devices, agriculture, and many industries pose serious concerns to the environment and human health. Cadmium-based materials are known to cause structural and functional alterations in fish, and are even highly toxic during embryonic and early larval developmental phases at low concentrations. Cadmium telluride quantum dot nanoparticles (CdTe QDs) are used in the manufacture of semiconductors that are being used in biomedical applications. Therefore, in the present investigation to understand the developmental effects, zebrafish embryos after fertilization were exposed to environmentally concerned CdTe QDs at the concentrations 0.156, 0.313, 0.625, 1.25,2.5 and 5.0 mg/L and observed up to 216-hours post fertilization (hpf).

The CdTe QDs used were water-dispersible, highly stable, 3-mercapto propionic acid-functionalized having uniform spherical form with an average size of 3.8 ± 0.2 nm. Each group had 20 zebrafish embryos exposed individually in a 24-well plate

having solutions prepared by directly mixing the CdTe QDs in water.
The study showed that complete hatching of eggs happened between 48 and 72 hpf and the hatching rate at control was 83% whereas CdTe QDs groups exhibited 55 to 75%.
Varying coagulated embryos were observed at 24 hpf across the groups including the control. No toxic signs and mortality of larva were observed in control and CdTe QDs groups of 0.156 and 0.313 mg/L. The first mortality of larva was observed at 5.0 mg/L at 72 hpf and the percent mortality at 216 hpf was 27.3, 30.8 and 64.9 % of hatched larvae at 1.25, 2.5, and 5.0 mg/L, respectively. Toxic signs first appeared around 96 hpf with scoliosis at 2.5 mg/L, and scoliosis and lordosis at 5.0 mg/L; overall toxic signs at 216 hpf were observed at 0.625, 1.25, 2.5, and 5.0 mg/L.
In conclusion, CdTe QD nanoparticles were found toxic to zebrafish embryos even at 0.156 mg/L at 24 hpf, causes detrimental effects to hatched larvae at 0.625 mg/L appearing at 168 hpf but with no mortality till 216 hpf and induces toxic signs and mortality at 1.25, 2.5 and 5.0 mg/L under tested conditions.

6.08.P-Th543 Assessing Pre-guideline Literature Data on Bioaccumulation of CeO2 Nanoparticles in a REACH Context – Conclusions, Identified Issues, and Recommendations for Standardised Testing

Nele Deleebeeck*, Andreas Fettweis, Laura Lefèvre and Michiel Claessens, Arcadis, Belgium*

In view of the update of the REACH dossier for CeO2, the available literature on bioaccumulation of CeO2 nanoparticles in aquatic and terrestrial organisms was evaluated. In these studies, the uptake, bioconcentration, bioaccumulation, and trophic transfer was typically assessed based on measurements of cerium in the organisms and/or the exposure medium. These studies indicate poor bioconcentration/bioaccumulation in both aquatic and terrestrial organisms, as well as trophic dilution. Although there are currently no standard testing guidelines or recommendations for investigating bioaccumulation of nanomaterials, it is obvious that the uptake and bioaccumulation of the CeO2 nanoparticles as such should be investigated as well next to the total, Ce-based uptake and bioaccumulation. The few studies that addressed this in their experimental setup used various techniques to identify nanoparticles in the organisms studied. However, in most studies, no quantification is done and therefore no bioaccumulation factors are derived or can be derived from the observations. In this poster, we will inform on the conclusions that could be drawn for the aquatic and terrestrial bioaccumulation endpoints based on the available non-standard studies, as well as the implications for potential exposure assessment. We will also discuss the need for standardised testing, to be able to differentiate between bioaccumulation of nanoparticles with different properties and to understand how environmental conditions may affect bioaccumulation of nanoparticles.

6.08.P-Th544 Towards Improved Reliability in The Characterization of Metallic Nanoparticles in Environmental Samples

Rosa C. Rodríguez Martín-Doimeadios[1]*, María Jiménez Moreno*[1]*, Armando Sánchez-Cachero*[2] *and Marta Hernández-Postigo*[2]*, (1)Analytical Chemistry and Food Technology, Castilla La Mancha University (UCLM), Spain, (2)University of Castilla-La Mancha (UCLM), Spain*

The use of metallic nanoparticles (NPs) has exponentially grown in recent years owing to their exceptional physical and chemical attributes at nanoscale. This widespread application inevitably leads to their growing discharge into the environment, but limited knowledge exists regarding NP fate and the possible alterations that they might undergo upon release. Thus, the characterization of NPs within environmental samples is crucial for understanding their behaviour, potential risks, and impact on ecosystems and human health. The quest for enhanced reliability in this characterization process is paramount, considering the inherent NP nature and their ubiquitous presence in various environmental matrices.

The complete NP characterization involves not only the determination of size, shape, or composition typically obtained by microscopic techniques, among others, but also quantitative information about NP (mass and number) concentrations. However, ensuring the reliability and accuracy of these measurements remains an analytical challenge due to the complexity of environmental matrices which results in limitations in sample preparation and/or the analysis. Consequently, there is still the need to develop innovative analytical methods capable of reliably detecting, characterizing, and quantifying NPs in relevant environmental and toxicological systems.

In this context, inductively coupled plasma mass spectrometry in its single particle mode (SP-ICP-MS) has emerged as an interesting alternative to conduct a simultaneous sizing and counting of NPs as well as the quantification of its ionic forms. The potential of this approach for the NP characterization in complex samples may be hampered by matrix effects affecting the adequate discrimination between ionic and particulate signals.

To overcome this limitation and improve the performance in challenging scenarios, in this work, an analytical tool of high metrological quality such as the isotope dilution analysis (IDA) has been explored in combination with SP-ICP-MS. The potential of IDA to better discern between signals has been thoroughly evaluated using platinum NPs as a model. Limitations related to matrix effects caused by different environmental factors have also been assessed. Our findings suggest that IDA-SP-ICP-MS holds promise as a tool for characterizing metallic NPs in environmental samples. Nevertheless, further comprehensive investigations are necessary to fully understand its capabilities.

6.08.P-Th545 Hydrodechlorination of Mine Water-specific Polychlorinated Biphenyls (PCBs) Using Palladium Nanocatalysts

***Katrin Wiltschka**, Silviu Bobric, Rolf-Alexander Düring and Leonard Böhm, Institute of Soil Science and Soil Conservation, Research Centre for BioSystems, Land Use and Nutrition (iFZ), Justus Liebig University Giessen, Germany*
Polychlorinated biphenyls (PCBs) were used, amongst others, in mining for fire protection reasons until they were banned worldwide. Even today, mines can still be contaminated with PCBs from leaks and abandoned equipment [1]. Mine water must be continuously pumped out and discharged into surface waters. Unlike for diffuse sources, efficient technologies could be easier applied to these point sources to reduce environmental impact.

A perspectively promising approach is the catalytic dechlorination of PCBs using palladium (Pd) nanoparticles. The aim of the present study was to determine the dechlorination rates of selected mine water specific PCBs both under optimal reaction conditions and in matrix-rich mine water. For dechlorination experiments, small amounts (150 µg L-1) of suspended Pd nanoparticles were added to both PCB containing laboratory solutions and mine water. The experiments were conducted under anoxic conditions with hydrogen for hydrodechlorination reactions. Simultaneous extraction and detection of reactants, intermediates and fully dechlorinated biphenyl were performed by SPME-GC-MS [2]. The Pd particles showed high catalytic activities for dechlorination of mine water specific PCBs under optimal conditions (up to 4400 L min-1 g-1), but not in the matrix-rich mine water. Here, the catalytic activity was strongly inhibited by catalyst poisons present in the mine water (e.g. sulfur compounds). Therefore, the consecutive goal is to protect the nanoparticulate Pd catalysts from deactivation by catalyst poisoning. To maintain high catalytic activity, experiments are underway to incorporate the Pd particles into a surface coating of the reaction vessels. Coatings must allow PCB diffusion to the catalysts while at the same time hinder entering of catalyst poison. Beside increased degradation rates, the coating is intended to prevent Pd discharge into the environment during on-site applications, thereby avoiding costs and environmental harm by nanoparticles. To maintain catalyst activity, it is planned to apply an additional protective layer to further protect the Pd particles from catalyst poisons and ensure a long catalyst life. This would allow for in-situ dechlorination of PCBs, making the technology scalable for on-site treatment of contaminated water.

6.08.P-Th546 Trimethyl chitosan magnetic nanosorbents efficiency and safety - Remediation of waters contaminated with glyphosate and aminomethylphosphonic acid

*Joana Santos[1], Sofia S. Soares[2], **Ângela Barreto**[3], Vera Maria[3] and Ana L. Daniel-da-Silva[2], (1)Department of Biology & CESAM, University of Aveiro, Portugal, (2)Departament of Chemistry & CICECO, University of Aveiro, Portugal, (3)Departament of Biology & CESAM, University of Aveiro, Portugal*
Glyphosate (GLY) stands as one of the most commonly used herbicide worldwide, with its main metabolite being aminomethylphosphonic acid (AMPA). The pressing need for their effective removal from water sources arises from their recurrent presence in both ground and surface waters and the recognized environmental risks they pose. In this study, magnetic nanosorbents, developed by us, comprising magnetite nanoparticle core coated with trimethyl chitosan-silica hybrid shells, were investigated for the adsorptive removal of GLY and AMPA from ultra-pure water and wastewater samples. Additionally, a Fish Embryo Acute Toxicity test with *Danio rerio* was conducted to evaluate the safety of the magnetic nanosorbents, assessing parameters such as survival, hatching, heartbeat rate and malformations occurence in a 96 hours exposure. The results showed that, in ultra-pure water, the magnetic nanosorbents (0.5 g/L) removed 96% of GLY (initial concentration = 3 µg/L; pH = 5) , while for AMPA, a removal of 67% was observed under the same conditions. Notably, increasing the dosage of magnetic nanosorbents to 2.5 g/L resulted in an 89% removal of AMPA (initial concentration = 3 µg/L; pH = 5) from ultra-pure water. These findings indicated that, in ultra-pure water, the magnetic nanosorbents were able to reduce realistic environmental concentrations of GLY and AMPA to levels that are below the maximum permissible value (0.1 µg/L) as defined by the European Directive of Drinking Water. When applied to spiked wastewater samples (initial concentration = 3 µg/L; pH = 7.5), the magnetic nanosorbents (2.5 g/L) removed 42% of GLY and 54% of AMPA, demonstrating the preliminary applicability of these nanomaterials in more realistic conditions. Furthermore, no toxic effects were found on embryos exposed to 2.5 mg/L of magnetic nanosorbents, indicating that these nanomaterials seem safe for zebrafish embryos considering the individual endpoints assessed. Our results collectively suggest that assisted magnetic water remediation using these nanosorbents could offer an efficient and safe process of eliminating GLY and AMPA from contaminated waters. Our study provides valuable insights into the potential for advanced nanomaterials to address the pressing issue of herbicide contamination in aquatic environments.

6.08.P-Th547 Nanoherbicides and its impacts on weed management: an alternative for sustainable agriculture

***Gustavo Vinícios Munhoz-Garcia**[1], Vanessa Takeshita[1], Leonardo Fernandes Fraceto[2] and Valdemar Luiz Tornisielo[3], (1)University of São Paulo (USP), Brazil, (2)Science and Technnology Institute (ICT), São Paulo State Univeristy "Júlio Mesquita Filho" (UNESP), Brazil, (3)Sao Paulo, Center of Nuclear Energy in Agriculture (CENA), University of São Paulo (USP), Brazil*
Herbicides have negative environmental impacts but they are still necessary to keep crop productivity and ensure efficient weed control in agricultural areas. Nanotechnology has become an essential tool in improve herbicides effectiveness, increasing toxicity to the target species, leading to effective management with reduced rates of active ingredient (a.i.) due to changes in herbicide delivery. An in-depth investigation concerning the effect of nanoparticles (NPs) in herbicide's mode of action (MoA) in target species is important to a safe and sustained by-design (SSbD) approach. The objective of this work was to highlight the effect of NPs as carriers on herbicide MoA in plants integrating results from radiometric and microscopic

techniques. A critical investigation was done in recent literature using nanotechnology, pesticides, radiometric, and microscopic as keywords in the Web of Science database. In general, the studies with plants use NPs as models, and the effective tracking of pesticide-loaded NPs is not deeply investigated. For example, radiometric techniques (RdT) allowed an evaluation of ^{14}C-graphene NP translocation through a symplastic pathway in wheat, suggesting that graphene is a nanocarrier through plasmodesmata. In another and more realistic approach, RdT was used to identify the behavior of ^{14}C-nanoatrazine in plants and ^{14}C-nanometribuzin in soil. These works highlight herbicides radiolabeled with ^{14}C as a useful tool for regulatory and SSbD approaches in developing NPs as herbicide carriers. Besides that, complementary techniques as confocal microscopic (CfM) with fluorescent marker is essential for understanding NPs behavior in plants, because radiometric techniques are restricted to mapping the a.i. behavior. CfM was able to study the movement of atrazine-polymeric NPs via root; and was also able to identify stomata as an absorption pathway of nanoatrazine applied through the leaf. Moreover, tracking nanoherbicides needs an interdisciplinary approach to determine the integrated behavior of pesticides and NPs in plants, as well as the effect of NPs in herbicide MoA. This work highlights the importance of understanding the interaction between nanoparticles and herbicides to optimize their effectiveness and minimize potential negative environmental impacts. Additionally, this research opens new possibilities for developing more sustainable and efficient weed control methods in agriculture.

6.08.P-Th548 Pesticide Nanoformulation Is a Solution for Agriculture? Fate, Efficacy, and Challenges of Metribuzin Herbicide as Case of Study

Vanessa Takeshita[1]*, Gustavo Vinícios Munhoz-Garcia*[1]*, Brian Cintra Cardoso*[2]*, Camila de Werk Pinácio*[2]*, Valdemar Luiz Tornisielo*[3]*, Lucas Bragança de Carvalho*[4] *and Leonardo Fernandes Fraceto*[4]*, (1)University of São Paulo (USP), Brazil, (2)Center of Nuclear Energy in Agriculture (CENA), University of São Paulo (USP), Brazil, (3)Sao Paulo, Center of Nuclear Energy in Agriculture (CENA), University of São Paulo (USP), Brazil, (4)Science and Technnology Institute (ICT), São Paulo State Univeristy "Júlio Mesquita Filho" (UNESP), Brazil*

Nanoformulation is reported as a solution for pesticides in agriculture to increase target delivery, protect active ingredients against biotic and abiotic losses, and reduce environmental risks without efficacy decrease. For herbicides, the main pesticide class used in the world, nanoformulations can be a strategy to reduce environmental concentration and manage difficult-to-control weed species simultaneously, mainly for pre-emergent actives that are applied directly in the soil. Metribuzin polymeric nanoformulation was used as a study model for nanopesticide environmental fate and efficacy. Poly-ε-caprolactone (PCL) nanoparticles (NP) were developed based on the nanoprecipitation method, and metribuzin (MTZ) herbicide radiolabeled was encapsulated as a tracer. A radiometric technique was applied to track nanoparticles in soil (mobility, degradation, and non-target effect assays), at field metribuzin dose (480 g a.i. ha^{-1}). Also, weed control assays were carried out, with non-radiolabeled nanoparticles to investigate the enhanced activity of metribuzin in broad-leaf plants (0, 48, and 480 g a.i. ha^{-1}). Stable nanoformulation for MTZ was obtained with PCL, resulting in 289 nm of hydrodynamic size and -31 mV of surface charge (ζ potential) over 120 days. In the soil, nanoparticles showed no increment in the persistence of MTZ herbicide (half-life of 17 d), with similar mobility to the commercial metribuzin treatment (retention factor of 0.45-0.5). The bioaccumulation of MTZ in earthworms was higher (1.76 times) than NP with MTZ. In plants, a different pattern of absorption by roots was observed, concentrated in the vascular system for NP and all-plant distributed for commercial MTZ (3.9-5.4%). MTZ (NP and commercial) reach a satisfactory weed control of *Amaranthus viridis*, even in low doses for MTZ NP. Therefore, MTZ NPs were environmentally safe without compromised efficacy. Our research evidenced that the radiometric technique was an excellent tool for tracking nanoformulations in soil and organisms (non-target and target plants). MTZ nanoformulation can be a relevant tool for weed management in agriculture. Also, other nanopesticides can be developed in the same way. However, a simple solution is not available, and the design needs to be thought out for each specific case of agrochemical, target, and environment to be inserted.

6.08.P-Th549 Freshwater ecotoxicity and life cycle risks of nano-encapsulated imidacloprid compared to its conventional analog

Fan Wu *and Jing You, Jinan University, China*

The application of nanotechnologies in agriculture raises concerns about the safety of nanopesticides, yet research has not fully characterized their potential environmental risks compared to conventional pesticides. To support sustainable food production, we compared the ecotoxicity of nano-encapsulated imidacloprid (nano-IMI) and its active ingredient in non-target freshwater invertebrate and embryonic vertebrate models (Daphnia magna, Chironomus kiinensis, and Danio rerio). Results showed that nano-IMI had approximately 5 times lower 50% lethal concentration (LC50) than IMI in zebrafish embryos, while no significant difference was observed in invertebrates. Through toxicokinetic modeling, no difference in bioaccumulation was observed between nano-IMI and IMI in D. magna based on one-compartmental toxicokinetic model. A two-compartmental model successfully simulated the slow elimination of IMI from C. kiinensis and confirmed that both pesticides reached toxicologically relevant targets at saturated levels. In addition, due to the unintentional partitioning, zebrafish chorion was detached to elucidate organismal uptake. Nano-IMI exhibited significantly higher bioaccumulation potential than IMI in zebrafish embryos, explaining the higher toxicity observed. Furthermore, the freshwater ecotoxicity of pesticides from production to the end-of-life emission were predicted synergistically using life cycle assessment, USEtox and SimpleBox4Nano models. The ecotoxicity characterization factor for IMI ranges from 1.25E+04 to 3.29E+05 CTUe under various scenarios considered, which is higher than that of nano-IMI (3.76E+03 CTU). Although with a relatively higher ecotoxicity in fish embryos, our study demonstrated that the substitution of IMI with nano-encapsulated IMI is anticipated to mitigate their life cycle freshwater risks. In conclusion, the present study provides a comprehensive understanding of nano-IMI's environmental risks and its potential impact on freshwater ecosystems compared to IMI. Nano-IMI may not always be safer than its conventional counterpart, but its use may be more sustainable if proper management measures are implemented during its production and application.

6.08.P-Th550 Assessment of Innovative Polyurethane Coatings: Anti-Corrosion Performance and Ecotoxicological Effects

Fernando Perina[1], Joana Figueiredo[2], Diogo Gama[2], Muhammad Ahsan Iqbal[3], Cristina Neves[3], Frederico Maia[4], João Tedim[3], Susana Loureiro[5] and ***Roberto Martins**[5]*, *(1)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)CICECO - Aveiro Institute of Materials & Department of Materials and Ceramic Engineering, University of Aveiro, Portugal, (4)Smallmatek, Small Materials and Technologies Lda., Portugal, (5)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal*

Corrosion mitigation poses significant economic and environmental challenges, mostly due to the use of protective coatings containing toxic corrosion inhibitors (CI), that are released to the seawater during the coating's life cycle. Thus, a new generation of nanostructured bio-based CI, less toxic than the widely used compounds, has been developed in the framework of the NANOGREEN project, using layered double hydroxides (LDH). LDH are a class of anionic-exchange nanoclays characterized by positively charged metal (e.g., Zn^{2+}, Al^{3+}) stabilized by anions (e.g., NO_3^-, CIs^-). Such nanostructured forms (LDH-Gluconate, LDH-Glutamate, in slurry, or powder) and biobased CIs soluble (gluconate, glutamate), were used as anti-corrosion additives in a model polyurethane (PU) coating. This study aims to assess these novel PU coatings' anti-corrosion efficacy and safety. Anti-corrosion properties were analyzed over 21 days using electrochemical impedance spectroscopy. Coated plates (~43cm²) were then immersed in artificial seawater for 84 days, and leachate samples were collected periodically for chemical and ecotoxicological tests. Metals (Zn and Al) were analyzed using ICP, and key anions/CIs (nitrites, nitrates, chloride, gluconate, glutamate) were analyzed using HPLC and ionic chromatography. Ecotoxicological tests involved microalgae (*Tetraselmis chuii* and *Phaeodactylum tricornutum*), a rotifer (*Brachionus plicatilis*), and a crustacean (*Artemia salina*). Multivariate data analysis using Principal Coordinates Analysis evaluated the temporal trends in ecotoxicological data and their correlation with environmental descriptors (chemical and physicochemical data). Globally, the PU coatings exhibited good anti-corrosion properties, including satisfactory adhesion and barrier protection, better in the case of the nanoadditives-based coatings. Leachates from LDHs/PU coatings showed no significant toxicity on the tested species. Released metals and anions had a limited impact since pH and conductivity were the most correlated environmental factors with the ecotoxicological data. This suggests that the concentrations of metals, anions, and biobased IC were insufficient to cause ecotoxicological responses, indicating minimal release from the coatings over the 84 days. The new bio-based nanoadditives PU coatings showed good performance for maritime applications with no/low environmental impact, which can mitigate the early leaching of conventional corrosion inhibitors.

6.08.P-Th551 The dampening impact of the dual transformation of ENPs for their phytotoxicity

***Izabela Jośko**[1]*, *Mikołaj Edward Feculak[2] and Patryk Oleszczuk[3], (1)Institute of Plant Genetics, Breeding and Biotechnology, University of Life Sciences in Lublin, Poland, (2)Institute of Plant Genetics, Breeding and Biotechnology, University of Life Sciences, Poland, (3)Department of Radiochemistry and Environmental Chemistry, Maria Curie-Skłodowska University, Poland*

The galloping production and usage of engineered nanoparticles (ENPs) entail their dissemination in the environment. Once ENPs are released into the environment, they undergo physical, chemical, and biological transformations, altering their properties. The environmental-induced modification of ENPs is dynamic and once transformed ENPs may be the subject to subsequent processes. In this regard, the properties of transformed ENPs (*trans*ENPs) will differ from the pristine ones (*p*ENPs), and finally, it may determine their fate and toxicity. The goal of this study was to assess the phytotoxicity of pristine heavy metal-based ENPs (ZnO, CuO), single (sulphidised) and double-transformed (sulphidised covering with protein corona). The properties of *p*- and *trans*-ENPs, including the transformation rate, were characterized in terms of the phase composition, size, zeta potential, crystallinity, size of surface area, and dissolution rate. The toxicity of ENPs was evaluated using the seed germination and root elongation test on *Lepidium sativum*. The more transformed ENPs revealed lower toxicity compared to sulphidised or *p*ENPs. The higher mitigation in phytotoxicity under transformation was noted for the CuO ENPs than ZnO ENPs. The attenuated toxicity could be related to the decreased concentration of Zn or Cu ions in the exposure to *trans*ENPs. The effects may also result from the distinct interactions (mostly tend to adhesion) between ENPs and the surface of seedlings. The obtained results first reported the decreased phytotoxicity of chemically-biologically transformed ENPs compared to pristine nanomaterials. Further studies on the chronic effects of modified ENPs are requested to gain the full picture of their fate in the environment.

6.08.P-Th552 Ecotoxicity Tests of TEMPO Oxidized Cellulose Nanofibers

Rie Tai, Isamu Ogura and ***Hiroyuki Mano***, *National Institute of Advanced Industrial Science and Technology (AIST), Japan*

Cellulose nanofibers (CNFs) are novel nanomaterials derived from plants. Based on their inherent attributes, which include high strength, high water retention characteristics, and transparency, CNFs have been extensively applied across diverse fields, such as pharmaceutical products, cosmetics, food thickeners, automotive engineering, reinforcing tire, household electrical appliances, and house construction materials. As such CNFs are expected to contribute to a sustainable society and ongoing technological advancements have been made to increase their practical applications. An increase in the mass production of CNFs could result in increased material disposal into the environment, leading to potential ecological effects on aquatic organisms. Hence, the effects of CNFs on aquatic organisms should be evaluated in parallel with the development of CNF. However, there is little information available on the aquatic ecotoxicity data of CNFs. nanomaterials such as CNFs are treated as difficult-to-test substances in existing guidelines. For example, the properties of CNFs, such as dispersibility and dispersion stability, are prone to alteration in response to changes in water quality. Without an understanding of the properties of CNFs in the test medium and the variation in the properties due to variations in test conditions, the ecotoxicity of CNFs cannot be adequately assessed. Thus, in this study, we have established the methods for ecotoxicity tests dedicated CNFs and get toxicity data for aquatic organisms. In this presentation, we will report the results of the ecotoxicity test method investigated and tested using algae, daphnia, and fish for 2,2,6,6-tetramethylpiperidine-1-oxyl radical (TEMPO) oxidized CNFs.

6.08.P-Th553 Mesocosm-based Studies for Assessing Impacts of Nano-enabled Pesticides on Freshwater Ecosystems: Results & Opportunities

Tom Adrianus Pieter Nederstigt[1]*, Willie Peijnenburg*[2] *and Martina G. Vijver*[3]*, (1)Institute for Environmental Sciences, Leiden University, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)Institute of Environmental Sciences (CML), Leiden University, Netherlands*

Recent agricultural and food policy reforms across the globe have placed a strong focus on the mitigation of environmental risks associated with pesticide use. Nano-enabled pesticides, i.e. pesticidal products containing nanoscale active substances and carrier systems, are increasingly proposed to possess properties which could aid in the attainment of such objectives. Experimental assessments of their potential favorability over non-nanoscale analogues to date has predominantly relied on their enhanced pesticidal- (i.e. target) efficacy and efficiency, and less so on their possible collateral environmental impacts. Such a focus is likely to skew evaluations with regards to their potential benefits towards the former. Furthermore, few studies up to now have evaluated non-target impacts of nano-formulated pesticides using mesocosm setups, which has resulted in a lack of understanding of their potential adverse environmental impacts at higher levels of ecological organization. We present an overview of findings from our recently published and currently ongoing studies concerning freshwater mesocosm-based assessments of nano-enabled pesticides, focusing on two different formulations. Of a (nano)TiO_2-based formulation of carbendazim, we demonstrate impacts on a variety of taxonomy- and function based community parameters of macroinvertebrates and zooplankton, which could predominantly be attributed to effects induced by carbendazim. Of a (nano)clay-based formulation of clove essential oil, we demonstrate that abundances of emerged insects exposed during aquatic larval stages are partially attributable to the presence of the clay carrier, but that community parameters overall show minimal response to clove essential oil. Our findings illustrate the suitability and feasibility of mesocosm studies for the evaluation of risks and benefits associated with the use of nano-enabled pesticides. To facilitate future work in this regard, we use our findings to outline how we believe the selection of specific formulations and experimental designs can best be tuned to provide relevant and generalizable insights.

6.08.P-Th554 Toxicity of Repeated Exposures to Electronic Cigarette and Heat-not-Burn Aerosols on Human Bronchial Epithelia: Combining Biological Assays and Microscopy Analysis

Ursula Fiorela Navarro Abarca[1]*, Mathilde Delaval*[2]*, Daniel Egli*[3]*, Heinz Burtscher*[3] *and Marianne Geiser*[2]*, (1)University of the Basque Country (UPV/EHU), Spain, (2)Institute of Anatomy, University of Bern, Switzerland, (3)Institute of Aerosol and Sensor Technology, University of Applied Sciences and Arts Northwestern Switzerland (FHNW), Switzerland*

The use of electronic cigarettes (e-cigs) and Heat-Not-Burn (HnB) products is fast growing, raising concerns regarding their potential harmful pulmonary effects in former and current smokers. However, evidence-based data are still lacking for assessing the human health risk related to exposure to e-cig and HnB aerosols. Thus, the characterization of inhaled aerosols and the evaluation of their effects on the target tissue are necessary.

The present study aimed to evaluate the effects of repeated exposures of e-cig and HnB aerosols on normal human bronchial epithelia (HBE) using realistic in-vitro technologies. A complimentary goal was to improve our understanding of cytotoxicity effects using microscopic evaluation to strengthen our knowledge of potential adverse effects of e-cig and HnB aerosols on human airway cells.

Aerosols were produced from a Joyetech e-cig (third generation) and an IQOS HnB with a specifically developed aerosol generation chamber mimicking user puffing behavior. Air liquid interface cultures of reconstituted normal human bronchial epithelial cells (HBEC) were exposed to single or multiple puff topographies of e-cig aerosols, using the (nano)aerosol deposition chamber NACIVT. The Stepanizer software tool was used for semi-quantification of cell detachment on light microscopy images taken directly after exposure, at 4 h and 24 h post-exposure. Cell death (lactate dehydrogenase release LDH), and epithelial damage (electron microscopy) were evaluated at 4 h and/or 24 h after exposure to the aerosols.

Previous analysis showed that repeated exposures to e-cig and HnB aerosols caused cytotoxic effects in a dose-dependent manner. LDH levels increased with the number of produced puffs and were higher for Joyetech aerosol. Our semi-quantitative evaluation revealed epithelial damage by cell detachment of cells exposed to the first puff topography in a dependent manner to deposited aerosol mass and post-exposure time. Ongoing analysis focuses on the evaluation of cell detachment following repeated exposures with an increasing number of puff topographies.

6.08.P-Th555 Advanced Materials Earliest Assessment (AMEA)

Wendel Wohlleben, Dr.[1], *Michael Persson*[2], *Blanca Suarez Merino*[3], *Anders Baun*[4], *Veronica Di Battista*[1], *Susan Dekkers*[5], *Eugene Van Someren*[5], *Dirk Brossell*[6], *Burkhard Stahlmecke*[7], *Martin Wiemann Dr.*[8], *Otmar Schmid*[9] *and Andrea Haase*[10], *(1)BASF SE, Germany, (2)Chalmers University of Technology, Sweden, (3)TEMAS Solutions GmbH, Switzerland, (4)DTU Sustain, Technical University of Denmark (DTU), Denmark, (5)TNO, Netherlands, (6)BAuA, Germany, (7)University of Duisburg-Essen (Uni DUE), Germany, (8)IBE R&D Institute for Lung Health gGmbH, Germany, (9)Helmholtz Center Munich, Germany, (10)Federal Institute for Risk Assessment (BfR), Germany*

Advanced materials are rapidly being developed in different material categories. They share little commonalities apart from their novelty, which raises concerns that these materials may fall into a regulatory gap with potentially inappropriate risk management. But how to assess materials that are still under development? Here we present the Advanced Material Earliest Assessment (AMEA) approach to fill this gap by proposing simple assessment steps and guidance for design rules being applicable by innovators in early material development phases (ideation, business case and lab phases). AMEA provides a structured approach to exploit the available knowledge at each phase, starting from the intended product, application and global region, starting also from the conventional material in the same application, of which the sustainability benefits and sustainability challenges often constitute the motivation for advanced material development. During the lab phase, AMEA recommends focusing on acquisition of data by selected New Approach Methods (NAMs) with discriminating power, and triggers *more requirements* and/or *specific testing methods* depending on the positioning of the material with respect to the three dimensions “nano-enabled?”, “advanced?”, “containing particles?” The methodological part can be amended for other material classes without relevance of nanostructures. Similarity and ranking approaches compare material versions synthesized in lab phases against each other and the conventional material in terms of performance, lifecycle emissions/exposures and hazards. AMEA prioritizes the discriminating power of specific data to refine the design targets instead of using generic assumptions with high uncertainties.

AMEA is currently being implemented as an online tool that provides safe-and-sustainable-by-design (SSbD) prioritisation and guidance for each of the three innovation phases based on the categorization that follows answering the three main questions (https://diamonds.tno.nl/projects/harmlesspublic). It is the entry point of the HARMLESS decision support system which covers also the ensuing pilot and launch phases of innovation management to implement SSbD material development.

This work has received funding from BMBF (German Federal Ministry of Education and Research) within the project InnoMat.Life (03XP0216) and from EU-H2020 project HARMLESS (GA 953183).

6.08.P-Th556 Cellular Responses of Eisenia fetida Coelomocytes Exposed to Wastewater Treatment Plant-Transformed Isotopically Enriched Nanomaterials

Anastasia Georgantzopoulou[1], *Sebastian Kuehr*[1], *Ralf Kaegi*[2], *Mark Rehkamper*[3], *Ralph A Sperling*[4], *Karl Andreas Jensen*[5], *Ana Catarina Almeida*[1] *and Claire Coutris*[6], *(1)Norwegian Institute for Water Research (NIVA), Norway, (2)Process Engineering, Swiss Federal Institute of Aquatic Science and Technology (Eawag), Switzerland, (3)Imperial College London, United Kingdom, (4)Fraunhofer IMM - Institute for Microengineering and Microsystems, Germany, (5)Norwegian University of Life Sciences (NMBU), Norway, (6)Bioforsk, Norway*

Most nanomaterials (NMs) used in commercial applications enter wastewater streams and reach wastewater treatment plants (WWTP), where the vast majority is concentrated in sewage sludge and applied on agricultural land. By the time NMs enter soils, they have undergone various transformation processes, which results in particles with altered properties, bioavailability and toxicity which can differ from the original pristine NMs. While less documented than for pristine NMs, the environmental hazard of environmentally relevant chemical forms of NMs is critical knowledge for risk assessment. The aim of this study was therefore to assess the potential environmental hazard of WWTP-transformed NMs in environmentally relevant exposure conditions.

To be able to trace low concentrations of NMs in complex matrices like sewage sludge and soil, with high natural metallic background, isotopically enriched ^{109}Ag, $^{46}TiO_2$ and ^{68}ZnO NM were synthesized and introduced to a pilot WWTP. The resulting sludge was applied to soil microcosms with *Eisenia fetida* earthworms, and the potential toxicity of the transformed NMs was assessed in coelomocytes isolated from the exposed earthworms. Coelomocytes are primary immune cells involved in phagocytosis, encapsulation and humoral immune responses, sensitive towards metal and NM pollution, and thus a promising method for high-throughput assessment of NM immune-related effects.

NM characterization was performed with dynamic light scattering (DLS), single particle-Inductively Coupled Plasma Mass Spectrometry (sp-ICP-MS) and transmission electron microscopy (TEM). The NM-containing sludge was characterised by ICP-MS using a developed isotopic ratio method. The effects of the sludge containing aged NM on the coelomocyte population, metabolic activity, lysosomal integrity, reactive oxygen species formation, mitochondrial membrane potential and immune responses were assessed and compared to control (non-spiked) sludge after 1 and 4 weeks of exposure. Nanoparticle uptake and intracellular localisation were evaluated with sp-ICP-MS. The importance of taking NM transformation into account and the sensitivity of the *E. fetida* coelomocytes as a cell model to study immune-related responses of transformed NMs are discussed.

Acknowledgement – Financial support from the Research Council of Norway (project ENTRANS, Grant Agreement number 302378/F20) is gratefully acknowledged.

6.08.P-Th557 In Vitro to Organ Level Effect Extrapolation for Human Risk Assessment of Nanomaterials

Jimeng Wu[1]*, Peter Wick*[2] *and Bernd Nowack*[1]*, (1)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Particles-Biology Interactions, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Nanomaterials exhibit distinctive properties at the nanoscale and have become integral to diverse industrial sectors, including energy, food, and medicine. Despite their transformative impact, growing concerns surround the potential adverse effects of nanomaterials on human health and the environment. This study investigates the application of risk assessment to identify and quantify the risks associated with nanomaterial release, with a particular focus on the challenges posed by limited in vivo studies due to ethical considerations. Risk assessment serves as a tool to identify and measure the risks associated with the release of nanomaterials into the environment and the subsequent exposures to humans and ecosystems. However, in the field of human nanotoxicology, we have the challenge that only few vivo studies are available. The emergence of new nanomaterials further complicates the timely calculation of dose-response assessments. In vitro analysis provide a promising alternative to obtain hazard data for nanomaterials, but their integration into risk assessment remains in its infancy.

This research investigates strategies for extrapolating toxicity data from in vitro studies to organ-level effects. The approach involves the development of a combined dosimetry model that integrates in vitro dosimetry with in vivo dosimetry (Physicologically-based pharmacokinetics model). This model aims to predict safety levels for human nanomaterial uptake, translating cellular-level internal doses into concentration levels that trigger organ reactions. The focus is particularly on the liver, which accumulates some of the highest concentrations of all organs. When faced with diverse in vitro nanotoxicity datasets, Bayesian statistical analysis emerges as a valuable tool for characterizing uncertainties arising from inter-experimental variations. This study not only contributes to advancing our understanding of nanomaterial toxicity but also provides insights into assessing the influence of experimental result variability on extrapolating safe nanomaterial concentration levels for humans. It effectively bridges the gap from in vitro studies to prediction of organ-level effects in the context of human risk assessment, contributing to the comprehensive evaluation of nanomaterial hazards.

6.08.P-Th558 Safety Assessment of Hexagonal Boron Nitride at the Skin Level: an In Vitro Study on 3D Reconstructed Human Epidermis and HaCaT Keratinocytes

Michela Carlin[1]*, Alessandra D'Arelli*[1]*, Ester Vázquez Fernández-Pacheco*[2]*, Silvio Sosa*[1]*, Maurizio Prato*[3]*, Aurelia Tubaro*[1] *and* ***Marco Pelin***[1]*, (1)Department of Life Sciences, University of Trieste, Italy, (2)University of Castilla-La Mancha (UCLM), Spain, (3)Department of Chemical and Pharmaceutical Sciences, University of Trieste, Italy*

Hexagonal boron nitride (hBN) is a novel two-dimensional nanomaterial, constituted of boron and nitrogen atoms, that is currently developed in many technological applications, spacing from electronic to biomedicine. However, the enhanced use of hBN needs a careful evaluation of its impact on human health. Skin contact can be considered one of the most relevant exposure routes to this material not only in occupational settings but also considering a final user exposure.

To investigate the cutaneous effects of hBN, NAMs for skin irritation and corrosive properties assessment were applied in compliance with the Organization for Economic Co-operation and Development (OECD) test guidelines 439 and 431, respectively, using an *in vitro* advanced 3D model of reconstructed human epidermis. When applying these test guidelines, hBN resulted a non-irritant and non-corrosive material at the skin level. Moreover, it possessed also an extremely low pro-inflammatory potential.

Subsequently, an *in vitro* toxicity study of hBN was carried out on HaCaT cells, an immortalized human keratinocytes cell line. hBN was able to be massively internalized by keratinocytes; however, it induced a significant reduction in cell viability and mass exclusively at very high concentrations (>50-100 μg/mL) only after 72 h exposure. In the effort to explore the mechanisms underlying its cutaneous toxicity, even if low, hBN was assessed for its ability to alter a series of cellular parameters. In particular, the disruption of plasma membrane integrity induced by hBN appeared associated to a mitochondrial damage causing a significant reactive oxygen species production.

In conclusion, these results demonstrate the lack of irritation and corrosive potential of hBN but also its ability to induce very low cytotoxic effects on HaCaT keratinocytes, suggesting its good biocompatibility at the skin level.

6.08.P-Th559 Global RNA Sequencing of Escherichia coli from Exposure to Nanodiamonds and Carbon Nanotubes with Surface Coatings

Joanne Vassallo[1]*, Laura Saarimäki*[2]*, Antonio Federico*[2]*, Dario Greco*[2]*, Rich Boden*[3] *and Richard D. Handy*[4]*, (1)School of Biological and Marine Sciences, Vitis Regulatory, Pean Hill, United Kingdom, (2)Tampere University, Finland, (3)University of Plymouth, United Kingdom, (4)School of Biological and Marine Sciences, University of Plymouth, United Kingdom*

Engineered nanomaterials can be tailored with specific physico-chemical properties to satisfy required commercial, medical or any other need. These materials can drive innovation as a result of the infinite chemical structures that can be produced. There are also concerns that these materials will negatively affect microbes that inhabit end-of-pipe ecosystems. Global RNA sequencing was used to describe gene expression levels, as messenger RNA abundance, in response to different test exposures. Global RNA sequencing is valuably used to describe gene expression levels, as messenger RNA abundance, in response to different test exposures. This has been made easier through fast genomic sequencing and the identification of differentially regulated genes in response to stimuli. Such approaches, despite still being immensely costly, can be used to refine animal testing and provide a basis for non-animal methods of hazard assessment with nanomaterials. The bacterium *Escherichia coli* K-12 MG1655 was used as this organism is well annotated in molecular databases and has environmental significance. The materials included in the study were nanodiamonds and multi-walled carbon nanotubes with carboxylate, amine and polyethylene glycol coatings, respectively. This research aimed to see if changes in RNA expression reflect the toxicity ranking of these materials from *in vivo* results. Sub-lethal exposure concentrations were necessary such that adaptive molecular responses could be identified, rather than the omics of a dying organism. All test suspensions were characterised for particle number concentration and particle size distribution. The increases in RNA expression relative to the unexposed control generally reflected the toxicity ranking from the *in vivo* results. The biggest RNA increases were related to genes involved in monosaccharide transport (*Isr* genes), glycolate metabolism (*glcE*) and lactate transporters (*glcA*). Global RNA sequencing detected differences in gene expression that suggest material-type effects and also specific coating effects within these nanomaterials. ENMs. However, these observations were not so evident *in vivo* with growth as an endpoint.

The research was funded by EU FP7 NANOSOLUTIONS Project, Grant Agreement No. 309329.

6.08.P-Th560 Beyond Conventional Measures: Embryotoxicity Evaluation of Innovative Nanostructured Corrosion Inhibitors

Fernando Perina[1], Joana Figueiredo[2], Frederico Maia[3], Susana Loureiro[1] and ***Roberto Martins****[1], (1)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (2)Department of Biology, University of Aveiro, Portugal, (3)Smallmatek, Small Materials and Technologies Lda., Portugal*
Metallic corrosion has been mitigated through specialised coatings containing efficient but often toxic corrosion inhibitors (CIs), such as 2-mercaptobenzothiazole (MBT). Recent developments have proposed using engineered nanomaterials, like layered double hydroxides (LDH), to immobilise CIs, such as MBT (abbreviated as LDH-MBT), for controlled release with environmental benefits. However, the long-term effects are scarcely understood. In this context, the current study focused on the embryotoxic effects of LDH-MBT, as well as unloaded LDH (Mg-Al LDH-NO_3) and MBT in the soluble form, using the sea urchin *Paracentrotus lividus* as a model organism. Unloaded LDH was categorised as not toxic (EC_{50}>100 mg/L). In contrast, both forms of MBT were categorised as very toxic, with EC_{50} values estimated at 0.49 and 0.93 mg MBT/L for MBT and LDH-MBT, respectively, and presented a similar NOEC value (0.137 mg MBT/L). However, detailed observations of embryo-larval development revealed distinct effects between the soluble and nanostructured MBT forms. For instance, embryo development was interrupted at the first cell divisions at 33.3 and 100 mg MBT/L of soluble MBT, whereas the morula stage was reached with the corresponding concentrations of LDH-MBT. Furthermore, at 11.1 mg MBT/L, the morula stage was observed for MBT, whereas the blastula stage was reached for its nanoform. At 3.7 mg MBT/L, embryos reached gastrula and prism stages in LDH-MBT treatment, compared to the morula and blastula stages observed at the same concentration for soluble MBT. At 1.23 mg MBT/L, animals reached the pluteus stage for both forms of MBT. Therefore, this study emphasizes the need for a more comprehensive strategy using the embryo-larval responses. The analysis reveals that, although the LDH-MBT is classified as very toxic, the methodology employed in this study evidenced a retard effect, probably related to the controlled release capacity of this innovative nanoform which limits the exposure concentration of soluble MBT over time. These findings highlight that a mere classification of toxicity based on traditional analysis is insufficient. It underestimates the comparative severity of impacts, indicating a need for a deeper understanding of the embryo-larval developmental effects as a sensitive endpoint to ensure an environmentally responsible application of these innovative materials.

6.08.P-Th561 Differentially induced autophagy by engineered nanomaterial treatment has an impact at cellular homeostasis and cytotoxicity

Victor Alcolea-Rodríguez[1], Verónica I. Dumit[2], Rico Ledwith[2], ***Raquel Portela****[3], Miguel A. Bañares[1] and Andrea Haase[2], (1)ICP, Spanish National Research Council (CSIC), Spain, (2)Federal Institute for Risk Assessment (BfR), Germany, (3)ICP, Spanish National Research Council (CSIC), Madrid, Spain*
Considering the escalating production of engineered nanomaterials (ENMs), hazard needs to be carefully evaluated in order to foresee detrimental future consequences for human health and the environment. In order to reduce animal testing, New Approach Methodologies (NAMs) emerge as promising tools, but the development of effective NAMs necessitates a thorough understanding of ENM’s mode of action (MoA). In this work, a detailed set of *in vitro* tests has been constructed to facilitate the categorization of 10 ENMs by unraveling their mode-of-action with the help of *in chemico* assays. Cell viability testing via WST-1, LDH release estimation of cell permeability, autophagosome detection, and proteomics are employed to study toxicity in lung epithelial A549 and differentiated THP-1 (dTHP-1) macrophage-like cells, which has been correlated with the reactivity of the nanomaterials' surface. For instance, non-reactive nanomaterials like SiO_2 NM-200 do not affect cell viability. In contrast, highly reactive ENMs like CuO and ZnO (NM-110 and NM-111) substantially impact the viability of A549 and dTHP-1, leading to a loss of homeostasis. Yet, unique protective mechanisms emerge for moderately reactive ENMs: we have observed for the first time that TiO_2 (NM-101 and NM-105), known for its acidic behavior, and CeO_2 (NM-211 and NM-212),

recognized for its oxidative surface reactivity, prompt the formation of autophagosomes. This is evidence of autophagy induction, which appears to be activated as a protective measure against the MoA of these reactive ENMs, helping to maintain cell homeostasis.

6.08.P-Th562 Safer by design approach to support innovation: a practical case study with polymers
Torres Anaelle[1]*, Jacques-Aurélien Sergent*[2]*, Mickael Cregut*[3]*, Laurent Garel*[3] *and James Wilson*[1]*, (1)Rhone, Solvay - Biomattech RIC-Lyon, France, (2)Solvay SA, Toxicological and Environmental Risk Assessment unit, Belgium, (3)Solvay - Biomattech RIC-Lyon, France*
Solvay aims to develop different activities to assess the potential impact of substances during their manufacturing, their use or their degradation/release. A safer-by-design approach enables the selection of the best candidates from application performance tests, (eco-)toxicological assays and biodegradability results. These approaches are employed during the development of a new range of safe and sustainable products by our Research and innovation function.

As part of the safer by design approaches, we carry out toxicological evaluations at an early stage of development. In the context of the minimization of animal experimentation with the 3R strategy (Reduce, Reuse and Replace), the development of *in vitro* evaluation protocols is attractive, at least for the initial phases of toxicological assessments for new substances. Therefore, Solvay uses and develops *in vitro* models relevant to assess typical exposure routes (*i.e* pulmonary, cutaneous, intestinal systems) associated to expected final end-markets of market end points.

Among the materials which have gone through this process during the past years, some polymer case studies are presented here. Polymers are widely used in various materials, consumer or industrial applications such as paints, household and personal care formulations, packaging etc. with increasing human exposure and thus the potential risks related to short- and long-term toxicity for both consumers and workers. Today, polymers are not REACH registered, but the reacted monomer and the other substances that form part of it, must be registered if their concentration exceeds 2% (w/w) or if their quantity exceeds 1 tonne per year. Considering these uses and the diversity of polymers, innovative methods able to predict and assess effects at environmental release and exposure level are required.

The battery of tox evaluations presented here include a catalog of cell lines mimicking different organs and an exposure up to 100h using real time monitoring of cell proliferation allowing a direct comparison between the candidates but also to compare observed effects toward a control (non exposed condition).

6.08.P-Th563 Biological Effects of Microcapsules
Norihisa Tatarazako and ***Yukiyo Okazaki****, Ehime University, Japan*
Microcapsules are the minute particulate matter which encloses various chemical substances inside of the core. The outer shells are often made by a kind of plastics so it could be regarded as microplastic.
They are used in many aspects including drug delivery, stabilizing the agricultural chemical effects and to keep fragrance durability of the softening agent.

The behavior of the chemical in the capsules changes depending on the properties of outer shell.
It means the characteristic of microcapsules such effect like easily decomposable chemicals to stable or volatile component to less diffusible, provides the change to the behavior of encapsulated chemicals, may cause the hazard in the environment.
Encapsulation allows any chemical substance to have long-distance mobility and resistance to decomposition, and may have properties equivalent to so-called POPs. Therefore, with the aim of clarifying the ecological effects of chemicals mediated by microcapsules, we synthesized microcapsules ourselves and investigated changes in the toxicity of chemicals before and after embedding them in capsules, and here we report.

As for the toxicity test, a Daphnia acute toxicity test in accordance with OECD Test Guideline 202 or a fish acute toxicity test in accordance with OECD Test Guideline 203 was conducted. Capsule shape and number were determined using an optical microscope and a particle counter.

6.08.P-Th564 Application of Adverse Outcome Pathway framework in assessing nanogold exposure to Daphnia magna
Tarryn Lee Botha[1]*, Avela Mbangatha*[2] *and Victor Wepener*[3]*, (1)Department of Zoology, University of Johannesburg, South Africa, (2)North West University (Potchefstroom Campus), South Africa, (3)Water Research Group, Unit for Environmental Sciences and Management, North-West University, South Africa*
Nanotechnology has permeated almost every aspect of technology, science, and daily life, and it is a promising field for future advancements. Nanomaterials (NMs) are materials with a one-dimensional size range of 1-100 nm and can exist in a variety of elemental cores and shapes with varying surface coatings. The developmental of nanogold (nAu) has become advantageous as it is applicable for medicinal diagnosis, imaging and as a drug delivery vector. When NMs are released into the aquatic environment, they have the potential to harm aquatic organisms at all stages of their product lifecycle. However, there is little known about the harmful effects of these NMs, particularly at the molecular level. The adverse outcome pathway (AOP) framework was utilized in this study to address adverse effects of nAu (CTAB capped rod shaped nAu and citrate capped spherical nAu) and ionic Au on *D. magna* at different levels of biological organisation using M7 media. The molecular

initiation event was determined at the molecular level using metabolomics, Key Events at the whole organism level using physiological changes based on swimming behaviour, heart rate, and respiration and an Adverse Outcome at community level (reproduction and functional response). CTAB capped rod shaped nAu with a size of ± 40 nm had an LC50 of 12.1 µg/L, the highest acute toxicity of all groups tested. Ionic Au had an LC50 of 57 µg/L while spherical citrate capped nAu had a size of ± 20 nm had an LC50 of 70 mg/L. Several metabolic pathways were affected after 48 h exposure and these included the biotin metabolism, insect hormone biosynthesis, amino acid metabolism and nicotinate and nicotinamide metabolism. CytoViva darkfield imaging confirmed adhesion of nAu to the carapace of daphnids and higher concentrations were observed on molts. The heart rate increased significantly at the LC20 for all groups, while respiration increased for nano-exposed groups and decreased for the ionic Au group while reproduction was significantly decreased compared to control for all groups. The behaviour of daphnids was significantly altered between groups where citrate capped nAu had increased molting and remained mobile in the bottom zone, while CTAB and ionic Au were found significantly more within the top zone. The functional response tests indicated a decreased escape response in daphnids, and therefore survival. Nano-specific effects were observed in two types of nAu when compared to their bulk ionic counterpart.

6.08.P-Th565 Two-dimensional Hexagonal Boron Nitride (h-BN) and One-dimensional BN Nanotubes (ID-BNNTs): Structural Analogs to Graphene and Carbon Nanotubes with Distinct Effects

Mona Connolly *and José M. Navas, Department of Environment and Agronomy, Institute for Agricultural and Food Research and Technology, Spanish National Research Council (INIA-CSIC), Spain*

Through tailoring of nanomaterials the future will see more advanced and 2D materials emerging. For example, h-BN´s honey-comb hexagonal atomic structure is isomorphic to graphene, while BN nanotubes (BNNT) are analogous in shape to carbon nanotubes. Besides the similar form there are unique properties conferred upon these materials, by replacing carbon with boron and nitride atoms, that make them very attractive in a wide range of human activities. Expanding our knowledge about the particularities of the interaction of these materials with cellular systems is essential for an appropriate risk assessment of these substances, but also for the application of safe and sustainable by design (SSbD) frameworks and for the use of grouping and read-accross approaches.

In order to generate data about possible environmental effects of h-BN and BNNT, the rainbow trout (*Oncorhynchus mykiss*) was used as a model aquatic test organism and a range of cell lines from the same species: *RTgill W1, RTG-2, RTH 149, RTL W1*. Effects on cellular metabolic activity, plasma membrane integrity and lysosomal functioning were characterised and any increases in reactive oxygen species (ROS) were compared and contrasted. While h-BNs were visualised enclosed in endosomes, BNNTs were observed free in the cells cytoplasm with no apparent mechanism of uptake or intracellular processing. BNNTs caused a dose dependent reduction in cellular metabolic activity in all cell lines, and to a similar extent, while no effects were evidenced for h-BN. Instead h-BNs only caused effects on the plasma membrane, and while increases in ROS levels were measured this did not lead to a reduction in cellular metabolic activity. Effects on lysosomal functioning could not be interpreted due to interference of the materials with the neutral red dye used in this assay.

These findings highlight that apart from elemental composition, material form and atomic arrangement play a decisive role and will dictate the extent of advanced materials interactions with biological systems. As material science expands into the 2D materials space with endless possibilities of atomic replacements and combinations, cellular *in vitro* testing platforms can provide key mechanistic focused information in SSbD frameworks.

6.08.P-Th566 Comparing the Effects of 6PPD and a Mixture of Atmospheric Transformation Products on Immortalized Chicken and Double-Crested Cormorant Hepatic Cell Lines

Tasnia Sharin[1]*, Vincent Buiel*[2]*, John Liggio*[3]*, Chao Peng*[3]*, Tom Harner*[3]*, Amandeep Saini*[3]*, Doug Crump*[4] *and Jason O'Brien*[1]*, (1)Ecotoxicology and Wildlife Health Division, Environment and Climate Change Canada, Canada, (2)University of Ottawa, Canada, (3)Environment and Climate Change Canada, Canada, (4)Ecotoxicology and Wildlife Health Division, Environment and Climate Change Canada (ECCC), Canada*

N-(1,3-dimethylbutyl)-*N′*-phenyl-*p*-phenylenediamine (6PPD) is an antioxidant added to tires to prevent degradation. 6PPD reacts with atmospheric oxidants and creates transformation products either on tire surfaces or on particles emitted into the atmosphere. One of its transformation products, 6PPD-quinone, has been found to be toxic to aquatic organisms, especially coho salmon in the Pacific northwest. However, little is known regarding the toxicological properties of 6PPD and/or its transformation products (TPs) and mixtures of TPs in birds. In this study, cell viability, reactive oxygen species (ROS), oxygen consumption rate, and changes in mRNA expression will be determined in immortalized chicken and double-crested cormorant hepatic cell lines, LMH and DCH22, cultured as 3D spheroids following exposure to 6PPD and four mixtures of TPs formed under various typical atmospheric conditions. Screening 6PPD and the mixture of TPs will provide improved understanding on the effects of these compounds given the large differences in sensitivity between aquatic species. The TPs were generated in the presence of ultraviolet radiation (UV), ozone (O3), hydroxy (OH) radical, and nitrogen oxides (NOx; in the presence of OH) using a custom oxidation flow reactor. Neat extracts were dissolved in DMSO, and serial dilutions were prepared in DMSO. Cell viability and ROS were evaluated using intracellular ATP concentration and oxidation of 2,7-dichlorofluoroscin diacetate (DCFDA) fluorogenic probe by ROS, respectively. Customized species-specific PCR arrays comprising 48 genes will be used to determine changes in mRNA expression. The O3 and UV TPs were the most cytotoxic and caused an increase in ROS in LMH spheroids. The OH and NOx TPs had similar cytotoxicity as 6PPD (LC50 values between 0.09-0.18) in LMH spheroids and all three mixtures increased ROS concentration. The decrease in ATP concentration and increase in ROS by 6PPD and the TPs suggest impairment of mitochondrial function in LMH spheroids. The rate of oxygen consumption in the spheroids will elucidate more information on mitochondrial toxicity, while gene expression data will provide information on the mechanism of toxicity for 6PPD and the TPs. Based on the prevalence of these compounds, this study will generate much needed toxicity data for avian species.

6.08.P-Th567 Instantaneous photocatalytic degradation of pesticides over coupled ZnO@CdS nanocomposite via greener approach

***Jyoti Yadav** and Manviri Rani, Chemistry, Malaviya National Institute of Technology Jaipur, India*

Photoactive ZnO@CdS coupled nanocomposite was designed by *Azardirachta indica* extract via greener mode. Consequently, the targeted pesticides chlorpyrifos (CP) and atrzaine (ATZ) have high poisonous and persisting behavior in the environment. Different spectroscopic and microscopic techniques were performed to characterize the coupled nanocomposite. Crystalline behavior and irregular shape with 50nm particles size was suggested by PXRD and FE-SEM analysis, respectively. New spectroscopic vibration of Zn-S and Cd-O rooted the coupling of parent nanomaterials. The photo-catalytic activity of ZnO@CdS for degradation of pesticides was monitored at different concentration of pesticides, catalyst dose, variable pH parameter and irradiation source (light and dark). The large extent of degradation (89-91%) to visible region was due to reduction in band gap (1.67 eV), enhanced surface area ($111 m^2 g^{-1}$) and diminished ionic species recombination capability. The generation of photo active radicals was confirmed by scavenger analysis. The Effect of ionic strength was helpful to understand the interaction mechanism involved in the removal of contaminants. Being more effective than natives, ZnO@CdS has substantially suppressed the half-life of pesticides as revealed from generation of smaller and less toxic metabolites. The generation of smaller and non- toxic byproducts was analyzed by GC-MS technique. Langmuir model amd first- order kinetics followed by photocatalyst in degradation process. Robust and photocatalytic behavior of ZnO@CdS upto 10^{th} cycle could deep-rooted its sustainability high efficiency for environmental and industrial purposes.

6.08.P-Th568 Co(II) oxidation to Co(III) at magnetite surface under oxidizing conditions

***Laura Fablet**[1], Mathieu Pédrot[2], Rémi Marsac[3], Anthony Beauvois[4], Valérie Briois[4] and Fadi Choueikani[4], (1)Géosciences Rennes UMR 6118, University of Rennes, France, (2)Géosciences Rennes - UMR 6118, Univ Rennes, CNRS, France, (3)IPGP, France, (4)Synchrotron Soleil, France*

Magnetite (Fe_3O_4) and maghemite (Fe_2O_3) nanoparticles are widely used in environmental applications, particularly for soil and water decontamination. However, the interactions between metal ions and magnetite are not yet well understood, especially for transition metals. Our recent work[1] allowed to identify the formation of different Co(II) species at the surface of stoichiometric magnetite (Fe(II)/Fe(III) = 0.5). However, magnetite nanoparticles are most often used under oxidizing conditions. Therefore, the influence of oxidation on Co adsorption on oxidized magnetite (with Fe(II/Fe(III) ratio = 0.1) was here studied.

Magnetite nanoparticles were synthesized by co-precipitation of iron salts under anaerobic conditions, then oxidized with H_2O_2. Co adsorption kinetics were performed under aerobic and anaerobic conditions, and revealed different adsorption behavior, with instantaneous adsorption under aerobic conditions and longer under anaerobic conditions. Batch adsorption studies were carried out under oxidizing conditions, with Co concentrations ranging from 0.1 to 12 mM, at pH 8, at room temperature. Some of the samples were filtered to determine the extent of Co removal from the solution. The solid phase was analyzed at SOLEIL synchrotron by X-ray spectroscopy (XAS) and X-ray magnetic circular dichroism (XMCD) at Co $L_{2,3}$-edge. Furthermore, Co-magnetite reaction kinetics were followed by Quick-XAS at Co K-edge and multivariate curve resolution with alternating least-squares fitting (MCR-ALS).

Batch adsorption kinetic of Co onto magnetite drastically differed between aerobic and anaerobic conditions. Three Co species could be differentiated over time after MCR-ALS treatment of the Quick-XAS data. The first one, characteristic of Co(II), rapidly vanish, while the third one corresponds to Co(III) and, therefore, to the oxidation of Co(II) to Co(III). These results are supported by those obtained on the DEIMOS line, where the spectra reveal, once the reaction is complete, the presence of a mixture of Co(II) and Co(III) on the surface of the magnetite, with a larger proportion of Co(III) at high [Co]. The second species, difficult to determine, might therefore be a mixture of oxidized Co(II) and precipitated Co(II).

This study highlights the formation of mixed species of Co(III) and Co(II) precipitated on the magnetite surface, depending on the initial Co concentration, which might play a role in Co behavior and fate in oxic environments.

6.09 Plastic Pollution: Bridging the Gap Between Science and Policy Needs

6.09.T-01 Experimental Assessment of Plastic and Biota Removal by Plastic Clean-up Mechanisms

***Giulia Leone**[1,2,3,4], Ana I Catarino[5], Ine Pauwels[3], Mattias Bossaer[2], Regine Oco Conda[6,7,8], Chia-Yu Chu[7], Peter Troch[9], Peter Goethals[10] and Gert Everaert[5], (1)Research Group Aquatic Ecology, Faculty of Bioscience Engineering, Ghent University, Flanders, Belgium, (2)Flanders Marine Institute (VLIZ), Belgium, (3)Research Institute for Nature and Forest (INBO),*

Belgium, (4)Ghent University (UGent), Belgium, (5)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium, (6)Faculty of Science and Bioengineering Science, Free University of Brussels (VUB), Belgium, (7)Faculty of Science, Ghent University (UGent), Belgium, (8)Faculty of Sciences, Antwerp University, Belgium, (9)Dept. of Civil Engineering, Ghent University (UGent), Belgium, (10)Research Group Aquatic Ecology, Faculty of Bioscience Engineering, Ghent University (UGent), Belgium
Due to mismanaged plastic and its accumulation in the environment, various technologies have been developed and deployed to collect legacy plastic. However, because of the novelty and multitude of these technological mechanisms (i.e., the mechanical processes by which litter is gathered to a collection point, to be collected), their positive and negative impacts on the environment are, so far, largely unknown. As plastic clean-up technologies play a significant role in minimizing plastic litter in the environment, and as the United Nations Environment Assembly is working towards a legally binding and international treaty to target plastic pollution by 2024, empirical data are needed to guide and regulate the use of these technologies to ensure their net benefits. Since numerous parameters determine the collection of plastic and biota by plastic clean-up technologies, this study aimed to experimentally investigate the effects of four parameters (i.e., flow velocity, biota shape, plastic type, and plastic load) on the recovery rates of plastic and biota. Without intending to mimic the exact design of any specific company, we tested two independent, generic, and non-commercial plastic clean-up mechanisms, which we custom-built specifically for the experimental setup. The experiments were performed in a laboratory flume in which various conditions of each of the selected parameters were controlled and individually tested. For instance, three flow velocities (i.e., 0.1, 0.2, and 0.3 m / s) were separately assessed, while the other parameters were kept constant. Our preliminary results suggest that changes in flow velocity might have different effects on the recovery rate of biota. In a real case scenario, the removal of plastic or biota by a plastic clean-up mechanism is a combination of multiple parameters interacting with each other. Nevertheless, empirical studies such as this are necessary to establish baseline effects of each single parameter, contributing to the parameterization of hydrodynamic and ecological models.

6.09.T-02 Predicting Plastic Degradation and Fragmentation in the Environment
Sam Harrison[1]*, Brandon Lopez*[2]*, Katherine Santizo*[3]*, Joana Marie Sipe*[2]*, Patrizia Pfohl*[3]*, Richard Cross, PhD*[1]*, Antonia Praetorius*[4]*, Gbotemi Adediran*[1]*, Claus Svendsen*[1]*, Wendel Wohlleben, Dr.*[3] *and Mark Wiesner*[2]*, (1)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom, (2)Duke University, (3)BASF SE, Germany, (4)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands*
The degradation and fragmentation of plastic in the environment is an important process that can have a significant impact on fate, exposure, bioavailability and ultimately risk. Therefore, future policy needs should consider the ensuing heterogeneity in sizes, shapes and degradation states. To enable this, prospective risk assessments must include information on plastic degradation and fragmentation, requiring the ability to make predictions of these across a range of environmental compartments and polymer types. In recent years, our mechanistic understanding of degradation and fragmentation has been developing, but until now, that knowledge has not been embedded into predictive modelling approaches. In this presentation, we introduce the FRAGMENT-MNP model – the first model to embed a mechanistic conceptualisation of plastic degradation and fragmentation, thus enabling realistic predictions of fragmentation and the subsequent evolution of size distributions for a broad range of polymers, environmental compartments and their environmental stresses.

The model conceptualises fragmentation rates, dissolution rates and fragment size distributions (the split of fragmenting mass amongst smaller size classes) that are functions of the degradation state of the polymer, polymer type, particle size, and mechanical power input. To parameterise the model, a comprehensive database of degradation and fragmentation experiments has been compiled. This includes a broad range of polymers (LDPE, PP, HIPS, PU, PET, PLA, and PA) that have undergone photolysis, hydrolysis and enzymatic hydrolysis at different temperatures and humidities, followed by mechanical disruption. We fit a machine learning model to these data in order to scale fragmentation rates, degradation rates and fragment size distributions to those corresponding to degradation stresses and mechanical powers likely to be encountered in the environment.

Our model is open-source and pragmatic in its data requirements, making it an easily usable tool for industry, regulators and academia, as well as being easy to integrate into exposure models. This offers a strong bridge between scientific understanding and potential future policy needs that take plastic heterogeneity into account.

6.09.T-03 Leveraging Physiology & Behavior to Better Understand Exposure, Uptake, & Elimination of Micro- and Nanoplastics (MNP) in Pelagic & Benthic Species within the Context of Quantitative Risk Assessment
Benjamin Patrick de Jourdan[1]*, Danielle Philibert*[1]*,* ***Davide Asnicar***[1] *and Craig Warren Davis*[2]*, (1)Huntsman Marine Science Center, Canada, (2)ExxonMobil Biomedical Sciences, Inc.*
A significant body of ecotoxicological data have been developed for micro- and nanoplastics (MNPs). However, there remain challenges in synthesizing and interpreting these data within the context of ecological risk assessment. While many of these challenges are being addressed, particularly those around study design, QA/QC, and reliability, one significant challenge remains - identification of relevant species for use in the development of ecological protection criteria (i.e., PNECs, HC5). Previous studies have attempted to derive these values, however significant differences in species sensitivity have been observed for micro- vs. nano-sized particles. This results in (1) significantly different PNEC values as a function of the selected particle size / size range, and (2) uncertainty as to the relative sensitivities of different aquatic species to different MNP size, shape, and polymer types.

This work summarizes results of a systematic quality review of over 500 MNP biomonitoring studies using criteria previously developed by Hermsen et al., with minor modification to integrate relevance and reliability more clearly for risk assessment & prioritization of potential future environmental monitoring programs. For studies that met the criteria, trait-based descriptors and particle characteristics and distributions were compiled for all species to provide guidance on (a) species selection and (b) environmentally relevant exposure profiles for informing future biomonitoring and risk assessment studies.

The long-term objectives of this work are three-fold – first, to systematically compile and evaluate physiology and behavioral data for a wide range of freshwater and marine species into a searchable database for use in identification of sentinel species for ecosystem health & quality monitoring, and ecological risk assessment. Second, this work is intended to provide a biologically-relevant framework against which the relevance of existing (and developing) MNP reference materials may be evaluated and additional studies prioritized. This can provide a systematic basis for the inclusion or exclusion of species or materials for the purpose of quantitative risk assessment in various environmental compartments. Third, available information on ingestion and egestion rates as well as behavior and habitat can inform the selection of relevant and efficient species for integrated biomonitoring programs in sea surface, subsurface, estuarine, and sediment environments.

6.09.T-04 Considerations Regarding the Representativeness of Microplastic Concentrations in Aqueous Systems: Are the Data Fit-for-Purpose?

***Richard Cross, PhD**, UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*

A significant source of uncertainty in environmental exposure and risk assessment for micro- and nanoplastics (MNPs) stems from a lack of standardized methodologies and guidance related to sample collection strategies, extrapolation, and reporting of relevant computed values and their associated statistical variability. This lack of standardization further obfuscates the relevance and reliability of these data for use in the calibration and validation of quantitative exposure assessment models. The purpose of this work is to understand common sampling strategies, identify key parameters which may propagate uncertainty & variability in these techniques, and ultimately to develop a framework for systematically assessing relevance and reliability of these data for use in quantitative risk assessment of MNPs.

The development of guidance and best practices presented in this framework focus on several key areas for evaluation and categorization within a standardized rubric / system: (1) Synthesis and evaluation of existing methods for collection, quantifying, extrapolating, and reporting of environmental micro- and nanoplastic (MNP) samples, (2) communication of limitations & uncertainties of sampling strategies with respect to relevance and reliability (e.g., collection of samples by trawl vs. grab samples, sample volumes / trawl lengths, etc.), and their representativeness (e.g., limited geospatial or temporal scales) for informing an exposure assessment for the purposes of assessing risk, and (3) further identification and characterization of ancillary data collection and reporting metrics which are required / desired to increase the reliability and utility of existing and planned environmental MNP data (e.g., ocean current / river flow measurements, water chemistry, sampling depth, particle size range of sampler device, etc.). The relevance of data must be considered in the context of problem formulation and the purpose to which the data is put. We provide an approach to evaluate relevance of data and estimate representative sample volumes for a given study design, important aspects which can help with harmonisation efforts in this area.

6.09.T-05 A little less conversation: How existing governance can strengthen the future global plastics treaty

***Thomas Maes**[1], Nicole Wienrich[2], Laura Weiand[2] and Emily Christine Cowan[3], (1)GRID-Arendal, United Kingdom, (2)Research Institute for Sustainability (RIFS), Germany, (3)SINTEF Ocean, Norway*

The growing plastic production, the lack of their waste management, and fragmented regulatory responses have increased their abundance in the environment. Plastic pollution has created significant environmental concerns leading to planetary boundary threats. As a result, an increasing number of governments and non-state actors have begun negotiations on a legally binding treaty to cover the full-life-cycle of plastics by 2024. While the negotiations were mandated at the United Nations Environment Assembly 5.2 in March of 2022, how the new agreement would link to existing governance bodies addressing plastic pollution at the global, regional, national and local levels requires careful consideration. This analysis examines the main multi-level governance structures in place to govern plastics while highlighting their principal roles as well as shortcomings and gaps. It then explores ways a new global agreement could complement existing governance structures without imposing and duplicating the work of previous agreements.

6.09.P Plastic Pollution: Bridging the Gap Between Science and Policy Needs

6.09.P-Mo508 Harmonizing beach litter data: A cornerstone for impact assessment

***Fei Song**[1], Francesca Verones[2], Martin Dorber[1] and Johan Pettersen[1], (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Industrial Ecology Programme, Norwegian University of Science & Technology (NTNU), Norway*

Plastic litter poses a global environmental problem, impacting marine and coastal ecosystems, human health, and societal well-being on a global scale. Plastic debris on beaches are an issue for wildlife, but also impacting cultural ecosystem services. Life Cycle Assessment (LCA) is one of the most used approaches for environmental assessments, but models to account for plastic impacts are scarce and for impacts of beach litter on cultural ecosystem services non-existent. However, the development of such a model is crucial for shaping policies and sustainable plastic management strategies.

Knowing the quantity of floating marine plastic that ends up on beaches is a prerequisite for any impact assessment model for beach litter. However, the unavailability or inconsistency of beach plastic litter reporting between countries makes this no easy task. Moreover, databases predominantly report the number of plastic items, rather than mass, which again may introduce variations in the data.

To address this issue, we investigated how big the discrepancies and potentials for harmonization between different reporting standards is and developed an approach to convert number of plastic items to mass. We collected data from 20 coastal countries and 8 years in Europe . Based on the composition of plastics item, the weight average of mass is calculated, either country specific or as a global average

With this knowledge impact assessment models for beach litter impacts on cultural ecosystem services can be developed, based on the willingness to pay for clean-up activities and this may help to develop appropriate policies for individual countries to combat coastal plastic pollution.

6.09.P-Mo509 Towards a Safe Circular Plastic Economy: Using a Dynamic Probabilistic Material Flow Analysis Approach to Capture Japanese Plastic Flows

Yiwen Zhang[1]*, Zhanyun Wang*[2,3] *and Bernd Nowack*[4]*, (1)Technology and Society Laboratory, Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)Chair of Ecological Systems Design, Institute of Environmental Engineering, ETH Zurich, Switzerland, (4)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*

With the increasing production and consumption of plastics, a huge amount of waste is generated and subsequently discharged into the environment, posing unprecedented environmental challenges. The transition to a circular plastic economy is regarded as a solution to plastic pollution and resource depletion. Different from the traditional linear product lifecycle, a circular economy creates cycles where products, materials and chemicals are maintained in the cycle via reuse, recycling and so on. As one of the leading countries in recycling practices, Japan announced the Resource Circulation Strategy for Plastic in 2021, setting targets regarding the reduce, reuse and recycling of plastics. To achieve these targets, it is important to re-design the product lifecycle and develop a domestic circulation system to increase material efficiency. To do so, it is critical to first understand the current plastic use and waste management practices. However, the resolution of existing studies is not sufficient to provide such in-depth insights into the waste management of specific product categories, and a comprehensive investigation of all relevant industrial sectors and applications is missing. In this study, we model the domestic plastic flows in Japan since 1950, using a Dynamic Probabilistic Material Flow Analysis (DPMFA) approach and with a high resolution of the waste management systems. Plastic stocks in use and waste streams are estimated according to historical activity data and corresponding product lifetimes. The uncertainties of all parameters are evaluated using a data quality indicator matrix, and the model was solved 10,000 times following a Monte-Carlo method to present the variance of the model results. The model results present hotspots and blind spots of plastic losses from the technosphere, thus providing guidance on future research and action to enhance plastic circularity in Japan and other parts of the world.

6.09.P-Mo510 Remobilization and Deposition of Plastics along Riverbanks in a Typical French Estuary During Complete Tidal Cycles

Rosa Sawan[1,2]*, Perine Doyen*[3]*, Guillaume Veillet*[1]*, Florence Viudes*[1]*, Celine Mahfouz*[4] *and Rachid Amara*[1]*, (1)UMR 8187 - LOG – Laboratoire d'Océanologie et de Géosciences, Univ. Littoral Côte d'Opale, CNRS, IRD, Univ. Lille, France, (2)Cnrs-L, National Center for Marine Sciences, Lebanon, (3)UMRt 1158 BioEcoAgro, USC ANSES, INRAe, Univ. Artois, Univ. Lille, Univ. Picardie Jules Verne, Univ. Liège, Junia,, Univ. Littoral Côte d'Opale, France, (4)National Centre for Marine Sciences-Lebanon, Lebanon*

Estuaries are dynamic ecosystems that act as essential transition zones between freshwater and marine environments. They are considered to be areas of accumulation or reservoirs for plastics . The Slack estuary, a small estuary that flows into the English Channel at Ambleteuse (France), provides a remarkable example. Some plastics were collected in this estuary in order to define a set of 480 plastics of various types (shapes and polymers) and sizes, including microbeads (3-4 µm) and meso- and macroplastics (1 cm² to 25 cm²). Further, these plastics were then strategically placed along the banks in three types of quadrats with distinct substrates: gravels, sand and vegetation. The remobilization of these plastics was analyzed during six different campaigns, corresponding to dry and wet seasons, with high tidal coefficients and different environmental parameters (e.g. wind, current speed). Observations were made during two consecutive tides, leading to the monitoring of a complete tidal cycle. During this cycle, the plastics deposited by the tides were also observed. Our results showed that more than 90% of the manually deposited plastics were remobilized in water and that macroplastics were the least remobilized and that most of them remained in their substrates. For plastics that have not been remobilized, gravels and vegetation retained all types of plastic, with vegetation exhibiting the highest retention. Conversely, sand does not retain microbeads. This underlines the importance of substrate type in the remobilization of plastics. Moreover, negative correlations between environmental parameters and plastic remobilization were highlighted, underlining the complex interaction between ecosystem conditions and the distribution of plastics. After one complete tidal cycle, a deposition of 2.6 ± 2.07 plastics/m^2 was observed. Macroplastics, especially fibers and ropes from maritime activities, seem to be key contributors to plastic pollution at the studied site. Finally, all the results showed the importance of understanding the remobilization and deposition of plastics along riverbanks in order to develop effective mitigation and remediation strategies.

6.09.P-Mo511 Exploring How AI Can Fill Data Gaps for Better Decision Making on Plastics Governance

Lara Veylit[1], *Pavel Stránský*[2], *Tuva Grytli*[3], *Mikkel Sornes Solbakken*[4] *and Shraddha Pankaj Mehta*[5], *(1)SINTEF Ocean, Norway, (2)SINTEF Helgeland, Norway, (3)Sustainable Energy Technology, SINTEF Industry, Norway, (4)Data & Analytics, Deloitte, Norway, (5)Climate and Environment, SINTEF Ocean, Norway*

The omnipresence of plastics has led to policy makers asking questions about the environmental and health impacts of plastic use. These questions can be difficult to address as the specific composition of plastic products, packaging, and products containing plastics by different polymers is highly varied. Further, the volumes of plastics and their composition by polymers can differ across countries due to variations in economic sectors across countries. There is therefore a strong need for country-specific studies tracing the volumes of plastics from production through to end-of-life by economic sector for informed decision making. Mapping the flow and stocks of plastics through an economy can be challenging, however, due to data gaps. Possible data gaps include the composition of products by plastics, the composition of plastics by polymers, and on the lifetime of products and plastic components. In addition, trade data is not fit-for-purpose for country-specific mapping of plastic flows; the standardization of product groups across countries requires manual work to tailor the creation of groups that accurately reflect products traded in a specific economy. Here, we quantified the material flows and stocks of plastic polymers in the Norwegian economic sector using a static probabilistic material flow analysis (MFA). The data used in the model are a combination of trade statistics and data generated by Open AI's generative AI model Chat GPT-3.5 turbo (using a few-shot approach with fine tuning) where data gaps occurred. Specifically, AI generated estimates were used to estimate the compositions of product groups containing plastics by different polymers, the composition of packaging by polymers, and product group lifetimes. To test the robustness of these estimates, these were compared to data from random small samples of waste and national waste statistics. In this study, we found estimates provided from generative AI were broadly accurate and allowed for a more complete model of how plastics flow through the Norwegian economy. This study demonstrates that emergent AI technologies can allow us to fill data gaps to a certain extent for the creation of models tailored to specific contexts for more informed decision making.

6.09.P-Mo512 Paving the Way with a Holist Approach Combining Technologies and Actions to Reduce Litter in European Rivers

Mariana Nogueira Miranda[1], *Ana I Catarino*[1], *Daniel González-Fernández*[2], *Liesbeth De Keukelaere*[3], *Tim H.M. van Emmerik*[4], *Lisa Inès Devriese*[1], *George Triantaphyllidis*[5], *Joydeep Dutta*[6], *Gaetano Bertino*[7], *Annamaria Vujanović*[8] *and Gert Everaert*[1], *(1)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium, (2)Universidad de Cádiz, Spain, (3)Flemish Institute for Technological Research (VITO), Belgium, (4)Hydrology and Environmental Hydraulics Group, Wageningen University & Research (WUR), Netherlands, (5)MINDS Technologies & Environmental Sciences, Greece, (6)KTH Royal Institute of Technology, Sweden, (7)Alchemia-nova research & innovation gemeinnützige GmbH, Austria, (8)University of Maribor, Faculty of Chemistry and Chemical Engineering, Slovenia*

The transport of litter, including macro-, meso- and microplastics, from rivers to the coast and ocean is of particular concern due to the potential ecological impacts of plastic litter in both freshwater and marine environments. The Innovative Solutions for Plastic Free European Rivers (INSPIRE) Horizon Europe project main goal is to significantly contribute to the reduction of litter through a holistic approach, that will enable the detection, collection and prevention of litter in river systems. To achieve this, our project will empower research and innovation, together with stakeholder and citizen participation, and blue investments. Through INSPIRE, we have enlisted collaborative efforts and know-how in disrupting plastic pollution, bringing together 20 technologies and actions in a consortium of 26 partners across Europe and Thailand. The project solutions include the implementation of strategies to i) collect litter from rivers (water, sediments, and riverbanks) using different technologies but also through organised cleanups with local citizens, ii) prevent litter by collecting and eliminating it from its waste streams before it reaches rivers and estuaries, and iii) develop alternatives for currently non-degradable polluting products (e.g., films used in agriculture and plastic packaging). Their technical feasibility and optimisation will be supported by cost-benefit and sustainability analyses and will include the development of business cases, strategic blueprints for scaling up and replication, and comprehensive mapping and modelling. A strategy will be in place for community engagement and dynamic communication, leveraged on multiple channels and tools to increase awareness locally and internationally. These elements converge to create a master plan to address the litter pollution related challenges at the European level and to contribute to the objectives of Mission 'Restore our Ocean and Waters' (European Commission). In this work, we share the INSPIRE innovative and collaborative approach by showcasing the six European rivers study cases where we are developing, deploying/installing, and testing innovative solutions. The complementarity of the technologic and behaviour-based solutions is explored, as well as how this concerted framework seeks to elucidate on litter pathways from rivers to the sea, paving the way for informed and evidence-based policy-making and mitigation strategies with the ambition to obtain plastic free European rivers.

6.09.P-Mo513 Mapping inland plastic flows in Santa Cruz, Galapagos

Daniela Flor[1], *Andrea Milena Osorio Baquero*[1], *Lara Pinheiro*[1], *Penelope Lindeque*[2], *Estelle Praet*[3], *Ricardo Zambrano*[4], *Ceri Lewis*[1] *and Tamara Susan Galloway*[1], *(1)Biosciences, University of Exeter, United Kingdom, (2)Plymouth Marine Laboratory, United Kingdom, (3)Department of Archaeology, University of York, United Kingdom, (4)Galapagos Conservation Trust, United Kingdom*

Plastic demand is growing rapidly. Mapping of sources of plastic pollution is needed to inform intervention strategies. A major gap in such data exists for remote yet ecologically important locations such as the Galapagos archipelago. This study focuses

on mapping and understanding the anthropogenic factors influencing litter quantity in the most populated island in the Galapagos, Santa Cruz. First, we used data from products imported in 2022 to quantify the plastic input in the Galápagos Islands and the potential to become litter in a year. Then litter was collected in kerbside transects randomly selected to identify leakage of plastics inland. Furthermore, real time data of human movement was gathered using passive infrared sensors. To evaluate the influence of human movement (sensors data) with the quantity of litter found in each transect, we obtained a Spearman Correlation coefficient. Then the influence of the area type (urban, rural or protected) in litter quantity was studied using Kruskal-Wallis test, along with Conover-Iman test.

Results showed that food packaging contributes the most to litter generation in a year. This is not different from the data obtained in kerbside transects, where the most common items found were food plastic packaging. Moreover, the statistical analyses showed human movement had a weak influence on the quantity of litter found in kerbside transects. The quantity of litter items is significantly influenced by whether an area is urban, rural or protected. Further analysis will be performed regarding the different variables that can affect littering like the presence of industries, houses, parks, dumpsites, among others in the surroundings. These results aim to contribute towards informing interventions to reduce plastic waste, specifically in islands.

6.09.P-Mo514 Environmental Fate of Plastic Pellets
Hanne Diels[1]*, Raewyn M. Town*[2] *and Ronny Blust*[2]*, (1)University of Antwerp, Belgium, (2)ECOSPHERE, University of Antwerpen, Belgium*
Plastic pollution is increasingly threatening ecosystems' health. In the environment plastics are subjected to a range of degradation processes that lead to changes in their physicochemical properties and eventual breakdown into smaller pieces. The fate and ecological impact of aged plastics may well differ from that of their pristine counterparts.

We present a case study of the Scheldt estuary, located in northern Belgium, where the Port of Antwerp-Bruges, a large polymer hub for production, handling and distribution of industrial plastic pellets is located. Beginning decades ago, plastic pellets are being unintentionally released into the environment and finding their way to the Scheldt river. Measures are taken to prevent pellet loss but the problem is not yet solved. The environmental fate of the pellets is poorly documented and understood.

To identify the current extent of plastic pellet loss, 57 critical points on the port roads are being monitored using manual sampling (50´50 cm quadrant). Each season 5 samples are taken at each point over 2 weeks. Constructive communication with the companies and the port authority was the key to the establishment of this monitoring campaign. Analysis of the results reveals that pellet loss is ongoing in the port of Antwerp at an average rate of 3 to 4.5 plastic pellets per day per m² at the critical loss points.

To elucidate the environmental fate of the released plastic pellets, an extensive monitoring was set up. Pellets were manually sampled (50´50 cm quadrant) on the port road(side), on the Scheldt riverbank downstream and upstream. The spatial distribution of the number of pellets on the riverbanks reveals that more pellets are found upstream from the port than downstream. Physical and chemical properties, such as polymer type, chemical bond structure, morphology and surface roughness are being determined by Fourier-transform infrared spectroscopy, X-ray tomography, stereomicroscopy and scanning electron microscopy. The images reveal changes in colour and breakdown of the surface of pellets found on the riverbank.

Insights into the extent of pellet loss and the fate of the pellets provide an estimate of the current and future dynamics of the pellets in the harbour and estuary including the potential ecological risk. Results are shared regularly with the companies, which provides the opportunity to interact with managers and employees to implement best practises approaches towards zero plastic pellet loss.

6.09.P-Mo515 Floating Barriers as a Monitoring Tool for Riverine Solid Litter: A Case Study in South America
Lara Pinheiro[1]*, Diana Ita-Nagy*[2]*, Desireé Hidalgo*[3]*, Daniela Flor*[1]*, Andrea Milena Osorio Baquero*[1]*, Nicole Becerra*[4]*, Inty Grønneberg*[3]*, Ian Vázquez-Rowe*[5]*, Ramzy Kahhat*[6] *and Tamara Susan Galloway*[1]*, (1)Biosciences, University of Exeter, United Kingdom, (2)Pontificia Universidad Católica del Perú (PUCP), Peru, (3)Ichthion Limited, Rourke House, United Kingdom, (4)Ichthion, United Kingdom, (5)Pontificia Universidad Catolica del Peru, Spain, (6)Peruvian Life Cycle Assessment and Industrial Ecology Network (PELCAN), Department of Engineering, Pontificia Universidad Católica del Perú (PUCP), Peru*
This work aims to provide a tool for environmental monitoring of riverine solid litter contamination and potential input into the ocean, by presenting a new clean-up technology currently being used in the Portoviejo River in Ecuador. Large amounts of solid waste are discharged via rivers to world oceans due to a combination of increased production of anthropogenic materials and waste mismanagement. Observational data on the contribution of South American rivers to litter export to oceans currently lack on recent global estimates, which highlights the need for appropriate environmental analysis feeding on management and policy measures to reduce waste. To address this issue, Ichthion Limited (https://ichthion.com/) developed an extraction tool for riverine floating litter called the Azure system which is currently operative in the Portoviejo River (Ecuador) at 1° 01' 23.9" S, 80° 29' 35.6" W. Litter collected over two years of operation (2021, 2022) was weighed and classified according to their

probable source. Meteorological data retrieved from Ecuadorian National Institute of Meteorology and Hydrology was used for correlation analysis with litter quantity. A total of 13.8 metric tons (MT) of solid litter were removed from the Portoviejo River by the Azure system in 2021 and 2022, of which 6.2 MT (ca. 44%) was either confirmed by visual inspection to be plastic or estimated to be plastic based on the composition profile of domestic waste. Filled plastic bags had the highest contribution in weight for total waste removed and were related to domestic waste. Open dumping of domestic waste in plastic bags is a common practice and constitutes a main source of riverine contamination globally, and highlights the pressure on waste management systems in regions such as the Portoviejo River water basin. There was a significant negative correlation between litter quantity and precipitation, with more waste being collected during the dry season, which is in accordance with recent arguments that litter might have increased mobilisation in rivers only during extreme events such as strong floods. The data generated using the Azure system will be further used to validate riverine plastic emissions calculated using material flow analysis. Ultimately, the innovative technology involved in the Azure system represents a promising tool to inform policy measures with consistent data aiming to tackle local anthropogenic contamination.

6.09.P-Mo516 Comparison of applicability of water column plastic sampling methods

Stephanie Oswald[1]*, Paul Vriend*[2]*, Ad M. J. Ragas*[3]*, Margriet M Schoor*[2] *and Frank Collas*[1]*, (1)Radboud University Nijmegen, Netherlands, (2)Rijkswaterstaat, Ministry of Infrastructure and Water Management, (3)Environmental Science, Radboud University Nijmegen, Netherlands*

Plastic pollution has been considered one of the major contemporary environmental challenges. Even though environmental effects associated with plastic pollution have been largely known, research on plastic concentrations mainly focuses on the marine environment. In recent years, an increasing number of studies reported environmental consequences and concentrations of plastic particles in freshwater systems comparable to those found in marine ecosystems. The magnitude of plastic particle abundance in ecosystems may be influenced by factors other than the real presence of plastics in the aquatic environment, such as sampling methods, and identification processes. Thus, a multitude of monitoring techniques have been used to collect information on the presence of macro- and mesoplastics in river systems. In this study, we assessed the variation in macro- and mesoplastic abundance and composition between two different sampling methods used to sample plastic pollution in the river Rhine, e.g., larvae net and trawl net. Additionally, we highlighted the strengths, weaknesses, opportunities, and threats (SWOT analysis) of the used methods for plastic monitoring. A difference was observed in the number of OSPAR categories in relation to the collected macro- and mesoplastic pieces between different methods. It was observed that the trawl net collects more different categories than the larvae net. However, the main categories follow the same patterns among methods, and the relative abundance per method slightly differs. The most dominant category in both methods was ‘Plastic film 2.5 -50cm (soft)’ and ‘Plastic film 0 - 2.5cm (soft). A list of 20 factors was considered to obtain an extensive multi-criteria decision approach. The key factors can be grouped into monetary factors, for example, price per day, lab cost, and the minimum number of staff required; adaptability factors, for instance, if anchoring is required, different depths at which the method can be applied, the spatial location; operational factors, for instance, the width set-up from the boat and the net, the number of samples per day, the mesh size of the net; and limitations factors, for instance, the risk of the net getting clogged, permits required, the discharge sampling range, selective filtration limitations, and fish and plant bycatch. The outcome of the current study is relevant to assist policymakers in the development of targeted measures and mitigation strategies.

6.09.P-Mo517 Establishing a methodology for monitoring microplastics in water intended for human consumption

Dora Mehn, PhD, Douglas Gilliland, ***Francesco Fumagalli****, Claudia Cella, Rita La Spina, Guillaume Bucher, Susanne Belz and Birgit Sokull-Kluettgen, European Commission - Joint Research Centre (JRC), Italy*

Micro- and nanoplastics are ubiquitous pollutants with continuously increasing levels in the environment. As the awareness surrounding this issue continues to grow, so do the concerns regarding potential impacts on human health due to exposure to microplastics. Currently, evidences indicating any health effect are very limited. However, there is a need to better understand the possible risks. This requires a greater knowledge about our exposure through, for example, ingestion of food and drinking water. In order to gain more information regarding the exposure to microplastics, the recast Drinking Water Directive (DWD) of the European Union (Paragraph 6 of Article 13 of Directive (EU) 2020/2184) has empowered the Commission to adopt a methodology to measure microplastics in drinking water, which may then be placed on a watch list of pollutants that have to be monitored by Member States. As no internationally recognized standard method exists at this time, it has been necessary to undertake a targeted study to determine an appropriate methodology for the purpose of this legislation.

To support the establishment of a suitable methodology a literature review was carried out. The objectives were to identify the methods used to analyse microplastics in drinking water, including sampling procedures and analytical techniques used to identify and quantify microplastics. Capabilities and limitations of the published sampling and analytical techniques were reviewed and the quantities, size, composition and shape of microplastics found by published studies were examined. This was supplemented by consultations of experts in the field, nominated by the EU Member States. Elements of the suggested methodology – including sampling, various spectro-microscopic techniques and software solutions – were tested in the JRC laboratories.

The methodology suggested for application in the framework of the DWD foresees the use of in-line filtration as separation method and vibrational spectro-microscopic techniques (µRaman, µFT-IR, QCL microscopy) for identification and number-based quantification of microplastic particles water intended for human consumption. For monitoring purposes, the size range of 20-5000 µm is targeted, and two groups of morphologies (“particle” and “fibre”) are considered, as well as the identification of priority polymers to facilitate consistent reporting.

6.09.P-Mo518 The Unaccounted Presence of Plastic in Sea Turtles

*Miguel J Sánchez-Guerrero-Hernández[1], Sandra Manzano-Medina[1], Rocío Quintana[1], Carolina Fernández-Maldonado[2], Elisa Martí[1], Andrés Cózar[1], **Carmen Morales Caselles**[3] and Aina Jaume[3], (1)University of Cádiz, Spain, (2)Seahorse, (3)University of Cadiz, Spain*

Marine plastic litter poses a significant environmental threat in the 21st century, and while concerns are growing, available information on marine litter remains scattered and disconnected. This study focuses on the hypothesis that sea turtles, particularly species at risk, are profoundly affected by litter and microplastics. Current monitoring protocols, however, concentrate on plastics larger than 1 mm, neglecting smaller plastic sizes. Collaborating marine scientists from the University of Cadiz, specializing in marine litter, and veterinarians formed a team to investigate the impact of marine litter on two vulnerable sea turtle species: *Caretta caretta* and *Dermochelys coriacea*, prevalent in the Gulf of Cadiz and the Alboran Sea. Preliminary findings reveal a variable number of plastic debris items in all analyzed turtles, averaging 11 items per turtle, with an average plastic quantity of 32 mg. Plastic sizes varied from 0.2 to 127 mm, with a notable abundance of small fragments (0.5 to 15 mm), including identifiable items such as a gum wrapper, a lid, and a straw. The predominant plastic fragments extracted were composed of polyethylene and polystyrene. Despite these observations, the link between the presence of plastic items and their potential role as a cause of death, either indirectly or directly, remains uncertain and necessitates further investigation. Given the pervasive presence of plastic debris in sea turtles, particularly small-sized fragments, this study advocates for an updated and standardized methodology for identifying plastic debris in these organisms, proposing a lower size limit of at least 0.2 mm. Such standardization is essential for a more comprehensive understanding of the impact of plastic pollution on sea turtles and for the development of effective conservation measures.

6.09.P-Mo519 Open Database of chemicals measured in plastic products

*Helene Wiesinger[1], **Zhanyun Wang**[2], Stefanie Hellweg[1], Anna Shalin[1], Niels Plinke[1], Armin Siegrist[1], Xinmei Huang[1] and Lu Meng[1], (1)ETH Zurich, Switzerland, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*

Plastics are widely used materials employed in various industrial sectors. They can contain various chemical substances, including residual monomers, additives, processing aids and non-intentionally added substances (NIAS), which can be released and negatively impact human and environmental health and the circular economy. Information on the presence and concentration of individual substances in specific plastic products is scarce and scattered. For this study we compiled the existing information by systematically reviewing recent measurement studies focusing on chemicals in plastic products. More than 4’000 substances have been detected in various products in recent literature. About 75% of these substances were only found in non-targeted workflows, often indicating non-intentional use. Targeted workflows and quantification efforts focused on a few typically well-regulated substances (e.g. metals, brominated flame retardants, *ortho*-phthalates). Overall, non-targeted studies show that many more substances than regularly measured in targeted analysis may be present in plastic products. At the same time, even when focusing solely on well-known and regulated substances, many new products on the market still contain them and thus can pose a risk to human health, the environment and the transition to a circular economy. Few studies have looked at the presence and concentrations in recycled plastics, and generally show large concentration variations but higher detection frequencies and concentrations in the recycled fraction. The compiled database may be useful for prioritizing substances, identifying blind spots and the need for additional measurements, and as input for substance flow analysis and exposure modelling to identify current and potential future exposure situations (e.g. when modeling circular economy scenarios). While the scientific community has made great efforts to monitor substances in plastic products, monitoring and subsequent removal are not sufficient to comprehensively manage hazardous substances in plastic products. In addition, cleaner production strategies and better supply chain communication are needed to ensure safe and sustainable use and recycling.

6.09.P-Mo520 Vegetated Discharge Areas for Plastic Debris Removal: Deciphering of their Deposition on Various Substrates

***Margaux Kerdiles**[1], Mélanie Davranche[2] and Mathieu Pédrot[3], (1)University of Rennes 1, France, (2)Geosciences Rennes, France, (3)Géosciences Rennes - UMR 6118, Univ Rennes, CNRS, France*

Wastewater treatment plant effluent plays a significant role in the discharge of plastic debris into the oceans. Conventional treatment systems cannot allow for the retention of all microplastics (Carr et al., 2016). Developments known as vegetated discharge areas (VDAs) could improve this performance through terminal refinement. These zones made up of vegetated basins have several vocations, including filtering residual micropollutants (Boutin et Prost-Boucle, 2012). There is currently no data available on the capacity of these natural filters to retain plastic debris.

This work is a preliminary study, evaluating the performance of two substrates in retaining microplastics. An inorganic substrate conventionally used in ZRVs was tested, along with an organic substrate derived from a waste recycling process. Despite their recognized adsorption properties and nutrient-rich composition, organic substrates are rarely, if ever, used in ZRVs. For the sake of environmental representativeness, the microplastics used were obtained from plastic waste collected on a beach near the North Atlantic gyre. After mechanical fragmentation in the laboratory, microscopic analysis confirms that microplastics are polydispersed in size and polymorphic.

The experiments were carried out in columns, where a flow of microplastics passed through the substrates following two modes. Pulses injections are carried out to compare the substrates' retaining performances. Continuous injections are also performed to test the saturation of the substrates. Various parameters are tested, such as the volume of substrate in the column and the flow rate. In parallel, a reliable and robust method for quantifying microplastics is being developed using pyrolysis-gas chromatography-mass spectrometry. The substrates selected showed very high microplastic retention performance (70% on average), particularly for the organic substrate (up to 90%). The same experiments were carried out with potassium bromide as a non-reactive tracer, to further characterize the filtering properties of the substrates.

6.09.P-Mo521 Characterizing Micronized Plastic Particles (10-200 µm) for Exposure Studies and Risk Assessment – A Comparison of Different Methods

Claudia Lorenz[1]*, Monica Hamann Sandgaard*[1]*, Nanna B. Hartmann*[2] *and Rodrigo Almeda*[3]*, (1)Department of Science and Environment, Roskilde University (RUC), Denmark, (2)DTU Sustain, Technical University of Denmark (DTU), Denmark, (3)EOMAR, ECOAQUA, University of Las Palmas de Gran Canaria, Spain*

Microplastics (MPs) are widely recognized as multidimensional contaminants due to their variability in size, shape, polymer type, and chemical composition, all of which potentially impact their toxicity. Consequently, adopting a multidimensional risk framework for MPs that acknowledges the complexity of these contaminants is crucial.

Realistic exposure studies must reflect this multidimensionality. However, the challenge lies in preparing and characterizing micronized plastic particles that meet these criteria. To address this, we utilized four different plastic types (polypropylene (PP), polyethylene (PE), polystyrene (PS), and polyvinyl chloride (PVC)), that were artificially and environmentally aged, ground, and sieved to obtain a desired size fraction of 10-200 µm.

We analyzed the resulting particle suspensions of these micronized plastic particles utilizing four different techniques: Coulter Counter, FlowCam, LDIR chemical imaging, and stereomicroscopy. Preliminary results from FlowCam measurements indicate that the size distributions of the four different micronized plastic particles were similar in terms of the mean equivalent spherical diameter (ESD) and standard deviation. The smallest particles were observed for PS (17.99 ± 11.21 µm) followed by PVC (24.14 ± 14.21 µm) and PA (24.38 ± 17.30 µm), while the largest were amongst PP (31.61 ± 17.57 µm). Additionally, the predominant shapes of all the micronized plastic particles were quadrilateral and oval shapes.

When comparing concentrations in the size range of 10-120 µm the FlowCam results ranged from 2316 to 10464 particles per mL. In contrast, the results from the Coulter Counter were between 47 to 188 particles per mL, thus two orders of magnitude lower. However, both techniques agreed on PS being most abundant and PP being least abundant.

Further measurements using stereomicroscopy and LDIR chemical imaging will be conducted to investigate these differences and provide additional insights into particle size distribution and shape characterization.

The size, shape, and concentration of MPs are critical aspects in experimental laboratory studies and risk assessment. This study compared various techniques to provide particle counts and characteristics, enabling researchers to obtain comprehensive data on MP properties. Such data can aid in understanding the environmental impacts of MPs and address critical information gaps that hinder the ability to conduct reliable and relevant risk assessments.

6.09.P-Mo522 The Application of Bayesian Networks to Integrate Microplastics and Nanoplastics into Regional Scale Multiple Stressor Risk Asssessments: San Francisco Bay and the Delta as a Case Study

Wayne G. Landis[1]*, Cynthia C. Kuhn*[2]*, Emma Sharpe*[3]*, Susanne M Brander, (she, her, hers)*[4]*, Brittany Cunningham*[5] *and Stacey L Harper*[6]*, (1)Western Washington University, (2)Institute of Environmental Toxicology and Chemistry, Western Washington University, (3)Environment Science, Western Washington University, (4)Department of Fisheries, Wildlife, and Conservation Sciences, Oregon State University, (5)Toxicology, Oregon State University, (6)Oregon State University*

It is now understood that micro-, nanoplastics, and their leachates are part of the contaminant loading of marine, estuarine, and freshwater systems. These materials are only one of many other contaminants and other inputs that affect water quality. Current risk assessments for micro/nanoplastics are based on species sensitivity distributions (SSDs) derived from regressions of the results of toxicity tests to a variety of species. It has now been demonstrated that it is possible to build probabilistic Bayesian networks (BNs) to estimate risk to a variety of types of microplastics and to well understood contaminants (Hg, pesticides, organics EDCs) to provide comparisons to stressors undergoing regulation and management. Bayesian networks can incorporate specific pathways, be spatially explicit, incorporate other types of contaminants, include water quality parameters, and estimate risk to multiple endpoints derived from regulations and local stakeholders. San Francisco Bay serves as the model case study because of the extensive data base on chemical contaminants and the intense sampling program conducted by the San Francisco Estuary Institute to quantify microplastics at that site. Toxicity tests demonstrate that there are multiple modes of action in addition to the dilution of or reduction to the quality of food uptake. The experimental data and the context provided by the BN relative risk model (BN-RRM) demonstrate the relative risk of each of these types of contaminants to the San Francisco Bay-Delta region. Uncertainty is explicit in the methodology and the relative assessment puts each into the current regulatory environment. The BN-RRM approach has a number of advantages in comparison the SSD derived hazard quotients. First, the conceptual model is explicit with the cause-effect pathways clearly delineated. Second, the Bayesian network approach has been demonstrated in multiple previous environmental assessments including the effects of climate change. The various BN software tools allow for the characterization of uncertainty and sensitivity. Finally, BNs can be used to calculate the environmental required to meet the management goals. Consequently, microplastics and eventually nanoplastics can be integrated into the overall evaluation and management of contaminants for the study area and other aquatic sites.

6.09.P-Mo523 Addressing Chemicals and Polymers of Concern in the UN Plastics Treaty
Martin Wagner[1]*, Hans Peter Arp*[2]*, Ksenia J Groh, PhD*[3]*, Mari Engvig Løseth*[2]*, Jane Muncke*[4]*, Zhanyun Wang*[5]*, Raoul Wolf*[2]*, Lisa Zimmermann*[6] *and Laura Monclus*[1]*, (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)Eawag - Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (4)Food Packaging Forum Foundation, Switzerland, (5)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (6)Food Packaging Forum (FPF), Switzerland*
UNEP estimates that >13,000 chemicals, that is, additives, processing aids and non-intentionally added substances, are used or present in plastics. Being aware of the governance gap regarding these chemicals, many governments express the need to better regulate them in the global plastics treaty. However, the challenge to do so is substantial due to fragmented scientific knowledge and the sheer number of chemicals to consider. Therefore, we have built a harmonized database of >16,000 plastic chemicals and have developed a conceptual framework to identify and prioritize chemicals and polymers of concern. Here, we focus on our approach to regulate groups of chemicals as well as polymers of concern based on their content of hazardous chemicals. In an iterative process, we grouped >10,000 plastic chemicals in 80 groups based on their structures and prioritized groups based on the hazard profile of their members. We applied a similar approach for polymers: Using peer-reviewed, empirical data, we identified polymer types that have been shown to contain hazardous chemicals. For both aspects, we have developed multiple regulatory scenarios to predict the implications of certain policy decisions and support policymakers in taking decisions that are evidence-based and adaptive to the needs expressed in the plastics treaty.

6.09.P-Mo525 CircleHealth – The Danish Hospital Sector Towards a Circular Transition of Textile and Plastic Waste
Nikoline Oturai[1]*, Thomas Christensen*[1]*, Steffen Foss Foss Hansen*[2]*, Susanne Pedersen*[3]*, Sarafina Liv Taudal*[4] *and Kristian Syberg*[1]*, (1)Roskilde University (RUC), Denmark, (2)Technical University of Denmark (DTU), Denmark, (3)Aarhus University, Denmark, (4)Design School Kolding, Denmark*
In 2020, the Danish Ministry of Climate, Energy, and Utilities, passed the Climate Act, committing Denmark to reduce its greenhouse gas emissions by 70 % (compared to 1990) and become climate neutral in 2025 (Climate Act, 2020). To achieve these national goals, four large mission-driven green research and innovation partnerships were established to accelerate the development of cutting-edge solutions with an equal focus on short-, mid-, and long-term impacts. One of these mission-based partnerships, focusing on plastics and textiles, is 'Trace – a transition to a circular economy'. This partnership facilitates collaborations between 90 partners including universities, knowledge institutions, and public and private companies, with a focus on the transition to circular economy (Kirchherr et al., 2017) for plastic and textiles (Trace, 2023). One of these projects is the four-year CircleHealth project, concentrating on textiles and plastics in the healthcare sector.

Extensive consumption of single-use medical products, materials, and resources in hospitals is often seen as a sterility necessity, resulting in massive amounts of hospital waste incinerated (Kane et al., 2018; Ramos et al., 2023). Despite being considered unfit for circulation, 85% of the general hospital waste is non-hazardous and can be compared to household waste (HCWH, 2020). Many of these products hold the potential for reduction, reuse, and recycling, and, thus, the CircleHealth project aims to explore measures to reduce plastics and textile consumption in Danish hospitals.

In CircleHealth, 11 partners - three universities, three Danish Regions, two knowledge institutions, and three private companies - collaborate to implement circular economy principles throughout the lifecycle of three selected plastic products and one textile product at partner hospitals. The project objectives take a starting point in the Waste Hierarchy as established in the EU waste framework directive (Directive 2008/98/EC, 2008), and aim to facilitate a vertical shift of the four healthcare products and move these, e.g., from 'incineration' to 'recycling', or from 'recycling' to 'reuse'.

The project's deliverables build on a mixed methods approach that includes the development of design strategies, Mass Flow Analyses and Life Cycle Assessments for the target products along with observations of consumption patterns and interviews with healthcare professionals to understand challenges and to test implementation.

6.09.P-Mo526 From Teams® to Transects – Local Knowledge Challenges our Understanding of Beach Litter
Thomas Stanton[1]*, Emily Johns*[2]*, Melissa Schiele*[3]*, Deirdre McKay*[4]*, Nicholas Midgley*[5]*, Antonia Law*[4]*, Catherine Sanders*[6] *and Savannah Worne*[7]*, (1)Loughborough University, (2)Skye Beach Cleans, United Kingdom, (3)Wolfson School, Loughborough*

University, United Kingdom, (4)School of Geography, Geology and the Environment, Keele University, United Kingdom, (5)School of Animal, Rural, and Environmental Sciences, Nottingham Trent University, United Kingdom, (6)Department of Geography, University of Lincoln, United Kingdom, (7)Geography and Environment, Loughborough University, United Kingdom
In 1972, Gerald Scott published the seminal academic publication to link marine anthropogenic debris (hereafter litter) at sea to litter surveyed on two beaches on the Isle of Skye, a Hebridean island in Scotland, UK. Scott foreshadowed the state of marine and coastal environments today. We now know the consequences of this litter are varied, including animal entanglement and ingestion, chemical transport, and fragmentation. Despite representing ~32% of the UK's coastline, the Hebrides and northwest mainland Scotland are underrepresented in UK beach litter monitoring. But when surveys are conducted, beaches here represent some of the most polluted in the UK.

Here we present the findings of *50 Years of Litter on Skye*, a community co-designed research project that retraced Scott's footsteps with the help of the people of Skye. Two weeks of fieldwork were informed by six months of online community engagement. Nine beaches were surveyed following the OSPAR protocol, with survey areas split into 10m wide transects (the smallest width OSPAR permit). Where possible brand, provenance, and age were recorded. Community interviews were conducted to understand local beach cleaning efforts, common litter types, and the social significance of litter and beach cleaning in the community.

We categorised 13 909 items of litter across surveyed beaches, finding beach litter density to be one order of magnitude greater than the UK average. Litter populations varied significantly between beaches, with most litter associated with the fishing industry. Litter recovered dated back to 1989, and its provenance was traced to specific fishing regions along the east coast of North America. We found significant intra-beach variation between 10m transects, suggesting this survey width is not appropriate.

Community engagement identified specific issues with OSPAR categories. Adaptations to these may increase the suitability and uptake of OSPAR surveys in this region. Traversing the shore (Gaelic: siubhal a' chladaich) for marine debris has a long regional history, but the nature and value of the debris has changed considerably.

Accurately understanding beach litter is vital to informing industrial and legislative action. But standardising pollution survey methods for international applications necessitates generalisations that underrepresent, and fail to appropriately protect, certain coastlines and communities. Local knowledge is key in efforts to improve international litter monitoring.

6.09.P-Mo527 Citizen Science Integration and Public Engagement for Plastic Litter Monitoring in the North Sea Region: Insights from the TREASURE Project in the Living Lab Nieuwpoort

Therese Nitschke[1]*, Lisa Inès Devriese*[2]*, Gert Everaert*[2] *and Ana I Catarino*[2]*, (1)Flanders Marine Institute (VLIZ), Belgium, (2)Ocean & human health, Flanders Marine Institute (VLIZ), Belgium*

Global plastic pollution is an ongoing and ubiquitous issue of environmental concern, requiring authorities, the industry, the public and researchers to work together and implement innovative methodologies to assess its impact and mitigate it. Within the framework of the TREASURE (Targeting the REduction of plAStic oUtflow into the noRth sEa) project, we will initiate a series of targeted activities within the Living Lab of Nieuwpoort, Belgium. These activities will encompass mapping plastic accumulation and fate in the environment, identifying potential sources, and developing guidelines for effective collaboration with citizens and stakeholders, and to provide insight so mitigation measures can be established by policymakers based on our findings and results. Additionally, we will prototype a system to collect and remove plastic, and the knowledge gained will be shared and capitalized on for broader North Sea region improvements. To generate a broad dataset for plastic litter monitoring and to ideally spark environmental consciousness within the society, one of the strategies is to involve the general public in scientific projects, i.e. in citizen science projects. A successful example, among others, is the Plastic Pirates EU-project (www.plastic-pirates.eu/en), in which high school teachers and children participate in litter collection observation campaigns on riverbanks, or near water bodies. We will apply the Plastic Pirates methodology in the Living Lab of Nieuwpoort (Belgium) and the data acquired from these campaigns will inform stakeholders about accumulation zones and types of litter requiring mitigation management actions. We will further focus on questions such as assessing the efficiency of citizen science observations of plastic litter and on how to improve the data flow, including for EMODnet submission, to inform local authorities. In this work we aim to demonstrate the integration of citizen science into sampling and monitoring strategies for plastic litter, providing valuable insights to empower and inform local stakeholders.

6.09.P-Mo528 The PlastChem Project: Compiling material flows of plastic to prioritize action on polymers of concern

Mari Engvig Løseth[1]*, Hans Peter Arp*[1,2]*, Raoul Wolf*[1]*, Zhanyun Wang*[3]*, Jane Muncke*[4]*, Lisa Zimmermann*[4]*, Ksenia J Groh, PhD*[5]*, Laura Monclus*[2] *and Martin Wagner*[2]*, (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian University of Science & Technology (NTNU), Norway, (3)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (4)Food Packaging Forum, Switzerland, (5)Eawag - Swiss Federal Institute of Aquatic Science and Technology, Switzerland*

According to the Global Plastic Outlook report, the production of plastic has been increasing exponentially, from ~ 2 million tonnes/year in the 1950s to 460 million tonnes/year in 2019 (OECD, 2022). Moreover, the business-as-usual scenarios indicate that plastic production would continue to expand from 460 to 1 230 million tonnes by 2060. Overall, about 2-19% of the plastic weight put-on-market consists of chemicals or additives such as plasticizers, fillers, antioxidants or flame retardants. Towards 2060, based on current trends, the mass of plastic chemicals is projected to increase by a factor of 5, from approximately 2-10 million tonnes/year in 2016 to 10 to 100 million tonnes by 2060. Of the plastics put on the global market each year, approximately 20% is landfilled and over 2% are emitted to the environment as micro- and macroplastics. Further, about 42% of plastic waste is incinerated, while 25% is recycled or reused. Both environmental emissions, landfilling and recycling present timepoints where both environment and humans can be exposed to hazardous plastic chemicals.

The PlastChem project provides a state-of-the-science report on plastic chemicals and polymers of concern that enables evidence-based policy development. Further, we aim to identify suitable measures, including suggested policy approaches for managing plastic chemicals and other actions that enable a non-toxic circular economy which ultimately reduces the spread of plastic chemicals and polymers of concern. With this purpose, material flow analyses (MFAs) of plastic and polymers were reviewed addressing the current and projected use and management of plastic in Norway, Europe, China and globally. Where available, we collected information from the different sectors “Packaging”, “Construction”, “Agriculture”, “Transportation”, “Electronics”, “Other plastics” which includes e.g. personal care and cosmetic products, household plastic and “Textiles” which includes technical textile, household textile and garments.

By analyzing the compiled MFAs, we have identified (i) sectors with high potential for improved waste management; (ii) polymers with high potential for recycling and reuse within each sector; and (iii) polymers of concern due to high potential for human or environmental exposure to their hazardous chemicals.

6.09.P-Mo529 Sustainable Personal Care; Emission Estimation, Time-series Forecasting and Policy Measures for Microplastic Beads from Personal Care Products; A Study from India

***Riya Kumbukattu Alex Miss**, School of Environmental Studies, Cochin University of Science and Technology, India*

Plastic microbeads in personal care products are still an underestimated primary source of intentionally added microplastics. These are added for the purpose of cleansing, exfoliation and aesthetics. This study assessed 47 different categories of personal care products: face wash, face scrub, shower gel and body scrub from the Indian market and assessed their abundance, size, colour, shape and polymer composition. Also, an emission estimation and time-series-based forecast for 2030 were done using ARIMA (0,2,0) for individual categories and overall. The study reveals that 49 % of the products contained microplastic, with Polyethylene being the dominant one, followed by Polypropylene, Polystyrene, PMMA and Nylon 6,6. A significant number of products (22%) contained cellulose microbeads, with ambiguity regarding their biodegradability. The identified microbeads were mainly irregular in shape and granular in texture, especially scrubs. White/transparent colour dominated the identified microbeads, followed by blue, pink, yellow, red and green. The average size of microbeads was found to be 640.74μm, 452.45μm, 556.66μm and 606.30μm in different categories. The overall annual emission estimation was 3.24×10^{19}(highest), 2.49×10^{18}(lowest) and 1.32×10^{19}(average) in 2021 and forecasted to be 3.82×10^{19}(highest), 2.95×10^{18}(lowest) and 1.55×10^{19}(average)in 2030. This exorbitantly high value is due to India's significant population, globalisation, inefficient wastewater efficiency, growing economy and disposable income. A lack of policies and adequate regulations further add to this. The presence of other chemical like TiO_2, microcrystalline wax, etc need further studies to establish their potential harm to the environment and humankind. The presence of plastic exclusively from international brands which are also imported ones throw light into the ongoing transboundary movement of plastic. Thus, this study emphasises the need to develop stringent policies for India and other well-tailored mitigation measures. Some policy recommendations are also developed in this study to curb this threat.

Keywords - microplastics; emission; policy solutions; forecast model; personal care products

6.09.P-Mo530 Event Ethnography to examine needs in the global negotiations on the Treaty to end plastic pollution: Dataset from the first session of negotiations (INC-1)

***Emily Christine Cowan**, SINTEF Ocean, Norway*

Plastics and their chemical pollution are now a planetary boundary threat. The recognition of this threat was demonstrated in March of 2022 when a historic mandate was adopted between United Nations Member States to begin negotiations on a treaty to end plastic pollution, taking a full lifecycle approach. The first round of negotiations began at the first International Negotiating Committee (INC-1) in Uruguay at the end of November 2022 and since then two additional sessions have taken place. In this presentation, Event Ethnography (EE) is utilized as a methodology to examine and document environmental agreement-making throughout the Global Plastic Treaty (GPT) negotiations. EE is a method increasingly recognized to study multilateral political and international negotiations within the science-policy nexus to examine emerging obstacles, trends, power dynamics, and actors (both state and non-state) at play in the negotiating arena. This research builds the foundation for systematically tracking the developments throughout the GPT negotiations via an ethnographic dataset. This dataset can be used to improve the understanding of the actors influencing negotiations, while also allowing scientists to understand the needs of policymakers within the negotiating arena while creating synergies with other Multi-lateral Environmental Agreements (MEA).

6.10 Science Communication: Reaching Outside of the Scientific Bubble

6.10.T-01 A Decade of Science Communication on Food Contact Chemicals: Approaches and Learnings

Joel Scheuchzer[1]*, Justin Michael Boucher*[2]*, Birgit Geueke*[2] *and Jane Muncke*[2]*, (1)Food Packaging Forum, Switzerland, (2)Food Packaging Forum Foundation, Switzerland*

Ensuring the public and its governing bodies have access to scientific research is pivotal for societal progress that is based on scientific facts. However, in the realm of science communication, effectively disseminating knowledge within and beyond the scientific community can be challenging. The intricate and nuanced nature of scientific information, particularly concerning environmental and human health issues, demands strategic communication methods. Even for experts within the scientific community, it is hard to identify and keep track of relevant publications amidst all the surrounding noise. Here we explore the complexities and approaches in bridging the gap between scientific research and diverse audiences.

We present a comprehensive framework developed over our years of experience in the field of science communication focusing on food contact chemicals and their interactions with human and environmental health. This includes presenting challenges faced, real examples from our previous communications, and some valuable insights gained along the way.

Our approach starts with the crucial aspect of adapting content for different audiences. Recognizing the diverse needs and levels of understanding between journalists, scientists, policymakers, or industry professionals, we supplement peer-reviewed publications with varied content forms. These include news articles, blog posts, press releases, illustrations, fact sheets, dossiers, and webinars. Each is based on a clear narrative and serves a unique purpose, catering to specific preferences and increasing the likelihood of engagement.

Furthermore, we offer tangible examples of successful (and less successful) science communication in action. We use a recent 2022 peer-reviewed article on migrating food contact chemicals as a case study. By employing a range of communication techniques, including developing narratives, visuals, and data-based tools, we effectively reached beyond the scientific 'bubble' into the realm of policymakers, advocacy organizations, and the concerned public.

Through sharing our science communication approach, we hope others can learn from our experiences and try out new communication formats to help them in expanding the reach of their own research.

6.10.T-02 Science Communication as a Tool to Recruit the Next Generation of Scientists

Rozarka Jilkova[1]*, Jitka Vanackova*[2] *and Petra Nezvalova*[2]*, (1)Faculty of Science, Masaryk University, Czech Republic, (2)RECETOX, Masaryk University, Czech Republic*

Science and innovation are essential for solving the world's most pressing challenges. However, to attract the students to science requires multiple strategies, and especially effective communication strategies.

Over the past six years, we have actively engaged in initiatives and activities to attract students to our newly launched "Environment and Health" study program, mostly at the bachelor level. These efforts have included lectures and seminars at high schools, laboratory tours and workshops in our department, and also individual mentoring for high school students participating in scientific competitions. We have discovered that staying connected to the younger generation through social media is important, even though not all the social networks are used by teenagers; some are used more by their parents. Moreover, we have engaged the online influencer, who is known among young generation (especially high school students at the age 15 until 20), namely those who are interested in chemistry and STEM. Additionally, engaging high school teachers is essential as they play a significant role in informing students about study opportunities. To this end, we offer science programs for their classes and organize workshops for teachers focused on both science and teaching skills. Parents also exert a profound influence on their children's career aspirations, and we actively participate in public outreach activities such as Researcher's Night and the Festival of Science.

While some of our efforts have not yielded significant results, others have been successful. In this overview, we share what lessons have been learned from our science communication efforts, and what strategies are now fundamental aspects of our communication to general public and high school students.

6.10.T-03 Breaking Down Silos Between Science and Communication: U.S. Environmental Protection Agency's Innovative Approach to Research Outreach and Communications

Esra Mutlu*, Scarlett Vandyke, Jessica Daniel, Christina Baghdikian and Monica Linnenbrink, U.S. Environmental Protection Agency (US EPA)*

Scientists at the U.S. Environmental Protection Agency (EPA) conduct critical research to inform Agency decisions and support the emerging needs of partners and the public by advancing, developing, and applying innovative research to rapidly evaluate the health effects of chemicals and inform chemical risk assessments. Along with conducting cutting-edge science, effectively engaging end users of the science is vital to better understanding their research needs and increasing their awareness, understanding, and use of the science. Strategic stakeholder engagement and outreach assist with identifying knowledge gaps and subsequent training opportunities and provide opportunities to collect and incorporate feedback into ongoing training efforts.

A common challenge in science is the ability to effectively communicate complex research to audiences representing various backgrounds, including non-scientists. Recognizing the importance of engaging with and training these audiences, EPA's research arm created an outreach, engagement, and training team to increase the awareness, understanding, acceptance, and use of new computational toxicology and exposure research data. A primary goal of the team is to establish scientific confidence in the application of new methodologies for regulatory decision making through a targeted New Approach Methods Training Program.The team uses a multifaceted approach, including user-friendly websites, informational and training programs, webinars, workshops, newsletters, social media, and pre- and post-feedback surveys.

This approach is already yielding positive results. Since its formation in 2022, the team has hosted 5 training webinars with nearly 500 average participants. Surveys of training attendees have shown increased intent to use tools as a result of trainings and overall satisfaction with the trainings and materials. The team's training website featuring tool resources has seen a 126.2% increase in users.

This presentation aims to provide an overview of the multifaceted outreach and engagement approach, results from engagement activities, examples of challenges encountered, outcomes of addressing these unique challenges, a summary on what went well and what didn't, and how lessons learned are being used to inform the future direction of these efforts.

The views expressed are those of the authors and do not necessarily reflect the views and policies of the U.S. EPA.

6.10.T-04 What Are the Effects of Human Activity on Aquatic Ecosystems: Interdisciplinary Workshop and Hands on Training for Secondary School Students

Vera Slaveykova[1]*, Elodie Moulin*[1]*, Giulia Cheloni*[2]*, Eleonore Perrenoud*[3]*, Remy Kopp*[4]*, Anouchka Lang*[3]*, Philippe Jenni*[4]*, Sarah Fragniere Abouljad*[5] *and Andréas Mueller*[5]*, (1)Département F.-A. Forel des sciences de l'environnement et de l'eau, University of Geneva (UNIGE), Switzerland, (2)MARBEC, Univ. Montpellier, CNRS, Ifremer, IRD, INRAE, France, (3)Department of Education, Training and Youth (DIP), Switzerland, (4)University of Geneva and Département de l'instruction publique, de la formation et de la jeunesse (DIP), Switzerland, (5)Institut Universitaire de Formation des Enseignants (IUFE), University of Geneva (UNIGE), Switzerland*

Here we present a science communication initiative addressing environmental pollution's impact on aquatic organisms, particularly phytoplankton. The project targets secondary school students (13-15 years old) through an interdisciplinary teaching sequence (biology and geography) comprising 4-session workshop within build experimental kit. The sequence lets participants study the following guiding question: What are the effects of human activity on aquatic ecosystems? The interactive experimental kit simulates an aquatic environment with the green alga *Chlamydomonas reinhardtii*, showcasing its role in CO_2 consumption and O_2 production via photosynthesis. The kit's oxygen sensor tracks O_2 levels affected by pollutants from daily use products, demonstrating reduced photosynthetic activity and the interconnectedness between human activities and the environment. Pilot and main runs involving 72 and 123 students respectively evaluated the workshops via questionnaires and feedback, showing positive reception, especially regarding experiments and pollutant effects. Aligned with the French-speaking Swiss 10th/11th-year curriculum, these activities serve as a resource for educators interested in integrating environmental topics into science education. Furthermore, this initiative aligns with UNESCO's Global Education 2030 strategy, empowering learners with skills and values for a more sustainable society.

6.10.P Science Communication: Reaching Outside of the Scientific Bubble

6.10.P-We537 Using a Consumer-App to inform citizens and pressure chemical substitution and regulation

Janna Kuhlmann *and Luise Körner, Bund für Umwelt und Naturschutz BUND eV, Friends of the Earth Germany, Germany*

We know the story: Scientists find out, that a chemical substance poses a risk and then it takes forever, until it is regulated. Examples are microplastics, which recently have been regulated and PFAS, which are now in the process of being regulated. Often, a general awareness in the public and with policy makes is needed, before action is taken. Here, civil society organisations such as environmental NGOs play a crucial role to raise awareness on pressing issues.

Imagine, having an App, which informs consumers about the hazardous chemicals in their everyday products they buy and giving them the possibility to send complains.

Ten years ago, the non-profit environmental NGO BUND developed the ToxFox-App, which does exactly this. As for cosmetics the ingredients are known, we use scientific publications and lists of regulatory bodies to flag PFAS, Microplastics and Endocrine Disruptors, among others. We try to extend the information with new publications regularly. However, also toys, electronics and all kinds of other products can be scanned with the app to request data on substances of very high concern (SVHC) from the producers. According to the REACH regulation, consumers have this right to know. These requests increase pressure on companies to improve their chemicals management.

Regularly, a company takes a product from the market thanks to our work. However, we are relying on transparency on ingredients in products and on easily available scientific studies and lists of harmful substances and the products they are potentially used in for the success of this work.

Next to presenting the App and the challenges around it, the need for exchange between NGOs and scientists will be discussed. This includes open access to review articles and creating affordable places where civil society organizations can meet with scientists.

6.10.P-We538 Bridging the Gap in Science Communication: From Scientific Understanding to Public Reception
David Mennekes *and Denise M Mitrano, Environmental Systems Science, ETH Zurich, Switzerland*
Environmental pollution, particularly plastics pollution, is a topic of widespread concern among the general public. However, the pathway from new scientific understanding to become accurately presented information in media can be long and challenging. Moreover, when results are communicated, they are often given in isolated examples, but this approach often lacks general contextualization of how this fits into the broader picture of plastics pollution and impacts. We explored current constraints in science communication in the field of plastics research and what motivated journalists to report about plastics in the environment and under which conditions, were they writing about plastics By surveying and interviewing a broad range individuals working in science and media, we discerned how the communication of the risks of environmental plastics presented by scientists are perceived by journalists, public media, and ultimately the general public. To understand this, we focused on 1) how are scientific findings in the field of plastics research are communicated 2) how are science communicators in different media formats receive, filter and select this information and 3) how this information is translated into a digestible format suitable for the general public with different levels of interest, expertise and engagement with scientific topics. More specifically, we explored the communication of results by scientists, for instance, how the information of environmental concentration and environmental risks of plastics are perceived. Environmental concentrations are often presented either as mass concentrations (e.g., g plastics/kg soil) or particle concentrations (e.g., # plastics particles/kg soil); yet these contrasting presentations of environmental concentrations are not directly comparable and may lead to differences in comprehension of the extent of the issue. Ultimately, high particle concentrations may represent very low mass concentrations, but this information is not easily contextualized. Collectively this analysis on how to bridge the gap on environmental plastics pollution and risks communication can facilitate the interactions between journalists, and scientists, and consequently the general public will benefit from a streamlined, more digestible and targeted communication of scientific understanding.

6.10.P-We539 Sharing your Science and Making it Sticky
Laura McConnell[1]*, Timo Werneke*[2]*, Leah S Riter*[1]*, Lisa S. Ortego*[1]*, Greg Watson*[1]*, Zi Liu*[1]*, Sarah Eliza Lockwood*[1]*, Camille Ryan*[3] *and Carl-Christian Kolbe*[2]*, (1)Bayer Crop Science, (2)Bayer AG, Germany, (3)Bayer Crop Science, Canada*
Why do some scientific messages stay with you for days, weeks and even years later yet others are simply forgotten? Who are your science communication heroes? How do they deliver those memorable messages that inspire other scientists and the public? Scientists are trained in their technical disciplines and in the analysis of scientific data. They are trained to write proposals and peer-reviewed publications, but most scientists are not highly effective communicators. The quality of an engagement is determined by the quality of the connection you have created with your audience and not by the volume of data, evidence, and facts that you have shared with them. The moment we understand this is the moment we begin to truly engage. To quote Sydney J. Harris: “Information is giving out. Communication is getting through.” Even within the scientific community, there are a diversity of audiences. It is important to know your listeners and consider their point of view. Too often we assume we know our audience, and don’t care enough about their needs, or we use jargon and acronyms. There are tools that scientists can use to make their communications more “sticky” and impactful. Bayer carried out a “Science Engagers” training course for cohorts of scientists. These cohorts have continued to support each other after the training. One of the key tools in this training was focused on SHARP: Stories, Humor, Analogies, References and Quotes, and Pictures. This presentation will provide an overview of the SHARP tools and will provide some examples of different types of projects that emerged from participants to introduce these concepts to the SETAC community.

6.10.P-We540 The Interweaving – of the synthetic and natural world
Hans Peter Arp[1,2] *and Elizabeth Ellenwood*[3]*, (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)Artist*
Brought together by an interest and concern for pollution, an artist and scientist began having conversations and sharing resources. Through this collaboration, they discovered a common thread among their work:

The interweaving of the synthetic and natural world.

Together they created artistic images and science-based text expressed in a poetic form that are an honest depiction of what is seen and studied in research labs and the field. From microscopic images, collected objects from the sea, and written scientific studies. This poster offers insight into our current pollution challenges the natural world is facing. The viewer of the images and text are asked to question how they understand pollution, and what is their role in a sustainable future.

6.10.P-We541 ZeroPM on youtube

Hans Peter Arp[1,2] *and Sarah Hale*[3]*, (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)DVGW: TZW*

The H2020 research and innovation project, ZeroPM, has an ambitious Youtube strategy. Over the course of our 5 year project we are targetting over 200 videos on the channel to disseminate and communicate the aims and outcomes of ZeroPM. To facilitate this, there were three main strategies: 1) develop an overall production element for all videos using standard vignettes and graphic templates, 2) different types of video content organized on channels and 3) assigned targets and deadlines videos for each partner to produce. The channels ZeroPM uses include: 1) Partner introductions: where each partner is tasked with introducing themselves, their facilities and what they will do in the project; 2) There is what where: used for content aimed at the general public, which are short, informative videos; 3) ZeroPM In depth: featuring technical interviews with ZeroPM partners; 4) ZeroPM Pieces: lunch time seminars given by menbers of ZeroPM to each other of ca 15-30 minutes of their research; 5) ZeroPM webinars: Webinars open to the public where a researcher in ZeroPM in collaboration with an external research give a broad 40 minute presentation of a research field with Q&A; 6) ZeroPM Science-Policy Webinars: where policy makers co-present with ZeroPM researchers on how the work effects the science-policy interface; 7) Workshop vidoes – videos filmed at workshops, including interviews and presentations; 8) ZeroPM news – where latest results of the project are presented as a news broadcast. Currently the most popular channels are related to the Webinar channels, followed by ”ZeroPM-in depth”, which includes music video ”The PMT substances song”.

Curious to learn more, visit our poster and https://www.youtube.com/@ZeroPM-H2020

6.10.P-We542 The PARC ambition to communicate to gain impact

Sónia Namorado[1]*, Marianne Bom*[2]*, Tamás Szigeti*[3]*, Maria Uhl*[4]*, Daniela Zanini-Freitag*[4]*, Dennis Sarigiannis*[5]*, Spyros Karakitsios*[5]*, Nikiforos Alygizakis*[6]*, Roser Gasol*[2]*, Dora Rolo*[1]*, Eugenia Dessipri*[7]*, Aglaia Koutsodimou*[7] *and Maria Silva*[1]*, (1)National Institute of Health Doutor Ricardo Jorge, Portugal, (2)European Environment Agency, (3)National Center for Public Health and Pharmacy, Hungary, (4)Environment Agency Austria (EAA), Austria, (5)Aristotle University of Thessaloniki, Greece, (6)Environmental Institute, Slovakia, (7)General Chemical State Laboratory*

The Partnership for the Assessment of Risks from Chemicals (PARC) is a public-public partnership using research and innovation for the benefit of human health and the environment by improving chemical risk assessment and supporting the implementation of new/better policies. More than 200 partners in 29 European countries are involved in the seven-year project co-funded by the European Commission (2022-2029).

In pursuit of its objective to significantly contribute to the EU Zero Pollution goal of achieving a non-toxic environment by 2050, PARC has an ambition to build bridges between academia, national and international regulatory bodies, industry, NGOs, decision makers and European citizens. The exchange of knowledge among these stakeholders, and potentially others, is crucial for PARC to gain real impact to protect human health and the environment.

Besides building interactions with Boards, including stakeholders (Stakeholder Forum) and experts from areas related to risk assessment (International Board), PARC developed a communication and dissemination strategy and is establishing synergies with external scientific activities, to boost its impact. The communication and dissemination strategy considered relevant methodologies for successful internal and external communication in order to reach specific target groups, e.g., industry, professional groups, and citizens, and engage them in supporting the aforementioned strategic goals. Various communication channels, including a website, four social media channels, and two newsletters were conceptualized and implemented. Further activities for engagement and exchange like a synergies network (SYNnet), facilitating collaborations between external activities and PARC, have been established to support the defined strategy. Local national hubs have also been established with the responsibility to build and strengthen local dialogues within each country and build the necessary connections with PARC.

In this presentation we will present the PARC ambition to gain impact, the organization of PARC and its communication and dissemination strategy, as well as the challenges PARC has been facing and is working to overcome in order to succeed.

6.10.P-We543 Communicating the Complexities of Plastic Pollution in a Polarized Media Landscape

Nanna B. Hartmann*, Encvironmental and Resource Engineering, Technical University of Denmark (DTU), Denmark*

In our endeavor as scientists to disseminate our findings, we are faced with a multifaceted challenge: Firstly, academia is a competitive environment and attracting funding is intertwined with our visibility and ability to communicate complex scientific ideas in an accessible manner. Secondly, visibility must be achieved in a saturated information landscape, which may tempt us towards oversimplified narratives to gain visibility. Thirdly, when operating within this space, maintaining our code of ethics and credibility as scientists in society is paramount. These challenges are accentuated within areas of broad societal awareness such as plastic pollution.

This presentation will draw upon personal experiences and lessons learned from interactions with the media under different circumstances. The focus, however, will be on a current podcast production: "Plast tur-retur" (Plastic roundtrip). The aim of this podcast series is to shed light on the causes of and solutions to plastic pollution, including biodegradable plastic as an alternative material, sorting and recycling of plastic, as well as the need for legislation and changes in consumer behavior. This is achieved through conversations with fellow scientists, while transcending the boundaries of traditional academic discourse and reaching a broader audience.

In summary, this presentation will offer insights into the complexities of communicating scientific research on plastic pollution, striking a balance in the realm of visibility/credibility/responsibility. It will underscore the importance of upholding scientific integrity while effectively engaging with the public and media, thus contributing to a more informed and balanced understanding of plastic pollution and its interconnectedness with other environmental issues in society.

6.10.P-We544 Phytoremediation for Public Engagement – An Interdisciplinary Project Bringing Together Art and Science

Jessica Chadwick, *GEES, University of Birmingham, United Kingdom*

Soil pollution is a huge problem for the organisms that inhabit the soil, the people that use the land with wider nutrient cycling implications. Heavy metals, like lead, arsenic, and mercury, can have severe negative consequences on plant growth and development, and can be dangerous to human health. The soil contaminants found next to the Grand Union canal in Birmingham (UK) were many times greater than the recommended safety limits, with some found to be over 100 times greater than the safe concentration. Working together with local art and community project, Grand Union Gallery, we ran a community focussed project on site. We used a range of different plant species, including alder, sunflowers, and clover, to attempt phytoremediation of the area to try and reduce the mobility of these heavy metal contaminants, either through immobilisation in the soil or by uptake into plant tissues for safe removal. The project has now evolved into helping vulnerably housed people gain work experience, with individuals from across Birmingham getting involved in learning about soil science and pollution.

6.10.P-We545 Scientific Communication from an Industrial Science Perspective: Gaps and Opportunities

*David MV Saunders[1] and **Erin Maloney**[2], (1)Shell Global Solutions, Netherlands, (2)Shell International, Netherlands*

Although professional courses in scientific communication are becoming more available and accessible, many students still undergo ‘informal training’ in science communication throughout the course of their studies. Often, this takes the form of developing posters or presentations for scientific conferences, reports for university or college classes, and/or publications to be submitted in scientific journals under the guidance of academic instructors or supervisors. Development of technical communication skills is very important for enabling peer-to-peer communication within the scientific field; thus, this type of (in)formal scientific communication training remains highly valuable for (under)graduate students. However, this type of training often overlooks aspects of scientific communication which are extremely important in the field of industrial science. Industrial scientists are often required to communicate with diverse stakeholders, regulators, and collaborators with differing backgrounds, perspectives, levels of technical expertise, and priorities. For example, along with peer-to-peer technical communication, industrial scientists may have to communicate with advocacy and policy experts, product stewardship, marketing and business representatives, industrial regulatory specialists, regulators, or manufacturers (amongst others). Thus, to ensure understanding, the same scientific output (e.g., idea/concept, study) will effectively have to be ‘translated’ for different stakeholders while retaining key concepts and a high level of informational accuracy. Moreover, this often occurs on a global scale, introducing additional challenges associated with of language, culture, and regional priorities.

This presentation aims to illuminate the unique challenges associated with scientific communication in industrial science, driving a discussion between the differences in academic and non-academic communication coming from the perspective of scientists working within industry. Altogether, we aim to highlight current gaps and opportunities to enable further development of tripartite scientific communication training practices in the SETAC community

6.10.P-We547 Bridging the Gap Between Research and Stakeholder Needs for Effective AquaticPollutants Management

*Katie Carter[1], Maité Fournier[2], Corinne Merly[3], Nicole Baran[3], Manon Berge[2], Lara Bagheri[1], **Sabrina Giebner**[1], Gunnar Thorsén[4] and Thomas Track[1], (1)Society for Chemical Engineering and Biotechnology e.V. (DECHEMA), Germany, (2)ACTeon Environment, (3)BRGM French Geological Survey, (4)IVL Swedish Research Institute*

Within the ERA-NET Cofund AquaticPollutants, there are 18 international research projects developing analysis, assessment and management solutions to address the presence of contaminants of emerging concern (CECs) and antimicrobial resistance (AMR) in water resources. Their exploitable results span products, technologies and materials, procedures and protocols, policy briefs, capacity building workshops, all addressing the presence and impact of these aquatic pollutants in various parts of the ecosystem chain. But what do the projects’ target stakeholders need to know, how does this align with the expected projects’ outputs, and how can these external stakeholders best be reached? These are the questions that the research within the AquaticPollutantsTransNet (“TransNet”) transfer project is aiming to answer.

To answer this first question, we conducted over 50 stakeholder interviews from Germany, France, Sweden and the EU level, hosted two national workshops and analysed the national and EU regulatory context pertaining to CECs, AMR and pathogens. Through conversations with stakeholders from the public authority, water utility, applied research, NGO, industry, and research sectors, we established an inventory of ‘knowledge demands’, or knowledge needs stemming from the *insufficient* *transfer of existing knowledge* or from *knowledge that is missing altogether*, classified by country, stakeholder sector and pollutant class (i.e. CECs, AMR). Coupling this inventory with an analysis of the state-of-art scientific knowledge and the expected outputs from the 18 research projects, we can align the knowledge demands of end-users to the research project outputs to support improved knowledge uptake and implementation.

This knowledge demands inventory will be developed into an online tool meant for researchers, providing a novel approach for connecting research outputs with stakeholder needs and aligning communication methods to stakeholder sectors – in this way answering our three initial questions. The communication methods and techniques will be developed for the various target sectors based on desk research, stakeholder interviews and results from various co-creation efforts. This tool will help bridge the gap between research and practical application in addressing aquatic pollutants – not only by assisting in dissemination activities, but also by identifying future research needs based on acute demands.

6.10.P-We548 Sailing Scientists- Exploring water quality through water sports

Katie Reilly[1] *and Iseult Lynch*[2]*, (1)University of Birmingham, United Kingdom, (2)School of Geography, Earth and Environmental Sciences, University of Birmingham*

Public engagement on environmental issues is increasingly acknowledged to be an important aspect of understanding and effectively addressing these challenges. Water quality has been increasingly reported as a concern to a range of different stakeholders, including dog walkers, anglers, water sports users (including open water swimmers), boat owners (such as canal boats) and artist/photographers.

Exploring water quality through the lens of water sports is an interesting and challenging angle, as most water sports users are increasingly concerned about the quality of the water that they are engaging with. This project works with Sea Cadets (UK) to assess water quality at their main boat stations, and to train a generation of young people (ages 9-18) in water quality assessments, experimental design and science communication throughout the project. Water quality assessments include pH, temperature, conductivity, nitrates and phosphates, dissolved oxygen, turbidity and visual indicators of pollution. Through these initial water quality parameters, we discussed areas of pollution that are of interest to the cadets and explored experimental designs to capture this going forwards, for example including plastic pollution and microplastic detection methods.

The ability for young people to have their voices heard is an important part of engaging the public in these topics. Ecoanxiety goes beyond focusing on climate issues to encompass a wider collection of environmental issues including water quality. Through the codesign process, the young people are supported and encouraged to investigate issues that are important to them, and given the opportunity to communicate these to different audiences. The results and outputs from this project are written into peer education training materials for use in groups ages 9-18, as legacy training resources.

In addition to working with a subsection of the public, this project also provided and opportunity to involve and support researchers with public engagement but providing a framework for training and experience. This enabled a diverse and engaging skills exchange between different groups which will hopefully inspire and support further public engagement projects and codesign research in the future.

6.10.P-We549 Watch on the Rhine – RIWA-Rijn - Turning River Water Quality Data into a River of Quality Water Data

Gerard Stroomberg[1] *and* ***Rozemarijn Neefjes***[2]*, (1)RIWA Rijn, Netherlands, (2)RIWA-Rijn, Netherlands*

RIWA-Rijn is an association of drinking water companies in the Netherlands that use the river Rhine as a source. Established in 1952, making it one of the earliest NGOs worldwide to focus on protecting the river as an invaluable yet vulnerable resource for drinking water. In total 5 million people in the Netherlands depend on the river Rhine as their resource for drinking water.

RIWA-Rijn strives for such a quality of surface water that natural purification processes suffice to prepare impeccable drinking water. In line with Article 7 of the European Water Framework Directive, water quality must continuously improve, so that the level of the purification treatment effort can be reduced over time. RIWA-Rijn collects and disseminates data and knowledge on the water quality of the Rhine, informs governments and industry on our findings and represents the interest of its members in various (trans)national and European bodies. RIWA-Rijn maintains a database with water quality data of a vast number of substances, many of which go back over multiple decades.

RIWA-Rijn produces an annual report both in Dutch and German which describes the water quality of the Rhine in three parts. We assess the water quality of the Rhine on the basis of (1) the European River Memorandum that specifies a water quality that allows drinking water production with near natural treatment methods, (2) WFD article 7.3 which aims “to reduce the level of purification treatment required in the production of drinking water", (3) the Rhine Ministers Conference target of a 30% reduction of emissions into the Rhine.

The data is collected from our own monitoring program, from our members and Rijkswaterstaat, the national Dutch water authority. Besides the targeted assessment we publish all our available data with general statistics such as annual averages, minimum, maximum values and percentiles. And calculate 5-year trends for concentrations our over 650 parameters, which include pesticides, pharmaceuticals, industrial contaminants, and consumer products.

Besides sending our report to in print stakeholders in the Rhine catchment, we make our reports available to the general public through our website. Monitoring downloads of our report show an increasing the interest in our report, particularly in the Rhine catchment area. Other NGOs are increasing finding their way to our data and are using them for there own purposes, but most of all for protecting the water quality of the Rhine.

6.10.P-We550 Full STEAM Ahead: Merging Science and Communications to Investigate Environmental Questions
Gretchen K. Bielmyer-Fraser[1]*, Annmarie Kent-Willette*[1] *and James Nienow*[2]*, (1)Jacksonville University, (2)Biology, Valdosta State University*
This project focused on a case study and best practices surrounding a successful STEAM interdisciplinary research project. The study focused on graduate and undergraduate interdisciplinary research in the fields of Environmental Science and Communications. Specifically, a variety of water quality parameters and metals were measured, and phytoplankton abundance and diversity were assessed in water samples collected from eight sites in the lower St. Johns River, in Florida from 2019 to 2022. The project and resulting data were publicized using a multimedia communication approach including social media, in tandem with more typical scientific and academic approaches including presentations at meetings and journal publications. This project focused on how cross discipline collaboration led to grant applications and ultimately secured funding, how the work successfully incorporated research opportunities for students, the role multimedia communications and a strategic social media plan played in community awareness and support, and how the project successfully communicated meaningful research while managing teaching across very different disciplines.

6.11 Science for Global Management of Chemicals

6.11.T-01 Why we need science free of Conflict of Interest for Global Management of Chemicals
Miriam L. Diamond[1]*, Andreas Schäffer*[2]*, Martin Scheringer*[3]*, Marlene Ågerstrand*[4]*, Ksenia J Groh, PhD*[5]*, Gabriel Sigmund*[6]*, Bethanie Carney Almroth*[7]*, Rainer Lohmann*[8]*, Anna Soehl*[9]*, Noriyuki Suzuki*[10]*, Marta Venier*[11] *and Penny Vlahos*[12]*, (1)University of Toronto, Department of Earth Sciences, Canada, (2)Institute for Environmental Research, RWTH Aachen University, Germany, (3)ETH Zurich, Switzerland, (4)Stockholm University, Sweden, (5)Eawag - Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (6)EDGE, Wageningen University & Research (WUR), Netherlands, (7)University of Gothenburg, Sweden, (8)Graduate School of Oceanography, University of Rhode Island, (9)International Panel on Chemical Pollution, Switzerland, (10)National Institute for Environmental Studies (NIES), Japan, (11)Paul H. O'Neill School of Public and Environmental Affairs, Indiana University, (12)University of Connecticut*
The issue of Conflict of Interest (COI) is critical to consider when developing the structure and scope for the new Science-Policy Panel (SPP) for chemicals, waste and pollution prevention. Specifically, experts participating in the decision-making process and the core work of the SPP should not stand to gain materially from the work of the SPP or promote conflicting and/or incompatible outcomes or delayed implementation of solutions.

COI refers to financial or other related interests which could significantly impair an individual's objectivity or create an unfair advantage for any person or organization. It is unavoidable that every expert holds a particular point of view or perspective that could be seen as biased; here we focus on an individual, while pursuing a scientific question, would have a financial or material gain from a certain outcome of their scientific work, so that this gain is in conflict with the impartial investigation of the scientific question.

What are the tactics used by those having a COI? According Schäffer et al. (2023), more than 20 tactics have been used by with COI to counter scientific evidence or to promote narratives favourable to specific industry sectors. Examples are: Criticizing study designs or overemphasizing the shortcomings of scientific studies; Discrediting, intimidating or threatening scientists; Publishing misinformation; Cherry-picking data, designing studies to fail or come to a desired conclusion, or conducting meta-analyses that dilute scientific evidence; Extensive lobbying towards regulators and policymakers so that the voice of the vested interest is often the main or even the only one heard in public consultations.

For the work of the new SPP we recommend: 1. Define and strictly enforce rigorous COI provisions. Experts with a COI should not be allowed to participate in the decision-making process and the core work of the Science-Policy Panel, but may still participate and contribute as observers. 2. Implement independent audits to a) review compliance with the COI provisions, and, if needed, recommend corrective measures to the governing body, and b) ensure that the Science-Policy Panel's outputs are transparent, impartial, credible and scientifically robust, as mandated by the UNEA Resolution 5/8. 3. Include as many elements of transparency as possible and apply FAIR and CARE principles for scientific data management and stewardship.

6.11.T-02 Sustainable Chemicals and Materials Policy – The Need to Develop Globally Binding Rules
Janna Kuhlmann[1]*, Klaus Günter Steinhäuser*[2] *and Markus Große Ophoff*[2]*, (1)Bund für Umwelt und Naturschutz BUND eV, Friends of the Earth Germany, Germany, (2)Environmental Chemistry Working Group BUND eV, Friends of the Earth Germany*

Pollution by chemicals and waste is threatening human health and ecosystems on a global scale like climate change and biodiversity loss, resulting in UN framing it as a triple planetary crisis. Sustainable management of chemicals and materials deals not only with the assessment of hazards and risks of chemicals to health and environment in accordance with classic chemicals policy, but also the management of material flows from the extraction of raw materials up to waste. The constant increase in material flows threatens the Earth system. Persson et al. showed that the planetary boundaries for 'novel entities' have already been significantly exceeded. There exist close links between the increasing consumption of materials and the emission of climate gases as well as the losses of biodiversity.

A holistic sustainable chemistry can provide a significant contribution to the future management of substances, resources and materials. For chemicals, this means that they should be inherently safe, that is, they should not have hazardous properties. In particular, they should no longer be persistent. 'Forever chemicals' create problems that are ever increasing and irreversible. Material flows must be significantly reduced in order to reduce resource consumption significantly. Reuse and recycling of materials are crucial elements of a circular economy. The raw material feedstock of chemical production must also change: Alternative resources must replace mineral oil and natural gas. Three complementary strategies are critical to reducing material flows: efficiency, consistency and sufficiency.

Unlike climate change and biodiversity, no comprehensive legally binding international agreement exists for the management of substances and materials. Individual topics are covered, for example, in the Stockholm and Basel Conventions. The World Chemicals Conference in September 2023 resulted in a good declaration of intention. A trend to a legally binding framework convention is not discernible, however. One encouraging step may be the establishment of a Science Policy Panel on chemicals, waste and pollution prevention like the IPPC for climate and the IPBES for biodiversity. It will only be a success, if this committee will be independent and conflicts of interest will be avoided. The development of binding rules is urgent to avoid the overloading of the Earth system.

The work of environmental NGOs can benefit from an enhanced dialogue between science and civil society.

6.11.T-03 The PlastChem Project: An evidence-based framework for identification and prioritization of chemicals of concern in plastic
***Laura Monclus*[1]*, Hans Peter Arp[1,2], Zhanyun Wang[3], Jane Muncke[4], Raoul Wolf[2], Lisa Zimmermann[4], Mari Engvig Løseth[2], Ksenia J Groh, PhD[5] and Martin Wagner[1], (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (4)Food Packaging Forum Foundation, Switzerland, (5)Eawag - Swiss Federal Institute of Aquatic Science and Technology, Switzerland*
Plastics are complex materials that contain a large number of diverse chemical substances, which can be released through the life cycle of plastics, i.e., production, use and end-of-life stages. They can negatively impact human and environmental health as well as hamper a safe and sustainable circular economy. Plastic chemicals are therefore one of the crucial aspects for the future Global Plastics Treaty. Yet, current information on plastic chemicals is fragmented and scattered over the public domain, and important gaps of knowledge remain on how to effectively and efficiently manage the large number of chemicals of concern in plastics. The PlastChem project aims to provide a state-of-the-science report on plastic chemicals and polymers of concern that enables evidence-based policy development. With this purpose, we systematically collected, compiled, and harmonized up-to-date scientific and regulatory information into a comprehensive database of all known plastic chemicals. We annotated these plastic chemicals with updated hazard information obtained from 15 regulatory and industry sources and conducted a weight-of-evidence analysis for the identification and prioritization of chemicals of concern, taking into account persistence (P), bioaccumulation (B), mobility (M), and toxicity (T). We further included additional regulatory-status information under existing chemicals and waste Multilateral Environment Agreements (MEAs) and scientific data on the presence and release of plastic chemicals from polymer plastics. We identified more than 16,000 plastic chemicals with unique chemical identities, from which more than 4,000 chemicals (25 %) were recognized as chemicals of concern following the assessment of their PBMT properties. Among the chemicals of concern, 13 % of them are currently being regulated under MEAs. Almost 4,000 chemicals were identified in extracts or leachates from plastics, and 25 % of them were among those identified chemicals of concern. Our weight-of-evidence framework integrates all this information, resulting in a compendium of lists that organize the universe of plastic chemicals according to different hazard scoring and prioritization levels. This work shed lights on an evidence-based regulation for identification and prioritization of chemicals of concern in plastic.

6.11.T-04 POPs Global Monitoring, capactiy building and data integration under the UNEP/GEF projects
***Victor Hugo Estellano Schulze*[1]*, Haosong Jiao[1], Kei Ohno[2] and Ludovic Bernaudat[3], (1)UNEP Chemicals & Health Branch, Switzerland, (2)UNEP BRS Secretariat, (3)Chemical and Health Branch, United Nations Environment Programme (UNEP)*
The UNEP Chemicals and Health Branch, through Global Environment Facility funded POPs monitoring projects, data generation and capacity building in developing countries and countries with economies in transition, to facilitating the implementation of the Global Monitoring Plan (GMP) and evaluating the effectiveness of the Stockholm Convention (SC) on POPs. The second round of projects was implemented from 2016 to 2023, covering 42 countries. The key activities include monitoring POPs in core matrices air, water and Human milk, along with providing trainings and a global interlaboratory assessments. Data on POPs levels in humans and the environment are crucial for; ensuring the availability of data on exposure to POPs; understanding of data for effective actions in implementing the Convention; and strengthening global and regional

collaboration to address data gaps. Furthermore, capacity building is key component for generating high-quality data. Under the project, 26 training sessions have been conducted involving participants from 37 countries. The four rounds of interlaboratory assessments included results from 228 laboratories across 72 countries. Results showed that data gaps still exist, in particular for the newly listed POPs under the convention, as well as the growing complexity of chemical analyses.

The World Environment Situation Room (WESR) is UNEP's platform for data, information, and knowledge, facilitates access, visualization, sharing, and downloading of real-time information on the global environmental situation. The POPs monitoring dashboard, a complementary tool for data integration and sharing within the UNEP/GEF POPs projects, aims to enhance accessibility and understanding of data for a broader range of stakeholders, supporting informed decision-making alongside other data hubs like the GMP data warehouse. Long-term, high-quality data, information, and knowledge stand as fundamental pillars for assessments and decision-making processes. Establishing sustainable mechanisms to promote data usage in decision-making strengthens commitments to data generation and capacity building. Regional collaboration plays an important role in bridging data gaps. Mechanisms should be in place to enable contributions from broader stakeholders, to support data generation and the sound management of POPs. The knowledge generated on POPs is critical for addressing other global challenges such as plastics, climate change and biodiversity loss.

6.11.T-05 Assessing Regional / National Capacity for Monitoring and Research on POPs in Water in Selected UNEP regions

Derek C.G. Muir[1]*, Victor Hugo Estellano Schulze*[2]*, Haosong Jiao*[2] *and Tom Harner*[3]*, (1)School of Environmental Sciences, University of Guelph, Canada, (2)UNEP Chemicals & Health Branch, Switzerland, (3)Environment and Climate Change Canada, Canada*

Knowledge of water concentrations of persistent organic pollutants (POPs) is important for understanding sources and global distribution as well as exposure of aquatic organisms and their food webs. The Global Monitoring Plan (GMP) under the Stockholm Convention (SC) on POPs currently includes data for perfluorinated alkyl substances (PFAS), but not for other POPs in water (https://www.pops.int/Portals/0/download.aspx?d=UNEP-POPS-COP.11-INF-38.English.pdf). The goal of this study was to assess the extent of the measurement data for monitoring of POPs in surface waters of Africa, GRULAC (the UNEP region comprising Latin America and the Caribbean), and Asia-Pacific, as well as adjacent coastal seas and oceans. With this information we assessed national capacities for measurement of POPs in water and propose a strategy for the monitoring at the national or subregional level. A detailed review was conducted of scientific papers and technical reports on chemicals listed under the SC that had been measured in surface waters over the time period of 2011 to 2022. The DDT and HCH groups predominated with over 150 reports in freshwater for 4,4'-DDE, 4,4'-DDT and γ-HCH. Endosulfan, dieldrin, endrin, aldrin, heptachlor, and heptachlor epoxide were also frequently reported. The results of this review identified laboratory and institutional capacity, expertise, data availability, and existing interlab programs that could form the basis of future monitoring of POPs in water. While no formal global monitoring program exists for POPs in water, the recently completed AQUAGAPS-MONET passive sampling study has provided a limited picture for non-polar POPs in global surface waters (Lohmann et al. ES&T 2023). The latter project used a central lab distribute passive samplers and to analyse samples. The use of a central expert lab for global studies of POPs is generally recommended, however, it does not provide for capacity building at the national and regional level. Taking the above points into consideration, a future framework for water sampling and POPs analysis at the national and subregional level would ideally be based on passive samplers provided by a central lab but analysed by individual labs. This strategy has already been used for interlab comparisons of passive samplers. The results would contribute to the GMP but would provide information on concentrations in water at the national level that could be useful for broader water quality assessment goals.

6.11.P Science for Global Management of Chemicals

6.11.P-Mo531 Recommendations for the Deliverables of the new Science and Policy Panel on Chemicals, Waste and Pollution Prevention

Penny Vlahos[1]*, Martin Scheringer*[2]*, Miriam L. Diamond*[3]*, Marta Venier*[4]*, Marlene Ågerstrand*[5]*, Andreas Schaeffer*[6]*, Anna Soehl*[7]*, Noriyuki Suzuki*[8] *and Rainer Lohmann*[9]*, (1)University of Connecticut, (2)ETH Zurich, Switzerland, (3)University of Toronto, Department of Earth Sciences, Canada, (4)Paul H. O'Neill School of Public and Environmental Affairs, Indiana University, (5)Stockholm University, Sweden, (6)Institute Environmental Research, RWTH Aachen University, Germany, (7)International Panel on Chemical Pollution, Switzerland, (8)National Institute for Environmental Studies (NIES), Japan, (9)Graduate School of Oceanography, University of Rhode Island*

The United Nations Environment Assembly (UNEA) resolved to establish an independent, intergovernmental science-policy panel on chemicals, waste and pollution prevention (SPP). I accordance with resolution 5/8 an Open-Ended Working Group (OEWG) was established with its charge resolve anticipated for June 2024. Following efforts to set priorities and define the work of the SPP we present options for deliverables that may aid in the framing of the upcoming SPP's charge. We compare reports from both the Intergovernmental Panel on Climate Change (IPCC) and the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) and identify areas in which deliverables of the SPP can complement and provide synergistic advances to existing reports. We propose possible frameworks for SPP deliverables while preventing overlap and duplication of efforts. Consequently, we also propose possible reports that are likely to arise from member states and how these too may compliment current IPCC and IPBES efforts.

6.11.P-Mo532 The International Panel on Chemical Pollution (IPCP): Academic scientists' voice in support of the Intergovernmental Science−Policy Panel on Chemicals and Waste

Rainer Lohmann[1], *Marlene Ågerstrand*[2], *Thomas Backhaus*[3], *Miriam L. Diamond*[4], *Joan O. Grimalt*[5], *Andreas Schäffer*[6], *Martin Scheringer*[7], *Anna Soehl*[8], *Noriyuki Suzuki*[9], *Marta Venier*[10] *and Penny Vlahos*[11], *(1)Graduate School of Oceanography, University of Rhode Island, (2)Stockholm University, Sweden, (3)Biological and Environmental Sciences, University of Gothenburg, Sweden, (4)University of Toronto, Department of Earth Sciences, Canada, (5)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (6)Institute for Environmental Research, RWTH Aachen University, Germany, (7)ETH Zurich, Switzerland, (8)International Panel on Chemical Pollution, Switzerland, (9)National Institute for Environmental Studies (NIES), Japan, (10)Paul H. O'Neill School of Public and Environmental Affairs, Indiana University, (11)University of Connecticut*

In 2020, the IPCP called for the establishment of an intergovernmental **Science−Policy Panel (SPP) on Chemicals and Waste** to address gaps in current science-policy interface in international chemicals and waste governance, including the lack of (1) coverage relative to the large and growing universe of chemicals and waste; (2) horizon scanning and early warning mechanisms; (3) bidirectional communication between policy-makers about the scientific community, and (4) engagement of the wider scientific community. International negotiations on such a panel are currently on-going. [1]

In 2023, key principles for the SPP were published [2], in particular (1) to fill a critical gap pertaining to the mounting and accelerating impacts on human and environmental health caused by chemical pollution and waste globally; (2) to avoid "paralysis by analysis" by repeatedly re-assessing the same topics and substances; (3) for a broad and inclusive SPP to properly respond to the breadth and complexity of global chemical production, use, releases, and disposal; (4) to be policy-relevant but not policy-prescriptive to support sound, evidence-based policy development; (5) Governments should nominate independent experts as the main "workforce" of the SPP, with independent scientists providing primary scientific results; (6) to establish and enforce a strict conflict-of-interest (COI) policy; (7) include a wide range of data from the peer-reviewed scientific literature, gray literature, and existing biological and chemical monitoring programs; (8) to apply a transdisciplinary approach to the integration of knowledge, across different temporal and spatial scales and different regions of the world; (9) for the outcomes to be policy-relevant, but not policy-prescriptive; and (10) to ensure that all countries are adequately represented in terms of experts and their backgrounds, data, and access to information.

The importance of a strict COI policy for the SPP is needed to avoid established tactics to manufacture doubt in favor of vested interests.[3] The authors rebutted an assertion voiced by some that the chemical industry should be directly involved in the panel's work because it possesses data on chemicals essential for the panel's activities. Steps should be taken to prevent the detrimental impacts of conflicts of interests on the panel. In particular, an independent auditor should be included in the panel to ensure that participation and processes follow clear COI rules.

6.11.P-Mo533 Obstacles to Scientific Input in Global Policy

Bethanie Carney Almroth[1], *Amila Abeynayaka*[2], *Miriam L. Diamond*[3], *Trisia Farrelly*[4], *Marina Olga Fernandez*[5], *Sedat Gündoğdu*[6], *Ibrahim Issifu*[7], *Idun Rognerud*[8], *Andreas Schäffer*[9], *Martin Scheringer*[10], *Patricia Villarrubia-Gómez*[11], *Rufino Varea*[12], *Penny Vlahos*[13], *Martin Wagner*[14] *and* ***Marlene Ågerstrand***[15], *(1)University of Gothenburg, Sweden, (2)Tokyo City University, Japan, (3)University of Toronto, Department of Earth Sciences, Canada, (4)Political Ecology, Research Centre, Massey University, New Zealand, (5)IByME-CONICET, Argentina, (6)Faculty of Fisheries, Cukurova University, Turkey, (7)Fisheries Economics Research Unit, Institute for the Oceans and Fisheries, University of British Columbia, Canada, (8)Norwegian Institute for Water Research (NIVA), Norway, (9)Institute for Environmental Research, RWTH Aachen University, Germany, (10)ETH Zurich, Switzerland, (11)Stockholm Resilience Centre, Stockholm University, Sweden, (12)School of Agriculture, Geography, Environment, Ocean and Natural Sciences, University of the South Pacific, Fiji, (13)University of Connecticut, (14)Norwegian University of Science & Technology (NTNU), Norway, (15)Stockholm University, Sweden*

The planetary crisis, as identified by the United Nations, stems from climate change, biodiversity loss, and pollution. Addressing these challenges requires informed decision-making based on reliable scientific insights. However, the utilization of pertinent research in policy planning is hindered by constraints imposed on scientists' involvement in the process by policy-making entities. While the United Nations Environment Programme (UNEP) encourages the engagement of independent scientists without conflicts of interest, the accreditation process poses difficulties for many due to stringent eligibility criteria. UNEP mandates that accredited organizations cannot receive government funding, creating challenges for scientists affiliated with government-funded institutions, including universities.

This restriction, while aiming to avoid conflicts of interest arising from political messaging, fails to differentiate between government-funded institutions with scientific independence, such as universities, and those that may compromise scientific integrity. As a result, public universities, in Europe and globally, face exclusion from UNEP accreditation. Scientists from government-funded institutions may seek alternative entry routes, like joining national delegations or non-governmental organizations (NGOs). However, such pathways may compromise their independence and raise concerns about the credibility of their policy recommendations.

A viable alternative for scientists affiliated with government-funded institutions is accreditation through multilateral environmental agreements like the Basel, Rotterdam, and Stockholm (BRS) Conventions. This underutilized option offers a less stringent process, increasing the likelihood of eligibility. We argue that UNEP should enhance the visibility and accessibility of this alternative. Furthermore, we propose that UNEP, with the backing of member states, should recognize universities as independent, self-governed entities eligible for direct accreditation. This shift, coupled with support from academic institutions, would empower scientists to contribute effectively to global negotiating processes. By improving accessibility and inclusivity, UNEP can ensure the meaningful participation of independent scientists in policy negotiations, leveraging their trusted collective knowledge for a more sustainable future.

6.11.P-Mo534 Enhance the Science-Policy Panel´s Impact by Leveraging Synergies with Innovation

Anja Klauk[1] *and Alexis Bazzanella*[2]*, (1)German Environment Agency (UBA), Dessau-Rosslau, Germany, (2)Project Management, Dechema e.V., Germany*

With UNEA Resolution 4/8, sustainable chemistry has been anchored as being an element of the sound management of chemicals and waste. Furthermore, the United Nations Environment Programme's Green and Sustainable Chemistry Framework Manual highlights the crucial importance of environmentally sound innovation. Innovation implementing new chemistry-based concepts, products, processes and services should therefore be perceived as a pathway towards sustainable chemistry solutions and the prevention of pollution. This should also be reflected in the remit for a corresponding science-policy panel.

In order to evaluate the importance of sustainable chemistry innvation in the aforementioned context, the ISC_3 database of 210 start-ups from all over the world has been analysed and a thorough sustainability assessment of the proposed innovation and business concepts has been conducted. The corresponding solutions are predominately motivated by solving immanent (local or regional) problems and challenges. They are characterised by a holistic life-cycle thinking avoiding environmental trade-offs and often show a strong socio-economic innovation component, creating employment for local communities and facilitating capacity building at regional level in conformity with the Agenda 2030. 60% of the entrepreneurs are situated in the global south including African and Latin American countries or India. Likewise the annual ISC_3 innovation challenges show a strong participation from the global south, indicating that innovative sustainable chemistry solutions are not biased towards the global north. Entrepreneurship activities and their success thereby strongly benefit from supportive framework conditions, including policy recognition and incentivisation, visibility and facilitation of investments. The SPP could promote and facilitate innovations and contribute to visibility. Overall, awareness about approaches to and merits of innovations based on sustainable chemistry can pave the way to policy-relevant and impact-oriented recommendations of the future SPP.

6.11.P-Mo536 Monitoring of Toxicity of Plastic Recyclates from Low- and Middle Income Countries by Bioassay Panel to Support the Global Management of Chemicals in Plastics

Peter Alexander Behnisch[1]*, Ludwig Gruber*[2] *and Roland Weber*[3]*, (1)BioDetection Systems BV (BDS), Netherlands, (2)Fraunhofer Institute IVV, Germany, (3)POPs Environmental Consulting, Germany*

More than 13,000 chemicals are associated with plastics including more than 3200 chemicals with hazardous properties. The large number of non-intentionally added substances (NIAS) including degradation products, processing aids, impurities in plastic additives and transformation products are present to various degree and are often not monitored by instrumental target analysis. In particular the recycling of plastic result in complex chemical mixture which even can include POPs if e.g. e-waste plastic is recycled into toys. There is a lack of knowledge of POPs and other hazardous chemicals in plastic recyclates and related toxic risk in particular in low- and middle income countries (LMICs) which often lack analytical capacity. Therefore, activities were conducted under the UNEP/GEF Global Monitoring Plan projects to monitor plastic recyclates from Africa, Asia, and the GRULAC region. In addition to target POPs analysis also the screening of toxic effects of selected plastic recyclates can contribute valuable information to expose risk. We applied a panel of human cell-based biological detection methods (i.e. CALUX assay) to assess the migration from plastic recyclates used to produce food or skin contact products on a range of toxicity pathways (e.g. cytotoxicity, genotoxicity, oxidative stress, endocrine effects, and PAH toxicity). The migration experiments were conducted by comparing three different extraction/migration experiments (A: THF/hexane; B: 50% ethanol/water at 60°C for 3 days; C: 20% ethanol/water at 40°C for one day). Highest in vitro toxicities were found in PVC LDPE, and HDPE recyclates from Nigeria. Cell death, PAH-, estrogen- and anti-androgen-like toxicities were frequently dedected. None of the initial samples tested showed genotoxic effect (no p53 DNA repair activation by p53 CALUX). In most cases the full extraction Method A resulted in considerable higher toxicity compared to the two migration tests (B and C). Such effect-based bioanalysis allows for detection of the integrated toxicity of the chemical mixture in plastic recyclates and can be used in combination with instrumental analysis for effect-directed analysis. Since bioassays require relative low resources and maintenance of equipment while covering known and yet unknown toxic relevant compounds, they could be a useful tool for monitoring and controlling toxic chemical mixtures in plastic recycling in LMICs.

6.11.P-Mo537 Enhancing POPs Measurements and Reporting for Air: Keeping up with the Demands of the Global Monitoring Plan

Tom Harner[1]*, Jacob Mastin*[1]*, Lauren South*[1]*, Amandeep Saini*[1]*, Jasmin Schuster*[1]*, Anita Eng*[1]*, Derek C.G. Muir*[2]*, Victor Hugo Estallano Schulze*[3]*, Haosong Jiao*[3]*, Ramon Guardans*[4]*, Gamini Manuweera*[3]*, Penny Vlahos*[5] *and Kei Ohno*[6]*, (1)Environment*

and Climate Change Canada, Canada, (2)School of Environmental Sciences, University of Guelph, Canada, (3)UNEP Chemicals & Health Branch, Switzerland, (4)POPs, MITERD, Spain, (5)University of Connecticut, (6)UNEP BRS Secretariat
This paper summarizes the findings related to air, for a UNEP report on assessing POPs measurement capacity in air and water and strategies for sustainable data generation to support the Global Monitoring Plan (GMP) of the Stockholm Convention (SC) on POPs. The SC on POPs is an international agreement that aims to protect human health and the environment from the harmful effects of POPs. Global monitoring data for the listed POPs in core media (i.e., air, human milk and blood, water) is compiled and reported every 6 years in support of the Effectiveness Evaluation (EE), which informs the Conference of the Parties (COP) on the state of progress and relevant issues with respect to the listed POPs. A re-occurring issue in past GMP reports is the challenge for monitoring programs to keep pace with an expanding list of POPs in particular in developing countries and countries with economies in transition, which has more than doubled (since 2004) to 34 POPs.

A secondary aspect of this paper is to highlight some of the new developments under the Global Atmospheric Passive Sampling (GAPS) Network - also related to the topic of enhancing POPs measurements in air and meeting future challenges through cross-cutting studies. As the only continuously monitoring global-scale program investigating POPs in air, the GAPS Network is raising awareness and generating impacts through cross-cutting research at the science-policy and policy-policy interfaces. Examples will be presented on new areas of GAPS-driven research on topics such as, *inter alia*, health, climate, biodiversity and chemical waste.

6.11.P-Mo538 Do simple screening criteria capture a chemical's potential for adverse effects in remote regions?
*Knut Breivik[1], Michael McLachlan[2] and **Frank Wania**[3], (1)Norwegian Institute for Air Research (NILU), Norway, (2)Department of Environmental Science, Stockholm University, Sweden, (3)Department of Physical and Environmental Sciences, University of Toronto, Canada*
The Stockholm Convention (SC) on Persistent Organic Pollutants (POPs) provides a framework for global action on substances which are likely to lead to significant adverse environmental and/or human health effects in remote regions as a result of long-range environmental transport (LRET). However, in order for risk profiles on nominated chemicals to be prepared and evaluated (Annex E), the chemicals first need to be deemed to fulfill four screening criteria outlined in Annex D (persistence, bio-accumulation, LRET, as well as adverse effects). We used a modified version of the OECD P_{OV} and LRTP (long-range transport potential) Screening Tool ("The Tool") for assessing chemicals for persistence (P) and LRTP to analyze (i) if all screening criteria (Annex D) really need to be fulfilled for a chemical to be likely to result in adverse effects as a results of LRET and (ii) to what extent the existing modelling approach recommended by the OECD is therefore fit for the purpose of identifying chemicals proceeding to the risk profile stage. Based on a model-based analysis of 12,615 organic high production volume chemicals (HPVs), we find that a set of alternative LRTP metrics, referred to as the Emission Fractions Approach (EFA), classifies a larger number of HPVs as having the potential for accumulation in surface media of remote regions than is classified as POP-like by the existing method recommended by the OECD. Many chemicals in the screening data set with the potential to accumulate in surface media of remote regions do not meet the screening criteria for LRET (half-life in air < 2 days) and P (half-life in water < 2 months) of the SC. We conclude that screening for LRTP under Annex D using the existing OECD Tool could potentially prevent chemicals from proceeding to the risk profile stage or being nominated in the first place. It is therefore recommended that assessments of a chemical's potential for accumulation in surface media of a remote region, such as offered by the EFA, should play a more prominent role in model-based assessment under Annexes D and E of the SC.

6.11.P-Mo539 Needs for Sound Science across Existing National and International Management Structures – Implications from Observation in a Global Mercury Study
***Noriyuki Suzuki**[1] and Masaki Takaoka[2], (1)National Institute for Environmental Studies (NIES), Japan, (2)Kyoto University, Japan*
Variety of national and international organizations have been working at the management of chemicals. At least partly because of the real wide diversities of chemicals in their nature, and also the long history of chemicals management as probably one of oldest environmental concern on pollution, each country established their original legal/national frameworks and also several international organizations have worked on the issue from each standpoint, of course with efforts of collaboration among them [e.g., 1].

Now many chemicals are used in all global, nearly ubiquitous manner. Chemicals that will be long-range transported in natural environment are managed by specific legally-binding instruments like Stockholm Convention on POPs, however, many chemicals that may be outside the scope of such global frameworks also may exist in the environment ubiquitous way, maybe because of widespread and common use in the world, transport by artificial mechanisms, or maybe other reasons. Clearly as we should not establish independent global legally-binding instruments for all hazardous chemicals for each, we need to think about better structure of chemicals management in global system.

The discussion here is based on the outcomes of a research project "Intervention Scenarios and Global Mercury Modelling for Effectiveness Evaluation of the Minamata Convention on Mercury" [2], which was lead by a co-author Takaoka and participated by another co-author Suzuki in this abstract.

As observations and conclusions based on our case study on mercury, the holistic understandings of chemicals in globe is essential and effective for global management, however for many chemicals and waste issues, including industrial chemicals, e.g., PFAS, plastic additives, widely-used pesticides and other examples, may not have such sound scientific understandings. To achieve the most trustful and sound scientific understandings, we need independent scientific structure consisting of wide range of sciences in the way of avoiding any conflicts to the interest that expecting analysis may refer.

6.11.P-Mo540 Needs for sound science across existing national and international management structures – implications for the marine ecosystems

Joan O. Grimalt[1], *Marinella Farre*[2] *and Marta Llorca-Casamayor*[1], *(1)Environmental Chemistry, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (2)Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain*

The chemical production of new compounds has followed an exponential increase between 1800 and the present, with an average annual rate of increase of 4.4%. In 1800, about 40 manufactured compounds were in use and in 2023 more than one million [1]. Specific legally binding instruments exist, such as the Stockholm and Minamata conventions on POPs and mercury, respectively, but it is clear that the high number of new chemical species introduced into the environment and into the human diet necessitates an IPCPW that can address this enormous challenge in a holistic manner [2]. Poorly managed waste is one of the priority pathways by which these compounds enter the environment. Marine ecosystems receive enormous quantities of these chemicals, such as pharmaceuticals, personal care products, petroleum residues, flame retardants, pesticides, plastic additives, prefluoroalkyl and polyfluoroalkyl substances, nanoparticles, microplastics and nanoplastics, to name a few. Untreated or poorly treated wastewater is one of the main carriers of these pollutants. These waters are usually discharged in the areas of influence of the coastline, i.e. the marine zones of greatest productivity and biodiversity.

The number of countries that treat more than 75% of wastewater discharges is very limited, which implies a regular discharge of pollutants into the marine environment, especially in coastal areas, where biodiversity is higher and a substantial part of fish and seafood is collected for human consumption. These discharges may also be mediated by rivers, for example, an estimated 275 million metric tons of plastic waste were generated in 192 coastal countries in 2010, of which between 4.8 and 12.7 million metric tons entered the ocean [3]. In addition, maritime areas have eventually been used as waste dumps. Ship traffic is also source of pollutants if they release untreated sewage or ballast waters into the oceans and seas, particularly near harbour areas while waiting to be loaded or unloaded. In addition, some compounds such as mercury and halogenated persistent organic pollutants can be incorporated into the oceans through long-range atmospheric transport.

An important aspect to elucidate about these discharges is the residence time of the contaminants, which in the case of microplastic debris has been calculated to be much longer than previously expected [4]. This finding implies a generalization at source of the presence of contaminants in the marine system and the need to consider the waste released in a global context rather than relating it to local discharges.

According to the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services, one in five people worldwide depend on wild species for food and income, with fisheries being one of the main sources of food from wild species. Unfortunately, many of the pollutants discharged, especially those with high chemical and environmental stability, return to humans because they accumulate in fish, as is well known in the case of mercury and microplastics.

The future IPCPW should focuss specific attention to the management of discharges of sewage and waste in the marine areas. This approach will allow to creating synergies with the promoters of panels specifically devoted to the marine system such as the International Panel on Ocean Sustainability [5].

6.11.P-Mo541 A Cheminformatic Exploration of Chemicals on the Global Market

Jonathan Blumenthal[1], *Zhanyun Wang*[2] *and Bernd Nowack*[3], *(1)ETH Zurich, Switzerland, (2)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (3)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*

The years since the Second World War have seen exponential increases in the volume and diversity of chemicals produced, but a failure of regulatory capacity to keep up. Consequently, although chemical pollution has been recognized as one of three planetary crises threatening the survival of humanity, many chemicals in commerce remain poorly understood and studied.

Building off previous work by Wang et al. (2020), we compile an updated global inventory of chemicals in commerce, covering more than 350,000 chemical entities across 23 regulatory jurisdictions, and including specialized inventories such as the European Inventory of Cosmetic Ingredients. By applying cheminformatic tools to screen these chemicals, we gain the most in-depth understanding of the properties and diversity of chemicals on the global market.

In particular, we use fingerprint-based clustering approaches to assess geographic and temporal trends in chemical usage, identifying chemical families common to multiple inventories, or those unique to certain jurisdictions. We also use data on the registration dates of chemicals to identify areas of chemical innovation. In parallel, we investigate more specific questions, including whether the more than 100,000 chemicals listed as previously registered in the European Union and which were not carried over into REACH ceased production or were instead listed in other jurisdictions.

To assess the extent to which computational models for property prediction are valid for chemicals on the global market, we identify chemicals falling outside or on the borders of the applicability domains for several quantitative structure-activity relationships, and make practical recommendations to facilitate improved assessment of these chemicals. For those chemicals that do fall within the applicability domain, we make several property predictions to explore the property distributions of chemicals on the global market.

It remains a challenge to obtain unambiguous chemical identifiers for all chemicals on the global market – only 70% have their assigned CAS numbers identified, and UVCBs, polymers, and mixtures account for 21% of the inventory. However, our analysis provides important insights into trends in the chemical industry and regulatory efforts, as well as targeted recommendations for improving regulatory capacity to assess novel chemicals.

6.11.P-Mo542 Continuing large-scale global trade and illegal trade of highly hazardous chemicals
Zhanyun Wang[1]*, Hongyan Zou*[2]*, Tao Wang*[2] *and Zhong-Liang Wang*[3]*, (1)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Tianjin Key Laboratory of Water Resources and Environment, Tianjin Normal University, Tianjin, P.R. China, (3)Tianjin Key Laboratory of Aquatic Science and Technology, Tianjin Chengjian University, China*
Anthropogenic chemical pollution stands as a significant contributor to the interconnected triple planetary crisis of climate change, biodiversity loss and pollution. One important instrument in regulating the cross-border movement of hazardous chemicals is the Rotterdam Convention, providing nations with a framework to manage the international trade of specified perilous substances. However, an evaluation of the Convention's effectiveness has been notably limited in existing research. In our comprehensive analysis, we delved into 66,156 trade records sourced from the United Nations Comtrade database. This rigorous examination revealed that, between 2004 and 2019, a staggering 64.5 megatonnes of 46 listed chemicals were traded. Alarmingly, illegal trade was pervasive, accounting for at least 25,324 trade records and a volume of 25.7 megatonnes. While the Convention demonstrated positive impacts for over 70% of the listed chemicals, persistent large-scale trade of notorious substances like tetraethyl and tetramethyl lead persists. Addressing these concerns necessitates concerted global efforts. Improving the global trade dynamics of highly hazardous chemicals requires enhanced enforcement of the Rotterdam Convention, tackling illicit trade head-on, and promptly including problematic chemicals—such as chrysotile asbestos—within the Convention's regulatory purview. Such concerted global action is imperative to safeguarding the planet from the detrimental consequences of unregulated chemical in commerce.

6.11.P-Mo543 How Do We Adress the Global Threat of Irreversibly, Accumulating Trichloroacetic Acid (TFA)?
Hans Peter Arp[1,2]*, Andrea Gredelj*[2]*, Juliane Glüge*[3]*, Martin Scheringer*[3] *and Ian Cousins*[4]*, (1)Norwegian University of Science & Technology (NTNU), Norway, (2)Norwegian Geotechnical Institute (NGI), Norway, (3)ETH Zurich, Switzerland, (4)Department of Environmental Science, Stockholm University, Sweden*
Trifluoracetic acid (TFA) is a small, hydrophilic, non-degradable molecule that has been detected in diverse environmental media, from precipitation and ice cores, air, soils and sediments to human serum and plant-based foods and drinks. TFA, which is also regarded as the smallest of the per- and polyfluoroalkyl substances (PFAS), has been referred to as a "substance from multiple sources (SMS)". TFA was not commonly reported in non-atmospheric environmental media until very recently. All of these reports collectively indicate its concentration is orders of magnitude higher than other PFAS.

One major source, particularly responsible for the accumulation of TFA in remote areas suand in precipitation are "F-gases", a group of hydrofluorocarbons used as part of the Montreal Protocol's substitution from the ozone-depleting chlorofluorocarbons (CFCs). Some emerging F-gases allowed by the Montreal Protocol, such as HFC-1234yf, are anticipated to accelerate the irreversible, global accumulation of TFA, by orders of magnitude from 2050, depending on future developments of the global regulations, including the Montreal Protocol. However, even if F-gases are banned, there are many other sources, like pesticides, pharmaceuticals and industrial substances containing a -CF_3 group, or (fluoro)polymers. TFA concentrations will increase in the coming decades and it is unclear when and if it will ultimately plateau.

The global threat of TFA is that while it is increasing it may cross a threshold concentration that will cause severe ecological harm. Eco(toxicity) data is scarce, as most conclusions are based on aquatic studies that are near two decades old. In these studies, microalgae are considered the most sensitive ones. Current reported eco(toxicity) thresholds, e.g., PNECs for freshwater are reported to span between 0.12 µg/L and 5.6 mg/L. For terrestrial plants, where TFA accumulates in very high concentrations, safety thresholds based on toxicity tests corresponding to these high concentrations have not been determined yet.

Here, we will demonstrate the "case" of TFA as an omnipresent, persistent, and mobile contaminant that presents a planetary boundary threat. The TFA emitted today will be a legacy for countless of generations in the future. Global policy action towards solutions will be presented that will enable the plateauing if TFA concentrations, to prevent its planetary boundary from being irreversibly exceeded.

6.11.P-Mo544 Geospatial Dependent Pesticides Application Pattern for Selected European Countries

***Shiva Sabvezari*[1]**, *Jakub Hofman[2] and Evgenia Chaideftou[1], (1)RECETOX, Faculty of Science, Masaryk University, Czech Republic, (2)RECETOX, Masaryk University, Czech Republic*

The overall volume and quantity of pesticides currently employed for agricultural purposes in the European Union (EU) are rising due to demographic growth and increasing demand for food since the most efficient way of boosting agricultural yield is through utilization of plant protection chemicals. While the pesticides usage is inevitable, their occurrence and influence on the environment have attracted the attention of scientists and regulators due to several imperatives, such as regulatory compliance, optimizing application practices, and selection of safer pesticides. Nonetheless, the first step to environmental studies is foundational comprehension of the input of pesticides into the environment. To estimate the input of the pesticides into the environment, it is essential to have information about the applied pesticides, their corresponding application quantity, and the targeted crops for each region. To achieve this objective, the integration and combination of two databases were undertaken for selected EU countries: 1) a registration database, detailing plant protection products registered for use, describing the approved quantity and pesticide composition for diverse crop types; and 2) a crop database, presenting geospatial information on cultivated crops. The registration database for each country was being harmonized in terms of layout, resolution, and language. The harmonized data were integrated and new datasets containing the information about the pesticides generalized application pattern for each country were generated. The new generated datasets were connected to the crop database and the integrated data were transformed into the maps illustrating generalized application pattern for each region. The outcomes of this investigation furnish valuable insights into the geospatially dependent potential input of pesticides into the environment, offering substantial utility in subsequent exposure, environmental fate, risk assessment studies and in general, essential for management of pesticides use.

6.11.P-Mo545 Can We Track the Origin of Rapidly Rising Releases of Hexachlorobutadiene to the Global Environment?

***Frank Wania*[1]**, *Chengkang Chen[1], Jenny Oh[2] and Faqiang Zhan[1], (1)Department of Physical and Environmental Sciences, University of Toronto, Canada, (2)Department of Chemistry, University of Toronto, Canada*

Hexachlorobuta-1,3-diene (HCBD) has been listed in Annex D and E of the Stockholm Convention on Persistent Organic Pollutants (POPs) in 2015 and 2017, respectively, meaning that both deliberate and unintentional production should be curtailed globally. Yet, air-monitoring has revealed that HCBD concentrations have been rising rapidly and continuously from 2008 to 2021, making it the most prevalent POP in the global atmosphere. Despite a long atmospheric residence time, HCBD's air concentrations are far from uniform in the Northern Hemispheric, but show a strong spatial gradient: Whereas background concentrations in the Northern Hemisphere increased from ~100 pg m^{-3} to ~1000 pg m^{-3} during the 2010s, levels recorded across Japan are somewhat higher (1,000 to 4,000 pg m^{-3}) and concentrations in Northeastern China, even distant from suspected sources, exceed 100,000 pg m^{-3}, often reaching levels over 1,000,000 pg m^{-3}. The unintentional production of HCBD in China has been estimated to have risen from ~100 MT a^{-1} in 2000 to 3000 MT a^{-1}in 2016, mostly as a result of tri- and perchloroethylene (TCE, PCE) production. We are using time-variant simulations with the BETR-Global model to explore whether the estimated unintentional Chinese emissions can explain the temporal and spatial trends observed in the atmosphere or whether additional emissions need to be invoked. We further discuss the implications of the apparent failure of the provisions of Article 5 of the Stockholm Convention in reducing, let alone eliminating, the environmental releases of unintentionally produced POPs, especially considering that the unintentional production of HCBD during TCE and PCE manufacturing has been known for many decades.

6.11.P-Mo546 Synthesis of Radiolabelled Industrial Chemicals, Drugs and Crop Protection Products from Carbon-14 Building Blocks

Jonathan Bristow[1], ***Nitesh Panchal*[1]**, *Emma Danby[2] and Victoria Remnant[3], (1)Metabolism, Labcorp, United Kingdom, (2)Labcorp Early Development, United Kingdom, (3)Environmental Sciences, Labcorp, United Kingdom*

Carbon-14 (^{14}C) is the key radioactive isotope used in metabolism studies supporting the development of industrial chemicals, drugs and crop protection products. Carbon-14 used in radiolabelling studies across the world originates from [^{14}C]carbon dioxide which is typically stored as [^{14}C] barium carbonate. This molecule is considered as the universal starting material from which all other carbon-14 labelled compounds are prepared. Four core building blocks stem from this universal starting material; [^{14}C]carbon dioxide, [^{14}C]metal cyanides, [^{14}C]acetylene and [^{14}C]barium cyanamide.

The four core building blocks can be further expanded via a variety of different pathways to give a multitude of different families of low molecular weight ^{14}C labelled intermediates. Access to these low molecular weight ^{14}C labelled building blocks allows for complete control when designing and developing the radiolabelling of a test item. As a result, multiple synthetic routes can be designed and multiple radiolabelling sites within the target molecule proposed. This process ensures a one-stop-shop, entirely controlled radiosynthetic process from design to execution to single or multiply radiolabelled test items.

The poster will show how these pathways can be utilized to provide options for the radiolabelling of industrial chemicals, drugs and crop protection products.

6.11.P-Mo547 Glyphosate and earthworms

Claudia de Lima e Silva[1] *and Celine Pelosi*[2]*, (1)Vrije University Amsterdam, Netherlands, (2)INRAE (Institut National de la Recherche Agronomique), France*

Introduction: Reliable data on the toxicity of this herbicide, not only to earthworms, but to soil invertebrates in general, are scarce and not consistent, leading to a lack of clarity on this subject. Aiming to shed light to the topic, we decided to review the literature using an exhaustive research to answer two questions: 1) Which endpoint is the most sensitive when assessing the effects of glyphosate or GBH in earthworms? 2) Are glyphosate and GBH harmful to earthworms when used at the recommended application dose (RAD)?

Materials and Methods: keywords in ISI Web of Knowledge and Web of Science, using the “All Databases” option, with the following formula: ‘*earthworm* OR lumbric* OR aporrect* OR eisen* OR dendrob* OR allolobaph* OR octolas* OR dendrodril* OR diporodril* OR eophil* OR helodril* OR kritodril* OR octodril* OR prosellodril* OR scherothec* OR satchell* OR proctodril* OR orodril* OR postandril* OR perelia* OR andrei* OR fetid* OR foetid** AND ‘glyphosate or roundup or Round-up or glyphosate-based-herbicide*’ in Topic.

Results and Discussion: Out of 307 potential papers, only 63 papers could be used, indicating that around 80% of the papers initially found on our search did not have sufficient and relevant information. The low number of papers assessing toxicity to reproduction (19% of all papers) can lead to an underestimation of the toxicity of the herbicide to this endpoint. Most of the papers using one application of the recommended application dose (RAD) did not find any impact of glyphosate or GBH on earthworm survival. However, glyphosate or GHbs, under RAD can cause toxicity to cocoon production, lysosomal destabilisation biomarkers (neutral red retention time or NRRT), number of juveniles, and others.

Conclusions:The review showed that glyphosate and GHB can be toxic to earthworms. Although different factors can influence toxicity and much remains unknown, data points towards negative impacts on reproduction and the provision of ecosystem services. Our results also indicate that the risk assessment process has gaps and is not strong enough to prevent future threats to biodiversity. There is an urgent need for government agencies to keep pace with updates on competent directives and other concerning legislation, standardised methodologies, and the development of the field of soil ecotoxicology, aiming to avoid possible underestimation of the potential risk of a pesticide in the near future.

6.11.P-Mo548 Conflicts of interest in scientific publishing: a cross sector perspective

Tobias Pamminger, Dr.[1]*,* ***Hannes A. Reinwald***[1] *and Magdalena M. Mair*[2]*, (1)Early Environmental Safety, Bayer AG, Germany, (2)Statistical Ecotoxicology, University of Bayreuth, Germany*

Scientific publishing is an essential part of the scientific process, allowing researchers to disseminate their findings and contribute to the advancement of science. However, conflicts of interest (COI) can arise when personal views or financial incentives have the potential to bias results in scientific publications. While financial COI are often easy to recognize and already disclosed in the relevant sections of the publication (e g. the private sector), authors from other sectors such as universities, non-governmental organizations (NGOs) and regulatory agencies often explicitly state in their papers that COI do not apply to them. We argue that while not necessarily financial in nature, relevant COI exist in all research sectors. In academia for example, they include the career-defining necessity to publish in high-impact journals and dependencies on grants, which are exemplified by integrity scandals including large scale falsification of research results. In contrast, NGOs often pursue a societal or political agenda, which can create COI independent of financial interests. While the nature of the COIs can be sector-specific, we argue that all stakeholders, regardless of their affiliation, need to clearly identify their sector specific COI and explicitly disclose their COI in their publications to allow for a more objective judgment of the presented work. We would like to use the SETAC EU meeting in Seville to invite scientists from all sectors to contribute ideas, suggestions, opinions and potentially co-author an envisioned short publication.

6.12 Science-Policy Dialogue on Per- And Polyfluoroalkyl Substances (PFASs) Towards a PFAS-Free Future: Latest Development and Future Needs

6.12.T-01 European Regulation of Per- and Polyfluoroalkyl Substances (PFASs) and its Connection to Research

Jona Schulze[1]*, Lena Vierke*[2]*, Wiebke Drost*[2]*, Stefan Kacan*[2]*, Claudia Staude*[2]*, Achim Helmedach*[2] *and Gabriele Treu*[2]*, (1)Chemicals, German Environment Agency (UBA), Germany, (2)German Environment Agency (UBA), Germany*

Risks from Per- and Polyfluoroalkyl substances (PFASs) are currently not adequately controlled. Therefore, in January 2023 the authorities from Denmark, Germany, the Netherlands, Norway and Sweden submitted a joint proposal to restrict all PFASs under Regulation (EC) No. 1907/2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals

(REACH), based on the shared concern about their very strong persistence. The proposal for a restriction of the non-essential uses of presumably more than 10,000 PFASs is one of the most comprehensive restriction proposals put forward thus far.

In order to understand the discussion around this broad PFASs restriction proposal and also to know where and how to best contribute with scientific data and knowledge, it is important to understand the restriction procedure, how scientific insights were used in the past and the future course of the broad PFASs restriction proposal.

The presentation is mainly based on the work of the following restriction proposals and preceding or follow-up work:

- Identification of PFOA as a Substance of Very High Concern (SVHC) under REACH and the restriction proposal following this identification
- Broad restriction proposal for PFASs under REACH.

The aim of the presentation is to show how scientific data and knowledge have contributed to the PFASs regulation under REACH from past to present and which research areas will be of relevance from a regulatory point of view in the future. It will also elaborate on the complex process of preparing the broad PFASs restriction proposal and outline how a step-by-step phase-out of PFASs in the EU through the implementation of the restriction could look like.

Due to the high relevance of scientific data and knowledge within regulatory processes discussions to continuously maintain and improve the link between science and regulation are of very high importance. The presentation is intended as contribution to facilitate this discussion

6.12.T-02 Database of Alternatives to Per- and Polyfluroalkyl Substances Based on the Functional Substitution Approach

Romain Figuière[1]*, Luc Miaz*[2]*, Eleni Savvidou*[2] *and Ian Cousins*[3]*, (1)Department of Environmental science, Stockholm University, Sweden, (2)Stockholm University, Sweden, (3)Department of Environmental Science, Stockholm University, Sweden*

Per- and polyfluoroalkyl substances (PFAS) are a group of fluorinated organic substances. The typical properties of the perfluoroalkyl moiety in PFASs (e.g., thermal and chemical stability, combined oleophobicity and hydrophobicity) have resulted in extensive use across diverse industrial and consumer applications. Due to their extreme persistency in the environment, regulatory activities have been increasing over the last few years to phase-out all uses of PFAS which encourages companies to find PFAS-free alternatives for their uses of PFAS. The aim of this study is to propose a database which (1) describes the uses of PFAS in order to understand the purpose they serve in each of their application; and (2) gathers information on potential alternatives which could deliver similar services. The main purpose is to gather information on alternatives to PFAS and to make it more accessible so it can be used to guide companies in their substitution activities. Following the functional substitution approach, the database provides information on the technical functions, end-uses and services provided by PFAS application of PFAS. Potential alternatives are also listed along with a short description of any potential loss in performance compared to PFAS, and whether they are available on the market or not. The annexes to the background document to the REACH restriction proposal on uses of PFAS served as the main source of information to build the database. In total, 37 different technical functions of PFAS were identified, which corresponds to up to 201 different services across 261 applications. The results suggest that waterproofing agent, corrosion inhibitor and heat stabiliser are the most common technical functions delivered by PFAS. It also suggests that PFAS deliver more than one service in the majority of the applications which makes the search for alternatives more challenging. Further analysis is still needed to identify the cases where PFAS could be phased-out because they do not provide a techical which is critical for the performance of the application. As of November 2023, 563 different alternatives are listed in the database for 211 applications. The majority of the alternatives identified are alternative substances or alternative materials. Further analysis is still needed to determine the cases where PFAS can already be substituted as suitable alternatives are already available and in use.

6.12.T-03 The PFAS Analytic Tools: Using Geospatial Information to Promote Transparency in Understanding and Managing Risk from Per- and Poly-fluoroalkyl Substances in the United States

Andrew Gillespie[1]*, Michael Barrette*[2] *and Nicholas Spalt*[2]*, (1)Office of Research and Development, U.S. Environmental Protection Agency (US EPA), (2)U.S. Environmental Protection Agency (US EPA)*

Per- and poly-fluoroalkyl substances (PFAS) are recognized as an urgent public health and environmental threat across the global community. In response, the United States Environmental Protection Agency (U.S. EPA) has developed a PFAS Strategic Roadmap documenting commitments to action in three domains: (1) research to increase understanding of PFAS risk and risk management responses; (2) restriction to prevent PFAS from further entering the environment at harmful levels; and (3) and remediation of existing PFAS contamination to protect human health and the environment. A key element needed to implement this strategy is transparent integration of the rapidly growing body of information about the species, presence, transport, fate, and potential exposures of PFAS in the environment. To address this, U.S. EPA has developed the PFAS Analytic Tools, a public web-based geographical information system for integrating data about PFAS reporting, testing, and occurrences in communities across the United States.

The PFAS Analytic Tools aggregates state and national PFAS data from 11 different datasets into a single searchable online platform. Users can filter data by PFAS or geographic area, explore application charts and maps, and download data for further exploration in other tools. The system integrates multimedia data from multiple federal and state agencies and is designed to be updated continuously as new data become available. The PFAS Analytic Tools enables risk managers, researchers, and community stakeholders to better understand potential PFAS sources in their communities and to develop effective management, policy, and other actionable responses.

This presentation will discuss the design of the tool as well as present several examples of applications to inform policy and management of risk from PFAS, to promote communication and transparency amongst communities and stakeholders, and to help address environmental justice concerns.

6.12.T-04 Per- and polyfluoroalkyl substance (PFAS) immobilization approaches with regenerated waste products in large scale unsaturated lysimeters

Michel Hubert[1,2]*, Björn Bonnet*[3]*, Lutz Ahrens*[3]*, Erlend Sørmo*[1,4]*, Gerard Cornelissen*[1,4] *and Hans Peter Arp*[1,2]*, (1)Norwegian Geotechnical Institute (NGI), Norway, (2)Norwegian University of Science & Technology (NTNU), Norway, (3)Department of Aquatic Sciences and Assessment, Swedish University of Agricultural Sciences (SLU), Sweden, (4)Mina, Norwegian University of Life Sciences (NMBU), Norway*

There are estimated to be more than 2,000 sites in Europe in which soil and leachate water contain highly elevated concentrations (>100 ng/L) of per- and polyfluoroalkyl substances (PFAS). The accumulative emissions of PFAS from these sites are a threat to groundwater and drinking water reservoirs. Immobilization technologies, aiming to stabilize PFAS within the soil and thereby prevent PFAS leaching, are a promising in-situ soil remediation strategy. However, a detailed understanding of the transport of PFAS in the unsaturated zone after soil amendment is currently lacking. Since fossil based PFAS binders (e.g. activated carbon from anthracite) are associated with high carbon footprints, there has recently been an emerging interest for biochar-based binders derived from waste, which can be produced with net negative carbon emissions. The presented study used 10 outdoor lysimeters to investigate how the presence of commercially available soil amendments and such biochars could be used to stabilize the transport and fate of PFAS in the unsaturated zone and to lower bioavailabilty of these substances.

The lysimeters (n = 10), with the exception of one lysimeter serving as a clean blank, were spiked with an Aqueous Film Forming Foam (AFFF) and a mixture of 18 PFAS. Two lysimeters remained non-amended, while two lysimeters were treated with commercially available PFAS immobilization binders (PAC, RemBind®).The remaining four lysimeters were amended with two types of biochar in two different concentrations each, one tested biochar being pyrolyzed from timber waste and a second one from PFAS-contaminated sewage sludge. Leachate water samples were collected weekly when available. After ending the experiment section-wise soil samples were taken from each lysimeter. All water and soil samples were extracted and analyzed for target PFAS. At selected time points the leachate was analyzed for dissolved organic carbon (DOC), anions, cations and heavy metals.

This study provides novel insight on how soil stabilization techniques, especially biochars can be used to reduce leaching of PFAS from highly legacy contaminated sites. Sludge derived biochar showed promising results in lowering leachate of PFAS from contaminated soil and can be a more sustainable and greener solution for soil remediation than traditional sorbents. Moreover, the potential to derive biochar from PFAS-contaminated feedstock represents a crucial step to handel PFAS contamianted organic material.

6.12.T-05 Insights Into the Atmospheric Sources and Fate of (Ultra-) Short-Chain Perfluoroalkyl Carboxylic Acids from New High Time Resolution Measurements

Cora Young[1]*, Jessica Clouthier*[1]*, Shira Joudan*[2]*, RenXi Ye*[3]*, Trevor VandenBoer*[3]*, Eric Vanhauwaert*[4]*, Jeremy Wentzell*[5]*, Mayre Rodriguez*[1]*, John Liggio*[5] *and Na-Yung Seoh*[1]*, (1)York University, Canada, (2)Chemistry, University of Alberta, Canada, (3)Chemistry, York University, Canada, (4)Department of CHemistry, York University, Canada, (5)Environment and Climate Change Canada, Canada*

The atmosphere is well-established as an important source and transport pathway for persistent perfluoroalkyl carboxylic acids (PFCAs). Despite its importance, measurement techniques for the gas and particle phase are limited to time-integrated methods, which limit our understanding of atmospheric processes. We have developed two in situ measurement techniques for PFCAs that allow us to capture PFCAs in the gas and particle phases. These techniques operate at timescales (i.e., seconds to one hour) that are similar to those of the atmospheric processes we wish to understand. We used the acetate chemical ionization mass spectrometer (CIMS) and ambient ion monitor-ion chromatograph-mass spectrometer (AIM-IC-MS) to make ambient atmospheric measurements of C2-C6 PFCAs in Toronto, Canada. These measurements clearly demonstrated the importance of PFCA atmospheric formation. Diurnal profiles of gaseous PFCAs were consistent with photochemical formation, with significant correlations to other photochemical products, such as ozone and formic acid. Particulate PFCAs were observed by AIM-IC-MS and showed a relationship to overall particle loading. The implications of these new observations for PFCA atmospheric fate and transport will be discussed.

6.12.P Science-Policy Dialogue on Per- And Polyfluoroalkyl Substances (PFASs) Towards a PFAS-Free Future: Latest Development and Future Needs

6.12.P-Tu531 Understanding Perfluoropolyethers and Their Life Cycle

Zhanyun Wang[1], *Marie-Ange Baucher*[2] *and Eeva Leinala*[2], *(1)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Environmental, Health and Safety, Environment Directorate, Organisation for Economic Co-operation and Development (OECD), France*

Per- and polyfluoroalkyl substances (PFASs) comprise a class of synthetic chemicals that have attracted much public attention since the early 2000s. Over time, research and risk management measures have expanded to a wide range of PFASs, but mostly on non-polymeric PFASs. To ensure the sound management of the entire class of PFASs, it is equally important to understand polymeric PFASs, which include side-chain fluorinated polymers (SCFPs), fluoropolymers and perfluoropolyethers (PFPEs). This poster presents a synthesis report by the OECD/UNEP Global PFC Group, synthesizing scientific and technical information on the life cycle of PFPEs, which are polymers that contain perfluorinated ether moieties such as $–CF_2–O–CF_2–$ as repeating units direct in the polymer backbone chain. It starts with a comprehensive overview on the chemical identities of PFPEs that have been on the global market, including a non-exhaustive list of 153 PFPEs. 134 of them have their assigned Chemical Abstracts Services Registry Numbers (CASRNs) identified, and only 23 have structures readily available on SciFinder. Then, the life-cycle information of different PFPEs is synthesized, including the production and use of respective PFPEs, presence of other PFASs in the commercial formulations, degradation of PFPEs during use and end-of-life treatment, and environmental releases of PFPEs and other PFASs present in the commercial formulations. Compared to many non-polymeric PFASs and other polymeric PFASs such as SCFPs, less public information is available on the life cycle of PFPEs. Nevertheless, a variety of structurally diverse PFPEs exist on the global market, and their use in various industrial applications and consumer products is extensive. Noticeably, many PFPEs have rather low molecular weight, even below 1000 Da in some cases. Some evidence does show that other PFAS may be present in PFPE commercial formulations from different origins, but further investigation is needed to capture a comprehensive overview. PFPEs are generally considered to be stable and inert, with high thermal stability. However, they are vulnerable to Lewis acid-catalyzed decomposition, including during some uses. These findings are only a first step towards understanding the life cycle of PFPEs and the extent of their use on the global market. Concerted action by all stakeholders is needed to address PFPEs in an efficient and effective manner, building on the gaps identified in the report.

6.12.P-Tu532 Emission inventory of PFAS and other fluorinated organic substances for the fluoropolymer production industry in Europe

Joost Dalmijn, *Department of Environmental Science (ACES), Stockholm University, Sweden*

Fluoropolymers are part of the broad class of substances known as per- and polyfluoroalkyl substances (PFAS). During their production, a wide array of additional fluorinated organic substances (many PFAS and some not defined as PFAS) are used, formed and emitted to air and water. This study aims to assess, and make an inventory of, all emissions of PFAS and other fluorinated organic substances by the fluoropolymer production industry in Europe using available emission databases and permits. Air emissions of the fluorinated gases chlorofluorocarbons, hydrofluorocarbons, hydrochlorofluorocarbons and perfluorocarbons (CFCs, H(C)FCs and PFCs) by this industry have reportedly decreased between 2007-2021 from roughly 500 to 150 tonnes/year. Emissions of fluorosurfactants to air and water have also been reduced significantly. However, large uncertainties remain regarding the emissions of substances that are neither CFCs, H(C)FCs, PFCs nor fluorosurfactants but are classified as PFAS, such as polymerization by-products, chain transfer agents and fluorinated solvents. The available data indicate that the release of these substances is not decreasing but remains relatively stable. As the current inventory probably underestimates emissions, further research, improved data availability and more harmonized reporting of emissions are necessary to obtain more accurate emission data for these substances. Nevertheless, based on the available data, it is clear that the emissions from fluoropolymer production plants to air and water are still significant and that the production of fluoropolymers continues to introduce persistent substances to the environment.

6.12.P-Tu533 Are Analysis-of-Alternative Methods Suitable for Per- and Polyfluoroalkyl Substances (PFAS) under REACH?

Rachel Lucy London[1], *Juliane Glüge*[2] *and Martin Scheringer*[2], *(1)Institute for Biogeochemistry and Pollutant Dynamics, ETH Zurich, Switzerland, (2)ETH Zurich, Switzerland*

As society transitions away from per- and polyfluoroalkyl substances (PFAS), it is crucial to avoid regrettable substitution and prevent the lock-in of undesirable substances in future technologies. Existing methods for analysing chemical alternatives, such as GreenScreen® and Multi-Criteria Decision Analysis (MCDA), have been recommended by regulatory bodies, but their suitability for the European marketplace and for PFAS and their alternatives remains unclear. This study evaluates seven analysis-of-alternatives (AoA) methods, focusing on their compatibility with PFAS and REACH. GreenScreen® and MCDA are further investigated using hypothetical and real substance datasets. Results reveal disparities between GreenScreen® and REACH, emphasizing the need for caution in interpreting GreenScreen® results, particularly regarding hazards like mobility and persistence. MCDA parameters are found to significantly influence outcomes, necessitating careful selection for substances with highly heterogeneous hazard profiles. A modified MCDA approach is proposed for analysis of chemical alternatives, including mixed aggregation, non-linear value functions, and an objective hierarchy with dependant attributes. The study underscores the importance of informed method selection when deciding on alternatives to PFAS with emphasis on limitations on the current version of GreenScreen® and the sensitivity of MCDA to parameter choices. The research's impact

lies in enhancing the effectiveness of AoA methods for PFAS alternatives under REACH, helping optimise the transition from PFAS, and contributing to the broader objective of a toxic free society.

6.12.P-Tu534 Exploring the Presence of Per- And Polyfluoroalkyl Substances (PFAS) in Dutch Surface Waters

Sanne Brekelmans, *The Water Laboratory, Netherlands*

Per- and polyfluoroalkyl substances (PFAS) are a group of anthropogenic chemicals that are ubiquitous in the aquatic environment. Exposure to PFAS is often associated with many adverse health impacts, including effects on the immune system and development of the unborn child[1]. Their unique physicochemical properties can make PFAS very persistent while also being water soluble. As a consequence, PFAS are poorly removed by conventional treatment steps and are partial discharged in surface water (SW). In the Netherlands, approximately 40% of drinking water (DW) is produced from SW. Therefore, PFAS are of concern for the preparation of DW.

The Water Laboratory developed an ultra-high sensitivity analysis of PFAS[2]. This method achieved sub-parts per trillion detection levels for 26 PFAS compounds, with LOQ values of down to 0.2 ng/L[2]. The method included perfluorocarboxylic acids (PFCA) and perfluorsulfonic acids (PFSA) and other PFAS such as HFPO-DA (Gen-X) and precursors. Additionally, the method separates and semi-quantifies *branched* isomers of PFOA, PFOS and PFHxS. Trifluoroacetic acid (TFA) is additionally monitored in a separate method.

Here, we show the highlights of our extensive PFAS monitoring data from different Dutch SW. The data demonstrate consistent presence of PFCAs, PFSAs and moderate frequency of other PFAS. The shortest-chain PFAS, TFA, was the dominant congener detected at µg/L level, whereas longer-chain PFAS were detected at the ng/L level. Branched PFAS were also frequently detected at concentration levels in the same order-of-magnitude as linear PFAS, thereby appearing as relevant to SW as their linear twins.

From 2026, PFAS levels will be limited in the EU at 100 ng/L for 20 specified PFAS, for which the investigated SW would pass[3,4]. The EU also proposes a 500 ng/L limit for a ‘Total PFAS’ parameter, that is, the totality of all PFAS -including the mentioned 20 PFAS. Interestingly, concerning this total limit, current levels of TFA alone would cause exceedance at the µg/l level.

Our monitoring data revealed that the presence of PFAS in SW is a threat to environmental quality, and to DW sources. Structured mitigation strategies, including the Dutch government's proposal for a complete ban on the production and use of PFAS in Europe this year, are necessary to decrease PFAS emissions into the environment. Producing safe DW from PFAS-contaminated SW is exceedingly challenging, where removing already-present PFAS is a significant burden.

6.12.P-Tu535 Alternatives to the use of per- and polyfluoroalkyl substances (PFAS) in the electrodes and electrolytes of lithium-ion batteries (LIBs)

Eleni Savvidou[1], *Amanda Rensmo*[2], *Jonathan P. Benskin*[3], *Steffen Schellenberger*[4], *Xianfeng Hu*[5], *Marcel Weil*[6] *and Ian Cousins*[7], *(1)Stockholm University, Sweden, (2)The Environment and Sustainable Chemistry, Uppsala University, Sweden, (3)Department of Environmental Science (ACES), Stockholm University, Sweden, (4)RISE Research Institute of Sweden, Sweden, (5)SWERIM AB, Sweden, (6)Helmholtz Institute Ulm, (7)Department of Environmental Science, Stockholm University, Sweden*

The broad proposed restriction on per- and polyfluoroalkyl substances (PFAS) will inevitably impact the energy sector, that relies on the use of PFAS in various renewable energy technologies. This includes the lithium-ion battery (LIB) sector, where polymeric PFAS are used as well as low molecular weight PFAS, but also other organofluorine compounds. In the PFAS restriction proposal, but also in publicly disclosed documents from industry, it is noted that to date there are no viable alternatives available on the market that could potentially replace PFAS in LIBs. For this study, these claims were examined by reviewing the literature, and interviewing experts from industry and academia in order to assess the current state of science and market regarding (organo)fluorine-free alternatives. The focus was on cathode materials (electrode) and electrolyte components, since these parts of LIBs cover the crucial uses of PFAS. The investigations revealed several companies that developed alternative materials which are PFAS-free/(organo)fluorine-free as well as ongoing research activities towards such materials. One of the biggest current challenges was identified to be the substitution of polyvinylidene fluoride (PVDF), which accounts for the biggest fraction of PFAS-content in LIBs, and supposedly is the material that works best in term of performance. The electrolyte composition does not necessarily rely on the use of organofluorine compounds, but this is dependent on the overall cell chemistry and performance requirements of the final battery application. However, more future investigations and assessments are needed to fully evaluate this and compare the current materials with the available alternatives regarding tradeoffs. Theoretically, it is possible to have a PFAS-free battery, and the PFAS restriction can be an opportunity to strive towards innovation. The overall conclusion is, that it is rather a question to find a balance between optimizing battery performance to combat climate impacts and using sustainable materials to avoid the use of hazardous chemicals, and consequently their adverse environmental impacts.

6.12.P-Tu536 Trade-Offs Between Climate and Perfluoroalkyl Carboxylic Acid Formation: Is it Possible to Minimize Both Global Warming Potential and Persistent Products in F-gases?

***Cora Young**, York University, Canada*
It is well established that certain volatile fluorinated heat transfer fluids, fire suppressants, and solvents (F-gases) can degrade in the atmosphere to form trifluoroacetic acid (TFA). Common F-gases can also degrade to form other perfluoroalkyl carboxylic acids (PFCAs), including perfluoropropionic acid and perfluorobutanoic acid. While certain mechanisms that form TFA as a major product have been well studied, there has been less focus (and a great deal of confusion) on mechanisms that form TFA and other PFCAs as minor products. Recent environmental observations have demonstrated the importance of F-gases to the environmental burden of TFA and other PFCAs. This is likely to continue as F-gases with high global warming potential and relatively low PFCA yield are replaced with F-gases that have low global warming potential and high PFCA yield. I will summarize the state of knowledge regarding atmospheric formation of PFCAs from F-gases. Using the full range of F-gases identified by the Intergovernmental Panel on Climate Change Assessment Report 5, I will identify the structural features that do and do not lead to PFCA formation. Among the same group of molecules, I will also highlight the structural features that underly F-gases with high and low global warming potential. The potential for chemical design that results in no PFCA formation and low global warming potential will be discussed.

6.12.P-Tu537 Assessing the Destruction and Gaseous Carry-over of PFAS during Hydrothermal Carbonization (HTC) of Sewage Sludge

*Georgia Altiparmaki[1], Georgia Gatidou[2], **Emma Knight**[3], Ian John Allan[3], Athanasios Stasinakis[2] and Stergios Vakalis[2], (1)University of Aegean, Norway, (2)University of the Aegean, Greece, (3)Norwegian Institute for Water Research (NIVA), Norway*
Per- and polyfluoroalkyl substances (PFAS) are characterized by their persistent and stable nature, possessing thermal and chemical stability that renders them suitable for diverse industrial uses. Owing to their extensive application and complex characteristics, PFAS have been identified in soil, water, groundwater, wastewater, and sewage sludge. Certain PFAS, notably PFOA and PFOS, have been established as harmful to both human and environmental health. The application of hydrothermal treatment emerges as a promising technology for PFAS elimination. This method entails subjecting contaminated materials to high temperatures and pressures with water or steam, effectively breaking down PFAS molecules into less harmful compounds like carbon dioxide and water [1]. On the one hand, it has been reported that perfluoroalkyl carboxylic acids (PFCAs) can be reduced via decarboxylation and subsequent defluorination reactions [2]. On the other hand, the nucleophilic substitution and decarboxylation reactions during HTC can lead to the reduction of PFOS [3].

Throughout this process of HTC, sludge undergoes thermochemical transformation in the presence of water under elevated temperature and pressure, yielding hydrochar—a carbon-rich material suitable for energy generation or soil enhancement. It should be stated that this thermochemical pathway produces all the three phases of outputs, i.e. gaseous, liquid and solid that should be studied for their quality. Conventional analysis includes the measurements of PFAS in the solid and liquid phases, but the parameter of PFAS reduction due to carry-over into the gaseous phase has not been studied and is a novelty of this study. In this framework, a unique PFAS-free gas sampling set-up was developed for the condensation of the liquid products, the cleaning of the gaseous products and the collection of PFAS from the gaseous phase on the adsorptive surface of specialized cartridges. The measurements of the HTC products were implemented on a Nexis 2030 GC-BID, while specialized columns for gaseous (RESTEK ShinCarbon 80/100) and liquid phases (J&W Agilent FFAP, MEGA-10) were utilized. An LC - MS/ MS was used for the analysis of PFAS on all three phases. Therefore, this study will present the preliminary results of the HTC product analysis and the fate of PFAS on sludges that undergo HTC.

Track 7. Moving Beyond – Cross Cutting Themes, Emerging and Transdisciplinary Topics

7.01 Climate Change and Chemical Contamination: From Combined Effect Studies to Environmental Risk Modelling

7.01.T-01 The Interactive Effects of Temperature and Chemicals at Different Levels of Biological Organization of Aquatic Ecosystems

Paul van den Brink[1]*, Anna Huang*[2] *and Markus Hermann*[3]*, (1)Wageningen University & Research (WUR), Netherlands, (2)Wageningen Environmental Research (WUR), Netherlands, (3)Aquatic Ecology and Water Quality Management, Wageningen University & Research (WUR), Netherlands*

This presentation aims to present the interactive effects of temperature and imidacloprid residues at different levels of biological organization. The research has been carried out under the ECORISK2050 project (www.ecorisk2050.eu). The ECORISK2050 project applied a holistic approach to address the numerous challenges arising from chemical risk assessment under global change. It was launched with support from the European Union Horizon 2020 program to support the European Union's goal of a non-toxic environment by 2050. Experiments were conducted to study the impact of temperature on the toxicokinetics and toxicodynamics of imidacloprid on individuals of the aquatic arthropod *Gammarus pulex*. These experiments were utilized to parameterize a toxicokinetic-toxicodynamic (TKTD) model which encompasses temperature-dependent parameters. Our findings indicate that toxicokinetic and toxicodynamic parameters scale differently with temperature, calling for further study to unravel the underlying mechanisms. An individual-based model (IBM) was used to evaluate the impact of temperature on the effects of imidacloprid at the population level. This highlights the significance of integrating temperature-sensitive parameterization into population models to conduct reliable risk assessments, considering the projected climate conditions characterized by increased variability. Mesocosm experiments were performed to evaluate the interactive effects at the population, community, and ecosystem levels. The results revealed interactive effects of temperature and imidacloprid, which induced temperature-enhanced and time-accumulative toxic effects, with further implications for the recovery dynamics of different communities and populations, as well as the functioning of freshwater ecosystems . Although we can undertstand how temperature affects chemical toxicity at the individual level, we have difficulties to understand the effects at the community and ecosystem level. To gain more understanding, we can link the suborganismal level with individual-level approaches like TKTD, population level models such asTKTD based IBMs, and population level approaches with community and ecosystem level models like food web models. Overall, our findings signalize that the health of freshwater ecosystems and other interconnected ecosystems in the future will rely on local and global efforts to mitigate the impacts of these multiple stressors.

7.01.T-02 Combined effects of heat waves and pesticide pollution in aquatic ecosystems: does the timing of stressor matter?

Andreu Rico[1]*, Francesco Polazzo*[2] *and Ariadna García-Astillero Honrado*[3]*, (1)Cavanilles Institute of Biodiversity and Evolutionary Biology, University of Valencia, Spain, (2)Evolutionary Biology and Environmental Studies, University of Zurich, Switzerland, (3)IMDEA Water Institute, Spain*

Most investigations assessing the combined effects of chemical and non-chemical stressors on aquatic ecosystems have been based on simultaneous stressor applications. However, asynchronous exposure scenarios may be more common in nature, particularly for pulsed stressors such as heat waves and pesticide concentration peaks. In this study, we investigated the single and combined effects of the insecticide chlorpyrifos (CPF) and a heatwave (HW) on a zooplankton community representative of a Mediterranean coastal wetland under synchronous (CPF+HW) and asynchronous (HW->CPF and CPF->HW) exposure scenarios using microcosms. The CPF concentration used in the experiments was 0.8 µg/L (single pulse), and the HW was simulated by a temperature increase of 8°C above the control temperature (20°C) for 7 days. The interaction between stressors in synchrony resulted in negative synergistic effects at the population level (*Daphnia magna*) and additive at the community level. In addition, it determined an increase in tolerant species (*Moina* sp.). The abundance decline caused by the asynchronous exposure scenarios at the population level were similar to that observed by the synchronous one; however, the timing of stressor resulted in different responses in the long term. In the HW->CPF treatment, the *D. magna* population recovered faster than in the CPF+HW treatment, probably due to survival selection and cross-tolerance mechanisms. In the CPF->HW treatment, the effects lasted longer, and the population did not recover within the experimental period, most likely due the high energetic costs of detoxification and damage repair, which affected survival and reproduction. Indirect effects in competing species differed among the tested asynchronous scenarios, which were translated into different long-term structural effects at the community level. Our study highlights the relevance of considering the order of stressors to predict long-term effects both at the population and community levels.

7.01.T-03 Future Risks for Migrating Salmonids Exposed to Chemicals from Road Runoff

Rik Oldenkamp[1]*, Valerio Barbarossa*[2] *and Niko Wanders*[3]*, (1)Vrije University Amsterdam, Netherlands, (2)Leiden University, Netherlands, (3)Physical Geography, Utrecht University, Netherlands*

Climate change is projected to increase the intensity and frequency of extreme weather events. Prolonged periods of drought will result in more buildup of harmful chemicals on impervious road surfaces. During first-flush events, this chemical buildup can runoff to surrounding streams, leading to higher peak exposures for species in receiving waters. Explicitly linked to runoff from roads is 6PPD-q (6-para-phenylenediamine quinone), an ozonation transformation product of the common tire antioxidant 6PPD. 6PPD-q is lethal to various salmonid species, whose temporal and spatial migration patterns coincide with early autumn first-flush events along the northwestern American Pacific coast. Massive pre-spawn die-offs of coho salmon are well-characterized and associated with the extent of urbanization and motor vehicle traffic density near spawning habitats. Climate change will increase the frequency, magnitude, and geographical extent of pre-spawn die-off events. To support current and future environmental risk assessment of road runoff-associated chemicals such as 6PPD-q, a spatiotemporal integration of dry spell duration, road intensity and geospatial species occurrence is necessary. We show here that such an integration of local climatic, infrastructural, and ecological information allows for a meaningful first-tier risk mapping for four particularly sensitive salmonid species (rainbow trout, brook trout, white-spotted char and Chinook salmon). Risk maps based on historical species occurrence data (1950-2023) and current climate conditions were in line with georeferenced data on historical pre-spawning mortality in North America. This agreement puts confidence in the risk maps we are currently creating for future climatic conditions. For these risk maps, projections of future dry spell duration are generated using seven global climate models (IPSL, Nor-ESM, HadGEM, GFDL-ESM2M, CSIRO, bcc-csm, ACCESS) from the CMIP5 ensemble for RCP4.5 and RCP8.5. Future road intensity will be projected using the GRIP database (Global Roads Inventory Project). We expect our approach and resulting maps to provide insights in future areas and species of concern, i.e., where drought intensity and timing of first-flush events will coincide with salmonids migrating through increasingly urbanized areas.

7.01.T-04 Adaptation of Metals Risk Assessments to Consider Climate Change

Eric Van Genderen[1], *Elizabeth Middleton*[2], *Jennifer Stauber*[3,4], *Kevin J Farley*[5], *Inna Sokolova*[6], *Patrick Van Sprang*[7], *Patricio H. Rodriguez*[8], *David Boyle*[9], *Jelle Mertens*[10], *Stijn Baken, PhD*[11], *Yamini Gopalapillai*[12], *Erin Smith*[13], *Adam C Ryan*[14], *Christopher Cooper*[15], *Hugo Waeterschoot*[16], *Josephine Robertson*[17] *and Claudine Albersammer*[17], *(1)International Zinc Association, International Zinc Association, (2)NiPERA Inc., (3)CSIRO, Australia, (4)La Trobe University, (5)Manhattan College, (6)University of Rostock, Germany, (7)ARCHE Consulting, Belgium, (8)PHR Consulting, Chile, (9)Cobalt Institute, United Kingdom, (10)EPMF, Belgium, (11)European Copper Institute, Belgium, (12)International Copper Association, Ltd., (13)Copper Development Association Inc., (14)International Zinc Association, (15)International Zinc Association, Belgium, (16)Chemicals Management, (17)International Council on Mining and Metals, United Kingdom*

Climate change is a complex topic which will have major impacts on the physical and chemical constituents in the environment and may alter the framework upon which environmental risk assessments are conducted. The risk assessment paradigm for metals is unique in accounting for specificities such as essentiality, speciation, partitioning, and bioavailability. The exposure scenarios are further complicated as the push for green technologies in Europe and around the world is inextricably correlated with an increased demand for metals. Events such as temperature rise, ocean acidification and freshwater salinization are just three examples of occurrences linked to a changing climate that have the ability to modify metal toxicity. If the effects of the changing environment are not considered in risk or impact assessments, increased toxicity observations could be attributed solely to metal contamination. This may lead to challenges in compliance assessment, derivation of environmental quality standards, and hazard classifications on a global scale. A general framework for applying environmental risk assessments under different climate scenarios is needed in order to employ best chemical management practices.

Five experts were charged with reviewing the available metals environmental risk assessment guidance materials to identify areas which require alterations to ensure environmental risk assessments remain applicable and accurate as we navigate the changing climate. The exposure scenarios of metals are expected to be altered by changes in both emissions patterns and chemical fate and transport. Characterization of environmental hazards are expected to be impacted through both Climate-Induced Toxicant Sensitivities (CITS) as well as Toxicant Induced Climate Susceptibilities (TICS). In response to these issues, bioavailability models will also require some degree of adaptation to ensure they maintain the capacity to generate relevant predictions for bioavailable metal concentrations and organism toxicity. Several areas have been identified as requiring immediate focus, including a better understanding of temperature impacts and parameterization of organic matter binding properties, and expanded pH boundaries to better account for acidification.

Informed by these conclusions, the authors aim to generate a peer-reviewed scientific article highlighting the necessary changes to the Metals Environmental Risk assessment paradigm and targeted for completion in mid-2024.

7.01.P Climate Change and Chemical Contamination: From Combined Effect Studies to Environmental Risk Modelling

7.01.P-Th569 Combined Pesticide and Temperature Stress Marginally Affect Leaf Decomposition in an Outdoor Stream Mesocosm

Verena Christina Schreiner[1], *Naeem Shahid*[2], *Erika Juliana Pérez Manosalva*[3], *Matthias Liess*[4] *and Ralf Bernhard Schaefer*[5], *(1)iES Landau, University of Kaiserslautern-Landau (RPTU), Germany, (2)System-Ecotoxicology, Helmholtz Centre for Environmental Research (UFZ), Germany, (3)University of Kaiserslautern-Landau (RPTU), Germany, (4)Department of System Ecotoxicology, Helmholtz Centre for Environmental Research (UFZ), Germany, (5)iES - Institute for Environmental Sciences, University of Kaiserslautern-Landau (RPTU), Germany*

The decomposition of allochthonous organic matter is the base of the so-called brown food web, which dominates in headwater streams. Stressors such as pesticides as well as temperature increase are known to affect organic matter decomposition by impacting associated organisms such as aquatic fungi or macroinvertebrate shredders. To be as close to natural systems as possible, we conducted an outdoor stream mesocosm study with repeated pesticide exposure and two temperature levels to investigate effects on microbial and total (microbially and macroinvertebrate-mediated) decomposition at two time points. We hypothesised that microbial and total decomposition will be reduced with increasing pesticide exposure, while the temperature increase at high exposure levels intensified the reduction but mitigated the effects at low exposure levels. We repeatedly spiked three levels (+ a control) of a realistic mixture containing 13 pesticides were repeatedly spiked to heated (temperature increase ~2.5 °C) and non-heated mesocosms. Per mesocosm, we deployed three fine and coarse mesh bags each filled with black alder leaves (*Alnus glutinosa*, (L.) Gaertn.) for two weeks allowing for microbial and total (microbial and macroinvertebrate) decomposition, respectively, at two time points. We investigated effects on organic matter decomposition, fungal biomass, exo-enzyme activity as well as fungal communities. In contrast to our expectations and previous findings, the temperature normalised microbial organic matter decomposition at the first time point did not differ between different pesticide exposures irrespective of the temperature treatment. The total decomposition also showed no response to pesticide exposure at temperature control levels, which is in contrast to previous findings under controlled conditions and was previously detected in few cases. With temperature increase, however, the total decomposition at intermediate pesticide concentrations was increased in comparison to the controls, while the decomposition in the highest pesticide concentration was slightly reduced. This suggests that macroinvertebrate shredders compensated combined intermediate pesticide stress and temperature increase with higher feeding rates. During the conference, we will present and discuss data of the second time point as well as on responses of the fungal community, the fungal biomass as well as the exo-enzyme activity.

7.01.P-Th570 Robust adaptation to climate change in environmental risk assessments

Andrew John[1]*, Rory Nathan*[2] *and Avril Horne*[1]*, (1)University of Melbourne, Australia, (2)Engineering and IT, University of Melbourne, Australia*

Climate change poses diverse threats to ecosystems, affecting habitat, promoting invasive species, and increasing chemical exposure, disrupting native species' ecological processes. However, anticipating the magnitude of change, and thus the environmental impacts remains highly uncertain. Ideally, risk assessments that seek to adapt environments to the impacts of climate change would do so despite the uncertainty around the degree of climate change. Such adaptation would be considered robust.

One approach to assess climate change impacts and the effectiveness and robustness of adaptation is to use so-called “bottom-up” methods. These attempt to first understand system sensitivity to environmental change. Then, sensitivity of impacts is assessed in the context of information from climate models. These methods have benefits over traditional approaches in that they can show insights into non-linear system behaviour, such as thresholds in future conditions that lead to rapid performance degradation; and by assessing system performance with and without intervention, they can show the range of climate conditions in which adaptation is effective or not.

In a recent study on the Goulburn River basin in Australia, a bottom-up assessment indicated potential rapid decline in ecosystem health without adaptation under a more than 10% decrease in mean precipitation, exacerbated by increased mean temperature. This was well within the range of global climate model projections within the next few decades. One potential adaptation was to restore high flows that provide ecological benefits. Improving high flows increased the resilience of many ecological endpoints beyond their baseline sensitivity to climate change. After intervention, some ecological endpoints could now tolerate up to ~15% reductions in mean precipitation, although there were risks for some endpoints in wetter climates. There was also a degree of plausible climate change (generally >15% reductions in mean precipitation) beyond which the adaptation option did not offer environmental benefits.

Bottom-up methods can help practitioners learn more about their system by yielding insight into performance, sensitivity, and intervention robustness to uncertainty in the range of change of system stressors. Whilst not without their shortcomings, they are a useful tool in risk management approaches in a non-stationary environment.

7.01.P-Th571 Integrating Climate Model Projections into Environmental Risk Assessment: a Probabilistic Modeling Approach

Jannicke Moe[1]*, Kevin V Brix*[2]*, Wayne G. Landis*[3]*, Jennifer Stauber*[4]*, John F. Carriger*[5]*, John Daniel Hader*[6]*, Taro Kunimitsu*[7]*, Sophie Mentzel*[1]*, Rory Nathan*[8]*, Pamela Noyes*[5]*, Rik Oldenkamp*[9]*, Jason Rohr*[10]*, Paul van den Brink*[11]*, Julie Verheyen*[12] *and Rasmus Benestad*[13]*, (1)Norwegian Institute for Water Research (NIVA), Norway, (2)EcoTox LLC, (3)Western Washington University, (4)CSIRO, Australia, (5)U.S. Environmental Protection Agency (US EPA), (6)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (7)Center for International Climate Research, Norway, (8)Engineering and IT, University of Melbourne, Australia, (9)Vrije University Amsterdam, Netherlands, (10)University of Notre Dame, (11)Wageningen University & Research (WUR), Netherlands, (12)Biology, KU Leuven, Belgium, (13)Norwegian Meteorological Institute, Norway*

SETAC convened a Pellston workshop in 2022 to examine how information on climate change could be better incorporated into the ecological risk assessment (ERA) process for chemicals as well as other environmental stressors. A major impetus for this workshop was that climate change can affect components of ecological risks in multiple direct and indirect ways, including the use patterns and environmental exposure pathways of chemical stressors such as pesticides, the toxicity of chemicals in receiving environments, and the vulnerability of species of concern related to habitat quality and use. This presentation explores a novel modeling approach for integrating climate model projections into the assessment of near- and long-term ecological risks, developed in collaboration with climate scientists. State-of-the-art global climate modeling and downscaling techniques may enable climate projections at scales appropriate for ERA. It is, however, also important to realize the limitations of individual global climate models, and make use of climate model ensembles represented by statistical properties.

Our probabilistic modeling approach combines the projected climatic variables as well as the associated uncertainties from climate model ensembles in conjunction with ERA pathways. We draw upon three examples of ERA that utilized Bayesian networks for this purpose, and represented methodological advancement for better prediction of future risks to ecosystems. We envision that the modeling approach developed from this international collaboration will contribute towards better assessment and managing of risks from chemical stressors in a changing climate, taking into consideration society's multifaceted response to these changes.

The views expressed in this abstract are those of the authors and do not necessarily represent the views or the policies of the U.S. Environmental Protection Agency.

7.01.P-Th572 Environmental Behavior of a Novel Anti-Corrosion Nanomaterial in a Global Change Scenario
Mariana Bruni Marques do Prado e Silva[1,2], Joana Figueiredo[3], Fernando Perina[4], Susana Loureiro[5], Denis Abessa[1] and ***Roberto Martins***[4]*, (1)São Paulo State University (UNESP), Brazil, (2)CESAM & Department of Biology, São Paulo State University (UNESP), Brazil, (3)Department of Biology, University of Aveiro, Portugal, (4)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (5)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal*
Corrosion is the main cause of materials' degradation immersed in seawater. This process is minimized by applying protective polymeric coatings containing efficient anti-corrosion additives. However, such additives are often toxic to the aquatic biota, requiring their replacement by eco-friendly alternatives with good anti-corrosion efficacy. The Zn-Al layered double hydroxides (LDH) were used to immobilize benzotriazole (BTA), a well-known corrosion inhibitor, which can reduce its early leaching and extend the corrosion protection of metallic immersed substrates over time. Since LDH-BTA is a novel anti-corrosion nanomaterial, the present study aims to assess the release of BTA in different conditions, reproducing temperate and tropical environment conditions, in a global change scenario. Three different concentrations of LDH-BTA (1.23, 11.11 and 100 mg BTA/L) were placed at two different temperatures (20°C and 30°C), with different pHs (actual and with a decrease of 0.4 in the pH as predicted by SSP3 – 7.0 IPCC 2021) and in the presence or absence of dissolved organic matter (1 g/L of dissolved humic acid of Sigma-Aldrich) to determine the release profiles of BTA to the overlying water, over time. An aliquot was taken daily for five days and read in the spectrophotometer (275 nm) to estimate the concentration of BTA released into the water.High release of benzotriazole was detected in treatments containing dissolved organic matter at both temperatures, followed by the acidified warm water treatment and the dispersions at the higher temperature. The physical-chemical conditions of the environment can increasing the release of the compound from the nanoclay. The present findings raise a very important outcome facing the global changes and the IPCC predictions, showing that extreme scenarios can increase the release of corrosion inhibitors from the nanomaterials with a possible predictable ecotoxicological effects in the marine biota.

7.01.P-Th573 Assessing the dynamics of chemical pollution within urban environments: Toxicological implications for aquatic ecosystems in a changing climate
Jonas Zetzsche*, Gisela Horlitz, Manon Fallet, PhD, Ingrid Ericson Jogsten, Maria Larsson and Steffen H. Keiter, MTM Research Centre, Orebro University, Sweden*
Anthropogenic activities, including chemical pollution and climate change, continuously pressure aquatic ecosystems. Combined, these multiple stressors progressively threaten the resource water as well as freshwater ecosystems, leading to a loss of biodiversity and ecosystem function. However, traditional environmental risk assessment still focuses on individual stressors, ignoring their complex interactions and combined impact. Specifically, the impact of extreme weather events and altered water parameters on interactions between environmental matrices and chemical contaminants in aquatic environments is frequently neglected. Chemical contaminants, typically consisting of complex and unknown mixtures of pollutants, may undergo remobilization or introduction into freshwater environments due to increased flooding and stormwater run-off, altering their toxicological properties. The limited knowledge in our understanding of chemical pollution dynamics in urban aquatic ecosystems in the context of climate change serves as the starting point for this project. As part of the interdisciplinary WATCH project, the present investigations will focus on resulting toxicological implications, seeking molecular and mechanistic insights. The study design will follow a tiered approach. Hence, effect-directed analysis (EDA) with a combination of existing state-of-the-art bioreporter assays and chemical tools will serve as the basis to identify and characterize key toxicants in various environmental samples such as water, sediment, soil, and suspended sediment from selected catchment areas. The development of novel EDA approaches incorporating zebrafish embryos and bioassay-guided fractionation, will be employed to explore mechanism-specific toxicological effects and identify molecular biomarkers, via additional analysis of gene expression, developmental toxicity, and behavioral alterations. Following the tiered approach, in vivo studies using the zebrafish model will offer the opportunity to manipulate water parameters and exposure schemes, effectively simulating climate change effects. The utilization of adult zebrafish in a microcosm study encompasses multiple hierarchical levels of biological organization, including mechanism-specific toxicity, gene expression, reproduction, fertility, and behavioral measurements. Overall, we aim to provide a comprehensive understanding of the complex interactions and combined impacts of multiple stressors on aquatic ecosystems.

7.01.P-Th574 Impact of Global Warming on OECD Water-Sediment Test Systems
Sabine Eser[1]*, Nathalie Schwalbach[2] and Katrin Weber[2], (1)Eurofins Aquatics Ecotoxicology GmbH, Germany, (2)Eurofins Aquatic Ecotoxicology GmbH, Germany*

Water-sediment toxicity tests with *Myriophyllum spicatum* (OECD test guideline 239), *Chironomus riparius* (OECD 218/219) and *Lumbriculus variegatus* (OECD 225) are conducted at 20 ± 2 °C.

However, in the light of global warming it needs to be questioned whether increased water temperatures influence growth and development of test organisms in a water-sediment system and could therefore lead to a shift of toxicity endpoints.

To evaluate possible effects of higher temperatures, toxicity tests with *Myriophyllum spicatum* (OECD 239), *Chironomus riparius* (OECD 219) and *Lumbriculus variegatus* (OECD 225) were conducted at 20 ± 2 °C and 24 ± 2 °C. For each test system, both control growth/development and toxicity endpoints of the tests run at two different temperatures were compared to evaluate possible differences and thereby impacts of a higher temperature on the results of toxicity tests.

7.01.P-Th575 Evaluating Combined Effects of Temperature and Chemical Exposure in Daphnia magna

***Sophie Steigerwald*[1]**, *Roque Gastón Alurralde[2], Sebastian Abel[3], Ann-Kristin Eriksson-Wiklund[1], Anna Sobek[1] and Elena Gorokhova[2], (1)Environmental Science, Stockholm University, Sweden, (2)Department of Environmental Science, Stockholm University, Sweden, (3)Ecological Chemistry, Stockholm University, Sweden*

Assessing the risks and impacts of contaminants in aquatic environments requires a comprehensive understanding of combined effects involving environmental factors and chemical exposure. Temperature modulates virtually all physiological functions and often affects contaminant-organism interactions. Moreover, biological response to chemical exposure depends on the exposure duration. Hence, test temperature may alter both the exposure duration on the physiological time scale and chemical toxicity by affecting toxicokinetics. Here, we used a novel combination of the degree-days (DD, a proxy for physiological age) approach and the chemical activity concept to evaluate interactions between chemical exposure and thermal stress in the model organism *Daphnia magna*. In an acute toxicity test, the chemical activity range causing narcosis (0.01 – 0.1) was generated using a mixture of polycyclic aromatic hydrocarbons (acenaphthene, phenanthrene, fluoranthene, and fluorene) at two exposure temperatures (20 ˚C and 25˚C). We hypothesized that: (1) lower median lethal activity (La_{50}) occurs at the higher temperature if the exposure time is defined in calendar time (3 days) because of the temperature effects on the metabolic rate and time-to-toxicity, and (2) there is no temperature effect when the exposure time is defined in degree-days (corresponding to 60 DD) representing the physiological time at different temperatures. Our results confirmed a significantly lower La_{50} at 25 ˚C than at 20 ˚C (0.035 vs 0.068) after 3 d, whereas no significant difference was found when time was defined in DD (0.061 vs 0.068). Thus, the expected rise in toxicity at higher temperatures during the 3-day exposure period was confirmed. Moreover, the temperature controlled the toxicity rate (time to death) with no significant temperature × dose interaction, as indicated by similar La_{50} values for physiologically equal exposure durations. Therefore, when testing combined effects of temperature and toxic exposure, the exposure time should be adjusted to the physiological age of the test animals if we are to detect non-additivity of these effects for risk assessment, especially in the context of climate change and chemical pollution.

7.01.P-Th576 Impact of climate change on effects in Daphnia acute studies

Thomas Moser[1], Santos Garcia[2], Alan Samel[2], ***Valentina Selja*[1]** *and Katrin Weber[1], (1)Eurofins Aquatic Ecotoxicology GmbH, Germany, (2)Global Regulatory Sciences, FMC Corporation*

Acute toxicity tests with *Daphnia magna* (OECD test guideline 202) are currently conducted within the temperature range of 18 to 22 °C. This is considered the optimum temperature range for this organism.

However, in the light of global warming it needs to be questioned whether increased water temperatures outside its optimum range will affect the ability of this organism to adapt and continue to be used as the surrogate for tier 1 acute toxicity tests for aquatic invertebrates. Or could increased temperatures outside its optimum range create a scenario that could influence the effects of chemicals towards daphnids and could therefore, lead to a shift of toxicity endpoints?

To evaluate possible impacts of higher temperatures, acute toxicity tests with *Daphnia magna* (OECD 202) were conducted at 20, 23, and 25 °C. Tests included daphnids that were acclimated for a period of time to the new test solution temperatures and other tests where daphnids were transferred directly from optimum temperature solutions to test solutions at the higher temperatures. At each temperature boric acid and potassium dichromate were tested. Both, control immobilization and toxicity endpoints of the tests runs at the three different temperatures were compared to evaluate possible differences and thereby impacts of higher temperatures on results of toxicity tests with *Daphnia magna*.

7.01.P-Th577 The Effect of Combined Environmental Stressors on Daphnia magna and Brachionus calyciflorus.

***Apurva Deepak Bhatkhande*[1]**, *Sadiya Farooq[2], Ronny Blust[3], Raewyn M. Town[3] and Gudrun De Boeck[4], (1)University of Antwerp, Antwerpen, Belgium, (2)Biology, University of Antwerp, Belgium, (3)ECOSPHERE, University of Antwerpen, Belgium, (4)Biology, ECOSPHERE, University of Antwerpen, Belgium*

Multiple stressors pose a complex challenge to the environmental health of aquatic ecosystems. Due to climate change and increased anthropogenic influences, ecosystems are exposed to a variety of chemical and non-chemical stressors. However, most ecotoxicological studies focus on single stressors, neglecting the synergistic, additive, or antagonistic effects of multiple stressors. This makes it difficult to identify the main drivers of changes in aquatic ecosystems. Water quality parameters such as temperature, pH, and salinity are critical for the survival of an organism and can act as stressors when not present in optimal ranges. The upper and lower tolerance limits for these stressors have been studied individually for the sake of drafting policies and ecotoxicological tests with respect to various model organisms. However, in an ecosystem, these prevailing water quality parameters may be at sub-lethal or lethal levels and may have a synergistic, additive or antagonistic effect on each organism's sensitivity or tolerance towards them. This study delves into the combined effect of these three stressors on two model organisms used in freshwater ecotoxicological tests: *Daphnia magna* and *Brachionus calyciflorus*. The organisms were exposed to a pH range of 5, 6, 7, 8, 9 in combination with salinities of 0.5, 1, 2.5 and 5 PSU at 4 different temperatures- 15°C, 20°C, 25°C and 30°C for an acute test of 48hrs. The mortality was recorded every 12hrs to identify temporal trends. The ongoing study aims to elucidate how different combinations of non-chemical stressors affect organisms over time during acute exposures and is anticipated to provide valuable insights into ecologically relevant, multi-stressor conditions.

7.01.P-Th578 How Pyrene and Salinity Affect the Thermal Tolerance Thresholds of Copepods

Andrea Emilie Thorstensen Skari[1], *Mathieu Lutier*[1], *Heidi Sjursen Konestabo*[1], *Katrine Borga*[2] *and Khuong V. Dinh*[3], *(1)Department of Biosciences, University of Oslo, Norway, (2)University of Oslo (UiO), Norway, (3)Department of Biosciences, Department of Biosciences, University of Oslo, Norway*

The ocean is warming at a rate unprecedented over the past ten thousand years, and extreme warming events are both increasing in frequency and intensity. This could surpass the thermal tolerance threshold of marine species, a key tipping point that, when exceeded, can lead to abrupt and irreversible consequences. At the same time, the intensification of extreme weather events and human activities increase the exposure of marine organisms to decreasing salinities and emerging contaminants such as polycyclic aromatic hydrocarbons (PAHs). As organisms are simultaneously exposed to multiple stressors in their natural environment, it is therefore crucial to identify the effects these stressors have when combined to project their future in a changing world. The present study aims to investigate how multiple stressors (salinity and the PAH pyrene) affect the thermal thresholds of marine zooplankton. Copepods are key planktonic organisms and were selected as the study species due to their essential role in energy transfer in the marine food web. The first experiment aimed to determine how oil contamination alters the thermal tolerance threshold of *Chiridius* copepods. As a proxy for oil, the copepods were exposed to the PAH pyrene, at 5 different concentrations and at 7 different temperatures for a duration of 14 days. The second experiment aimed to determine how decreasing salinities alter the thermal threshold of *Calanus* copepods. The copepods were exposed to 5 different salinities at 5 different temperatures for a duration of 13 days. Copepods for both experiments were collected in the Oslofjord, Norway, and survival was checked every day during the experiments. For both experiments, increasing pyrene concentration and decreasing salinity were expected to reduce the copepods tolerance to warming. Findings from the study will provide important insights to the effects of multiple stressors and how it affects physiological tipping points.

Key words: Copepods, Multiple stressors, Tipping point, Reaction norm, Calanus, Chiridius, Marine heatwaves, Pyrene, Salinities

7.01.P-Th579 Influence of temperature and nutrient availability on the toxicity of the fungicide trifloxystrobin to the aquatic hyphomycete Articulospora tetracladia

Lais Conceição Menezes da Silva[1], *Alexander Feckler*[2], *Isdore Ogechi Agim*[1] *and Mirco Bundschuh*[3], *(1)RPTU Kaiserslautern-Landau, Germany, (2)Rhineland-Palatinate Technical University Kaiserslautern-Landau (RPTU), Germany, (3)Institute for Environmental Sciences, RPTU Kaiserslautern-Landau, Germany*

Fungicides represent 40% of pesticide sales in the European Union, therefore the possibility of these products reaching aquatic ecosystems following their application on agricultural fields is high. At the same time, studies that assess the responses of non-target aquatic fungi to fungicide exposure are scarce. In this context, we evaluated the toxicity of the fungicide trifloxystrobin to the aquatic hyphomycete *Articulospora tetracladia* at three temperatures (T1=12 ºC, T2=16 ºC and T3=20 ºC) and nutrient levels (F1=0% w/v, F2=0.5% w/v and F3=1.5% w/v) in agar medium. For this, we used five trifloxystrobin concentrations: 0, 1, 5, 25, 125 and 625 µg/L, each being replicated five times over 21 days. Fungal radial growth was measured using the software ImageJ. Effective concentrations (ECx) reducing growth by 10 and 50% at study termination were calculated ("drc" package) in parallel to traditional hypothesis testing (two-way ANOVA) using R version 4.2.2. The ECx values varied between temperatures and nutrient levels. At T1, T2 and T3 the EC10 and EC50 values were F1=128 and 877; F2=16 and 597; F3=17 and 332 µg/L; F1=97 and 834; F2=2 and 377; F3=32 and 589 µg/L; F1=12 and 553; F2=10 and 460; F3=15 and 223 µg/L, respectively. The ECx values showed that growth tended to be more affected at higher nutrient levels. Fungicide toxicity is also positively related to temperature, meaning that growth inhibition increased at higher temperatures. Regardless of the fungicide effects, growth increased with temperature and nutrient availability. Comparisons between the different nutrient levels at the same temperature and fungicide concentration showed no significant differences in fungal growth at 12 ºC and 16 ºC ($p > 0.05$). At 20 ºC, in contrast, all comparisons were significant ($p < 0.0001$). Between temperatures, all comparisons between 12 and 16 ºC and 12 and 20 ºC were significant ($p < 0.0001$). Between 16 and 20 ºC the comparisons are also significant, with the except between growth at F1 and F2. In summary, the impact of trifloxystrobin is temperature and nutrient dependent. The interaction of high temperature and nutrient levels can influence absorption, distribution and detoxification of the fungicide potentially explaining the results. This may represent a greater risk for *A. tetracladia* in regions with higher temperatures provided sufficient levels of nutrients are available, both of which can be assumed in (sub)tropical agricultural landscapes.

7.01.P-Th580 Mixture Toxicity of Two Pesticide Formulations on Aquatic Mesocosm Communities

Jonas Nelles, *Juliane Filser, Leonard Otterbein and Alica Rother, University of Bremen, Germany*

Pollution of surface water bodies with pesticide mixtures in agricultural landscapes is problematic because tank mixtures applied to fields often contain several pesticide formulations. Formulations are mixtures of active ingredients and adjuvants in undisclosed composition that alter bioavailability and therefore toxic effects of the product. Although pesticide formulations are more realistic, toxicity data is lacking, because most exposure experiments are conducted with active ingredients instead of formulations and often assess acute toxicity in laboratory conditions. The need for more realistic exposure scenarios is evident.

We set up a long-term experiment with aquatic mesocosms simulating a freshwater ecosystem. The mesocosms were incubated with sediment from a nearby lake and cladocerans from laboratory cultures. Two pesticide product formulations in common use were chosen to simulate a worst-case exposure scenario with renewed application throughout the year: a herbicide containing glyphosate as an active ingredient and the fungicide Funguran progress (FP), relying on the fungicidal activity of $Cu(OH)_2$ in nanoparticle form. Both products were applied individually and in mixture.

Preliminary results indicate a shift in the macrozoobenthos community over time in all treatments. Cladocerans were the organism group with the highest abundance at the start of the experiment, while the number of copepods and ostracods increased with ongoing succession of the mesocosms. Over the course of the experiment, more and more organism groups were detected in samples of the water column, including gastropods, turbellarians and larvae of nematocerans, ephemeropterans and odonates. Principal component analysis showed stable trends of copepod and ostracod abundance inversely correlating with glyphosate treatment, but copepods seem to correlate positively with FP. On the other hand, FP seemed to have a negative impact on abundance, at first on ephemeropteran and nematoceran larvae, and later on gastropods, turbellarians and odonate larvae. Algal blooms also impacted the community, as in spring samplings, cladocerans and nematocerans correlated with occurrence of algae in the mesocosms, likely because they act as a food source or microhabitat. However, variation in the same treatments was high due to differences in physico-chemical parameters like light and nutrient influx. Results from samplings in spring of 2024 will be included.

7.01.P-Th581 Effects of the Herbicide Terbuthylazine on Freshwater Communities Under Different Global Climate Change Warming Scenarios

Pierina I. Rivas-Comerlati[1]*, Ivo Roessink*[2] *and Paul van den Brink*[2]*, (1)Aquatic Ecology, Wageningen University & Research (WUR), Netherlands, (2)Wageningen University & Research (WUR), Netherlands*

Due to Global Climate Change (GCC), we expect rising temperatures and more often reoccurring heatwaves in aquatic ecosystems every year. Previous studies have found that warming may influence the toxicity of chemicals (*e.g.,* pesticides) in the environment by complex mechanisms not fully yet understood. However, in standard ecotoxicological testing warming conditions are not usually considered, and when considered, only as a fixed constant temperature, not representing natural fluctuating scenarios. Pesticides are common chemicals that pollute aquatic ecosystems through various pathways such as spray-drift, agricultural runoff, and chemical spills. Nonetheless, there is a lack of studies evaluating the possible combined effects of pesticides and warming. Terbuthylazine (TBA) is a photosynthesis inhibiting herbicide that is globally used as alternative to the more toxic and persistent atrazine. The aim of this study was to assess the single and combined effects of the herbicide TBA and GCC warming scenarios (fluctuating elevated temperatures and extreme heatwave events) on freshwater communities under a realistic set up (outdoor mesocosms). The experiment consisted of a full factorial design with 9 treatments, combining 3 temperature scenarios (ambient, elevated temperature (+4°C) and recurring heatwaves (+8°C for 1-week intervals)) with 3 TBA concentrations (0, 25 and 250 µg/l) over a period of 8-weeks during late summer 2023. Direct and indirect effects on different trophic levels including plankton, macroinvertebrates and macrophytes communities were evaluated. The main endpoints assessed included: biweekly samples of phytoplankton, zooplankton and periphyton; macrophytes coverage and dry weight; and *in-situ* identifications of macroinvertebrates community. Preliminary results show clear effects from the highest concentration of TBA on the dissolved oxygen levels, total algae concentration, and macrophytes' growth. Combined effects at low TBA concentrations seem to be antagonistic but further analyses will be conducted. We hope that the results from this study allows us a better understanding of the mechanistic pathways of these stressors' interactions for a more accurate risk assessment in the future.

7.01.P-Th582 Ecotoxicity Assessment of the Natural Dye Alizarin Using Aquatic Organisms

Amanda Rocha Rodrigues, Adria Caloto Oliveira, Gabriela Cristina F Almeida, Natalia de Farias, ***Marina Tenório Botelho*** *and Gisela de Aragão Umbuzeiro, Universidade de Campinas, Brazil*

Alizarin is a natural dye from the anthraquinone class. It has been used as an acid-base indicator and as a dye in several industrial processes including textiles. Therefore, they are potential environmental contaminants. Alizarin is mutagenic to bacteria in the Salmonella-microsome test with the addition of S9 metabolic activation and was toxic to the *Lemna gibba*, phytoplankton and zebrafish. Furthermore, in the aquatic environment, anthraquinones can undergo a photosensitization reaction, releasing reactive oxygen species, which can cause photoinduced toxicity. The aim of this work was to complement aquatic toxicity data using the microalgae *Raphidocellis subcapitata*, the freshwater microcrustacean *Daphnia similis*, the marine amphipod *Parhyale hawaiensis* and embryos of the freshwater fish *Danio rerio*. Also, the effect of light on its acute toxicity to *D. similis* was studied. Alizarin was dissolved in DMSO to its solubility of limit (1.93 g/L) and tested at the maximum concentration of 0.01% DMSO in the media as recommended by OECD in concentration response experiments. A 72-hour exposure chronic toxicity test was performed with *R. subcapitata*. Acute toxicity tests with *D. similis* were carried out for 48h with photoperiod of 16:8h, constant light and dark. Acute tests with *P. hawaiensis* and *D. rerio* were performed for 96h and 168h, respectively, with photoperiod of 12:12h. Data was analyzed applying generalized logistic models. Alizarin did not inhibit the growth of *R. subcapitata* or cause lethal effect for *P. hawaiensis* (IC_{50} or LC_{50}>193 µg/L). For *D. similis*, EC_{50} of alizarin was 90.3 ± 0.3 μg/L. Constant light did not alter the toxicity (EC_{50} 105 ± 55.8 μg/L) but in the dark, the toxicity increased (EC_{50} of 68.6 ± 1.2 μg/L). For *D. rerio* LC_{50} was 39.6 ± 7.2 μg/L. Alizarin can be classified as category 1 for aquatic toxicity in the Global Harmonization System (GHS). We concluded that *D. rerio* was the most sensitive organism and light did not increase the toxicity of this anthraquinone, at least for *D. similis.* Data were considered relevant and reliable after Criteria for Reporting and Evaluating ecotoxicity Data (CRED) evaluation and can be used in the future for Predicted No-Effect Concentration (PNEC) derivation.

7.01.P-Th583 Global change effect: when the inter-individual variability provides information about metabolic response in a sentinel species facing extreme events and multi-metallic contamination

Fanny Louis[1], *Laetitia Minguez*[2], *Vincent Felten*[1], *Sandrine Pain-Devin*[1], *Simon Devin*[1] *and Laure Giamberini*[1], *(1)Université de Lorraine, CNRS, LIEC, France, (2)French National Centre for Scientific Research (CNRS), Paris, France*

Global change issues are new challenges in ecotoxicology. The frequency and the magnitude of heat waves still increasing, and a significant relation was established between the occurrence of extreme events and global changes according to the last GIEC rapport. The basal metabolic activity of ectotherm organisms could be strongly affected by quick temperature variations, limiting thus their capacity to face additional stresses. This study aimed to assess the combined effects of a multi-metallic stress and recurrent heat waves in a freshwater bivalve, *Dreissena polymorpha*. Mussels were exposed to an environmental concentration of a nickel-chromium mix solution (20 and 5 $\mu g.L^{-1}$, respectively) for 35 days. A weekly gradual increase of the temperature (+15°C) was performed in exposed media for 24 hours. Key metabolism functions were targeted along the biological organisation levels through a panel of markers involved in the energy metabolism, defence mechanisms and cellular damage. Different patterns of physiological responses were highlighted between males and females. Surprisingly, the main factor structuring the biological responses differed according to the biological organization level considered. Regarding the overall dataset, a significant effect of the accumulation of stress was observed through an increasing inter-individual variability. This study pointed out the need to consider (1) the gender of organisms, (2) the response at different biological organisation levels, and (3) the inter-individual variability. Hence, global change induces multifactorial stress. To assess its impacts, we need to gather a higher number of markers, encompassing the diversity of biological systems, even if it leads to patterns that are complex to analyse.

7.01.P-Th584 Using scenario predictions of climate, chemical, and physical stressors for probabilistic effect assessment of nearshore coral reefs

Sophie Mentzel[1], *Rory Nathan*[2], *Pamela Noyes*[3], *Kevin V Brix*[4], *Jannicke Moe*[1], *John F. Carriger*[3], *Jason Rohr*[5], *Julie Verheyen*[6], *Paul van den Brink*[7] *and Jennifer Stauber*[8], *(1)Norwegian Institute for Water Research (NIVA), Norway, (2)Engineering and IT, University of Melbourne, Australia, (3)U.S. Environmental Protection Agency (US EPA), (4)EcoTox LLC, (5)University of Notre Dame, (6)Biology, KU Leuven, Belgium, (7)Wageningen University & Research (WUR), Netherlands, (8)CSIRO, Australia*

Near shore reef systems of the Mackay Whitsunday coastal zone are particularly at risk to changes in climate and other anthropogenic stressors. These stressors include chemical, nutrient and sediment exposures that might increase in the future with more frequent and large rainfall events that enable runoff of contaminated waters. We aimed to examine the combined effects of climate change and chemical exposures which is essential for improving environmental risk assessments of vulnerable ecosystems such as the Great Barrier Reef. During the SETAC Pellston workshop on incorporating climate change into environmental risk assessment, we explored the incorporation of changing environmental variables into effect assessment by developing a Bayesian network that quantitatively compares the effects of historic and future climate on inshore hard coral bleaching, mortality, reproduction, and cover. Part of these efforts involved the use of various projection models whose outputs were used to parameterize the developed Bayesian network. We used various prediction models to project environmental variables/ parameters such as precipitation, temperature, streamflow, nutrient, and sedimentation loads to derive prior probabilities. For example, we used an ensemble of 16 downscale models representative of current climate conditions and future climate conditions assuming medium and high carbon emissions for two thirty-year periods centred on 2040 and 2085. The projections used showed an increase in air, sea surface temperature, and bleaching events, and a decrease in nutrient, sediment and pesticide loads for all used future scenarios. The derived future scenarios enabled us to examine the risk multiple stressors pose to inshore reef systems. Under the given assumptions, an increase in coral bleaching and coral mortality under all future climate scenarios was predicted by the Bayesian network. Disclaimer: The views expressed in this abstract/presentation are those of the authors and do not necessarily represent or reflect the views or the policies of the U.S. Environmental Protection Agency.

7.01.P-Th585 Projections of Future Climates, the Problem of Interacting Stressors, Endpoints and Management Uncertainties, and the Estimation of Ecological Risk at Appropriate Management Scales

Wayne G. Landis, *Western Washington University*

A special series has recently been published highlighting the importance of climate change in conducting ecological risk assessment. In the case studies and the description of methods it became clear that climate change is an important factor in the estimation of risk to a variety of aquatic habitats both alone and in conjunction with other stressors. Climate projections are constructed using a set of models based on first principles and set to predict global conditions. In contrast, risk assessments are performed for specific stressors upon set receptors-endpoints. The physical scale of these assessments can be at extent of a contaminated CERCLA or RCRA site, a watershed or landscape, a specific geographic region or to continental expanse. The species and their range also vary, from very limited spatial and temporal scales, from small critical habitats to joint oceanic and mountain ranges as in the case of salmonids. A specific challenge is the matching of the climate change projections with the scales appropriate both to the species involved and the management cycle. A major issue with climate projections has been adjusting the scales in time and space to forecast the amount, distribution, fate and transport, exposure and effects of contaminants to populations also exhibiting dynamics affected by historical events, life-history strategies, the distributions of habitat, genetics and human management. The epistemic (knowledge), aleatory (variability) and linguistic (communication) uncertainties in the models need to be understood and integrated. To ensure the use of these risk assessments into an adaptive management program the dynamics of that decision making process, and those uncertainties, need to be considered. Probabilistic methods are necessary to describe and manage the coupling of these factors. A number of probabilistic methods exist but this presentation will focus on Bayesian networks and several case examples-including but not limited to chemical contaminants. A strategy will be presented to integrate the uncertainties into an adaptive management process. The strategy starts with a careful and quantitative delineation of the management goals, the time periods involved and the specific management targets before either the establishment of a climate projection and risk assessment process. Model approaches are suggested, testing of the models described, and the operation of the adaptive management cycle presented.

7.01.P-Th586 Taking account of climate change in FOCUS PECsw calculations

Magnus Wang*, WSC Scientific GmbH, Germany*

For the pesticide risk assessment in the EU, predicted environmental concentrations need to be calculated in order to perform a risk assessment for non-target species. For the aquatic risk assessment, predicted surface water concentrations (PECsw) are calculated using FOCUS models according to current guidance. The weather files used in these models include data from several decades ago. For example, the weather files used in the latest version of FOCUS TOXSWA, used to calculate PECsw values, still date back to the period from 1974-1994. Hence the current aquatic exposure assessment is based on weather data which are about 40 years old and may not be representative for present conditions anymore. In addition, during the last years weather changes have become even more rapid, hence it can be expected that the currently used weather data become even less representative. Overall, one may question the relevance of the exposure assessment if data are not updated. We therefore evaluated the weather data used in FOCUS surface water scenarios and compared them to recent weather data. Furthermore, we also compared PECsw values obtained with the currently used old weather data form 40 years ago with those obtained using recent weather data, using the FOCUS PECsw automation system AutoPEC SW. We conclude that it may be appropriate to update weather data regularly for the risk assessment.

7.02 In Silico Approaches Toward Safer Use and Green Design of Chemicals: Present Achievements and Future Challenges

7.02.T-01 Comparative Toxicity of Perfluoroalkyl Substances for Safe-by-Design: Quantitative Adverse Outcome Pathway using Bayesian Network Model

Jaeseong Jeong*, Hyunwoo Kim and Jinhee Choi, School of Environmental Engineering, University of Seoul, Korea, Republic of (South)*

Per- and polyfluoroalkyl substances (PFAS) are a group of chemicals that have been widely used in industrial and consumer products. However, there still exists a knowledge gap in our understanding of the toxicity of the newly developed PFAS. A Bayesian Network (BN) is a model that presents probabilities of the dependencies between any two variables in a graphical form. It is capable of diagnostic, predictive, and inter-causal reasoning. In this study, the toxicity of 12 PFAS [Perfluoroalkyl sulfonic acids (PFSAs) with chain lengths C4-C8 and perfluoroalkyl carboxylic acids (PFCAs) with chain lengths C4–C14] were compared by employing BN model, focusing on variations in carbon chain length and functional groups. First, DNT AOP was developed based on common KEs of AOPs (AOP ID: 12, 13, 17, 48, 54, 260, 281, 442, 475, 483) from AOP Wiki, and KE relationships were adjusted by incorporation of existing knowledge from the literature. And experiments were performed on selected KEs using human neural stem cells. To determine which properties of PFAS affect toxicity, comparisons were made based on the number of carbon chains and functional groups linked to the active events in the BN model. Within the carbonate group, the larger the number of carbon chains, the lower the cell viability. Additionally, the sulfonate group was found to have a greater impact on low cell viability than the carbonate group. The results were not predicted based merely on the effects on cell death but also considered changes in the probability of toxicity pathways through the quantitative AOP concept, making them more reliable and explainable. This approach will promote the utilization of the Safe-by-Design concept for the safe development of PFAS.

7.02.T-02 First Do No Harm - A Framework for Intelligent Design of Safer Chemicals

Predrag V Petrovic[1,2] *and Paul T Anastas*[1,2]*, (1)Center for Green Chemistry and Green Engineering at Yale, (2)School of the Environment, Yale University*

In the last 200 years of performing synthetic chemistry, the main goal of chemists was to create chemicals and materials with a particular function or purpose as a focus. This led to the creation of wonderous products such as effective medicines, plastics, and fertilizers; however, it has also become obvious that these products can be toxic and cause harm to human health and the environment.

Green chemistry introduced safer chemical design as one of the core principles where the focus of synthetic chemistry should be adjusted to avoid present and future hazardous practices. The sensible way of creating less hazardous chemicals lies in applying knowledge gained in both fields of chemistry and toxicology over the decades, but even today, only a small number of chemical departments around the world offer integrated courses on molecular toxicology. Molecular insights into the causes of inherent hazards and ways to avoid them, lessons learned from practices in the pharmaceutical and pesticide industry, and numerous studies conducted to protect the environment offer a knowledge base to outline a conceptual framework for designing safer chemicals and materials. Based on this knowledge, it is possible to determine the relationship between the inherent properties of chemicals and the different types of hazards they can cause.

The basic guidelines on how to design safer chemicals can be represented through a molecular design pyramid, a symbolic representation of the factors that have an impact on different types of hazards that molecules can cause. The factors are arranged in terms of complexity, with the physicochemical properties at the base of the pyramid, the shape and structure of the chemicals higher up the pyramid, and the most intricate factors influencing the mechanism of action at the top. All of these factors can be predicted or simulated in silico, using a wide variety of methods and approaches used in computational chemistry and computational toxicology, which opens a path to the chemicals and materials that will have desired properties and behavior, with inherent hazard minimized or completely eliminated

7.02.T-03 The OECD (Q)SAR Assessment Framework for REACH Dossier Evaluation

*Andrea Gissi and **Doris Hirmann**, European Chemicals Agency (ECHA), Finland*

The OECD has published the (Q)SAR Assessment Framework (QAF) in 2023. The QAF is a guidance for the regulatory assessment of QSAR models, predictions, and results based on multiple predictions. The guidance is the result of a two-years project led by the European Chemicals Agency (ECHA) and the Italian Institute of health (ISS). The guidance is complemented by a checklist of assessment elements to consider when evaluating the validity of the (Q)SARs. In general, the framework is flexible enough to be applicable irrespective of the endpoint, modelling technique and regulatory purpose of use of the (Q)SAR. After the OECD publication, authorities are responsible for the application of the framework under the regulations they oversee.

The EU regulation for the safe use of industrial chemicals REACH allows the submission of (Q)SAR results as an adaptation to standard information requirements. ECHA has been assessing (Q)SAR submitted in REACH registration dossiers since 2007, and its experience has been reflected in the QAF. In fact, the framework is aligned with ECHA's current practices for (Q)SAR evaluation. Nonetheless, the publication of the QAF is a good occasion for ECHA to clarify further how (Q)SAR results are assessed under REACH dossier evaluation.

This presentation will discuss how ECHA evaluates the principles for validity and assessment elements listed in the QAF with illustrative examples tailored for environmental endpoints. The examples will cover the evaluation of (Q)SAR results against the principles listed in the QAF: a correct input, the substance falls within the applicability domain of a model, the prediction is reliable, and the outcome is fit for the regulatory purpose.

7.02.T-04 In Silico Gut Metabolism Model for Enhancing New Approach Methods (NAMs) towards Safer Use of Chemicals

*Shenghong Wang[1], Zhizhen Zhang[1], Minglian Fang[2], Dingsheng Li[1] and **Li Li**[1], (1)School of Public Health, University of Nevada, Reno, (2)Environmental Science and Engineering, Fudan University, China*

Chemical risk assessment increasingly relies on animal-free New Approach Methods (NAMs), utilizing in vitro assays and in silico computations. In vitro assays measure chemical concentrations in incubation media rather than in the body, necessitating reliable estimates of internal chemical concentrations from external exposure doses. Pre-absorption intestinal and hepatic biotransformation, also known as the 'first-pass effect,' reduces the entry of orally ingested chemical contaminants into the systemic circulation. While in silico high-throughput physiologically based toxicokinetic (PBTK) models consider hepatic biotransformation, intestinal biotransformation, also known as gut metabolism, is often overlooked, and the relative importance of pre- and post-absorptive biotransformation is unclear. Experimental evidence has shown rapid intestinal biotransformation, e.g., with a half-life at a level of minutes for certain phthalate esters in metabolism by lipases. Neglecting intestinal biotransformation may result in a substantial overestimation of exposure to chemicals in high-throughput chemical screening. In this presentation, using an in silico PBTK model, we evaluate (i) the relative importance of pre- and post-absorptive biotransformation in controlling the presence of chemical contaminants in the human body and (ii) important factors that govern such relative importance. Since in vivo biotransformation data are often inadequate for chemical contaminants, the model also includes an in vitro to in vivo extrapolation module to allow the use of in vitro data. The model shows that the relative importance of the rates of intestinal biotransformation and epithelium permeation greatly impacts intestinal absorption efficiency. In cases of phthalates where biotransformation occurs at a level of minutes, more than 60% of the ingested amount is biotransformed in the gastrointestinal tract before absorption. Overall, our work highlights the importance of intestinal biotransformation in human exposure and toxicokinetic modeling. This model also enables us to more accurately screen the absorption efficiency of chemicals through dietary and non-dietary ingestion.

7.02.P In Silico Approaches Toward Safer Use and Green Design of Chemicals: Present Achievements and Future Challenges

7.02.P-We551 Bridging Gaps, Recognizing Limits: Machine Learning in Chemical Toxicity Characterization

Kerstin von Borries[1]*, Hanna Holmquist, PhD*[2]*, Marissa B Kosnik*[3]*, Katie V Beckwith*[4]*, Olivier Jolliet*[1]*, Jonathan Goodman*[4] *and Peter Fantke*[5]*, (1)Technical University of Denmark (DTU), Denmark, (2)Swedish Environmental Research Institute (IVL), Sweden, (3)Department of Environmental Toxicology, Eawag: Swiss Federal Institute of Aquatic Science and Technology, Switzerland, (4)Department of Chemistry, University of Cambridge, United Kingdom, (5)Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark*

Global chemicals management is under pressure as the capacity for assessment cannot keep pace with the ever-increasing number and production of chemicals. Hence, there is an urgent need to increase the chemical coverage and reliability of tools that characterize chemical toxicity impacts. An essential roadblock is the lack of chemical property data these tools require to describe fate, exposure, and effects. Machine Learning (ML) is a promising technique frequently applied to improve predictions across scientific fields. However, the systematic adaptation for chemical toxicity characterization is still limited as the potential for developing ML-based approaches that can predict property data for the wide range of marketed chemicals is unknown. This work aimed to prioritize input parameters in toxicity characterization tools for developing ML-based approaches and assess the predictive potential of these approaches to fill input data gaps for diverse chemical structures. We prioritized input parameters to inform ML model development based on two criteria: (1) each parameter's relevance to robustly characterize chemical toxicity based on the uncertainty in characterization results attributable to each parameter, and (2) the potential for ML-based approaches to predict parameter values for a wide range of chemicals based on the availability of chemicals with measured parameter data. Characterization uncertainty attributable to each parameter was evaluated with an uncertainty analysis using USEtox 3.0 beta. Data availability was assessed based on the number of chemicals with measured parameter data available across large data repositories. Based on our analysis, we prioritized 13 out of 38 USEtox input parameters for developing ML-based approaches. In addition, nine parameters showed high relevance for obtaining robust characterization results but had low data availability and were, therefore, flagged as crucial data gaps. For all prioritized parameters, we performed a chemical space analysis that further assessed the potential for ML-based approaches to predict data for diverse chemicals, taking into account the structural diversity of available measured data. The analysis showed that ML-based approaches can potentially predict 8-46% of marketed chemicals based on 1-10% with available measured data. Our results can systematically inform future ML model development efforts to address data gaps in chemical toxicity characterization.

7.02.P-We553 Endocrine Disrupting Chemical (EDC) Screening of Additive Chemicals in Plastics Using In vitro ToxCast Data, In Silico Molecular Docking and QSAR Models

Kimoon Na*, Donghyeon Kim and Jinhee Choi, School of Environmental Engineering, University of Seoul, Korea, Republic of (South)*

Plastic additives are utilized in plastic products to enhance their properties and durability. However, their potential as Endocrine-Disrupting Chemicals (EDCs) remains largely unexplored. This study aims to screen plastic additives for their potential to act as EDCs by analyzing their binding affinity to EDC-related receptors, such as estrogen, androgen, and thyroid hormone receptors. Initially, 173 chemicals used as plastic additives were compiled from the ECHA database. Their bioactivities on EDC related receptors were analyzed in ToxCast bioassays. Among these, 95 chemicals lacked bioactivity data for all EDC-relevant receptors. To address this gap, we utilized in silico molecular docking (MD) simulations and quantitative structure-activity relationship (QSAR) models to predict their potential bioactivity with EDC-related receptors. Binding affinity for docking analysis was conducted using AutoDock Vina software and QSAR models were trained using six machine learning algorithms (gradient boosting tree (GBT), random forest (RF), multi-layer perceptron network (MLP), k-nearest neighborhood (kNN), logistic regression (LR), and naïve Bayes (NB)) and five molecular fingerprints (MACCS, Morgan, Layered, RDKit, and Pattern). As a result, 48 chemicals were predicted to be active in at least one receptor across MD and QSAR models across all target receptors, with 11 of them predicted to be highly active across all receptors. Consequently, 67 chemicals were prioritized using in vitro ToxCast data and in silico modeling. Considering that these chemicals are reported to have high-volume production—exceeding 100 tons per year—further, more comprehensive EDC assessments are needed. Our research highlights both the potential and challenges associated with using in silico MD simulations and QSAR-based predictions as rapid screening tools for industrial chemicals, such as additive chemicals in plastics.

7.02.P-We554 Chemical Space Covered by Applicability Domains of Quantitative Structure-Property Relationships and Semi-empirical Relationships in in silico Chemical Assessments

Zhizhen Zhang[1], Alessandro Sangion[2], Shenghong Wang[1], Todd Gouin[3], Trevor N Brown, PhD[2], Jon A. Arnot[2] and ***Li Li***[1]*, (1)School of Public Health, University of Nevada, Reno, (2)Arnot Research and Consulting Inc. (ARC), Canada, (3)TG Environmental Research, United Kingdom*

Thorough and defensible hazard and risk assessments are crucial prerequisites for the safer usage and green design of chemicals. In this context, in silico computational models, particularly mechanistic models based on (1) chemical partitioning and reactivity properties and (2) quantitative descriptions of chemical, physical, physiological, and toxicokinetic processes, are instrumental in achieving this objective. Nonetheless, for most chemicals detected in environmental samples or commercialized in the marketplace, there are insufficient experimentally measured chemical property data. In this context, it is necessary to use prediction of chemical property data applying (1) quantitative structure-property relationships (QSPRs), which correlate a chemical property of interest with variables describing chemical structure or molecule-level interactions, such as OPERA, EPI Suite, IFS-QSAR, and QSARINS, and (2) semi-empirical relationships, which correlate a chemical property of interest solely with other properties, without considering chemical structure or molecule-level interactions, such as Karickhoff relationships that predict K_{OC} from K_{OW}. Furthermore, it is imperative to evaluate the applicability domain (AD) of QSPRs and semi-empirical relationships to ensure their suitability for regulatory assessment purposes. In this presentation, we systematically reviewed the AD coverage of commonly used QSPRs and semi-empirical relationships when predicting seven partitioning and reactivity properties for chemicals registered in different chemical inventories. The results from this study show that more than half of the investigated chemicals are hydrophilic, lowly volatile and labile. The current QSARs can cover ~80% of chemicals in AD in terms of predicting K_{OW}, K_{OC} and biotransformation half-lives. However, K_{OA} medians for chemicals in and out of AD differ by 6 orders of magnitude. In addition, current QSARs exhibit a narrower AD coverage of air hydroxylation rate constant and biodegradation half-lives which are criteria for persistent and long-range transport potential assessment. Thus, it is important to exercise caution when utilizing current QSARs for persistence and long-range atmospheric transport assessment. The AD coverage for semi-empirical relationship depends on how the AD is defined. For the first time, this presentation systematically informs academia and regulatory agencies on the AD of QSARs and semi-empirical relationships.

7.02.P-We555 Consolidated Octanol/Water Partition Coefficients: Combining Multiple Estimates from Different Methods to Reduce Uncertainties in log Kow

Monika Nendza[1]*, Verena Kosfeld[2] and Christian Schlechtriem[3], (1)Computational Toxicology, Analytisches Laboratorium, Germany, (2)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany, (3)Bioaccumulation & Animal Metabolism, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

The octanol/water partition coefficient (Kow) is a key parameter for assessing the fate and effects of chemicals. The log Kow can be determined experimentally, but more often it is calculated. Different methods can sometimes perform better and sometimes worse for different chemicals due to differences in the applicability domain related to, e.g., training set coverage and descriptor relevance. Variability in log Kow may be substantial and can be propagated in, e.g., quantitative structure-activity relationships (QSARs), in vitro-in vivo-extrapolations (IVIVE) and can bias the results. The present study was developed in the context of bioaccumulation assessment and aims to derive coherent log Kow estimates with known variability by: (1) estimating multiple log Kow values by different methods for diverse case study chemicals to exemplify their variability, (2) analysing the variability of log Kow estimates with regard to underlying methods and in terms of different chemical classes, and (3) recommending approaches to obtain reliable and robust log Kow estimates for hazard and risk assessment.

The case study chemicals include POPs, PCB, PAH, siloxanes, flame retardants, PFAS, pesticides, pharmaceuticals, fragrances, biocides, surfactants, UV-filter, plasticizer, antioxidants, etc. Up to 36 log Kow values per substance were obtained experimentally or estimated by different computational approaches such as group contribution (e.g. ClogP, EpiSuite), linear solvation energy relationships (LSER), read-across (e.g. Opera, ChemProp), deep learning neural networks (e.g. OCHEM), quantum chemical methods (e.g. COSMOtherm). Comparative analyses revealed that experimental and calculated log Kow can be highly variable (>1 log unit over the log Kow range from <0 to >8). No method is consistently superior. For most chemicals, variability of more than 1 log unit is the rule rather than the exception. Lack of (experimental) reference values for e.g. PFAS, siloxanes, surfactants, etc. compromises calibration of modelling results.

These results indicate that the search for the one and only best method for estimating log Kow may be futile. Instead, the mean of multiple log Kow values, including valid experimental data and estimates calculated using different methods, can provide reliable log Kow predictions. The benefits of the suggested approach are consolidated log Kow values that are scientifically credible, robust and reproducible, as well as cost efficient.

7.02.P-We556 How to build trust in the use of Artificial Intelligence for Chemical Risk Assessment?

Pim Wassenaar[1]*, Jordi Minnema[1], Jelle Vriend[2], Jeroen Pennings[1], Willie Peijnenburg[1] and Anne Kienhuis[1], (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)National institute for Public Health and the Environment (RIVM)*

Risk assessment of chemicals is a time-consuming process and needs to be optimized to ensure all chemicals are timely evaluated and regulated. This transition could be stimulated by valuable applications of *in silico* Artificial Intelligence (AI)/Machine Learning (ML) models. However, implementation of AI/ML models in risk assessment is lagging behind the

scientific developments. Most AI/ML models are considered 'black boxes' that lack mechanistical explainability, causing risk assessors to have insufficient trust in their predictions.

In this study we stimulated the exchange of knowledge and information between computational modelers and chemical risk assessors. The aim was to work towards a common understanding of the possibilities of AI and the needs and requirements from a risk assessment perspective. We organized two workshops and collaboratively developed two predictive AI/ML models as case studies.

The results of this study highlight that trust is an essential factor towards regulatory adoption of AI/ML models and that it is not a static process, but needs to be built over time. We provide an overview of the elements of trust, including trust in technical (e.g., data quality, model uncertainty, etc.) and beyond-technical aspects (e.g., personal and societal beliefs), and highlight elements that are considered most important to build trust by risk assessors. These elements of trust should ideally be acknowledged in future developments to stimulate adoption of AI/ML models for regulatory purposes. In addition, we applied (most) of these recommendations in practice into two case studies: one on ecotoxicity for the prediction of Species Sensitivity Distributions, and one on human toxicity for the prediction of effects on development toxicity via the retinoic acid adverse outcome pathways.

This study highlights the importance of interdisciplinary activities to stimulate the adoption of state-of-the-art *in silico* models in a regulatory setting. Future efforts should further stimulate such collaborations between computational modelers and risk assessors, both at a national and an international level, as it will allow a more efficient and effective use of the already available data and knowledge.

7.02.P-We557 Ecotoxicological Quantitative Structure-Activity Relationship Model Performances, and how they Underpredict Very Toxic Compounds

Patrik Svedberg[1]*, Pedro A. Inostroza*[2]*, Mikael Gustavsson*[3]*, Erik Kristiansson*[4] *and Thomas Backhaus*[2]*, (1)Department of Biological & Environmental Sciences, University of Gothenburg, Sweden, (2)Biological and Environmental Sciences, University of Gothenburg, Sweden, (3)University of Gothenburg, Sweden, (4)Chalmers University of Technology, Sweden*

Estimations of the number of chemicals currently on the world market varies, but a recent study estimated over 350 000 chemicals and mixtures in the global inventories, and new chemicals are designed and made available every year. To keep up with the current pace of new chemicals, the use of high throughput predictive methods for ecotoxic effect assessment have been proposed, and quantitative structure-activity relationship (QSAR) models are commonly used for this purpose. In this study we have examined the predictive performance of three freely available ecotoxicological QSAR model frameworks: ECOSAR, Vega and T.E.S.T., for six endpoints commonly used in chemical regulation: acute and chronic toxicity for algae, daphnia and fish. We additionally examined the effect of ionizability, lipophilicity and experimental toxicity range of chemicals on prediction performance, through a scenario-based setup. For each scenario, model software and toxicity test, three performance metrics were calculated: coverage (ability to produce a reliable prediction), median error (median absolute log distance from prediction to experimental mean) and large deviations (predictions outside a factor 10 from experimental mean). Results indicate that there are differences in performance between models: Vega having the lowest coverage, while ECOSAR has the highest. For tests where T.E.S.T. can produce predictions, it has the lowest median error and lowest rate of large deviations. For other tests performance varies, and Vega performs better for chronic fish and daphnia, while ECOSAR has better performance for algae tests. Ionizability has very low impact on model performance for all models. For compounds with high logP values, the coverage of ECOSAR goes down (by 15 to 75 percentage points), and all models perform worse for acute daphnia and fish (most data rich endpoints). Toxicity range analysis show a troubling trend: QSAR models systematically underpredict toxicity for high toxicity compounds and overpredict toxicity for low toxicity compounds.

7.02.P-We558 Implementing in silico approaches for human toxicity prediction in the Dutch drinking water sector

Renske P. J. Hoondert[1]*, Thomas L. ter Laak*[1,2]*, Milo Leon de Baat, PhD*[3]*, Miina Yanagihara, PhD*[1,4]*, Tessa E. Pronk*[1]*, Daniel J. Duarte*[1]*, Sanah M. Shaikh*[1]*, Astrid Reus*[1] *and Milou M. L. Dingemans*[1,5]*, (1)KWR Water Research Institute, Netherlands, (2)University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics (IBED), Netherlands, (3)Freshwater and Marine Ecology, University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Netherlands, (4)Ehime University, Japan, (5)Institute for Risk Assessment Sciences, Utrecht University, Netherlands*

Over the years, an increasing number of chemicals and toxicological endpoints have been receiving attention in the (Dutch) drinking water sector. For many of these chemicals, little is known about their toxicity as it is time consuming and expensive to conduct *in vitro* and especially *in vivo* toxicity experiments. *In silico* approaches are useful in estimating hazards associated with such chemicals. Over the years, KWR Water Research has produced QSARs based on both linear regression analysis and Random Forest analysis to predict the toxicity, as measured in a large number of *in vitro* assays, of chemicals based on chemical structure and molecular descriptors. To gain insight into the toxicity of existing and emerging chemicals, the complete ToxCast dataset was downloaded. AC_{50} data (in μM) from this database were formatted based on a set of criteria. The resulting data consisted of 5,114 chemicals, and for 603 endpoints for *in vitro* assays. Toxicity (AC_{50}) was predicted using both Random Forest and linear regression models, based on chemical structure and molecular properties. These models were evaluated by looking at the model performance of a test dataset.

Overall, large variation in the predictive power of both models were observed across assay endpoints and modelling techniques. Furthermore, different structural elements and molecular descriptors of chemicals drive toxicity in different assay endpoints. In general, linear regression models performed better than Random Forest models. However, this does not necessarily imply that some endpoints may be easier to predict as there may be multiple explanations (i.e. the datasets may have been too small, the models may contain a large proportion of irrelevant structural elements or the AC_{50} data itself is expected to be noisy). The studies presented here aimed to gain a deeper understanding of the methodology of *in silico* prediction of toxicity using the ToxCast database, allowing the signaling of new and potentially hazardous chemicals that may emerge in the aquatic environment. Structural elements and physicochemical descriptors of chemicals for a subset of in vitro assay endpoints did accurately predict AC_{50}s and AC_{50} classes (i.e. 'low', 'medium', 'high'). In future research we foresee the development of a tool to predict toxicity classes, rather than exact toxicity (AC_{50}) values for particular subsets of endpoints, which may aid in the first prioritization of chemicals.

7.02.P-We559 Are We Justified in Modeling Human Exposure to Chlorinated Paraffin Mixtures Using the Average Properties of Congeners and Homologues?

***Chengkang Chen*[1]*, Li Li*[2]*, Satoshi Endo*[3]*, Shaoxiang Jiang*[4] *and Frank Wania*[1]*, (1)Department of Physical and Environmental Sciences, University of Toronto, Canada, (2)School of Public Health, University of Nevada, Reno, (3)Health and Environmental Risk Division, National Institute for Environmental Studies (NIES), Japan, (4)Institute for Global Health and Development, Peking University, China*

Human exposure to chlorinated paraffins (CPs) is a significant environmental and health concern due to the potential for persistence, bioaccumulation, and toxicity associated with these compounds. However, assessing human exposure to such mixtures is still challenging, given the facts that (i) CP mixtures consist of millions of components, making it difficult for existing analysis methods to separate and quantify them accurately and consistently; (ii) "complex" exposure modeling that accounts for each component is currently time- and resource-intensive. In this presentation, we explore whether and at what level (e.g., congener or homologue groups) we can aggregate CP mixtures by using average physicochemical properties in human exposure modeling. The central question guiding this exploration is the influence of physicochemical properties on human exposure to CP mixtures. Relying on properties predicted for individual CP isomers, we aim to answer this question by comparing exposure predictions obtained through a "complex" method utilizing isomer-specific properties against "simplified" methods that leverage average properties of congeners, homologues, or Short-/Medium-/Long-Chain CP groups. Our results reveal a broad range of physicochemical properties across CP mixtures and their dependence on molecular structures. These variances translate into an extensive disparity in whole-body concentrations predicted for different isomers, spanning ~11 orders of magnitude. CPs with 13-19 carbons and 6-10 chlorines exhibit the highest relative human exposure potential, primarily owing to their moderate to high hydrophobicity and slow environmental degradation and biotransformation. Except for highly volatile components, far-field exposure is dominant for most CP components. Despite the large variance in properties and human exposure potential of CP isomers, our work justifies that using average properties of congener, homologue, or S/M/LCCP groups yields results that are consistent with those derived from isomer-based modeling. This presentation not only enhances our understanding of human exposure to CPs but also provides insights into how in silico modeling approaches can contribute to efficient and practical human exposure assessment strategies for complex chemical mixtures.

7.02.P-We560 EAS-E Suite: A comprehensive web-based platform to integrate in vivo, in vitro and in silico data for chemical safety and sustainability

***Alessandro Sangion*[1]*, Li Li*[2]*, James M Armitage*[3]*, Liisa Toose, M.Sc.*[1]*, Trevor N Brown, PhD*[1] *and Jon A. Arnot*[1]*, (1)Arnot Research and Consulting Inc. (ARC), Canada, (2)School of Public Health, University of Nevada, Reno, (3)AES Armitage Environmental Sciences, Inc, Canada*

The modernization of chemical screening and risk assessment is confronted with the need to address data gaps in hazard and exposure. New Approach Methods (NAMs), such as in vitro bioactivity data, in silico approaches (e.g., Quantitative Structure Activity Relationship – QSAR), and high-throughput toxicokinetics (HTTK), have emerged as promising solutions. However, the effective application of NAMs for decision-making requires a deep understanding of their relevance, reliability, applicability domains (AD), as well as the integration of the different approaches in a coherent weight of evidence framework.

Exposure and Safety Estimation (EAS-E) Suite is a web-based platform designed to bridge the gap between advancing scientific methods and chemical safety assessment. EAS-E Suite serves as a hub for gathering, harmonizing, and integrating diverse chemical data, QSARs, environmental fate and exposure models. It houses a curated database containing experimental physical-chemical properties and toxicokinetic data. Additionally, it provides predictions from models like EPISuite, OPERA, IFSQSAR, and QSARINS-Chem, allowing for a consensus approach. Each QSAR prediction comes with additional information (e.g., AD) in compliance with the recently published OECD QSAR Assessment Framework. Moreover, predictions can be directly generated for chemicals not in the database using SMILES notation.

The databases and QSARs provide information to parameterize a suite of models to generate environmental fate and exposure predictions. EAS-E Suite includes models to estimate mode of entry and emission rates (i.e., CiP-CAFE) as well as regional, point source and indoor environmental fate, bioaccumulation, and exposure (e.g., RAIDAR, RAIDAR-Point Source, RAIDAR-ICE). A generic one-compartment physiologically based kinetic model that can be parameterized for different organisms (e.g., human, rat, fish) is implemented to allow HTTK simulations. All the models are harmonized and integrated to allow the estimation of aggregate exposure in the PROTEX-HT model. A preliminary version of sensitivity and uncertainty analysis in included in the simulations to investigate how uncertainties in input parameters propagate through the modeling process, improving the interpretability of the results. With entry of only chemical structure, the system can select the best values to parameterize the different models and provide critical information for holistic ecological and human health assessments.

7.02.P-We562 Developing Sustainable Alternatives for Persistent, Mobile, and Toxic Chemicals: A Safe and Sustainable by Design (SSbD) Approach

***Bianca Stadelmann*[1]*, Antonia Praetorius*[1]*, Agnes Oomen*[1,2] *and Annemarie van Wezel*[1]*, (1)Institute for Biodiversity and Ecosystem Dynamics, University of Amsterdam, Netherlands, (2)National Institute for Public Health and the Environment (RIVM), Netherlands*

Persistent, mobile and toxic (PMT) as well as very persistent and very mobile (vPvM) substances threaten drinking water quality and ecosystem health. PMT/vPvM substances do not readily biodegrade in the environment, can travel long distances and are difficult to remove with current water treatment technologies. PMT chemicals are also toxic to humans and/or biota. Despite current regulatory systems to manage the risks of chemicals, issues with chemical safety persist and concerns related to PMT/vPvM chemicals are pertinent. This highlights the need for additional measures to protect water resources, as well as human and environmental health from adverse impacts arising from exposure to these substances.

Recognised as highly effective methods for reducing environmental and human health hazards, are upstream preventative approaches. In particular the Chemicals Strategy for Sustainability acknowledges the Safe and Sustainable by Design (SSbD) approach. SSbD includes safety and sustainability considerations at the beginning of the chemical innovation process alongside functionality considerations, to aid in the selection of less hazardous chemical alternatives for a given application. The use of screening and predictive models can bridge the gap arising from limited experimental data on persistence, mobility and toxicity for most chemicals, to prioritise where further testing is needed. However, well-elaborated tools for the selection of SSbD alternatives for PMT chemicals that fulfil desired and essential functions in a given application are still missing.

The project presented here aims to develop a simultaneously concrete and generally applicable workflow for the selection of SSbD alternatives for PMT/vPvM substances that is applied in consultation with different stakeholders. Publicly available databases will be used to select relevant PMT/vPvM priority substances, based on problematic applications in consumer products. Large sets of potential chemical alternatives for these substances will be generated *in silico* and later screened for PMT/vPvM properties, as well as properties relevant to sustainability, and functionality. Existing databases and QSAR models, (e.g. EPISuite, BIOWIN and VEGA) will be used. Results of *in silico* screening will be complemented by experimentally generated data. Through this project we aim to make SSbD more mainstream, generally applied and well-accepted in daily practice.

7.02.P-We563 Support of persistence assessment under REACH and CLP using in silico predictions

Antje Gerloff-Elias*, knoell Germany GmbH, Germany*

With the introduction of hazard classes for persistent chemicals under Regulation (EC) No 1272/2008 (Classification, Labelling and Packaging of substances and mixtures - CLP), companies and European Member State authorities face the challenge of assessing the potential for persistence of a high number of substances in a complex regulatory environment, and within a short period of time.

More than 2000 substances registered under Regulation (EC) No 1907/2006 (Registration, Evaluation, Authorisation and Restriction of Chemicals - REACH) with a tonnage > 10 t/a are considered “potentially persistent” since they either fail the criteria for ready or inherent biodegradability, or due to a lack of suitable biodegradation data. In such cases, higher tier simulation biodegradation studies (i.e., OECD 307, 308, and 309) are required to derive biodegradation half-lives. Simulation studies are very expensive, technically challenging and have variable outcomes due to the considerable influence of environmental parameters and experimental design. For substances of unknown and variable composition (UVCBs), the experimental design is specifically challenging. It may even require several studies to run consecutively, or may not be feasible at all. Moreover, limited laboratory capacity and the relatively few knowledgeable experts in this field further limit the availability of sufficient higher tier experimental data for persistence assessment.

In addition to assessing the persistence of the parent substance, the persistence of relevant transformation / degradation products must also be considered (according to CLP and REACH). Furthermore, appropriate identification of metabolites by simulation testing of biodegradation is often missing.

Here we describe the challenges which authorities and companies face in coming to a conclusive persistence assessment under CLP and REACH. We present how *in silico*-generated predictions can support persistence assessments based on biodegradation screening test results. Furthermore, we present how the generation of potential transformation products may be predicted, and their respective hazard profile quickly assessed using *in silico* screening techniques. The proposed strategy represents a fast, cost-effective alternative to higher tier simulation testing.

7.02.P-We564 Computational Characterization of Sulfate-Reducing Bacteria Inhibitors to Overcome Methanogenic Competence and Optimize Green Biogas Production

David Talavera Cortés[1]*, Laureano E. Carpio*[1]*, Patricia Serrano Candelas*[2]*, Carlos Lafita López*[3]*, Maria José Tárrega Martí*[3]*, Ángela Baeza Serrano*[3]*, Pau Granell Muñoz*[3]*, Rafael Gozalbes*[1,2] *and Eva Serrano Candelas*[1]*, (1)ProtoQSAR, Spain, (2)MolDrug AI Systems, Spain, (3)Global Omnium, Spain*

Microorganisms play a crucial role in wastewater treatment plants (WWTPs). Such is the case of methanogenic archaea, which are able to break down organic matter and remove pollutants from wastewaters and sludges produced during its treatment, producing methane as a by-product. WWTPs could use this methane as a renewable energy source, instead of fossil energy, committing to the circular economy. However, sulfate-reducing bacteria (SRB) compete with methanogenic archaea for the same substrate in anaerobic conditions, thus reducing the efficiency of methane production and generating H_2S, a harmful gas that can also have adverse consequences on environment. Therefore, it is of utter interest to study the possible inhibition of SRB to both optimize the methane production and to reduce H_2S emissions.

In the present study we have employed different approaches to find potential SRB inhibitors. From one side, we have developed Quantitative Structure-Activity Relationship (QSAR) models and used them to perform virtual screening of COCONUT, a database of natural substances. From other side, different databases (KEGG, BRENDA, PDB and PubChem) were manually explored to find specific inhibitors. Finally, one interesting candidate from the virtual screening and an analogous were identified with similar predicted activity. All the candidates found with the three approaches were combined and a final step consisting of ecotoxicological predictions was implemented to remove all the possible ecotoxic molecules.

The QSAR models' metrics were acceptable for predicting the inhibitory activity against methanogenic archaea and SRB. The QSAR modelling and the exploratory approaches yielded 9 and 11 candidates respectively. Altogether, 20 potential inhibitors were obtained and only 4 were selected, based on commercial availability and several properties, to carry on with the experimental validation, which is currently ongoing.

The potential candidates identified might allow the reduction of the substrate competence between methanogenic archaea and SRB; therefore, methane production will potentially increase and could supply energy to the same WWTP. Consequently, this will lower the greenhouse gases by consuming self-produced biogas in WWTPs.

7.03.P One Health Approach: PFAS Exposure in Wildlife and Shared Health Risks Across Species Including Humans

7.03.P-Tu538 Striped Dolphins as Bioindicators: Tracing Per- and Polyfluoroalkyl Substances Pollution in the North West Mediterranean Over Three Decades

Pere Colomer Vidal[1]*, Odei Garcia-Garin*[2]*, Asunción Borrell*[3]*, Morgana Vighi*[3]*, Núria Trilla*[4]*, Alex Aguilar*[3]*, Manel Gazo Dr*[5]*, Juan Munoz-Arnanz*[1] *and Begoña Jiménez*[1]*, (1)Institute of Organic Chemistry, Spanish National Research Council (IQOG-CSIC), Spain, (2)University of Barcelona, Spain, (3)University of Barcelona and Biodiversity Research Institute (IRBio), Spain, (4)Global Change and Genomics Biogeochemistry research Group, Institute for Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Spain, (5)Department of Evolutionary Biology, Ecology and Environmental Sciences, Faculty of Biology, Universitat de Barcelona, Spain*

Poly- and Perfluoroalkyl Substances (PFAS) constitute a class of global and persistent pollutants with known biomagnification capacity, warranting their investigation as threats to the conservation of species such as marine mammals. This study explores striped dolphins as bioindicators of PFAS pollution in the North-Western Mediterranean Sea, evaluating biomagnification rates and temporal trends of PFAS over three decades (1990-2021) in stranded specimens. This study focused on evaluating PFAS biomagnification in mature striped dolphins in the NW Mediterranean and tracking PFAS concentration trends from 1990 to 2021.

PFAS analysis was conducted on striped dolphins' digestive content and liver, involving liquid-solid extraction and analysis using UPLC-MS/MS, identifying and quantifying 19 PFAS compounds. Thirteen PFAS compounds were identified in the digestive content, while liver samples revealed the presence of 17 PFAS compounds. Linear perfluorooctanesulfonic acid and perfluorooctanesulfonamide emerged as the predominant compounds in all samples, closely trailed by long-chain carboxylate acids. Long-chain PFAS exhibited greater biomagnification rates than short-chain PFAS, suggesting potential health concerns for striped dolphins. These results highlight the risks posed by the accumulation of long-chain PFAS, emphasizing the need to study PFAS profiles and their impact on vulnerable species.

Temporal trends showed an increase in concentrations of most long-chain PFAS from 1990 to 2004-2009, stabilizing during 2014-2021. This stabilization may signify the impact of regulatory measures and industry initiatives aimed at reducing PFAS pollution. However, analysis revealed that half of the digestive content samples exceeded Environmental Quality Standards from the Water Framework Directive, underscoring the need for ecological risk assessments and stricter regulations, and an emphasis on risk reduction and shared health risks across species.

In conclusion, this research contributes to the understanding of PFAS biomagnification in striped dolphins, revealing persistent contamination in the North-Western Mediterranean Sea and highlighting the interconnected health concerns of marine ecosystems and humans. In turn, this study builds up on the current urgency for continued research and stringent regulations able to address the lasting threat of PFAS in the environment.

7.03.P-Tu539 A comprehensive analysis of PFAS change points in humans and the environment using archived samples from Germany

Alexander Badry[1], *Bernd Göckener*[2], *René Lämmer*[2] *and Jan Koschorreck*[1], *(1)German Environment Agency (UBA), Germany, (2)Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

Per- and polyfluoroalkyl substance (PFAS) contamination is a widespread global problem that has a proven negative impact on the terrestrial, freshwater and marine environment. Due to their hazardous properties and high risks to humans and the environment, certain PFAS such as perfluorooctane sulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) were voluntarily phased out by their main manufacturer in the early 2000s and have been regulated by the European Union since 2006 and 2020 respectively. Global restrictions were introduced by the Stockholm Convention in 2009 for PFOS, in 2019 for PFOA and in 2020 for perfluorohexanesulfonic acid (PFHxS). While human and wildlife exposures are well characterised for the conventional target PFAS, little is known about time trends and the assessment of the effectiveness of regulatory changes. Previous analyses of suspended particulate matter (SPM) from Germany showed a log-linear decrease since 2005 for both, perfluorosulfonic acids (PFSAs) and perfluoroalkyl carboxylic acids (PFCAs). As the SPM sampling started only after the main PFAS were phased out, we performed a comprehensive time trend analysis of samples from the German Environmental Specimen Bank going back to the 1980s and early 1990s. These samples covered human plasma as well as samples from the terrestrial (deer liver), freshwater (bream liver and muscle) and marine environment (herring gull eggs). The aim of the study was to statistically evaluate the change points (CPs) of exposure and quantify the changes before and after the CPs to assess the effectiveness of the above measures. The CPs were estimated using the R-package “segmented” by two linear regression splines with the CP representing the joint point. The analysis demonstrated remarkably similar CP estimates across human and environmental matrices. The results showed that the maximum concentrations of PFOS were already reached before (late 1990s) the announcement of the phase-out by their main manufacturer. These results are similar for all tested PFSAs and indicate an earlier shift to PFAS alternatives than previously expected. For PFCAs, CPs were generally later (mid-2000s), possibly due to the delayed regulatory action on PFCAs and associated preceding production shifts. In general, regulatory actions were introduced ~10-15 years after the respective CPs, which demonstrates the need for earlier regulatory actions to effectively protect humans and the environment.

7.03.P-Tu540 Do Per- and Polyfluoroalkyl Substances (PFASs) and Other Pollutants Threaten Shorebirds Inhabiting Artificial Wetlands?

Tobias Ross[1], *Junjie Zhang*[2], *Michelle Wille*[3], *Tomasz Maciej Ciesielski*[2], *Alexandros G. Asimakopoulos*[2], *Prescillia Lemesle*[2], *Tonje G Skaalvik*[2], *Robyn Atkinson*[4], *Roz Jessop*[4], ***Veerle L. B. Jaspers***[2] *and Marcel Klaassen*[1], *(1)Deakin University, Australia, (2)Norwegian University of Science & Technology (NTNU), Norway, (3)University of Sydney, Australia, (4)Victorian Wader Study Group*

The prime threats perceived to contribute to the global decline of shorebirds include climate change and habitat loss, while the role of pollution in these declines has been less investigated. Whereas the rate of destruction of natural wetland habitats has been particularly rapid over the past decades, artificial wetlands, including wastewater treatment plants, have seen an increase over this time and provide alternative habitats for a wide range of bird species. These new habitats, in turn, pose a pollution risk to wildlife.

We compared exposure to pollution by 15 per/polyfluoroalkyl substances (PFASs) and 15 elements along with prevalence of avian influenza, oxidative stress and local survival in two long-distance migratory shorebird species, curlew sandpipers (*Calidris ferruginea*) and red-necked stints (*Calidris ruficollis*). Birds were sampled for blood from 2011-2020, at two contrasting habitats on their Victoria, Australia non-breeding grounds: a natural wetland on Western Port Bay and a putatively more polluted artificial wetland at Melbourne’s Western Treatment Plant (WTP), the latter of which processes the waste of approximately 5 million people.

Blood pellet concentrations of both carboxylate PFASs and sulfonate PFASs were found to be significantly higher at the Western Treatment Plant (carboxylate PFASs at WTP median: 15.7 ng/g, range: <0.01-107 ng/g; natural wetland: 2.05 ng/g, <0.01-62.3 ng/g - sulfonate PFASs at WTP median: 65.3 ng/g, range: <0.01-804 ng/g; natural wetland: 4.86 ng/g, <0.01-26.9 ng/g). Nevertheless, concentrations were generally below reported health risk threshold values.

Avian influenza prevalence was higher at the natural wetland, while seropositivity (representative of prior infections) was higher at the WTP. We also measured higher blood o,o’-dityrosine (an indicator of protein damage) at the WTP. No significant differences were found for adult survival, but survival of immature birds at the WTP appeared to be lower than those at the natural wetland.

Our findings showed that PFASs from wastewater treatment plants indeed contaminate the birds inhabiting the region. However, concentrations in most individuals were lower compared to health risk thresholds. These relatively low concentrations, together with limited other significant differences in pollution and health indicators, tentatively suggest that appropriately managed wastewater treatment wetlands may provide an alternative habitat to these migratory species.

7.03.P-Tu541 Gene Expression of Mitochondrial Antioxidant Enzymes in a Freshwater Fish Species (Squalius Cephalus) Exposed to Environmental Concentrations of Pfas in the Veneto Region.

Sara Pacchini[1], *Giacomo Vanzan*[2], *Elisabetta Piva*[1], *Sophia Schumann*[2], *Andrea Marion*[3], *Paola Irato*[2], *Gianfranco Santovito*[2] *and Andrea Bottacin-Busolin*[3], *(1)Department of Biology, University of Padova, Padova, Italy, (2)Department of Biology, University of Padova, Italy, (3)University of Padova, Italy*

Since its discovery in 2013, the Veneto region has been affected by one of the most extensive PFAS contaminations in the world, originated by a fluorochemical plant in Vicenza's province, active since the late 1960s. PFAS are highly persistent in the environment. Exposure to environmental stressors, like pollutants, can affect animals' physiology, in many cases inducing a response from the organism at the level of the antioxidant system. In particular, PFAS can bioaccumulate and biomagnify along food webs, affecting ROS production at the molecular level, hence unbalancing the cellular redox equilibrium. This may result in cell death, DNA damage, altered enzymatic function, and consequent oxidative damage to the entire organism. Therefore, variations in the content and the activity of antioxidant enzymes are useful as biomarkers for oxidative stress caused by contaminants in marine organisms, enabling evaluation of their potential risk for aquatic ecosystems and biota. The aim of the present study is to evaluate the possible effects of chronic exposure to different environmental concentrations of PFAS and the induced physiological responses in a freshwater fish species: *Squalius cephalus* (Linnaeus, 1758) which populates the Veneto rivers. In particular, some molecular and biochemical analyses, which consist in evaluating some oxidative stress biomarkers, were carried out in the kidney. Ten specimens of *Squalius cephalus* were sampled by electrofishing from three rivers in Vicenza (Veneto, Italy) characterized by three different levels of PFAS contamination. First, expression analyses were performed at the transcriptional level of genes coding for four mitochondrial isoforms (sod2, gpx4, prdx3, prdx5) of antioxidant enzymes, evaluating the mRNA accumulation by real-time qPCR. Then, two indicators of cellular damage were measured: Lipid Peroxidation and Advanced Oxidation Protein Products (AOPP) formation. To summarize the results, we can observe a qualitative response which is reflected in the involvement of different components of the antioxidant system, but also quantitative in relation to different levels of environmental contamination. Exposure to PFAS increases the rate of ROS formation, both of O_2^-, as demonstrated by the increase in sod2 expression, and of H_2O_2, as demonstrated by the activation of the scavenger enzymes of this ROS (gpx4, prdx3, prdx5).

Supported by Next Generation EU, PNRR, RETURN project. Grant Agreement No. PE0000005.

7.03.P-Tu542 Mapping PFAS Distribution in Flanders, Belgium: Results of an Extensive Aquatic Monitoring Campaign

Nathalie Briels[1], *Karel Vlaeminck*[2], *Karel Viaene*[2], *Maarten De Jonge*[3], *Marnix Vangheluwe*[2] *and Frederik Verdonck*[2], *(1)ARCHE Consulting, Ghent (Wondelgem), Belgium, (2)ARCHE Consulting, Belgium, (3)Flanders Environment Agency, Belgium*

In recent years, public awareness has increased regarding the presence of PFAS (per- and polyfluoroalkyl substances) in the environment. Until recently, little information was available on the occurrence of PFAS in Flanders. Therefore, a large-scale monitoring campaign was initiated by the Flanders Environment Agency (VMM) in 2022 to map the distribution of PFAS contamination in this region. Wastewater, surface water, sediment, fish, and groundwater were analyzed from both suspected and non-suspected sites for 43 PFAS (49 for groundwater). Although many PFAS were below the detection limit, at least one PFAS was detected in more than 90% of the wastewater, surface water and fish samples. For sediment and groundwater, this was around 30% of the samples. The median ∑PFAS concentration in industrial wastewater ranged between 50 and 570 ng/L, while effluent from sewage treatment plants (STP) had a median of 50 ng/L. Surface waters showed a similar median concentration compared to the STPs, namely 45 ng/L ∑PFAS, while the median groundwater concentration was about 5 times lower (8.7 ng/L ∑PFAS). The median concentration in sediment was 1.2 µg/kg dw ∑PFAS. These results were in the same order of magnitude as those in neighbouring countries and regions when comparing amongst highly urbanized or industrialized areas. Between matrices, some clear differences in PFAS profiles could be observed. Distinct fingerprints could be assigned to wastewater based on industrial sector. However, sector fingerprints were not distinguishable in surface water due to the diffuse sources in receiving waters. Overall, the water compartments (wastewater, surface water and ground water) showed similar PFAS profiles, although when including the confined aquifers, groundwater showed a different profile. In sediment and fish, long-chain PFAS and precursors were more prevalent, in contrast to short-chain PFAS in water. These differences are likely due to the physico-chemical characteristics of individual PFAS. Measured concentrations were compared to available thresholds for environmental and human health, showing most exceedances for surface water and biota, depending on the selected threshold value. Altogether, this report revealed that PFAS can be widely detected in the Flemish environment. The study outcome allows for decision-making by the Flemish government as part of the PFAS action plan and will aid to prioritize future sampling efforts.

7.03.P-Tu543 Toxicity assessment of per- and polyfluoroalkyl substances (PFAS) with varying chain lengths on Daphnia magna and Allivibrio fisheri.

Sara Villa[1], *Valeria Tatangelo*[2], *Emilio Brivio Sforza*[2], *Valeria Mezzanotte Prof*[3] *and Andrea Franzetti*[4], *(1)Dept Earth and Environmental Sciences, University of Milano-Bicocca, Italy, (2)Disat, University of Milano-Bicocca, Italy, (3)University of Milano-Bicocca, Italy, (4)Università degli Studi di Milano-Bicocca, Italy*

The LIFE CAPTURE project aims to investigate the characteristics and behaviour of PFAS and identify innovative remediation solutions for these persistent soil and groundwater contaminants. We seek to devise a practical approach for assessing the risks and effects of PFAS, utilising standardised bioassays (ecotoxicity tests) to ensure ease of implementation and economic viability. Special attention is paid to risk assessment for mixtures of PFAS and methods for assessing risk reductions achieved by remediation.

In this extensive project, we present the first results obtained on two standard organisms, namely *Daphnia magna* and *Aliivibrio fischeri*. For all the tested congeners, *Aliivibrio fischeri* showed greater sensitivity than *Daphnia magna*. Moreover, survival rates and light emission inhibition decreased with increasing chain length. For both model species the most toxic potential is found for the shortest chain PFASs (3 and 4 C). The confirmed pattern of additive concentrations is shown in the bioassay data obtained from test mixtures. Currently, PFAS toxicity is an active area of research since scientists aim to understand the mechanisms behind these effects in addition to their impact on aquatic ecosystems. These studies improve our understanding of how PFAS pollution can impact freshwater organisms, enabling the development of regulations and management plans to reduce harm to the environment. However, the overall comprehension of the toxicity of PFAS compounds, varying from shorter to longer chain ones, is still an area of ongoing research. Environmental conditions, interactions among different PFAS compounds, and their combined effects may also influence their overall impact on ecosystems. Environmental agencies evaluate continuously the toxicity of PFAS substances in order to formulate guidelines and regulations to mitigate their environmental and health effects.

7.03.P-Tu544 Hepatic concentrations of per- and polyfluoroalkyl substances (PFAS) in dolphins from south-east Australia: Highest reported globally

Chantel Sarah Foord[1], *Drew Szabo*[2], *Bradley Clarke*[2] *and Dayanthi Nugegoda*[1], *(1)School of Science, RMIT University, Australia, (2)University of Melbourne, Australia*

Per- and poly-fluoroalkyl substances (PFAS) are a diverse group of over 6,000 stable, man-made compounds found in a wide array of household and industrial products, creating a ubiquitous environmental presence. This study addresses the critical knowledge gap regarding PFAS contamination in Australian aquatic environments, focusing on marine mammals.

We conducted an investigation of PFAS concentrations in four dolphin species stranded along the south-east Australian coast. Here we report the highest concentration of any Cetacea globally, in the critically endangered Burrunan dolphin. Specifically, populations in Port Phillip Bay (median 9750 ng/g ww, n = 3) and Gippsland Lakes (median 3560 ng/g ww, n = 8) recorded concentrations 50–100 times higher than other species in the study, including common bottlenose dolphin (50 ng/g ww, n = 9), Indo-Pacific bottlenose dolphin (80 ng/g ww, n = 1), and short-beaked common dolphin (61 ng/g ww, n = 12). Also included in the results is the highest reported individual ΣPFAS (19,500 ng/g ww) and Perfluorooctane sulfonate (PFOS, 18,700 ng/g ww) concentrations, at almost 30 % higher than any other Cetacea reported globally.

PFOS was found to be the predominant PFAS compound, exceeding tentative critical concentrations in 42% of all dolphins and 90% of the endangered Burrunan dolphin. Notably, we identified for the first time novel and emerging PFAS; 6 perfluoro-3-methoxypropanoic acid (PFMPA), perfluoroethylcyclohexane sulfonate (PFECHS), 6:2 chlorinated polyfluorinated ether sulfonate (6:2 Cl-PFESA) and Perfluorobutane sulfonamide (FBSA), in southern hemisphere marine mammals, with high detection rates across the dataset.

This research provides the first documentation of PFAS in the tissues of multiple Cetacea species in the Australasian region. These findings emphasize the global significance of high PFAS concentrations in inshore dolphins and contribute vital baseline knowledge for understanding PFAS exposure and bioaccumulation in the coastal environment of south-east Australia.

7.03.PC One Health Approach: PFAS Exposure in Wildlife and Shared Health Risks Across Species Including Humans

7.04 Safe and Sustainable by Design Advanced Materials: What Does It Take?

7.04.T-01 Comparative Analysis between Tier 1 SSbD (Safe and Sustainable by Design) approach and Early4AdMa

Arianna Livieri[1], *Lisa Pizzol*[1], *Agnes Oomen*[2], *Kathrin Schwirn*[3], *Elmert Swart*[2], *Hubert Rauscher*[4], *Mar Gonzalez*[5], *Kimiko Yamamoto*[5] *and Danail Hristozov*[1], *(1)Ca' Foscari University of Venice, Italy, (2)National Institute for Public Health and the Environment (RIVM), Netherlands, (3)German Environment Agency (UBA), Germany, (4)European Commission - Joint Research Center (JRC), Italy, (5)Organisation for Economic Co-operation and Development (OECD), France*

The Chemicals Strategy for Sustainability (CSS) and Zero Pollution Action Plan call for a transition towards a Safe and Sustainable by Design (SSbD) approach for chemicals and emerging materials. This has led to the EC's Recommendation for establishing a European assessment framework for SSbD chemicals and materials. To facilitate the implementation of this framework the H2020 SUNSHINE project developed a tiered SSbD approach, while at the same time a consortium composed by RIVM (NL), BfR (DE), BAuA (DE) and UBA (DE) proposed the Early4AdMa early warning system. The SUNSHINE SSbD approach aims to provide support to industries in developing SSbD strategies for specific advanced materials an products incorporating them. The Early4AdMa system offers a structured methodology for pinpointing possible safety, sustainability, and regulatory issues that may arise from emerging advanced materials. The two approaches are similar, and in order to assist users in selecting the system that is most suited to their needs, a comparative analysis of the two methods was carried out, and it was performed in the frame of the OECD Working Party on Manufactured Nanomaterials and specifically in the Steering Group on Advanced Materials. The analysis aims to identify similarities, differences, strengths, weaknesses and targeted users. The two methods are composed of a questionnaire which questions were classified in common aspect categories such as safety, environmental, economic and social sustainability, and functionality. An additional category, applicability to regulatory frameworks, was relevant only for Early4AdMa. The results showed that the two approaches are highly complementary. Early4AdMa is instrumental in pinpointing safety and sustainability issues that may not be covered by current regulations and is therefore aimed for application by regulators. On the other hand, the SUNSHINE approach is tailored to identify hotspots of safety and sustainability concerns along the lifecycles of specific materials/products on a case-by-case basis to support SSbD decision making by industries, including SMEs. Thus, the two approaches can be synergistically applied to facilitate implementation of the SSbD framework by different stakeholders: SUNSHINE is better tailored to industries and consultans, while Early4AdMa is targeted at policy makers, the standardisation community and regulators. Further comparison on the output of the two approaches will be perfomed by assessing two cases

7.04.T-02 Holistic Design Methodology for Circularity adapted to the SSbD framework
Carolina Villa González[1]*, Laura Mayor Pérez*[2]*, Violeta Vargas-Parra*[2] *and José Jorge Espí Gallart*[1]*, (1)Fundació EURECAT, Spain, (2)Eurecat, Spain*
On the way to determine a path to avoid or reduce harmful effects on human health and the environment from materials and products throughout its complete life cycle, design plays a key role in innovation and business strategy settings. The development of the Safe and Sustainable by Design (SSbD) framework also highlights the relevance of design as a key driver to ensure more safe and sustainable chemicals and materials considering the three pillars of sustainability (environment, economic and social).

In this research, a SSbD eco-design methodology is presented. The bestowed methodology ensures the proper implementation of the framework, enhancing the analysis through continuous improvement at all stages, thus aligning with the various SSbD design principles. This approach stems from the integration of EURECAT's registered eco-design methodology and the above mentioned SSbD framework.

The SSbD eco-design methodology aims to be a holistic and iterative process that will provide an overall vision of the final product (chemical or material) and a set of priorities. Four key successive steps are defined following the Plan-Do-Study-Act (PDSA) approach: 1) Identification of Hotspots from the five steps described on the framework, 2) Eco-design SSbD principles and strategies definition and set up, 3) Re-adaption of technological procedures to the selected strategies and 4) Definition of concrete eco-design actions, for which all relevant stakeholders are invited to participate in order to obtain feedback from the different perspectives and experience to define specific actions and to prioritize them through the use of interactive platforms and the Analytic Hierarchy Process (AHP) methodology.

In conclusion, the application of the SSbD eco-design methodological approach ensures that the future chemicals or materials developed under this framework will have a lower hazard and risk impact in their conception and applicability while simultaneously improving its sustainable profile. Through its iterative process, a continuous improvement can be obtained without compromising technical performance, and the level of implementation of the actions is subject to the project development.

7.04.T-03 Life Cycle Safety and Sustainability Assessment of Innovative Solutions for Art Restoration
Martina Menegaldo[1]*, Elisa Giubilato*[2]*, Lisa Pizzol*[2]*, Elena Semenzin*[3] *and Elena Badetti*[1]*, (1)Ca' Foscari University of Venice, Italy, (2)GreenDecision S.r.l., Italy, (3)Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice, Italy*
The conservation of Cultural Heritage (CH) necessitates continuous interventions, that can be harmful to human health, particularly for operators and curators, and at the same time impactful to the environment. Coping with these issues, GREENART (GREen ENdeavor in Art ResToration) project, funded by the HORIZON Europe Programme, proposes new advanced materials and chemicals to conserve CH (i.e., cleaning systems, protective coatings and consolidants, packaging and sensors). As part of the project, a Life Cycle Safety and Sustainability Assessment is planned to provide step-by-step guidance to product developers to ensure the development of safe and sustainable innovative solutions. The research employed the sustainability framework established in the H2020 NANORESTART project, which implements the Safe by Design (SbD) concept, and integrates it with the "Safe and Sustainable by Design chemicals and materials" framework by the Joint Research Center (JRC). The initial step, focusing on hazard assessment, served as a guide for safety evaluations of GREENART chemical solutions. This first evaluation was performed according REACH and CLP regulations to look at the intrinsic properties of the chemical or material in order to understand its hazard profile before further assessing the safety during use. By combining Step 2 of the NANORESTART Framework and Step 1 of the SSbD Framework, all formulation ingredients were assessed for Human Health (H), Environmental (ENV) and Physical (P) Hazards, by consulting Safety Data Sheets and/or the ECHA dossier. Then, all ingredients were classified (Levels 0 to 3) according to the SSbD criteria for assessing intrinsic hazard properties. These initial results were communicated to the formulation developers along with observations for each

SSbD hazard level. Finally, a self-classification of the mixture in accordance with CLP guidance was performed. Based on the outcomes of this initial phase, the developers of the product have the option to modify the original formulation to minimize any potential risks, or they can choose to eliminate it altogether, if functionality cannot be preserved. This work will be completed by safety evaluation for the production and application phases and, finally, by Life Cycle Assessment (LCA) and Life Cycle Cost (LCC). This work is expected to contribute to the development of criteria for chemicals and advanced materials to support the application of the SSbD framework to the CH sector.

7.04.T-04 Application of the SSbD framework to biocidal nanocoatings: gaps and steps towards its implementation
Merve Tunali[1] *and Bernd Nowack*[2]*, (1)Swiss Federal Laboratories for Materials Science and Technology (EMPA), Switzerland, (2)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*
The Safe and Sustainable by Design (SSbD) Framework has the aim to facilitate the design and development of chemicals and materials to be safe and sustainable through research and innovation initiatives. The framework considers the intrinsic hazards of a chemical or material, environmental and human safety during production, use and disposal as well as environmental sustainability through life cycle assessments. The result of the assessments provides a score that indicates the level of SSbD. The SSbD framework is currently in the development and testing phase, and presently, there are no specific approaches available for specific groups of chemicals or materials. In particular it is unclear how functional and societal benefits can be included within the SSbD Framework. Biocides, for instance, are being used for the protection of living organisms against infectious diseases. Nevertheless, their impact may extend beyond controlling the intended harmful organisms, potentially affecting humans and non-target organisms in the environment. Biocides are also being promoted to achieve several United Nations Sustainable Development Goals, however, it is so far not possible to consider this within the SSbD. Thus, due to the dual nature of biocides—offering benefits and carrying negative effects caused by their nature as being toxic to target organisms—a specific SSbD approach considering their functionality is crucial for evaluating their safety and sustainability alongside societal benefits. In this study, we developed criteria that may be applicable to the SSbD framework for assessing the functionality-related benefits of biocidal products. Our study covers: *i)* assessing the data and methodological challenges to apply SSbD to biocidal products, and providing recommendations, *ii)* suggesting methodological approaches that can be integrated into the SSbD framework to account the benefits of the biocides, *iii)* addressing the challenges of applying SSbD to the early design stages of biocidal nanocoatings, and providing possible approaches, *iv)* presenting a case study demonstrating the application of the SSbD framework to biocidal nanocoatings for public transport use.

7.04.P Safe and Sustainable by Design Advanced Materials: What Does It Take?

7.04.P-We565 Safe and Sustainable-by-Design – A guidance to unleash the transformative power of innovation
Wibke Lölsberg[1], ***Eva-Kathrin Schillinger***[2]*, Ann Dierckx*[3]*, Franco Manfré, SEPPIC Manfré*[4]*, Rika Homma*[5]*, Denise Schütz-Kurz*[6]*, Diederik Schowanek*[7]*, Jessica Modin*[8]*, Tobias Borén*[8] *and John Hobdell*[9]*, (1)BASF SE, Germany, (2)European Chemical Industry Council (CEFIC), Belgium, (3)CEFIC - European Chemical Industry Council, Belgium, (4)SEPPIC, France, (5)Kao Corporation, Japan, (6)VCI, Germany, (7)Brussels Innovation Centre, Procter & Gamble, Belgium, (8)Nouryon, Sweden, (9)Huntsman, Belgium*
Cefic and its members have defined, in their previous reports from October 2022 and April 2023, Safe and Sustainable-by-Design (SSbD) as an iterative process guiding innovation and the placement on the market of solutions that are safe, and deliver environmental, societal, and/or economical value through their applications. In scope are new chemicals, materials, products, processes and services, as well as the re-design of existing ones.

The 3rd report proposes guiding design principles for a selected set of safety and sustainability considerations, dimensions or **criteria** to be assessed at the level of product-application combination in a stage-gate-like approach during innovation.

The basic principle when innovating to improve the functionality and performance of chemicals, materials, products, processes or services, is the aim to significantly improve performance in at least one of the dimensions of safety and sustainability without significant negative impacts in any of the other dimensions, compared to the incumbent solutions.

As a minimum, a sound implementation of "**Safety**" shall be applied by a risk-based assessment considering the hazard, use and exposure in line with REACH and anticipating future regulatory changes. But in applying SSbD, the chemical industry has the ambition to go *beyond* that legally fixed minimum requirement and go for continuous reduction of toxicological risks for humans and the environment especially for consumer use and considering end-of-life and circularity aspects.

The "Sustainability" assessment as an integral part of the innovation process shall cover the life cycle of a product-application-combination. All assessments shall, as a minimum, cover focus dimensions deemed of high importance to reach the Green Deal objectives. Additional sustainability contributions may be considered.

7.04.P-We566 Towards Regulatory Preparedness of Advanced Materials: the OECD Early4AdMa System
Elmer Swart[1]*, Mar Gonzalez*[2]*, Francis Peters*[3]*, Hubert Rauscher*[4]*, Kathrin Schwirn*[5]*, Doris Volker*[5] *and Agnes Oomen*[1]*, (1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)Organisation for Economic Co-*

operation and Development (OECD), France, (3)Business at OECD (BIAC), France, (4)European Commission - Joint Research Center (JRC), Italy, (5)German Environment Agency (UBA), Germany
Advanced materials, may offer many economic advantages and some of them could help to deliver solutions to societal problems such as the need to reduce reliance on fossil fuels. However, some advanced materials may pose risks to human health or the environment, as well as having the potential to create other unintended sustainability issues. Further, it is not clear whether the existing (inter)national legislation and test methods for chemicals (including nanomaterials) are 'fit-for-purpose' to cover the potential issues posed by advanced materials. Early identification of those issues is a first step for regulators (and innovators) to become prepared for possible action. Indeed it enables early anticipatory actions like pointing out to information gaps, concerns, and regulatory needs. Thus, providing the basis for relevant research and the development of guidance, test systems or adaptation of legislation to prevent possible negative impacts of newly developed materials. In this presentation, an early awareness and action system (Early4AdMa) that was developed within the OECD is presented. The system aims to systematically identify potential human health, environmental, sustainability and regulatory issues of advanced materials. The system is composed of two tiers. Tier 1 is a broad screening assessment. Tier 2 is a detailed assessment of potential issues of a selected advanced materials based on four sets of questions. Based on the identified issues in Tier 2, suggestions for follow-up action (e.g. research and/or regulatory activities) are identified. These can be communicated to regulatory decision makers, policy makers and risk assessors so that potential issues can be addressed early on. Further details on the different steps, scope and limitations, and notes on how to use the system will be presented. In addition, in the presentation, other activities towards regulatory preparedness of advanced materials that are being conducting within the OECD will be presented and discussed, amongst other the collaboration with the OECD Steering Group on the Safe-and-Sustainable-Innovation-Apporach (SSIA). The Early4AdMa system may help identify potential issues of newly developed materials, and thereby, aims to contribute to the delivery on solutions for societal and environmental challenges via application of advanced materials.

7.04.P-We567 Implementing Safe and Sustainable by Design (SSbD) approach in the design of biobased, recyclable multifunctional composites for automotive and aeronautical sectors

Elena Destro[1]*, Andrea Porcari*[1]*, Olmo Guagnetti*[1]*, Daniel Peral Crespo*[2]*, Ainhoa Tolentino*[2]*, Elvira Villaro Abalos*[3]*, Isabel Rodríguez-Llopis*[4]*, Leire Barruetabeña*[4]*, Alberto Katsumiti*[5]*, Cyrille Durand*[6]*, Christoph Olscher*[7]*, Florian Part*[7]*, Blanca Araujo*[8] *and Ana Branco*[8]*, (1)Italian Association for Industrial Research, Italy, (2)Onyriq Labs sl, (3)Avanzare Innovacion Tecnologica sl, (4)GAIKER Technology Centre, Basque Research and Technology Alliance (BRTA), Spain, (5)GAIKER Technology Centre, Spain, (6)TEMAS Solution GmbH, Switzerland, (7)University of Natural Resources and Life Sciences (BOKU), Austria, (8)SATURNTECH UNIPESOAL LD*
Advanced Materials (AdMs) are key to enable the green transition and are strategic for the transport sector, where a key driver to improve energy consumption is the adoption of lightweight materials, such as composites. Multifunctional composites are particularly interesting to reduce vehicle weight, for example by replacing components (e.g. embedding circuits to replace the use of wires) and improve efficiency, process and use conditions (e.g., health structural monitoring sensors into structural matrix). A breakthrough would be to have recyclable composites to replace existing plastic and (possibly) non-plastic components currently used. The Horizon Europe project REPOXYBLE (2023-2026, GA 101091891) is developing a new class of high-performance epoxy-biobased AdMs for the aeronautic and automotive sector, targeting safety, cost & energy effectiveness, recyclability, and thus sustainability. For this, a holistic and iterative approach incorporating the Safe and Sustainable by Design (SSbD) concept has been applied since the early stages of material design, to bring in-depth knowledge on the whole material life cycle and possible impacts of our product solutions, toward performance and sustainability optimization. REPOXYBLE is facing a combination of technical challenges, given the ambition to replace existing materials (epoxy resins for the automotive, titanium for aeronautic), without compromising performances. It will work to minimize the resource and energy demand during manufacturing, and to achieve high recyclability and re-use of the building blocks (monomers & hardeners) and additives via optimized chemical recycling. A Multi-Criteria Decision Analysis (MCDA), multidisciplinary approach is being used integrating qualitative to quantitative data related to six Lines of Evidence: Performance, Technological, Safety, Sustainability, Legal and Economic aspects. Raw materials selection and testing, safety assessment and preliminary LCA considerations run in parallel leading to the selection of materials to use for our composite solutions. REPOXYBLE took advantage of the multidisciplinary team of the project, involving partners from all over Europe covering the whole material value chain, and contribution from external experts. Current findings concerning methodologies, barriers and opportunities for practical implementation of SSbD, advancements in product solutions, will be presented.

7.04.P-We568 Learning from Safe-by-Design for Safe-and-Sustainable-by-Design: Mapping the Current Landscape of Safe-by-Design Reviews, Case Studies, and Frameworks

Akshat Sudheshwar[1]*, Christina Apel*[2]*, Klaus Kümmerer*[3]*, Zhanyun Wang*[4]*, Lya G. Soeteman-Hernandez*[5]*, Eugenia Valsami-Jones*[6]*, Claudia Som*[1] *and Bernd Nowack*[7]*, (1)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (2)Leuphana, (3)Institut für Nachhaltige Chemie und Umweltchemie, Leuphana University Lüneburg, Germany, (4)Technology and Society Laboratory, Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland, (5)RIVM, Netherlands, (6)University of Birmingham, United Kingdom, (7)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland*
With the introduction of the European Commission's "Safe and Sustainable-by-Design" (SSbD) framework, the interest in understanding the implications of safety and sustainability assessments of chemicals, materials, and processes at early-innovation stages has skyrocketed. Our study focuses on the "Safe-by-Design" (SbD) approach from the nanomaterials sector, which predates the SSbD framework.

In this assessment, SbD studies have been compiled and categorized into reviews, case studies, and frameworks. Reviews of SbD tools have been further classified as quantitative, qualitative, or toolboxes and repositories. We assessed the SbD case studies and classified them into three categories: safe(r)-by-modeling, safe(r)-by-selection, or safe(r)-by-redesign. This classification enabled us to understand past SbD work and subsequently use it to define future SSbD work so as to avoid confusion and possibilities of "SSbD-washing" (similar to greenwashing). Finally, the preexisting SbD frameworks have been studied and contextualized against the SSbD framework.

Several key recommendations for SSbD based on our analysis can be made. Knowledge gained from existing approaches such as SbD, green and sustainable chemistry, and benign-by-design approaches needs to be preserved and effectively transferred to SSbD. Better incorporation of chemical and material functionality into the SSbD framework is required. The concept of lifecycle thinking and the stage-gate innovation model need to be reconciled for SSbD. The development of high-throughput screening models is critical for the operationalization of SSbD. We conclude that the rapid pace of both SbD and SSbD development necessitates a regular mapping of the newly published literature that is relevant to this field.

7.04.P-We569 Safe and Sustainable Innovation Approach: Towards an agile system for dealing with innovation
***Lya G. Soeteman-Hernandez**[1], Mar Gonzalez[2], Bratati Kar[3], Cornelle Noorlander[4], Francis Peters[5], Araceli Sanchez-Jiménez[6], Hubert Rauscher[7] and Juan Riego Sintes[7], (1)RIVM, Netherlands, (2)Organisation for Economic Co-operation and Development (OECD), France, (3)Health Canada, Canada, (4)National Institute for Public Health and the Environment (RIVM), Netherlands, (5)Business at OECD (BIAC), France, (6)National Institute for Safety and Health at Work (INSST), Spain, (7)European Commission - Joint Research Center (JRC), Italy*
Advanced materials offer society economic and technological opportunities, but technological innovations pose a challenge to governance of human and environmental safety as well as to governance of sustainability due to the large difference in the pace between innovation and the development of suited governance. To cope with this difference in pace and move towards safe and sustainable innovations, an agile and robust system is needed that is pro-active and interactive, that deals with the fast pace of knowledge generation and helps to ensure that knowledge is transferred to adaptable safety and sustainability regulation. In this sense, the Safe and Sustainable Innovation Approach (SSIA) aims at reducing the time gap between the emergence of technological innovations and the development of suitable safety and sustainability assessment tools and frameworks. SSIA combines:

- Safe-and-Sustainable-by-Design (SSbD) concept, which is a central element of the EC Chemicals Strategy for Sustainability, recommends innovators to integrate safety and sustainability considerations as early as possible into the innovation process; and
- Regulatory Preparedness (RP) which aims to improve the awareness and anticipation of regulators to facilitate the development of adaptable (safety and sustainability) regulation that can keep up with the pace of knowledge generation and innovation of nanomaterials, nano-enabled products, and advanced materials.

Both the SSbD and RP concepts are supported by a process to share and exchange knowledge, information and views in a Trusted Environment (TE). SSIA thus relies on dialogue between innovators and regulators. SSIA brings significant cultural changes in comparison to current innovation management:

- SSbD incorporates considerations as early as possible in the innovation process thus the scope shifts from remediation (or precaution) to prevention.
- SSIA considers any concern on safety and sustainability, which may be generated by the innovation, from the design phase to the entire life cycle of any materials or articles obtained by this innovation.

The growing development, complexity, and opportunities brought by nano- and other advanced materials, are used as a case study for the development of the tools that should enable the implementation of SSIA. Work performed in the OECD Working Party for Manufactured Nanomaterials (WPMN) SSIA Steering Group will be presented.

7.04.P-We570 Sustainable product innovations for fast-moving consumer goods – Learning from companies' experiences for a more effective and accessible 'Safe and Sustainable by Design' framework
***Florence Bohnes**, Ian Malcomber, Sarah Sim, David Mason, Gordon Riley, Clare Rodseth and Evita Vandenbossche-Goddard, Unilever R&D Colworth, United Kingdom*
Advanced materials (including complex chemicals) represent a major opportunity for disruptive innovation as they can unlock novel benefits for consumers and manufacturers. In that context, it is essential to ensure that the new products and innovations related to these materials are safe and sustainable by design. The European Commission Joint Research Centre (EC JRC) has proposed the 'Safe and Sustainable by Design' (SSbD) assessment framework as an external, policy-supported methodology for sustainable product innovation. The framework is intended to support companies in their innovation journey by providing them with appropriate tools and methods.

Unilever is a global fast-moving consumer goods company with considerable portfolio diversity. Safety and sustainability are deeply embedded in our innovation process; a team of internal experts work closely with R&D teams from the earliest stage of product development. Hence, we support the ambition of the SSbD framework to integrate safety and sustainability in the core of innovation and help drive competitive and sustainable growth in the European Union.

Drawing on our downstream user point of view and our experience in designing safe and sustainable products for decades using our internal approaches, we offer some reflections on the SSbD framework proposed by the EC JRC. We have produced a case study in which we first describe our current approach to safety and sustainability during innovation. Our case study focuses on a biosurfactant used in Home Care products. Insights drawn from the case study are synthesised to offer recommendations for further development of the JRC SSbD framework. We focus our recommendations on methodological and technical aspects as well as practical feasibility of implementing the framework for companies of all sizes and with a range of in-house technical expertise in safety and sustainability.

7.04.P-We571 Safe, Sustainable and Recyclable by-Design (SSRbD) integrated approach applied to polymeric systems
*Sébastien Artous[1], Stephanie Desrousseaux[1], Lya G. Soeteman-Hernandez[2], Yvonne Staal[2], **Virginia Cazzagon**[3], Camilla Delpivo[3], Daniel Ganszky[4] and Simon Clavaguera[1], (1)Atomic Energy Commission (CEA), France, (2)RIVM, Netherlands, (3)Leitat Technological Center, Spain, (4)Geonardo Environmental Technologies Ltd. (GEO)*
A shift in mindset is required to ensure that newly developed materials integrate functionality with safety and sustainability aspects from the innovation phase through to the development of the final product. The Safe, Sustainable and Recyclable by-Design (SSRbD) concept identifies safety and sustainability hotspots early in the innovation and product development process to minimize potential hazards and exposure, maximizing sustainability while maintaining product functionality.

The purpose of this work is to present an integrated SSRbD approach to ensure SSRbD material development. The proposed method will assist material designers to integrate safety and sustainability assessments into the design process and facilitate dialogue with assessment experts. The integrated approach is an iterative process that considers the technology readiness level (TRL), avoids a potential gate effect, integrates a life-cycle vision and covers the five steps of the assessment of the safe-and-sustainable-by-design (SSbD) framework proposed by the European Commission (commission recommendation (EU) 2022/2510). The operationalization of the SSRbD integrated approach for polymeric materials is tested on three cases studies in the building, transport and the packaging sectors. The first step conducted early in the innovation process is to obtain an overview of each case study by filling a SSRbD matrix including safety and the three pillars of sustainability (environmental, social and economic) mapped across all life cycle stages. Based on the analysis of the SSRbD matrix, a second iteration loop is carried out at the middle stage of the innovation process.

The challenge is to establish the life cycle and development diagram (LCDD). The next steps will involve merging three life cycle inventories (hazard, exposure, LCA/LCC) into one to improve assesments efficiency. This integrated approach, developed and tested for plastics, could contribute to the operationalization of the SSbD framework and can easily be applied to other sectors.

7.04.P-We572 Safe and Sustainable by Design Framework for Advanced Nanomaterials: The Harmless Approach
*Veronique Adam DR[1], Wendel Wohlleben, Dr.[2], Beatrice Salieri Dr[1], Veronica Di Battista[2], Eugene Van Someren[3], Susan Dekkers[3], **Elise Morel**[4] and Blanca Suarez Merino[1], (1)TEMAS Solutions GmbH, Switzerland, (2)BASF SE, Germany, (3)TNO, Netherlands, (4)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*
The establishment of a European Framework for 'Safe and Sustainable by Design' (SSbD) for chemicals and materials is an important step towards the production of safer and more sustainable products. Yet, it requires resources that are not compatible with the expected commercial value at early innovation stages and makes use of methods that are not fully applicable to emerging materials such as advanced materials (AdMa). The purpose of the HARMLESS approach is to build a framework that considers variability in data availability and resources along the innovation process, is applicable to nano-enabled AdMa and is cost-effective. This framework is aligned with the EU framework, complemented with a flexible stage-gate model and implements New Approach Methodologies (NAMs) tailored to nano-enabled AdMa SSbD assessment, for both innovators and regulators.

Making sure there was mutual understanding between safety and sustainability communities, knowledge and know-how were gathered from experts within the HARMLESS consortium to create a knowledge-exchange platform leading to a blueprint of the HARMLESS framework. This was tested on industrial case studies to align with industry.

The HARMLESS framework includes three innovation stages: ideation, lab scale and pilot scale. It starts with the categorization module of AMEA (Advanced Material Earliest Assessment) at the first innovation stage, testing the applicability of the framework to the business case. At each innovation stage, five different modules enable the assessment of 1) intrinsic safety, 2) occupational and environmental safety at production, manufacturing and end-of-life, 3) consumer and environmental safety at use, 4) environmental sustainability at production and manufacturing and 5) environmental sustainability at use and end-of-life. Within each module, design principles are given to guide the user in making products as safe and sustainable as possible, and methods and tools are suggested to facilitate the SSbD assessment. NAMs are prioritized to make SSbD assessment as cost-effective as possible. After all modules are completed, a gate enables the user to balance the safety and sustainability of their product with cost and performance, thereby assessing the relevance of going to the next innovation stage. This framework guides the creation of an online decision support system, which will be publicly available to help industry making safer and more sustainable AdMa-containing nano-enabled products.

7.04.P-We573 A science-based innovative dashboard tool to operationalise Safe-and-Sustainable-by-Design

Leo Posthuma[1]*, Markus Viljanen*[1]*, Lisa Tostrams*[2]*, Jaap Slootweg*[1]*, Elmer Swart*[1] *and Lya G. Soeteman-Hernandez*[2]*,*
(1)National Institute for Public Health and the Environment (RIVM), Netherlands, (2)RIVM, Netherlands

The “Safe-and-sustainable-by-design” concept is one of the key innovations in the European Green Deal, representing a fully pro-active stance that is taken to phase out harmful chemicals and ensure that new chemicals are designed to serve desired societal functions with no or minimal harm. One of the biggest challenges in applying SSbD in practice is the lack of data early in the innovation process, because novel compounds are typically characterized by absence of data. How then to operationalize a good idea (SSbD) with (almost) no data?

This presentation is based on a forward-looking vision on how an ideal and operational environmental safety assessment for data-poor/lacking substances can be performed. A dashboard was envisaged, in which companies can enter simple information, such as the CAS-number of a chemical, to yield information on (un)safety in the format of a meaningful heatmap. The dashboard interface (being use-oriented also for Small and Medium Enterprises) is based on the innovative use of available ecotoxicity data. The scientific basis for bridging data gaps in ecotoxicity data was adopted from Viljanen en al. (2023) SAR QSAR Env Res 34 (765–788).

In the presentation, the dashboard concept, its utility and its scientific underpinning are shown for a sample of ecotoxicity data. That is, a sample of ecotoxicity tests data taken from a curated database of >250k aquatic ecotoxicity data (underlying Posthuma et al., 2019, ET&C) was used to predict all missing ecotoxicity data for the full matrix of species*compound pairs. The thus-completed species*chemical matrix was sorted to yield an ecotoxicity heat map. The heat map represents the full array of empirical “all-species” Species Sensitivity Distributions, which can in turn be used for hotspot identification and SSbD explorations.

If so desired, users can see whether and in how far a novel molecule, designed for a function based on CAS-number, may pose harm in comparison to others. Outputs can be comparatively used to head for a “green portfolio” of company products, derive chemical footprints of products and much more. The prototype dashboard is being further developed, as the underlying ways for the development of practical and easy-to-use tools to bridge the data gap can serve multiple important purposes in SSbD application, environmental protection, assessment and management.

7.04.P-We574 Socio-Economic Life Cycle-based Framework for Safe and Sustainable by Design of Advanced Materials

Stella Ivanova Stoycheva[1]*, Alex Zabeo*[2]*, Lisa Pizzol*[3]*, Danail Hristozov*[3] *and* ***Katharina Mayer***[4]*, (1)Yordas Group, United Kingdom, (2)GreenDecision S.r.l., Italy, (3)Ca' Foscari University of Venice, Italy, (4)Yordas Group, Germany*

This study describes an innovative approach to socio-economic assessment of (advanced) engineered nanomaterials and nano-enabled products (NEPs) to support safe-and-sustainable-by-design (SSbD) decision making by industries in the early stages of product development. This semi-quantitative methodology is developed based on a sound conceptual framework grounded in the combination of social life cycle analysis and multi-criteria decision analysis methods and supports decision making based upon socio-economic impacts assessed over the full life cycle of a product. To facilitate its application by industries, the methodology was developed as an excel-based tool and is currently being transferred to a web-based self-assessment tool. This easy-to-use, cost- and time-efficient tool can guide users through their SSbD decision making regarding newly developed nanomaterials and NEPs and can also be applied to re-evaluate existing materials and NEPs in order to improve their sustainability from a socio-economic perspective. The relatively low requirements of this tool regarding the level of efforts and expert knowledge needed for its application make it a good starting point for initial assessment to highlight socio-economic issues in the value chain. As a stepping stone for a more holistic assessment, the S-LCA self-assessment tool is now being integrated as a mid-level sustainability assessment in the H2020 SUNSHINE project e-infrastructure for SSbD of MCNMs. Currently, testing and refinement of the tool in real case studies is being conducted including but not limited to photocatalytic ZnO/Silica complexes used in scratch and abrasion-resistant coatings for the construction sector, core–shell silicon carbide (SiC)–titania (TiO_2) anti-stick coatings for use in consumer products and graphene oxide-based materials for electrodes and energy storage (batteries).

This work has been carried under the H2020 Gov4Nano and SUNSHINE projects.

Gov4Nano has received funding from the European Union’s Horizon 2020 Research and Innovation Programme under Grant Agreement 814401.

SUNSHINE project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 952924.

7.04.P-We575 SSbD application: widening Step 1 to environmental, economic and social considerations for early stage decision making

Sonia Martel Martín[1], Mario Santiago Herrera[1], Jesús Ibáñez[1], Julieta Díez Hernández[1], ***Natalia Fernández Pampín***[2]*, Rocio Barros[3], Carlos A Rumbo[4], Marta Sendra[5] and Ana García Moral[2], (1)University of Burgos, Spain, (2)Iccram, Universidad de Burgos, (3)Universidad De Burgos, Spain, (4)Iccram, University of Burgos, Spain, (5)Spanish National Research Council (CSIC), Spain*

The metallization of platics' industry emerged 50 years ago combining the benefits of processing, lightweight and cost of plastics, together with the durability, tribological and anticorrosion properties of metals. However, the traditional processing to obtain the metalization of polymers involves both, highly toxic substances (Cr 6) and also critical raw materials (Paladium). The concern about these substances is leading the research towards greener alternatives for plastics metalization.

FreeMe Project supports the development of two novel technologies, not yet systematically tested from the safety and sustainability perspective. FreeMe aims to couple the research and development of these technologies with an iterative safety and sustainability. This approach will support the identification of hotspots and criticalities and ellaborating recommendations for improvement before the processes evolves in the TRL, avoiding further costs and research efforts.

The application of the SSbD has proved to be a powerful tool to identify the most critical aspects of the novel technologies. The SSbD strategy has been temporalized for its application in this Project, advancing in paralel to the technical research. The first assessment (Step 1. Intrinsic properties) was carried out through the identification in the ECHA system of the compounds used in the novel and classical technologies. Step 1 can be addressed at very early stages of the development (TRL 2-3), providing guidance for the selection of the compounds.

Even though it is not foreseen in the SSbD framework, it was found useful to develop a sustainability pre-assessment. The environmental review was focused in the quantification of the impacts associated to the production of each of the substances under study, through literature and databases information (EcoInvent). Additionally, a literature review of the traditional technology, stablishing an environmental baseline.

From the economic perspective, the cost for the raw materials can be estimated from a literature and market, including environmental impact through a monetary valuation into the final cost. The materials and chemicals involved were also mapped to identify the main producers worldwide as well as the value chains and global trends associated to their production and commercialization. This will support economic and social decision making at a very early stage incorporating the sustainability dimension at low TRLs.

7.04.P-We576 Ensuring regulatory Alignment in the Research & Innovation of five market-relevant Advanced Materials

Steffi Friedrichs*, AcumenIST*

The MACRAMÉ Project on 'Advanced Characterisation Methodologies to assess and predict the Health and Environmental Risks of Advanced Materials' is fully aligned with the EU ambitions to secure the safety and sustainability of new chemicals, materials, products and processes in order to strive for zero pollution and toxic-free environments, as addressed in the EU's Chemical Strategy for Sustainability (2020), and in the European Green Deal (2019 & 2021); in doing so, the Project concentrates on methodologies that are applicable to nanomaterials, and widens them to 'Advanced Materials**'** (AdMas) – a material category that includes but surpasses that of 'nanomaterials' (EU, 'Definition of a Nanomaterial') - in commercialised products and that are aligned with the future-oriented innovation, safety and sustainability considerations of the OECD (OECD (2020)), the EU (EU (2022)), and several of its Member States (e.g. Germany (2021)). This will be achieved through development and demonstration of novel methodologies, and by advancing their harmonisation & standardisation on three MACRAMÉ Material Families of inhalable carbon-based AdMas of various morphologies and dimensions (Tiwari *et al.* (2012)), beyond spherical particles: (a) graphene-related material (GRM), (b) carbon nanofibres (CNFs), e.g., carbon nanotubes (CNTs), and (c) Poly Lactic-co-Glycolic Acid (nano)particles (PLGA). The focus on carbon-based AdMas addresses unsolved detection and characterisation issues, especially in complex media. In doing so, MACRAMÉ builds on >15 years of research and innovation (R&I) and knowledge pooling in nanosafety, formed through numerous European and international collaborations. MACRAMÉ will add value to the results of collaborations, such as the Malta-Initiative, and the Graphene Flagship Validation Service and Standardisation Committee, to proactively support EU industries in becoming world-leaders in clean technologies and products and achieving the Green Deal's ambitious timeline.

To ensure the maximum impact and engagement with industrial actors, policy-informing and –making, as well as standardising bodies, two MACRAMÉ Regulatory Risk Assessors Summits will be to enhance the chances of acceptance and advancement of the developed methods toward standardisation and harmonisation.

The discussions of the 1st Summit will be carefully reviewed and its results will be both published as part of a Project deliverable report and presented at the SETAC Europe 34th Meeting.

7.04.P-We577 Enhancing the European Commission's Safe and Sustainable by Design Framework for Chemicals and Materials

Irantzu Garmendia Aguirre[1]*, Elisabetta Abbate[2], Davide Tosches[1,3], Hubert Rauscher[3], Kirsten Rasmussen[3] and Serenella*

Sala[2], (1)European Commission - Joint Research Centre (JRC), Belgium, (2)Sustainable Resources Directorate, European Commission - Joint Research Center (JRC), Italy, (3)European Commission - Joint Research Center (JRC), Italy
Key for the Commission's vision for achieving the green industrial transition is the safe and sustainable by design (SSbD) framework developed by the JRC. It proposes a methodology that enables the evaluation of the safety and sustainability aspects of chemicals, materials and products (SSbD) before they are placed on the market, and can as well be applied to goods already on the market. The framework integrates safety and sustainability dimensions for the first time. In addition, it enables safety and sustainability considerations throughout the entire life cycle of chemicals, materials and products, to be assessed from the beginning of the R&D until end-of-life, which is a shift in the current practice. The framework can also be used as a tool for comparative assessment, which will be key to replace the most harmful chemicals and materials with more desirable alternatives and this way support substitution.

In order to improve the relevance, reliability and operability of the SSbD framework in R&I activities, the European Commission (EC) published in December 2022 a Recommendation establishing a European assessment framework for safe and sustainable by design (SSbD) chemicals and materials. The Recommendation establishes a two-year testing period in which stakeholders are invited to test the framework and provide feedback.

The aim of the presentation will be to raise awareness and promote the Safe and Sustainable by Design concept, to present the results of the first testing period and to inform on the on-going and future activities.

7.04.P-We578 Testing Tools for Suitability for SSbD in Early Phases of Innovation, Applied to BPA and Alternatives
***Maja Halling**[1], Tomas Vilhelm Rydberg[1], Ivo Iavicoli[2], Spyros Karakitsios[3], Magnus Lofstedt[4], Veruscka Leso[2], Bernd Nowack[5], Fotini Nikiforou[3], Dennis Sarigiannis[3], Rosella Telaretti Leggieri[1], Vrishali Subramanian[6], Joanke van Dijk[7] and Jaco Westra[6], (1)Swedish Environmental Research Institute (IVL), Sweden, (2)University of Naples Federico II, Italy, (3)Aristotle University of Thessaloniki, Greece, (4)European Environment Agency (EEA), Denmark, (5)Technology and Society Laboratory, Empa - Swiss Federal Laboratories for Material Science and Technology, Switzerland, (6)National Institute for Public Health and the Environment (RIVM), Netherlands, (7)Empa – Swiss Federal Laboratories for Material Science and Technology, Switzerland*
Within the PARC project (https://www.eu-parc.eu/), gathering a large number of research organisations and public bodies, one Task deals with Safe and Sustainable by Design for chemicals and materials, SSbD, in relation to the framework described by the European Commission in a recent study [1]. Experience of applying the suggested SSbD framework is so far limited. Various EU projects (e.g. PARC, IRISS) and national initiatives (e.g. Mistra SafeChem in Sweden) are in the process of advancing and/or evaluating tools for SSbD for a range of use cases. The authors are co-leading the work within PARC to test tools in case studies for SSbD and reports here on advancements in a case study on Bisphenol-A and selected alternatives.

In addition to Bisphenol-A, one similar compound, Bisphenol AP; and a significantly different one, Iso-sorbide, were chosen as test substances. Two rather broadly formulated application areas were also chosen for the further work, substituting BPA in polycarbonate food-contact bottles, and substituting BPA in an epoxy coating.

The purpose of the testing was not to find an optimum substitute, but rather to understand what different tools may provide in relation to the chemicals, applications, and given limited information.

The tool testing procedure called for volunteering experts to run one or several tools among the previously suggested ones, in the appropriate step of the SSbD framework: 1. Hazard assessment, 2. Exposure assessment, 3. Use scenario environmental and health risk, 4. Life cycle environmental sustainability and 5. Socioeconomic sustainability.

An important first part of the tool testing procedure was to provide only the structure in one or the other form, and the two selected intended application areas, in order to simulate an exploratory innovation stage.

initial findings:
- The complexity of SSbD lies in the breadth of assessment types that is required to cover the whole framework
- Safety and sustainability aspects have traditionally been dealt with separately; experts in the two domains have different backgrounds, training, and use of words. A lot of effort is needed to create a common understanding of SSbD.
- In early phases of innovation qualitative expert judgement, semi-quantitative models, and computational models, all have a role to play. Interestingly, this is a common denominator for all SSbD steps. And predictive models are needed, and are also available, for all steps.

7.04.P-We579 Safe and Sustainable by Design strategies validated for toxicity reduction applied to active nanomaterials with antibacterial and antiviral properties
***Arantxa Ballesteros Riaza**[1], Javier Alcodori[2] and Carlos Fito[3], (1)Processes and Products Safety Unit, Technological Institute of Packaging, Transport and Logistics, Spain, (2)Processes and Products Safety Unit, Technological Institute of Packaging, Transport and Logistics (ITENE), Spain, (3)Safety and environmental monitoring, Technological Institute of Packaging, Transport and Logistics (ITENE), Spain*

The development of coatings with antiviral and antimicrobial properties based on active nanomaterials (ANM), such as bio-based active materials and inorganic nanoparticles, are a promising alternative for minimise the risk of spread infections from harmful pathogens in different high traffic objects surfaces (metal, plastic and textiles).

However, these developments could have an impact on environmental and human health if the substances used for the coatings developments are not safe or have bad performance in terms of durability or efficiency. Therefore, the implementation of safe- and sustainable-by-Design (SSbD) approaches is a key element to guarantee their harmlessness. Developing ANM safely-tailored for the final applications when they will be used in coatings, with reduced cytotoxic and ecotoxic effects, has been one of the main goals of the HE SUSAAN Project.

The antibacterial power of zinc oxide nanoparticles is well known, but they also have effects at the cellular level and on aquatic organisms. One of the strategies applied to some of the ANMs developed in the project has been the encapsulation of these nanoparticles in silica, in order to minimise their hazards. To validate the reduction, *in vitro* toxicological studies have been performed on human cell lines representative of the main entry routes into the organism (inhalation, dermal, oral) to evaluate cytotoxic and dermal irritation effects, as well as bioassays using aquatic organisms according to OECD procedures (201, Algae growth inhibition test; and 202, *Daphnia sp.*, acute immobilization test).

The results have shown a significant reduction of the toxic effect of ZnO nanoparticles encapsulated in silicon oxide on cell viability in the case of the three lines used (HaCaT, A549 and CaCo-2), as well as in aquatic organisms.

Acknowledgement
The authors would like to acknowledge SUSAAN Project (SUStainable Antimicrobial and Antiviral Nanocoating). Horizon Europe Programme for Research and Innovation under the Grant Agreement N° 101057988.
In particular, special acknowledgement to partner Ludererra, for developing and supplying the nanoparticles and their encapsulants, and providing them for the development of the studies carried out.

7.04.P-We580 Challenges in the Evaluation of the Environmental Sustainability of Advanced Materials: the Case of Printable Electronics

Martina Pelliconi[1,2]*, Vito Vurro*[3]*, Beatrice Fraboni*[3] *and Serena Righi*[2,3]*, (1)Department of Physics and Astronomy "Augusto Righi", University of Bologna, Bologna, Italy, (2)Interdepartmental Centre for Research in Environmental Sciences, University of Bologna, Italy, (3)Department of Physics and Astronomy "Augusto Righi", University of Bologna, Italy*
Printed electronics (PE) have emerged as a possible approach for realizing cost-effective wearable and conformable devices. Over the course of the last two decades, organic semiconductors have been employed in a plethora of applications promising to revolutionize the market for everyday-life electronic circuits and sensors. Organic semiconductors are particularly interesting due to their compatibility with solution process deposition techniques compatible with industrial scale production (such as screen printing, roll-to-roll process and inkjet or 3D printing). Our research uses these fabrication processes to realize devices on glass, plastic and textile substrates for application in gas sensing, physiological parameter, analytes and radiation detection. Even though PE is a potential great breakthrough for an environmentally safe electronic production, researchers of the field are still struggling to ensure their compliance with Europe's Green Deal goals. Some challenges are common for all LCAs involving innovative processes, like the foreground data collected at lab-scale, which frequently don't match those of the operating production facilities. The required upscaling procedures also bring along a higher level of uncertainty within the impact assessment. Moreover, a new set of challenges are likely to be encountered when working with advanced materials (AdMa). To ensure a safe and sustainable by design approach, early-stage environmental evaluations must be performed. This often leads to the impossibility of carrying out a cradle-to-grave LCA because AdMa applications are still unclear. Therefore, system boundaries are narrowed down, and the functional unit refers to the minimum viable product, thus excluding other non-essential standard components and custom design parts. Also, the Life Cycle Inventory poses challenges, as the manufacturing process of AdMa often rely on uncommon substances for which datasets are not available, nor there is an urge to create them, since they would only be used by a niche of analysts. This situation is frequently coupled with limited literature and with data that cannot be early-published, due to the secrecy and non-disclosure agreements related to intellectual properties rights and patents. Therefore, to further the studies on AdMa, these issues need to be addressed, as both researchers and industrial partners would find value in building a network of shared data, methodology and knowledge.

7.04.P-We581 Assessing the Impact of Nanomaterials on D. magna, R. subcapitata, and E. foetida: Towards Safer and Greener Nanomaterials through SSbD strategies - Titanium Dioxide Nanoparticles as a case study

Javier Alcodori*, Processes and Products Safety Unit, Technological Institute of Packaging, Transport and Logistics (ITENE), Spain*
Nanomaterials, with their unique physicochemical properties, are promising for industrial applications such as electronics, medicine, and consumer products. However, their potential impact on human health and the environment is concerning. As nanomaterials enter the environment, they can interact with biological systems, causing adverse effects on organisms and ecosystems. Toxicity and ecotoxicity of these nanomaterials, rely mainly on their physicochemical properties, such as size, shape, surface charge, and solubility.

Release of nanomaterials into the environment, poses threats to ecosystems, raising questions about their long-term ecological consequences. To address these challenges, Safe- and Sustainable-by-Design principles are being developed and applied to engineer nanomaterials to reduce their toxicity and its environmental impact, and promotes the use of green synthesis methods, optimizing energy and resource use and design materials with minimal ecological impact.

Key SSbD strategies include (1) Hazard assessment and identification of nanomaterials with potential hazardous effects (2) Modifying the physicochemical properties of nanomaterials to reduce their toxicity and ecotoxicity, (3) Applying environmentally friendly methods for the synthesis and manufacturing of nanomaterials (4) Designing nanomaterials to reduce their environmental persistence and promote biodegradation, (5) Life cycle assessment, assessing the environmental and health impacts of nanomaterials throughout their entire lifecycle.

In the context of SbD4Nano and DIAGONAL projects ecotoxicological studies have been carried out, monitoring the effect of nanoparticles on different organisms, such as *Daphnia magna*, *Raphidocelis subcapitata*, and *Eisenia foetida*. This ecotoxicity assessment has not only been carried out to assess the effects of nanomaterials on these organisms but has also played a key role in the modification of nanomaterials following SSbD strategies to obtain safer and more sustainable nanomaterials with a reduced impact on health and the environment.

The ecotoxicity tests carried out should always be standardised, so that the tests are done in accordance with what is agreed by different organisations providing reliable results. The test on *Raphidocelis subcapitata* was carried out according to OECD 201, the test on *Daphnia magna* according to OECD 202 and the test on *Eisenia foetida* according to OECD 207.

7.04.P-We582 Safe and Sustainable by Design: Case Study of Microreactors and Bionanocompounds for Wastewater Treatment

*Amaimen Guillén-Pacheco[1], **Olga Patricia Fuentes Daza**[2], Verónica Akle[1], Johann F. Osma[1] and Guido Sonnemann[2], (1)University of Andes, Colombia, (2)University of Bordeaux, France*

Microfluidics, situated at the convergence of science and technology, is an envolving field dedicated to crafting small-scale devices for manipulating fluids and objects to achieve various functionalities, including environmental and biomedical analyses [1]. It showcases the potential of microreactors and bionanocompounds as a viable solution for remediating water sources contaminated by dyes from the textile industry. To ascertain their suitability, life cycle assessment (LCA) and operational efficiency analysis have been conducted [2]. This study reveals a promising pathway for designing innovative wastewater treatment systems that integrate high-performance microreactors and bionanocompounds. Moreover, the evaluation of potential toxicity risks of these nanoparticles have been conducted using a zebrafish animal model [3]

In aligment with the "Safe-and-Sustainable-by-Design" (SSbD) approach, this study proposes for integrating safety and sustainability aspects into the application of bionanocompounds for wastewater treatment. The study aims to identify and address industrial and regulatory challenges associated with this process. Following the guidance and initiatives of the European Commission, this study seeks to align its recommendations with broader regulatory frameworks, thereby promoting the responsible and sustainable use of innovative technologies.

Furthermore, this study delves into the application of the SSbD framework, emphasizing its potential impact on the design and implementation of wastewater treatment systems. By incorporating SSbD principles, the study envisions a comprehensive and proactive approach to the development of bionanocompounds, ensuring their safety, sustainability, and efficacy. Ultimately, the research aims to contribute valuable insights and recommendations to guide future endeavors in achieving a safer and more sustainable application of bionanocompounds in wastewater treatment processes.

7.04.P-We583 Investigation of ecotoxicological effects of fibrous and platelet-shaped advanced materials for deriving adapted testing strategies - the project FaPlaN

***Dana Kühnel**[1], Carmen Wolf, PhD[2] and Karsten Schlich[3], (1)Helmholtz Centre for Environmental Research (UFZ), Germany, (2)Institute for Environment & Energy, Technology & Analytics - IUTA e.V., Germany, (3)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

Advanced materials are a very heterogeneous group of materials, and used in many applications. Responsible use of these materials also includes the identification of potential threats to people and the environment as quickly and as precisely as possible. Hence it is unclear to date, whether OECD test methods in the field of ecotoxicology (already established and adapted for testing nanomaterials) may also be applicable for this class of materials.

Due to their special properties, fibrous and platelet-shaped materials represent advanced materials for which a reliable assessment of a potential environmental hazard based on the available test methods is challenging. The project "FaPlaN" presented here therefore aims to obtain information on the mechanisms of action (MoA) and thus a mechanistic understanding of potential toxic effects exerted by fibrous and platelet-shaped advanced materials. Based on this, methods will be adapted which will allow to identify related effects. By this, ecotoxicological assessment will be facilitated in the long term.

This poster will present results from a literature review on the effects of fibrous and platelet-shaped advanced materials in aquatic organisms, with a focus on identifying MoA. In addition, an initial proposal for test systems that will potentially be part of the future test strategy will be presented.

However, the main aim of this poster is to exchange experiences with other (eco)toxicologists to learn more about possible mechanisms of action and to take these into account when adapting the testing strategies as the project progresses. There are three key questions, which are of main interest.

Key question 1: Which physical-chemical material properties must be considered?
Key question 2: Which MoA are relevant for fibrous and platelet-shaped advanced materials?
Key question 3: How need test methods/test strategies be adapted for fibrous and platelet-shaped advanced materials?
Acknowledgement - The project FaPlaN is financed by the German Federal Ministry for the Environment, Nature Conversation, Nuclear Safety and Consumer Protection, Refo-Plan, FKZ: 3723 66 401 0.

7.04.P-We584 Eco/Genotoxicity Assessment Of Yeast-based Natural Astaxanthin Obtained Using Bio-Based Solvents
Amanda dos Santos[1], *Cassamo Ussemane Mussagy*[2], *Gabriely Fernanda Groto Militão*[3], *Jéssica C. S. de Oliveira*[4], *Gisela de Aragão Umbuzeiro*[3] *and Valéria de Carvalho Santos-Ebinuma*[1], *(1)School of Pharmaceutical Sciences - São Paulo State University, Brazil, (2)Facultad de Ciencias Agronómicas y de los Alimentos - Pontificia Universidad Católica de Valparaíso, Chile, (3)Faculdade de Tecnologia, Universidade Estadual de Campinas (UNICAMP), Brazil, (4)School of Technology - University of Campinas, Brazil*
It is already known about the widespread use of synthetic pigments in various industrial segments, and their potential to cause adverse effects on human and environmental health. The development of natural pigments, such as carotenoids, within the principles of green chemistry has been explored. Among them, it stands out that processes should be designed to use and generate substances that possess little or no toxicity to human health and the environment. Thus, our objective was to evaluate the aquatic toxicity and mutagenicity of microbial carotenoids (i.e., astaxanthin-rich extract) obtained from the wet biomass of the yeast *Phaffia rhodozyma* in a biorefinery approach, using bio-based solvents for solid-liquid extraction. Aquatic toxicity was evaluated using acute tests with the freshwater microcrustacean *Daphnia similis*, the marine amphipod *Parhyale hawaiensis*, and the fish embryo test (FET) with the zebrafish (*Danio rerio*). Mutagenicity was evaluated using an *in vitro* bacterial reverse mutation assay, the *Salmonella* microsome test, applying a battery of 5 strains (TA97a, TA98, TA100, TA102, and TA1535 of *Salmonella enterica* serovar Typhimurium) with the presence and absence of exogenous metabolic activation (+/-S9 mix). For aquatic toxicity tests, the data were modeled by a generalized logistic model. The data from the mutagenicity were analyzed using ANOVA/Tukey's test followed by a linear regression using the Bernstein model. The astaxanthin-rich extract presented acute toxicity to *D. similis* with a 50% effect concentration (EC50) of 5.7 mg/L (1.9-18.0). The extract did not present acute toxicity to *P. hawaiensis*. In the FET test, the extract induced only low toxicity in all tested concentrations (≥ 10% mortality), and at the end of exposure, the larvae that survived did not present any sublethal effects. The astaxanthin-rich extract was not mutagenic in the strains of *Salmonella* TA97a, TA98, TA100, TA1535 +/-S9, and TA102 +S9. For the strain TA102 -S9, the extract showed toxicity and was re-tested in non-toxic concentrations, and a negative response was obtained. The astaxanthin-rich extract has low toxicity for both *Daphnia* and fish and was not toxic for *P. hawaiensis*; it also was not mutagenic under the tested conditions, revealing a good option for application with lower impact. To better understand the impact of the entire production process, toxicity and mutagenicity tests will also be performed with the bio-based solvents used.

7.04.P-We585 Engaging chemists in ethical deliberations of relevance for chemical management
*Dasha Kaluyk, **Gunilla Oberg**, Emma Davy and Oksana Nadybska, University of British Columbia, Canada*
Chemistry plays a central role in virtually all societal areas such as health, food, energy, housing, transportation, clothing and hygiene. It is therefore not surprising that the chemical industry is one of the fastest growing sectors in society. While bringing many benefits, the chemical industry also brings harms to humans and the environment. This means that any potential benefits of chemical innovations must be weighed against the potential harm. With the increasing importance and impact of the chemical sector, it is crucial that chemists engage in ethical deliberations of relevance for chemical management and use their expertise to contribute to wise decisions. Such deliberations are complicated not only because it is challenging to assess the potential harm of chemicals but also because the 'goods' and the 'bads' are unequally distributed in society, with the most vulnerable populations commonly more exposed to hazards than other groups.

Some argue that chemists, with their specialist knowledge, have a moral obligation to engage in science-based considerations, particularly those that involve trade-offs. To be able to contribute constructively, chemists need to have a basic understanding of what it means to engage professionally in ethical deliberations of relevance for chemical management. Chemistry education does, however, rarely include learning how to identify and weigh aspects of relevance for different interest holders such as the industry, governments, consumers, disproportionally exposed groups, and the general public.

This presentation analyzes ethical guidelines for chemists in light of research on experts' moral obligations and discuss in what ways a strengthening of ethical standards in the field of chemistry might benefit the sector and society. It describes a recently launched seminar-based undergraduate honors class where students learn to identify ethical dilemmas and develop alternative action plans, using a case-study approach.

Track 8. Special Sessions

8.01 A Snapshot on Weapons and Military Chemicals in the Environment - Present Issues and Legacies from the Past

8.01.T-01 The impact of Chemical Warfare Agents in the Environment

Miguel A. Sierra, *Universidad Complutense de Madrid, Spain*

To understand the impact of chemical warfare agents (CWA) in the environment, it is necessary first to understand what a CWA is. According to the Organization for the Prohibition of Chemical Weapons (OPCW), integrating the Chemical Weapons Convention (CWC), chemical warfare agents (CWAs) are chemicals used to cause intentional death or harm through their toxic properties. Several incorrectly denominated chemical warfare agents are not included within this definition. Herbicides like 2,4-D and 2,4,5-T (orange agent), dioxines, white phosphorous and many other chemicals that have been used in war, having serious environmental impact fall outside this definition.

This presentation will focus on the impact of OPCW Schedule I chemicals in the environment.[1] Lessons learned from the massive use of CWA in the WWI and the Iran-Iraq war pointed to devastating effects in the environment (some remaining after more than 100 years of their use). Moreover, the enormous stockpiling of chemical weapons derived from the Cold War still has consequences. It should be noted that under the CWC premises, it is required not only the complete destruction of chemical weapons (CWs) but also mandates that environmental and public health be fully protected during the process of disarmament and disposal. The CWC specifically outlaws such disposal methods as open-pit burning, land burial, and sea-dumping. The procedures to destroy CWAs, rendering these chemical harmless to the environment, have been exquisitely tuned-up during the last 25 years, and they will be discussed. Despite the completely destruction of the declared CWs by the OPCW states parties, abandoned chemical weapons in projectiles and other dispersion media, together with uncontrolled dumping of munitions or raw CWA in several places around the world, have serious consequences for the environment and human beings. Approaches to solving this environmental problem will be presented.

[1] Fort the definition of Schedule 1 Chemicals see: https://www.opcw.org/chemical-weapons-convention/annexes/annex-chemicals/annex-chemicals.

8.01.T-02 Training activities in military ranges in Italy: environmental and health protection issues

Danilo Coppe[1] *and Manuele Bernabei*[2]*, (1)Istituto Ricerche Esplosivistiche, Italy, (2)Italian Air Force, Italy*

The training activities of the Italian Armed Forces are carried out in 86 military ranges distributed throughout the national territory. These activities, which produce potentially polluting emissions and residues for the environment and human health, are fundamental to ensure the country has a prepared and effective defense instrument.

The growing attention in society regarding environmental protection, and the health/safety of workers has characterized the Italian political scenario in the last 30 years. At the same time the operational training in military ranges of the Armed Forces has been even more necessary due to their commitment outside national borders.

The Armed Forces growing awareness to environmental issues in operational training activities results in environmental regulations for fire activities carried out within all of Italian military ranges, monitoring the environmental matrices with chemical assessments and with numerical models to predict the dispersion of the polluting substances produced and, finally, with holding training courses for environmental experts. These activities were conducted in cooperation with the national environmental agency (ISPRA), the national health institute (ISS) and the renewable energy agency (ENEA).

This work examines two case studies involving two military ranges present in Sardinia (Salto di Quirra and Capo Teulada) where several studies defined their chemical and geolithological characterization. The results highlight the exceeding of some concentration limit values (i.e. arsenic and antimony) were due to geolithological variations in the composition of the soil rather than to military activities. The presence of uranium depleted was never found, and the use of thorium-containing weapon systems did not entail any radiological relevance for the environment. It was also determined, through studies on the dispersion of pollutants, that discontinuous and infrequent emission produced by weapon systems and their rapid dilution in the atmosphere, never led to exceeding the limit values or the environmental criticalities which characterize, for example, urban centers with a high density of automotive circulation.

The military ranges in Italy were established between 1950 and 1980 and half of them (43 out of 86) are today overlapped or adjacent to protected areas defined by European directives for the protection of habitats and species, approved in Italy in the 2000s, 30 years after the establishment of those 43 military ranges.

Finally, based on the European database Natura 2000, it results that habitats and species in those areas have remained unchanged since 2012 until today. This demonstrates how the existence of military ranges since the middle of the last century constitutes a potential source of pollution but, in fact, still represents today an effective defense against anthropic settlements for the protection of habitats and species.

8.02 Are We There Yet? – Ways Forward for Mechanistic Effect Modeling in Environmental Risk Assessment

8.02.T-01 Industry opinion on model development and submission – Challenges and requests

Nika Galic[1] *and Thomas G Preuss*[2]*, (1)Syngenta AG, Switzerland, (2)Bayer AG - Crop Science Division, Germany*

Mechanistic models are a promising tool for the environmental risk assessment of plant protection products. This was also acknowledged by regulating authorities, such as EFSA, by providing guidance on how to develop and document models (EFSA Good Modeling Practice) and how to apply state of the art of Toxicokinetic/Toxicodynamic (TKTD) effect models for regulatory risk assessment of pesticides for aquatic organisms (EFSA 2018) .

This talk will provide an overview of the challenges encountered by industry, here represented via CLE, during the development and submission of mechanistic effect models for environmental risk assessment. Why we have very good experience in using effect models internal to understand how active ingredient act on different organisms and to optimize future active ingredients already in early phases, we see a reluctancy of regulatory authorities to investigate the potential of this methodology to answer the risk assessment questions. We will address the complexities and hurdles encountered during the development phase, emphasizing the need for dialogues with regulatory authorities. One of the main disadvantage in the application of models for pesticide risk assessment is that it does not fit into specific boxes of the risk assessment. Currently regulatory risk assessment is based on biotest in which several endpoints are evaluated over time. From all this endpoints the worst-case endpoint at the end of the experiment is selected to be compared to an exposure estimate. All the discussions within a risk assessment is about which of the endpoints and which of the studies to select. However, very often effect models can interpret the differences between the studies (e.g. food, temperature, exposure situation) and can explain the whole dataset.

Furthermore, we will share our experiences with model submission, shedding light on the challenges faced and the constructive feedback we anticipate or have received. We will also outline the requests and expectations from regulatory authorities, highlighting the need for more comprehensive and constructive feedback to improve the evaluation process.

By providing an industry perspective on model development and submission, we aim to contribute to the discussion on refining risks to non-target organisms. Our insights will offer a comprehensive understanding of the challenges faced, the feedback anticipated, and the requests we have to improve the overall process.

8.02.T-02 Regulatory perspective on model evaluation – Challenges and feedback

Matthias Fürst[1] *and Rachel Sharp*[2]*, (1)Austrian Agency for Health and Food Safety (AGES), Austria, (2)European Food Safety Authority (EFSA), Italy*

Effect models have long been recognised as useful tools in ecological research, offering insights into the dynamics of ecosystems and their response to various stressors. With the publication of the "*EFSA Scientific Opinion on good modelling practice in the context of mechanistic effect models for risk assessment of plant protection products*" in 2014, clarity was provided on the expectations on how effect models should be tailored to meet the requirements of regulatory ecological risk assessment. The industry has since started to implement these models in dossiers for active substances and plant protection products, encouraging regulators to engage with effect models and to evaluate them in ecological risk assessments. This presentation will feature the perspective of regulatory authorities sharing their experiences, both positive and negative, in assessing these models. They will highlight the primary challenges encountered during the evaluation process and propose potential solutions to improve the overall evaluation procedure in future applications. These insights should serve as a basis for the more detailed discussions during the panel session.

8.02.T-03 CRO's viewpoint on model development and evaluation – Challenges and feedback

Oliver Jakoby[1] *and Benoit Goussen*[2]*, (1)RIFCON GmbH, Germany, (2)ibacon GmbH, Germany*

The application of mechanistic effect models has gained increased attention in the higher-tier environmental risk assessments, particularly in refining the evaluation of risks to non-target organisms. These models and model applications undergo rigorous evaluation by regulatory authorities. Contract Research Organizations (CROs) occupy a distinct role within this field, actively participating in all steps, from model development to submission, communication, registration, and evaluation.

Our presentation will delve into the specific challenges encountered during the development of these models, illuminating the complexities involved, the required expertise and time demands. We will emphasize the need for fostering continuous communication and collaboration among stakeholders to ensure the suitability and acceptability of the models.

Furthermore, we will highlight the feedback inherent in the model submission and evaluation process, drawing insights from the experiences of CROs. Thereby, we aim to provide insights into the iterative refinement process essential for enhancing model robustness and regulatory compliance.

Finally, we will discuss options to improve the collaboration between CROs, academia, regulatory authorities and industry. By enhancing cooperation among all stakeholders, we expect a more streamlined and efficient model application and evaluation process, improving todays' and future environmental risk assessments.

8.02.T-04 Academic insights on model development and evaluation – Status and potential improvements

*Bas Buddendorf[1] and **Sandrine Charles, PhD, HDR**[2], (1)Environmental Risk Assessment, Wageningen University & Research (WUR), Netherlands, (2)Umr Cnrs 5558, University Claude Bernard Lyon 1, France*

Models are increasingly used to inform and support decision making in environmental risk assessment (ERA). These models are becoming increasingly complex and data-intensive, which presents a challenge for end users without a strong quantitative or modelling background. Therefore, model developers need to be made more aware of what constitutes good practice in model development, including appropriate documentation of models for users and the ability for users to critically review the usability of models. As academic researchers developing effect models, we feel the obligation to ensure that models of appropriate quality can be critically evaluated and eventually considered to be fit-for-purpose for the use in the risk assessment for chemicals. We will enumerate what we consider as the most critical points for developing parsimonious and operational models, rather than theoretical and deep mechanistic models, while still ensuring an appropriate complexity and quality of models. As well, from an academic point of view, it is required to maintain the possibility of investigating both methodological research questions and operational objectives, the latter feeding the former and vice versa. From a helicopter perspective, we will highlight our needs in model evaluation, emphasizing the need to be able to look under the hood of a model (e.g., domain of applicability), and identify some of the main challenges and issues for model development and evaluation. We will end our presentation with some feedback from our personal experience, before making some suggestions for the future.

8.03 Beyond the Conventional Ecotox Endpoints - Advances to Unravel Low, Chronic Exposure Risks

8.03.T-01 How to implement non-conventional endpoints in experimental ecotoxicology

***Nico van den Brink**, Wageningen University & Research (WUR), Netherlands*

.

8.03.T-02 When are non-conventional endpoints relevant for population modelling and how to implement them in modelling

***Nika Galic**[1], Thomas G Preuss[2] and Pernille Thorbek[3], (1)Syngenta AG, Switzerland, (2)Bayer AG - Crop Science Division, Germany, (3)Apd/EE, BASF plc, United Kingdom*

.

8.03.T-03 Behavioral consequences in wildlife birds, through telomere shortening due to chronic exposure to urban pollution

***Matteo Schiavinato**[1], Shivani Ronanki[2], Ignacio Miro Estruch[3], David Gómez Blanco[4], David Spurgeon[5] and Nico van den Brink[4], (1)University of Padova, Italy, (2)Department of Toxicology, Wageningen University & Research (WUR), Netherlands, (3)Toxicology, Wageningen University & Research (WUR), Netherlands, (4)Wageningen University & Research (WUR), Netherlands, (5)UK Centre for Ecology & Hydrology (UKCEH), United Kingdom*

According to literature data, urbanization may influence the expression of certain personality traits in free-living birds and alter their inter-individual variability in some behaviors. But how could live in the city influence animal behavior? Since the world population is growing exponentially, the associated urban pollution due to industrial releases or exhaust gases from traffic is rising. Exposure to such chemicals could lead to increased oxidative stress in animals, potentially disrupting the balance between oxidants and the antioxidant systems. Telomeres, non-coding DNA sequences located at the end of the linear chromosomes, are especially sensitive to oxidative damage because they especially target their guanine bases. These damages initiate the DNA base excision repair pathway by DNA glycosylase, an enzyme that catalyzes the removal of the damaged nucleotides and, thereby, parts of the telomere, leading to the shortening of the sequences. For this reason, the overall length of the telomere in bases, has been used as a proxy for individual or populations health status, since this shortening due to oxidative stress accelerates the normal telomere length reduction that happens due to aging, leading to premature biological senescence. Recent empirical evidences shows how individual differences in telomere length are also associated with differences in behavior: generally, the shorter the telomeres, the more impulsive and bold the birds are. The possible biochemical reason we are exploring that links telomere and behavior, could reside in the "telomere position effect" (TPE), a molecular mechanism that causes the reversible silencing of the genes at the end of the chromosome by the spreads of the telomeric heterochromatin. Therefore, the shorter a telomere becomes, the more the closer genes become expressed. TPE would provide a mechanism to incrementally alter the phenotype according to organisms' senescence through the different expression of specific genes involved in behavior, as the dopamine receptors. Chronic exposure to low levels of pollution, might increase oxidative stress and shorter telomere, influencing animals behavior and their future fitness.

8.03.T-04 Multigenerational long-term exposure to low concentrations of pharmaceuticals in an estuarine deposit-feeding polychaete

***Martina Santobuono**[1], Mette Albreksen[2], Wing Sze Chan[1], Elettra D'Amico[3] and Henriette Selck[1], (1)Roskilde University (RUC), Denmark, (2)Science and Environment, Roskilde University (RUC), Denmark, (3)INM, Roskilde University (RUC), Denmark*

Pharmaceuticals are a group of emerging contaminants that are increasingly present in the environment. Selective Serotonin Reuptake Inhibitors (SSRIs), such as the antidepressant sertraline, fall into the category of psychoactive drugs known for their reduced side effects. Consequently, in recent years, prescriptions of these antidepressants have increased.

Due to its lipophilic nature, sertraline can accumulate in sediments after being released into aquatic environments. Thus,

deposit feeders may be continuously exposed to lipophilic chemicals since they ingest sediment particles and feed on sediment organic matter. In marine ecosystems, deposit feeders, like the estuarine opportunistic benthic polychaete, Capitella teleta, play a key ecological role as decomposers, nutrient recyclers, pollutant biotransformers, and they further constitute a major food source for demersal fish.
Long-term exposures and exposures across multiple generations are some of the new frontiers in assessing the adverse effects of chemicals on non-target species. Despite this, there is limited knowledge of the sublethal effects of lipophilic chemicals on sediment-dwelling invertebrates, leaving the impacts on critical ecological benthic species largely unexplored.
Considering that exposure to antidepressants occurs long-term and at low doses, this study aimed to investigate whether environmentally realistic concentrations of the sediment-associated antidepressant sertraline impact the benthic deposit-feeder Capitella teleta across three generations. Both conventional (e.g., life-history traits) and non-conventional (e.g., egg allometry) endpoints were investigated to unveil sertraline's long-term effects on C. teleta.

8.03.T-05 Modelling pharmaceutical exposure and effects using a novel DEB organism
Jacqueline Hilgendorf[1]*, Neil Sherborne*[2]*, Diogo N. Cardoso*[3]*, Jesper Givskov Sørensen*[4] *and Susana Loureiro*[5]*, (1)CESAM - Centre for Environmental and Marine Studies & Department of Biology, University of Aveiro, Portugal, (2)Syngenta, United Kingdom, (3)CESAM - Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal, (4)Department of Biology, Aarhus University, Denmark, (5)CESAM-Centre for Environmental and Marine Studies and Department of Biology, University of Aveiro, Portugal*
Current environmental risk assessment (ERA) of chemicals is mainly based on acute toxicity data from high concentration exposures observing survival as a main endpoint. However, this approach differs significantly from the field, where organisms undergo long-term, low-level exposure, potentially leading to sublethal effects. The Dynamic Energy Budget (DEB) model can bridge the gap between ERA practices and realistic exposure scenarios, providing a framework for energy allocation throughout an organism's lifecycle. With DEBtox, the impact of chronic chemical exposure on sublethal endpoints can be modeled over time.

DEBtox models have received growing attention in recent years and are partly incorporated in ERA practices[1]. Although they are applied to various species, their use for sediment species like *Lumbriculus variegatus* is limited. Given *L. variegatus'* recommendation for sediment ERA and the advice to use the species for chemical testing more often in the future [2], understanding its individual-level responses to chronic exposure is crucial. However, its life history and chemical effects on the single life stages are less understood compared to most model species, and it has not been adapted to the DEB model yet.

In this study, a chronic experiment was conducted using the model chemical fluoxetine, an antidepressant well known for its environmental persistence and wide range of toxic effects. The three endpoints, survival, growth, and reproduction, were evaluated at seven time points (0- 28 days). Four fluoxetine concentrations (0, 0.0025, 0.25 to 25 mg/kg) were tested with three replicates for each time point. Data from the different time points was used to apply the DEB model to *L. variegatus*.

Constructing a DEB model for *L. variegatus* is especially challenging as the worms have a highly unusual reproduction mechanism involving fragmentation, which differs significantly from other DEB model organisms. We present how this reproduction can be mechanistically described within a DEB model and how this allows both increased and decreased fecundity to be quantified as a stress response.

8.03.T-06 New Approach Methodologies for the identification of environmental hazard and risk drivers
Jose Tarazona*, Instituto de Salud Carlos III, Spain*
The current risk assessment paradigm, for both human health and the environment, was built in the 20st century based on apical endpoints typically measured in "observational" experimental studies. For the environment, endpoints connected to population effects, i.e. mortality, growth, and reproduction, were selected and included in the protocols for regulatory ecotoxicity testing. Toxicology has evolved and the current focus is to minimize animal testing and generate mechanistic information, facilitating a better understanding of the interactions of the assessed chemical with biological structures, mostly at the sub-organism level and emphasizing human relevance. NAMs providing mechanistic information can also support environmental assessments, but the use of these novel endpoints requires a paradigm shift. Current risk assessments focus on the identification of thresholds of "no-effect", such as the Predicted No Effect Concentration, and the assumption that, for example, the reproduction NOEC for a parthenogenic daphnia is also applicable, through an interspecies extrapolation factor, to other aquatic invertebrates with very different reproduction physiologies. NAM-based endpoints can be used to confirm or to challenge this assumption. With our increasing knowledge on wild species biology and ecology, information on effects observed at early events could be connected with possible consequences at individual level for different species in line with their specific biology, and to infer the consequences in terms of population dynamics. This presentation challenges the current focus on concentrations with "no-

observed effects” on traditional apical endpoints, and explores a new approach. The focus should be on the “observed” effects and their potential environmental impacts, through the identification of the drivers for hazard (vulnerable species and expected effects) and risk (potential for disturbing population dynamics and community structures). The proposed implementation is as hypothesis driven next generation environmental risk assessments (NGERA), combining exposure-driven hypothesis, based on emissions and environmental fate properties, with effect-driven hypothesis, based on NAM bioactivity and the understanding of the potential consequences leading the environmental impacts. The approach is flexible and applicable to generic regulatory assessments as well as to spatially and temporally explicit landscape-based ERA.

8.04 Empowering Sustainable Innovations: Leveraging Alternatives Assessment for Safe and Sustainable Design in Practice

8.04.T-01 Methodological Needs and Opportunities between Alternatives Assessment and Safe and Sustainable by Design

*Peter Fantke[1] and **Kerstin von Borries**[2], (1)Quantitative Sustainability Assessment, Department of Environmental and Resource Engineering, Technical University of Denmark, Denmark, (2)Technical University of Denmark (DTU), Denmark*

‘Alternatives Assessment’ (AA) and ‘Safe and Sustainable by Design’ (SSbD) are both emerging concepts that support the transition toward safer and more environmentally benign chemicals in consumer products and industry processes alike. While both concepts have overlapping elements with strong focus on chemical substitution for specific or across different applications, they are applied in different decision contexts and with that come with different methodological needs and boundary conditions. This talk will identify such needs and conditions for both concepts and discuss opportunities for synergies in scientific advances and application of these concepts in decision support.

8.05.T-02 Background to the European Horizon Scanning process, final themes, and questions

***Paul van den Brink**, Wageningen University & Research (WUR), Netherlands*

The United Nations’ Sustainable Development Goals have been established to end poverty, protect the planet, and ensure prosperity for all. Delivery of the Sustainable Development Goals will require a healthy and productive environment. An understanding of the impacts of chemicals which can negatively impact environmental health is therefore essential to the delivery of the Sustainable Development Goals. However, current research on and regulation of chemicals in the environment tend to take a simplistic view and do not account for the complexity of the real world, which inhibits the way we manage chemicals. There is therefore an urgent need for a step change in the way we study and communicate the impacts and control of chemicals in the natural environment. To do this requires the major research questions to be identified so that resources are focused on questions that really matter. In the paper by Van den Brink et al. (2018), we present the findings of a horizon-scanning exercise to identify research priorities of the European environmental science community around chemicals in the environment. Using the key questions approach, we identified 22 questions of priority. These questions covered overarching questions about which chemicals we should be most concerned about and where, impacts of global megatrends, protection goals, and sustainability of chemicals; the development and parameterization of assessment and management frameworks; and mechanisms to maximize the impact of the research. The research questions identified provide a first-step in the path forward for the research, regulatory, and business communities to better assess and manage chemicals in the natural environment.

Blanca Serrano, *ECETOC, Belgium*

.

8.06.T-04 Panel discussion.

Wim De Coen[1], *Blanca Serrano*[2] *and Christoph Schaefers*[3], *(1)European Chemicals Agency (ECHA), Finland, (2)ECETOC, Belgium, (3)Ecotoxicology, Fraunhofer Institute for Molecular Biology and Applied Ecology (IME), Germany*

Panel members:
Thomas Backhaus, RWTH Aachen, Germany
Marie Collard, DSM-Firmenich, Belgium
Miriam Diamond, University of Toronto, Canada
Anu Kapanen, ECHA, Finland
Joop de Knecht, RIVM, Netherlands
Johannes Tolls, Henkel, Germany

Discussion topics:

1. New scientific data vis-à-vis regulatory use

- How to improve uptake of new scientific approaches/information/data/ publications into the regulatory hazard and risk assessment?
- What are the biggest bottle necks?
- What is needed to make progress?

2. Appeal of regulatory science

- Is regulatory science interesting enough for academia? If not, how to make it more attractive?

3. Regulatory research needs

- ECHA has published Key Areas of Regulatory Challenges for the future: https://echa.europa.eu/documents/10162/17228/key_areas_regulatory_challenge_en.pdf
- Are regulators clear in problem formulation?
- What other emerging research topics would you consider relevant to the regulators?

4. Improved interaction between regulators and academia

- How to improve the communication on regulatory scientific development needs between the regulatory bodies and academia?

- What is missing to close the gap between both worlds?

Set the context with predetermined questions
Michelle Bloor, United Kingdom
Question 1**.** How do we avoid the misuse of the phrase 'science-based'? What does it mean, is all data useful data, and what level of information is sufficient to make informed decisions?

Question 2. How do we avoid paralysis by analysis in decisions on chemicals? Are calls for more data slowing down the process? What data are truly needed to move forward, and what is needed by regulators?

Question 3. Multidisciplinary and transdisciplinary solutions are called for, but how do we (as SETAC members and stakeholders) facilitate and achieve effective collaborations between different disciplines involved in the design, production, and assessment of chemicals, on what topics, and to what end?

Question 4. What are the CSS's key science data gaps to both inform decisions on chemicals and shape future chemicals that are Safe and Sustainable by Design?

Panel discussion and interactive Q/A
Michelle Bloor, University of Glasgow, United Kingdom

- A moderated panel discussion will take place between seven invited speakers: Annegaaike Leopold (Calidris environment, The Netherlands), Ksenia Groh (Eawag, Switzerland), Leo Posthuma (RIVM, The Netherlands), Bruno Campos (Unilever, UK), Paul Thomas (Kreatis, France), Hans Sanderson (Aarhus University, Denmark) and Christoph Schuer (Eawag, Switzerland). The discussion panel will address the questions selected by the audience. The audience will also join in the discussion**.**
- During and panel discussion, the audience will also be asked to complete several Mentimeter poll questions to stimulate further engagement (a QR code linking to a Mentimeter poll will be shared with the audience for responses).
